During this open period I want to write to advocate for feedlot rules that protect our water, soil, and animal health. Please limit feedlot animal size and hopefully, reduce it! The waters in this state are polluted and it is unacceptable. Please limit feedlot size for the protection of us all. I am forever frustrated with policies that protect a few farmers, which huring the general population. I recently drove through Nicollet County, MN and it is a crime scene. Intensive farming, drainage and a resulting destroyed ecosystem. The Minnesota River is incredibly polluted. Southwest Minnesota has a small percentage of streams that can support aquatic life. It is time to stand up for what is right. Animal health and humanity should also be considered. I drive past feedlots and am appalled at what I see. Manure, dirt, no bedding, and terrible living conditions are seen for those animals. Please advocate for what is morally sound. Farmers cannot keep polluting to benefit themselves, which hurting us all.

As an annual out of state visitor and trout fisherman I am appalled at the frequent and continuing fish kills. It sickens me. The MPCA must make a greater effort to determine the sources of water pollution and monitor water runoff in the unique and beauriful MN Driftless area. Greater regulation, restrictions, and monitoring are the only ways to prevent future fish kills. Unless changes are made, I will take my tourist dollars else where.

Response:

Stephan Melson · Citizen · (Postal Code: unknown) · Jul 08, 2025 4:15 pm

James, I agree and am appalled by fish kills in Minnesota. Did you know towns and cities pumped raw sewage into rivers last summer across southern Minnesota? The city of Waseca irrigates their raw sewage onto farm fields. Runoff from roads and other impenetrable surfaces goes into storm sewers then directly into water bodies. If you are outraged by fish kills, you must be outraged by these examples of the MPCA having a double standard by regulating some industries but giving government agencies a pass.

Douglas Moran · Citizen · (Postal Code: unknown) · Jun 22, 2025 6:02 pm

I am writing to ask the MPCA to strengthen the Animal Feedlot Rule, Minnesota Rules, chapter 7020. The state must do more to protect Minnesota’s aquatic resources and feedlots produce large volumes of manure containing nitrogen, ammonia, and other chemicals that wash into waterways and groundwater.

Here's the facts:
-Only 0.5% of the earth's water is available fresh water.
-Humans die in 3-5 days without fresh water
-Fish and other animals die without water

Given the facts above, the MPCA must take action to protect what water we all have available!!

Here's the action that must take place (Remember, .05% of the water on this planet is freshwater and available for us!!!):

1. Require NPDE/SDS permits for feedlots with 600 or more animal units. [permits are currently required only if 1,000 or more animal units]

2. Require all feedlots with 300 or more animal units to prepare a manure management plan and maintain land application records, and submit these to the MPCA and county feedlot pollution control officer. [currently plan development required of only some operations and submittal of plans and records is not required]

3. When manure is transferred by a feedlot owner/operator for application to the land by someone else, require that the transferee also follow the requirements in the manure management plan.

4. Prohibit manure application on frozen or saturated ground, or when rainfall is likely.

5. Require greater setback distances for manure applications from water resources in the karst region and other vulnerable groundwater areas, including prohibiting manure applications within:
300 feet upslope or 100 feet downslope of a sinkhole or other direct conduit to groundwater
300 feet upslope of a public waterway or tributary of a public waterway
250 feet from a private well
1,000 feet from a community well

6. Prohibit livestock of a feedlot or facility capable of holding 100 or more animal units from entering a designated trout stream or tributary of a designated trout stream and prohibit livestock of a feedlot or facility capable of holding 300 or more animal units from entering any water of the State.

Thank you for your attention.

Respectfully,

Douglas E. Moran

Response:

Stephan Melson · Citizen · (Postal Code: unknown) · Jul 09, 2025 7:32 am

Douglas, I can tell by your comments that you are not involved in animal agriculture.
To your point #1, how is the permitting process going to help reduce pollution? Aside from more paperwork and bureaucracy, i think it will be zero. I've gone through the permit process myself and inspections and they have little impact, in my opinion.
Regarding your point #3, all this would do it take the responsibility of large companies to keep track of their manure and put it onto a farmer receiving it. It seems to be companies who own large amounts of livestock should have some sort of responsibility. Companies would love to give up their responsibility for keeping track of manure but that is a bad idea!
To your point #4, if winter manure application is prohibited, small farms will bear the brunt of the regulatory cost. Large newer CAFOs are built to hold large amounts of manure. Small farms typically are not. Do we want to keep small farms around or do we want to regulate them out of existence? Funding must be made available to build storage facilities for small farms otherwise we will only have large ones. In terms of application on saturated ground, the weather conditions take care of that point. When a soil is fully saturated, there is no way your are taking a manure applicator into that field. Unless the farmer enjoys getting stuck and compacting his land.
To your point #6, why are trout streams so special? What makes them any more sensitive than any other stream? There are plenty of ecosystems in the state of Minnesota just as important as trout habitat. Most just don't have the passionate anglers trying to catch them.

Stephan Melson · Citizen · (Postal Code: unknown) · Jun 25, 2025 12:15 pm

I am writing to oppose further regulations on Minnesota feedlots. Manure often gets the blame for fish kills and nitrate in surface and ground waters and I think there is a double standard. In 2024, municipalities all across southern Minnesota pumped raw sewage into rivers due to excessive rainfall. A farmer would never be allowed to do this. A feedlot must follow setbacks for land application of manure and for building new feedlot. Municipalities can build a sewage lagoon right next to a water body. Municipalities have a lot more money and lawyers to lobby for these things than the average feedlot owner.

Some of the proposed ideas are tone deaf. For instance, In the Request for Comments PDF under the Changes in Livestock and Poultry Production Techniques and Practices

heading, the MPCA seems to allude to the fact of more feedlots being permitted with 500 or less animal units just under permit thresholds as being a bad thing. How is this any different than deferring or taking income to change which tax bracket a person is in? The MPCA could set a threshold for permitting at 250 animal units and there would be facilities designed to be under that threshold. Don't hate the player, hate the game the government creates.

In the Request for Comments PDF under the Changes in Livestock and Poultry Production Techniques and Practices heading, increased reliance on commercial application of manure including use of manure pipeline/hoses to move liquid manure further from the point of origin - I think this is a great thing. Often fields adjacent to feedlots have a lot of manure history. Getting manure to other fields with less of a manure history is a good thing, not a bad one.

In the Request for Comments PDF under New Information, Research, and Understanding regarding agriculture and the environment heading, the MPCA's 2014 Nutrient Reduction Strategy is referenced as being a guiding document for updating the feedlot rules. #1 the 2024 Nutrient Reduction Strategy says feedlot runoff contributes less than 2% of all nitrogen and phosphorous to watersheds in Minnesota. #2 if the Nutrient Reduction Strategy is being updated in 2025, how can the MPCA use it to update the feedlot rules? Which version are we commenting on now, the 2014 available version or what might be in the 2025 version whenever that comes out? If the MPCA is to use the Nutrient Reduction Strategy document as a guide, should they wait until it is updated and published first.

Winter applications of manure are always a tough topic. If the MPCA is to restrict winter manure applications, are funds going to be made available to improve manure storage faculties? Without funding to improve manure holding, small farms will be forced to eat the cost of a storage facility or stop raising livestock. Small farms go out of business, large CAFOs keep getting built.

I question whether the University of Minnesota is conducting research that is relevant to crop production. The research on cover crops has saturated the agriculture field yet, the adoption of cover crops is limited. My experience is because cover crops are an additional expense with no return to the farmer and a decrease in yield plus additional management changes to try and make them work. If cover crops were as easy as claimed, why isn't adoption widespread? It's because they don't make the farmer any more money and they don't make life easier. When was the last time the availability of manure was researched at the University of Minnesota? That would be a wiser use of research dollars than cover cropping.

The current rules regarding manure management plans are more than adequate. Transferring manure should be no the seller of the manure not the buyer. I urge the MPCA to keep feedlot rules as is

Stephan Melson

I am writing to comment on the new Feedlot Rule and to request stricter requirements for regulating feedlots in Minnesota. As a statistician and environmental activist, I want to underscore the crucial importance of comprehensive and high quality monitoring in providing data. Any feedlot that has a moderate number of animals or is in an area with a vulnerable water source should monitor their groundwater discharges and automatically report their data to MPCA. We also need to require more feedlots to get water pollution permits so that they, at minimum, have to take steps to control their pollution and, ideally, become subject to the automatic monitoring described earlier. Doing this would ensure that a greater portion of our water sources are being regulated.

I am writing to ask the MPCA to do more to protect our lakes, rivers, streams, and groundwater by revising the Animal Feedlot Rule to address the crisis of nitrate pollution in our state. Feedlots are a major source of nitrate pollution in our waters, and by adding stronger rules for the handling of manure, MPCA can help ensure that all Minnesotans' water at the tap is safe to drink. This is important to me because nitrate is a human health threat. No one should lose loved ones to preventable pollution.

Response:
Stephan Melson · Citizen · (Postal Code: unknown) · Jul 08, 2025 3:48 pm
Can you cite a source on the last time someone lost their life to nitrate pollution in Minnesota? The 10 ppm nitrate concentration in drinking water came out of thin air and has no scientific value

Norway Beach, a public water access located in Cass County was closed in early-mid May to swimming due to elevated e-coli. Strict rules, regulations and permitting for surface/ground water is needed to protect public and environmental health for recreational purposes.

Response:
Stephan Melson · Citizen · (Postal Code: unknown) · Jul 08, 2025 3:55 pm
Lake Bde Maka Ska, Lake Hiawatha and four other popular lakes in Minneapolis, Minnesota had beaches closed in the summer of 2024 due to high bacteria levels. https://mndaily.com/285003/city/six-minneapolis-beaches-close-due-to-high-levels-of-bacteria/
Correct me if I'm wrong, but there are no feedlots in Minneapolis. The idea that feedlots and manure applications are solely to blame for pollution is a myth. If bureaucrats in the Twin Cities want to regulate livestock, perhaps they should start in

their own backyards.

Kristin Hogquist · Citizen · (Postal Code: unknown) · Jun 26, 2025 12:57 pm

I am a lifelong resident of Minnesota, and swimming, boating, fishing, and camping in our lakes and rivers is a huge part of my life. Over the years, I have seen steady an increase in agriculture in the state, and I am increasingly worried about water pollution resulting from agriculture.

We know that feedlots contribute to water pollution through nitrates and bacteria. The nitrate levels in many Minnesota waters are currently making the water unhealthy for humans to drink and to swim/recreate in. These high levels cause bladder and colon cancer and pregnancy problems among other health issues. E.coli and other fecal coliform bacteria also harm the health of people who drink and swim in these waters. These contaminants are causing fish kills in southern Minnesota in addition to harming human health. For these reasons, I want stricter limits on feedlot pollutants.

Specifically, I think the Minnesota should require more than just the largest feedlots to get water pollution permits. I recommend requiring permits for operation with at least 600 animals.

I would also like to see Minnesota require the largest feedlots to actually monitor discharges to groundwater and drain tile so they (and we) can know what is entering the water system.

I am also worried about those parts of the state that are more vulnerable to groundwater pollution because of the geology of the area. Since we have knowledge about this, I would like to see Minnesota leverage that knowledge and apply stricter rules in those areas. This could include requiring established cover crops if you apply manure in the fall, and no liquid manure application to frozen or snow-covered ground when it will just run off.

Response:

Stephan Melson · Citizen · (Postal Code: unknown) · Jul 08, 2025 4:11 pm
Kristin, you seem to be placing the blame for bacteria and nitrate in surface waters. Minneapolis had to close beaches last summer due to bacteria in those lakes. Where are there feedlots in Minneapolis? https://mndaily.com/285003/city/six-minneapolis-beaches-close-due-to-high-levels-of-bacteria/
Runoff from impenetrable surfaces like roads, concrete, buildings etc. goes straight into water bodies, untreated. Have you ever thought this is a huge pollutant source?.

Municipalities across southern Minnesota pumped raw sewage into rivers due to excessive rainfall. This was permitted by the MPCA. How come this isn't being addressed?

I am writing to submit my comments to the MPCA in support of more expanded protections for Minnesota's waterways, by increasing regulations on Minnesota's feedlots, which are an acknowledged source of groundwater and water pollution in our state. I am concerned with the pollution that has happened in Minnesota's most vulnerable waterways. The recent fish kills in the karst areas of Minnesota have me very concerned for the health and welfare of the wildlife that depend on our clean waters. These fish kills have been directly related to agricultural runoff and the increase of nitrites and ammonia in the water. I worry about the birds that also depend on these clean waterways and fish.
I believe that the rules should be expanded to apply to even more feedlots than are currently covered. Specifically, I would like to see any feedlots with 600 IUs or more be required to get water pollution permits.
I also believe that large feedlots should be required to monitor their discharges to ground water and drain tile in addition to the requirement currently in place that they monitor surface water runoff. I would like to see greater enforcement visits to ensure compliance by these feedlots as well.
Lastly, I would like to see stricter manure land application requirements and lower rates in the most vulnerable groundwater areas in Minnesota – such as those with karst geology and sandy soils. These areas are more susceptible to contamination of the water supply by manure and should be given greater protections.
As a resident of Bemidji, Minnesota, I truly value our waters and worry about how pollution is affecting them.

I'm writing to urge the MPCA to take stronger action to protect our natural waterways in Minnesota by revisiting the Animal Feedlot Rule (Minnesota Rules, Chapter 7020). Nitrate pollution is a growing crisis in our state, and large-scale animal feedlots are a significant contributor to this problem.

By strengthening rules and regulations around manure management, the MPCA has a critical opportunity to protect Minnesota's drinking water and the health of our ecosystems. Clean, safe water is essential for public health and recreation.

As someone passionate about the future of Minnesota's food systems and equitable access to clean water, I respectfully submit the following recommendations for your consideration:

1. Require more feedlots to get water pollution permits
2. Require large feedlots to monitor discharges to groundwater and drain tile
3. Require stricter land application requirements and lower application rates in Vulnerable Groundwater Areas

Thank you for your time and commitment to protecting Minnesota's environment and our communities.

Animal agriculture is one of the most destructive and violent industries on the planet. In addition to causing suffering on a monstrous scale, it is responsible for creating more greenhouse gases than all forms of transportation combined, environmental degradation, habitat and species loss, fresh water waste and pollution, ocean acidification and dead zones, has negative human health implications, is creating antibiotic resistant microbes and checks off all of the boxes for conditions that could/will lead to the next pandemic. We need to use the billions of dollars this industry receives to help farmers transition to a humane, efficient, sustainable and healthy plant-based food system. Reducing the size of feedlots is but one tiny baby step in the right direction. At the same time, the animals caught up in our food system deserve a life worth living and there must be a commitment to ensuring cattle are provided shelter from the elements and the ability to engage in natural behaviors.

Response:

Stephan Melson · Citizen · (Postal Code: unknown) · Jul 08, 2025 4:03 pm

More power to you if you desire a plant based food system. I like to eat meat and enjoy it on a nice summer day. That's the beauty of living in a free country, we each get to decide what we want to eat.

Has it ever crossed your mind that cattle might like to be out in the elements? You can go to a livestock auction, buy some cattle, and they can live in your house with you, humanely and see how it goes.

I am writing in regards to the Animal Feedlot rule, Minnesota Rules Chapter 7020.

MPCA should implement stricter rules governing animal feedlots to ensure that all Minnesotans have safe, drinkable water, as well as healthy aquatic ecosystems to boat, fish, and swim in.

As the land of more than 10,000 lakes, the home of the world-renowned Boundary Waters Canoe Area, and the headwaters of the Mississippi River, water is integral to our state’s identity and to Minnesotan’s way of life. Water is synonymous with life, and we must do all that we can to protect this vital resource.

An update to the MPCA’s animal feedlot rules is overdue. We must ensure that our waterways are not contaminated further by excess nutrients like nitrogen, or by pathogens and bacteria like e coli. Rules around which feedlots must seek a permit should be tightened, requiring operations of 600 animal units or more to go through the permitting process.

Additionally, large feedlots should be required to monitor their discharge to groundwater and drain tiles. Vulnerable groundwater areas should be protected with more stringent land application requirements — including mandating the use of cover crops. These common sense rule reforms will make everyone in our state safer.

Animal agriculture has changed in Minnesota, favoring larger operations which produce far more waste that can unfortunately harm humans and the environment. Our

understanding of the potentially expansive environmental impact of feedlot operations has changed too, and the MPCA's new rules should reflect that reality.

Response:

Stephan Melson · Citizen · (Postal Code: unknown) · Jul 09, 2025 7:41 am

Can you explain to me how mandating the use of cover crops is going to reduce bacterial loads in our surface waters? There are plenty of ways to reduce nitrate leaching like applying manure when soils are below 50 degrees, using a nitrification inhibitor, installing saturated buffers, installing bioreactors, etc. My neighbor seeded a cover crop last year that never germinated due to lack of moisture in the fall. Do you think his nitrate leaching was reduced? Not at all. Cover crops are all the rage because they look pretty and you can see them in the field, but are an imperfect management system to reduce nitrogen loss.

I am writing to comment on the new Feedlot Rule (Animal Feedlot rule, Minnesota Rules Chapter 7020) and to request stricter requirements for regulating feedlots in Minnesota. I encourage a new rule to be made for feedlots as the circumstances have changed. We now know more about the pollution problems associated with feedlots and they have been increasing in number and size. We now know that our legacy of abundant fresh potable water is threatened even as our climate warming world has increasing pressure on drinking water.

We now know that areas vary in their geological capacity to filter pollutants.

I feel obligated to steward for future generations as the abundant world was brought to me.

Sadly, we now have farm families telling themselves that it's normal to not have safe drinking water in agricultural areas. And sadly, humans are not the only important biological beings that are harmed by water pollution.

Nitrogen pollution has impact nearby and far away. Let's start with the drinking water in the areas of feedlots. I have friends who decided they had to move away from their town because the municipal water was too nitrate intense for their health circumstances. I have other friends who have a farm in the karst region that I get to visit. Their family has already suffered one death by cancer and they are taking steps to try to improve their well water. They are near the Whitewater River, known for trout fishing, and we also fear for the well-being of those fish— and that recreation asset— in particular. My children and I swim in these waters; E-coli is also a risk.

We have to get serious about protecting our water. Water permits should be required for 600 AUs or more. Karst regions and others with higher risks need stricter requirements. There should be basic monitoring and enforcement of feedlot regulations, especially appropriate manure management practices, such as amount, time of year, run-off risk, water discharge, cover crops.

The dead zone in the Caribbean is a serious threat to life/sustainability. While CAFO's are

not the only contributor, every polluting source needs to be diminished. We are all connected.

Charles Phelps · Citizen · (Postal Code: unknown) · Jul 04, 2025 5:54 pm

Happy independence Day!

I am writing to ask the MPCA to strengthen the Animal Feedlot Rule, Minnesota Rules, chapter 7020. The state must do more to protect Minnesota's aquatic resources and feedlots produce large volumes of manure containing nitrogen, ammonia, and other chemicals that wash into waterways and groundwater.

We should all be concerned about this because clean water is vitally important to both people and wildlife. Minnesota needs feedlot rules that not only work for farmers, but that also
protect the environment for humans and wild animals alike. With that in mind, the Feedlot Rule should be changed to:

1. Require NPDE/SDS permits for feedlots with 600 or more animal units. [permits are currently required only if 1,000 or more animal units]

2. Require all feedlots with 300 or more animal units to prepare a manure management plan and maintain land application records, and submit these to the MPCA and county feedlot pollution control officer. [currently plan development required of only some operations and submittal of plans and records is not required]

3. When manure is transferred by a feedlot owner/operator for application to the land by someone else, require that the transferee also follow the requirements in the manure management plan.

4. Prohibit manure application on frozen or saturated ground, or when rainfall is likely.

5. Require greater setback distances for manure applications from water resources in the karst region and other vulnerable groundwater areas, including prohibiting manure applications within:

300 feet upslope or 100 feet downslope of a sinkhole or other direct conduit to groundwater
300 feet upslope of a public waterway or tributary of a public waterway
250 feet from a private well
1,000 feet from a community well
6. Prohibit livestock of a feedlot or facility capable of holding 100 or more animal units from entering a designated trout stream or tributary of a designated trout stream and prohibit livestock of a feedlot or facility capable of holding 300 or more animal units from entering any water of the State.

Respectfully,

Charles Phelps

DOUBTS and DISHONOR !

Previously, In Wadena County citizens blocked the expansion of a 500 unit animal feedlot from growing to 1000 animals due to its near promimity to a tourism waterway and the operator's previous discharge failures and excesses. We were livid it was even possible or permittable considering the known record of the business.

But, that was in the past when citizens had some effective link to governance. Today, it is important for MPCA to understand that you and other state regulatory agencies are not trusted or honored. We see evidences of the cancer of regulatory capture by corporate agriculture. There is belief that no matter what the new regulations are there will be slow and lax enforcement and tactics to divert public attention and delay correction. This is the result of creeping internal origanizational and legislative pollution from industrial ag monies and pressures. Therefore, the MPCA, Department of Ag, and others with power to protect us have become blighted and subservient ...without honor.

Honesty can be clearly demonstrated by speed and absolute certainty in strict enforcement of regulations regardless of the guilty party. Now, accountability by the public and press will follow.

Response:

Stephan Melson · Citizen · (Postal Code: unknown) · Jul 08, 2025 3:57 pm

I happen to agree with you, Kent. A government that can't protect its citizens from dangers needs reform, not further power. I've never understood the mentality, the government fails at a task so the solution is to give them more money and make some new agencies.

Addison Otto · Citizen · (Postal Code: unknown) · Jul 07, 2025 3:46 pm

It is good that MPCA is considering revisions to the feedlot rules. Many compromises went into the current rule 25 years ago, the effect of which were not known at the time. An evaluation of the current rule's effectiveness is probably over due.

Nine years ago, my daughter's family was impacted by land application of dairy cow manure on a field adjacent to their home. The application was heavy and not quantified to the land owner, the farmer having requested permission on an emergency basis due to overflowing lagoons at his farm. The application went on for more than 24 hours on

the coarse soils of the field, followed by 3" of rain. My daughter's shallow well was severely impacted, and they had to install a deep well to get safe water. This was particularly dangerous because their baby was just transitioning to formula. While the farmer paid for the well upgrade, the situation was quite difficult for some time.

I advocate for stricter land application requirements and lower application rates in Vulnerable Groundwater Areas: Soils and geology vary across MN. In the most vulnerable parts of the state (karst geology, sandy soils), there should be stricter requirements for the land application of manure.

Environmental Working Group's comments on MPCA's Animal Feedlots Rule are attached. We recommend that the agency strengthen the rule considerably.

Response:

Stephan Melson · Citizen · (Postal Code: unknown) · Jul 09, 2025 7:56 am
In your attached PDF, the following is stated about your claim of nitrogen overloading in nine counties in Minnesota. ""In our report released in May of 2025, EWG analyzed which fields near feedlots likely received manure in 2024."" So you don't know which fields received manure, you don't know what rate of manure was applied, you don't what the nutrient value is of the manure, and you don't what practices were used to apply manure correctly like waiting until soils are below 50 degrees and yet the EWG can determine nitrogen overloading even with little to no actual information? Pardon my French, but that's just throwing sh** at a wall and seeing what sticks.

Jennifer Valentine · Citizen · (Postal Code: unknown) · Jul 08, 2025 2:09 pm

Some of the changes that Land Stewardship Project & I propose are:

More rigorous groundwater monitoring requirements for NPDES and SDS permit-holding feedlots.
More rigorous reporting when it comes to the transferring of manure.
Lowering the animal unit size threshold for feedlots to obtain NPDES and SDS permits to 600 animal units.
Changes to how a collection of small feedlots all under the same ownership structure is permitted.
Updating the new manure management plan mapping tool to include more information about spreading plans and manure infrastructure like digesters. This data should be made available to the public, not just to potential permitees while they are creating their manure management plan.

I am writing to ask the MPCA to strengthen the Animal Feedlot Rule, Minnesota Rules, chapter 7020. The state must do more to protect Minnesota's aquatic resources; feedlots are among the biggest producers of nitrogen waste that moves into our groundwater. Clean water is vitally important to both people and wildlife. Minnesota needs feedlot rules that not only work for farmers, but that also protect the environment for humans and wild animals alike. Even those of us that live far from agricultural land are aware of this issue and try our best to avoid heavy use of nitrogen-producing chemicals. Feedlots must be required to do the same. Thank you for efforts to protect all of us.

Leonard Sojka · Citizen · (Postal Code: unknown) · Jul 10, 2025 1:22 pm

1 Votes

I agree with the following comments:
MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.
MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.
MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that "stricter" requirements in existing rules prevent pollution.
MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.
MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.
MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Regardless of political preferences, it appears that a large majority of Minnesota residents want clean water. Further, they expect Minnesota agencies such as the MPCA to ENFORCE high clean water standards. Nobody wants to wait for a disaster to begin to act. Act now.

As such

MPCA needs to require pollution permits for a wider range of feedlots, say 300-999 animal units whichwhich contribute 43% of Minnesota’s total manure.

MPCA needs to set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

MPCA needs to prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution.

MPCA needs to state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

MPCA needs to strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

MPCA needs to prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.

MPCA needs to require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to

noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Clean water resources must be preserved for our future generations. The Land of 10,000 Lakes deserves to have a State full of clean, pristine, uncontaminated water. There must be rules that require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots in MN.
There needs to be a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed.
MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution.

I'm not a farmer or a trout fishermen but I am concerned about water and air quality. Please amend Rule 7020 to require pollution permits for all feedlots over 600 animals. Minnesota Pollution Control needs to enforce the "no discharge" regulations, as well as air quality regulations.

Thomas Sullivan · Citizen · (Postal Code: unknown) · Jul 11, 2025 1:58 pm

1 Votes

As someone deeply concerned about pollution and its effects on human health, ecosystems, and water quality, I urge the MPCA to adopt stronger rules to better control the environmental and public health impacts of animal feedlots in Minnesota. Manure from feedlots is one of the state's largest sources of pollution—both waterborne and airborne—and the current rules are inadequate to address the scale of the problem, especially in light of climate change and increasing agricultural concentration.

To that end, I strongly recommend the following rule changes:

1. Require NPDES/SDS permits for medium-sized feedlots (300–999 animal units). These operations produce 43% of the state's manure, yet are not required to hold permits that regulate pollution. This is a major regulatory gap that leaves waterways and communities vulnerable to contamination.

2. Set enforceable maximum limits on the size of individual feedlots and total animal units per watershed. Local hydrology, water availability, and community health must determine these limits. Without them, the state risks irreparable harm to both ecological systems and rural quality of life.

3. Prohibit new or expanded feedlots in karst regions. Karst geology is highly susceptible to groundwater pollution. Because contamination in these areas is effectively irreversible, "stricter" requirements are insufficient. The only responsible course is to prohibit development in such high-risk zones.

4. Enforce zero-discharge standards and pollution reduction in impaired waters. The rules must make clear that MPCA will actively enforce no-discharge requirements, require compliance with all pollution limits, and prevent degradation in currently healthy waters. Strong enforcement is essential for public confidence and environmental recovery.

5. Strengthen minimum technology standards for liners and leak detection. The rules must require modern containment systems. It is no longer scientifically defensible to assume that concrete or compacted soils alone are effective at preventing seepage, especially when exposed to years of manure storage.

6. Ban all wintertime manure application. Climate unpredictability has made current

winter spreading guidelines obsolete. Snowmelt and freeze-thaw cycles dramatically increase runoff risk, and rules must reflect these conditions to protect our lakes, rivers, and groundwater.

7. Require feedlots to comply with air quality standards at least 344 days per year. Hydrogen sulfide and other emissions cause serious health impacts. Feedlots should not be allowed to routinely exceed air quality standards. The current 21-day exemption is already generous.

In summary, I support a more proactive, protective approach that aligns MPCA rules with the reality of modern-scale animal agriculture and its pollution risks. The public deserves clean air and water, and the environment deserves robust stewardship.

Sincerely,

Tom Sullivan

Thomas Kunkel · Citizen · (Postal Code: unknown) · Jul 12, 2025 8:43 pm

I am concerned about the increase of the number and size of feedlots increasing drastically over the last 25 years. I realize that the economics of agriculture is driving this, but I feel that the situation is approaching the out of control situation in Iowa. There needs to be an attempt to find common ground that benefits all Minnesota residents, and that isn't happening without discussion. Several years ago, my wife's now deceased uncle bragged about manure being applied on his corn field until the tile lines ran green. That comment has stayed with me ever since. I think we can all agree that such a maneuver should not happen. Without more awareness and discussion of feedlot regulations, I fear that situation could happen again. Being 73 years old, I worry more for what the future holds for my grandkids rather than myself. Not only has the problem of water pollution risen rapidly in the publics eye, but one has to be concerned about the rising cancer risk, particularly in southwest Minnesota. Both of those issues have really raised concerns across Iowa and rightfully should concern us too. Sincerely, Thomas Kunkel

Minnesota deserves updated and comprehensive protections for clean water and air given the increasing size and number of feedlots across the state. This includes treaty territory protected by federal law that we have a duty to uphold. Climate change is at our doorstep adding additional stress. Future generations deserve good stewardship of Minnesota's land, rivers, and lakes now.

Specifically, I would like to see:

1. MPCA rules requiring pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.

2. MPCA rules requiring a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology

and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.

7. MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

As the previous writer mentioned, I support a more proactive, protective approach that aligns MPCA rules with the reality of modern-scale animal agriculture and its pollution risks. The public deserves clean air and water, and the environment deserves robust stewardship.

Thank you for your important work.

Lynn Anderson

I live n Northern Minnesota and have background in health care. I am firm believer in the need for clear water. We drink it bathe in it and really on it nutrition ally. I have lived alongside the Mississippi in Little Falls and saw municipal water supplies rendered unsafe to drink. A sad reality for those not able to leave the area is reliance on polluted water. With our state’s fresh water resources we should be a leader in protection of this necessity of life. I therefore believe it critical to re evaluate and update failed policy and rules regulating feedlot manure.

On a more personal note I am also a fisherman and fear fish kills across our state related to feedlots and manure containment. Loss of containment equals fish kills. This terrible management of our precious natural resources and should be avoided at all cost.

I believe the following would be a great step in a safer resource respectful direction:
MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.
MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.
MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution.
MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.
MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.
MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

I oppose tougher feedlot rules. As a smaller operator we already keep records of manure application, days when hauled and timely incorperation. Manure samples are taken every four years. The crop advisor calculates how much nitrogen is needed per acre to produce a average crop. We don't put any more nitrogen on then we have to otherwise it's wasted money. Many farmers in our area have a custom guy come in to haul their manure and in starts early September and goes until it freezes. We need this time to haul. We have 6.5 months storage for our manure and if we have to go to 9 months it will be a major cost with no benefit to land. Frozen manure hauling is up for debate. I can see liquid manure being a problem but pen pack manure is mostly straw and doesn't hardly move on frozen ground.

These rule changes for small farmers will be a bigger burden money wise on them and won't help the environment. You need to focus on the whole picture. Commercial fertilizer and manure from farms are items we know how much per acre is being put on, how about everyone who fertilizes their lawn submit application rates to mpca? If everyone is willing to do that then I will do the same.

We want the best thing for our land and more regulations will not help. Lets make it simple. More paperwork is not the answer.

As a cattle herd operator, I would like to caution against cumbersome legislation, implemented by non agriculture personnel, which could result in eliminating many farms. We are already using many good management practices. I find it unfair to blame the farmers for nearly every pollution problem, when the towns and cities contribute to the pollution situation. Some of the suggestions that have been presented may sound good on paper, but in reality just won't work. Such as using the weather report to determine if a farmer can apply manure. We all know that the weather reporting for a certain area is highly unpredictable. We watch the weather to try to determine when to cut and bale hay and we are lucky if they get it right half of the time. Another example is the suggestion of no manure application in the winter months. Every year is so different thus making this idea unreliable. In the area I live, the streams are thriving and the fishing is great. We are using good management practices. I caution against giving too much emphasis to the voice of those who don't understand agriculture and tend to blame the farmer for problems that they did not create. People are complaining about the high cost of food, yet they want to add more laws, which will only cause the prices to continue to increase. Please consider all the hard work farmers are already doing to put food on our tables and to preserve the environment. We live on our farms and of course we want to be healthy, too. Creating more regulations will only make things more complicated and will not make us any healthier. It will only drive us out of business, thus creating more problems for affordable food sources.

John Zimmerman · Citizen · (Postal Code: unknown) · Jul 14, 2025 1:38 pm

Please do not change the animal unit factor for turkeys in the feedlot rules. The current animal unit system is clear and reflects how turkey farms operate. Splitting AUs based on bird weight or sex might make sense on paper, but not in the real world. There is no meaningful difference in how we raise or manage turkeys based on those traits.
Also, turkey manure is dry and doesn’t pose the same risk as liquid manure. Trying to regulate turkey farms in a once size fits all approach doesn't work. We shouldn’t have to meet rules that don’t match our operations just because they were designed for a different species.
I urge MPCA to keep the rules simple and based on science and actual risk—not unnecessary complexity. We want to protect the environment, but we also need rules that make sense for how our farms work.
Thank you,
John Zimmerman

Jake Vlaminck · Citizen · (Postal Code: unknown) · Jul 14, 2025 2:42 pm
3 Votes

I respectfully ask MPCA to keep the current animal unit numbers for turkeys the same. The current breakdown already fits how our farms operate.
On turkey farms, our management doesn't change depending on whether the birds are

male or female, or by size. We treat them the same in housing, feed, and manure handling. Adding more categories would only confuse things and make the rules harder to follow, without improving environmental protection.
We need rules that reflect how our farms actually function, not a one-size-fits-all approach.
Please don’t make the rules more complicated than they need to be. The current animal unit system works.
Thank you,
Jake Vlaminck

Manure is Manure, whether it comes from a cow, pig, chicken, turkey or human. Nitrogen is Nitrogen and it is in large quantities when you confine animals(two legged or four). If the groundwater, lakes, rivers and streams are being polluted from too much nutrients, then the solution is to decrease the nutrient loading. The landscape before European colonization was diverse biomes with vast amounts of diversity in plants and animals. The wild creatures moved around and fed freely. This provided nutrients to thriving systems that cycled nutrients effectively and created beautiful topsoil. The systems of today are broken and driven by money. Working with the farmers to compost and return these nutrients back to the system in a form that does not leach, holds water and nutrients, and sequestors carbon seems to be a better option. Reducing the number of animals in any given area is a smart decision for those that do not make their living from meat production but it is exactly what is needed. The solution to pollution is dilution. Changing our lifestyle and way of making money is not just a simple rule change. The farmers are already struggling to make things work but we can’t continue down the road of degredation either. We need to work together for better solutions and realize that fresh, clean drinking water is critical to the survival of all life on Earth. It all begins in the SOIL!

As MPCA proceeds with its rule making on Animal Feedlots, it should clearly and specifically identify who,, how many, and where are the persons affected and which water bodies, surface or groundwater, they are affected by via feedlot contamination. Much of this information should be in the reports on non-compliance, and the WRAPS reports.
The Agency should also include sections that specify how existing or proposed changes are responsive to the 1999 Legislative Auditors report on Feedlots and the 1993 EPA/State Feedlot Workgroup Report. Finally, since both surface and groundwaters are affected by feedlot contamination, and each is or could be a source of drinking water, the Agency should clearly identify and linkages or gaps in the system of rules intended to protect water for domestic consumption

I am a licensed CAWT and owner of a 2400 hd finishing barn. We have a been in animal agriculture for over 40 years. There has been vast improvements in that time. I would caution against going overboard on any future regulation. Adding more paperwork will not increase water quality, it will just be more expensive and cause more farms to consolidate.

As a CAWT our business and myself do every thing that we can to make sure the valuable resource of manure and nitrogen stay where we put it in the field. We use manure tanks and incorporate immediately. I am disappointed with the quality of our work if any manure is on top of the soil. We have electronics in the cab to keep the rate consistent across the field and cover the fields corner to corner with very minimal overlap. We take manure samples every year so the farmers know what they are getting on fields and use a three year average to set our rates.

However, there are challenges with manure application. To be able to make the business viable and to keep barns from overflowing; we starting taking manure out of pits and incorporating it on the fields as soon as beans come off. Some farmers plant cover crops but struggle to get a good stand once every three years. Cover crops seem like a good idea on paper but are very hard to make work in real life. We finish applying manure around thanksgiving every year. There are times every year where large rains a forecasted and no rains come and when very little rain is forecasted and large quantities of rain comes. Our weather forecasting is not advanced enough to make rules upon it. Towards the end of season we hope to be finished before the ground is frozen, but sometimes have to incorporate the manure through a few inches of frost. It is far better to apply in the early fall or on half frozen ground that it is to let a barn overflow.

There must be allowances in the rules to allow putting manure on fields to prevent point source pollution from the feedlots.

The vast majority of point source pollution coming from a feedlot that I have seen is when the feedlot is under 300 animal units. I cannot recall an event of point source pollution coming from an area feedlot over 300 au in the 40 years in the business.

More things that I think are worth considering are: Do not lower au below 1000 for NPDES sites. Why are we only regulating down to 300 au? I believe we should lower that to 20 or 50 au. Those of us farmers that are doing every thing we can with the valuable resource that is manure will always think it is a different group that is causing the pollution. Therefore, we need to bring everyone onto the same level; whether that is small farms under 300 au that have cattle directly in the river or pigs playing in the mud next to creek, or municipalities that discharge right into metro area lakes or rivers. There needs to be consistency for everyone! I would support regulation that requires all manure to incorporated with 24 hours. As far as applying manure to vulnerable areas: looking at the map there are "random" small acres of fields all over our area that are listed as vulnerable surrounded by 1000s or acres that are not listed. It is overly burdensome to try to differentiate these acres. But, we do need to protect the karst regions.

In summary, the vast majority of farmers are doing their best to keep their manure in the fields where they need it as a valuable resource; do not over burden them with paperwork. If everyone is not on a level playing field (under 300 au, 300 to 1000 au, NPDES sites, and municipalities), then all the groups will always blame someone else for the problem. The weather is changing, so predicting it or making rules based upon it is unreasonable. Mother nature will always have the upper hand.

Regulating animal agriculture out of the great state of Minnesota will only result in a

negative impact on the world.

Thank you for your time,

Jake Vogt CAWT

Re: Animal Feedlot Rule, Minnesota Rules, chapter 7020

I was on Rush Creek three weeks prior to the huge 2022 fish kill, where an estimated 2,500 trout were killed. My 6-yr-old grandson presented his dry fly to the fish and caught his first trout on a fly on that day. The three of us had an amazing day and assumed we'd go do it again. I am compelled to do my part to protect our water for all living organisms, so our grandchildren and their grandchildren can live full, healthy lives and enjoy the stream as many of us do.

Trout are an indicator species needing high oxygen-saturation levels, clean water and invertebrates. They are a sensitive species worth saving. When trout are dying in water that can find its way into well water, we need to take note and take action to protect the fish and our neighbors. Jeff Broberg once told me they'd done dye tracing showing that stream water was making its way into private wells. Jeff was a certified geologist and co-founder of Minnesota Well Owners Organization (MNWOO).

In the past, we've largely been reactive, paying attention only after an event. This has not worked to keep our water safe. We need to keep our water resources clean and safe. Toward this goal, I make the following rule-change proposals.

1. Require feedlots of 300 or more animal units to submit manure management plans and maintain land application records (preferably electronic for ease of auditing), and submit these to the MPCA and county feedlot pollution control officer.

2. In addition to regulating the size of individual feedlots, control animal population density by establishing limits on the number of animal units per watershed. This is akin to carrying capacity. The intent here is to use objective data to limit future increases on CAFO size limits. This reduces the likelihood of a county like Fillmore County doubling or tripling its animal cap limit unless the land can support it. Recall that the Karst geology of SE MN is particularly susceptible to polluted surface water. In this area and in other areas such as the Central Sands area, polluted surface water more quickly reaches groundwater.

Respectfully submitted,
Lee Stoe

Regarding Animal Feedlot Rule, Minnesota Rules, chapter 7020.

I encourage MPCA to update the rules to cap unit size at 600 animal units or less. Each

increase in animal unit size puts an area at greater risk for contamination if there is any flaw in the operator's system. When a smaller system fails, the resulting problem is smaller as well.

It is mutual that we all want clean water. I feel the current rules are sufficient with some being excessive like why do I need to do a permit modification just to add a field to my manure management plan to apply manure on it? If there are issues with the Karst regions, then deal with those areas but don’t do a wide sweeping rule change. I live in the west central part of the state in a dense livestock area. Due to current requirements to test well water on any irrigated fields in our manure plans, I have found the nitrogen levels well below EPA standards with most close to zero. Farmers want to keep as many nutrients available for the crop as possible, it costs a lot to apply manure and for commercial fertilizer, so we apply accordingly. We use cover crops where it makes sense but why should we be required to put a cover crop out that isn’t going to have sufficient time to grow just so we are in “compliance”? As far as anything less than the 1000 animal unit requiring an NPDES or state permit, I feel that it is excessive and will cause an undue burden on small producers. A lot of this comes down to just a lot of extra paperwork that doesn’t provide any benefit. Please consider letting the current rules as they are.

My family has raised turkeys in Minnesota for over 30 years, and I'm writing to ask that MPCA leave the animal unit factors for turkeys unchanged. The current system makes sense and matches how turkey farms are managed. Whether the turkeys are toms or hens, light or heavy, we manage them the same way. Changing the animal unit factors by bird size or sex wouldn't reflect how real farms work-it would only create more regulation for the sake of creating more regulation. It's also important to point out that turkey litter is dry and stored inside. Turkey farms should be treated based on their real environmental risk not a one size fits all regulation. We care about clean water, and we already follow the rules to protect it. Please keep the current animal unit definitions and avoid making things more complicated for no reason. Sincerely, Butch Brey

My family and I are well-owners and we care deeply about the quality of the natural landscape and drinking water for all residents of our state. However, I'm very concerned about the rapid, and seemingly endless growth in large-scale animal agricultural farming and the impact of that on our water systems and air pollution. Given the increase in the number of feedlots with near threshold animal units, the changing climate that contributes to warmer winters, and advancements in manure treatment and storage technologies, I support the MPCAs proposed amendments to the governing rules for Minnesota feedlots, including enhanced use of regulatory strategies and technology, especially the demand for real-time information since farming practices and seasonal changes can make an immediate and irreversible negative impact on our waterways. Also, I support the proposed rule amendments around livestock and poultry production techniques and practices, new research (and dissemination of new findings to the public) for understanding agriculture and the environment, as well as regarding changes in crop production and nutrient management. I think that the additional requirements that apply to feedlots with a total of 1,000 or more AUs should be applied for facilities with as few as 250 AUs if they are in geographically vulnerable regions in terms of groundwater, such as the Southeast Minnesota karst region, places with shallow bedrock, and places along major rivers and their tributaries, including the Minnesota, Red, St. Croix, and Mississippi Rivers.

As a Minnesotan concerned about water quality in our state, I appreciate the MPCA’s work to update the animal feedlots rule and urge the agency to make it stronger. Large areas of the state, especially in vulnerable regions like southeastern Minnesota, are struggling with water quality issues caused by nutrient runoff, to which feedlot manure is a big contributor.

I ask that the MPCA take the following steps:

Lower the size for a feedlot operation to be required to apply for a water pollution permit. Currently, many feedlots skirt greater regulation by operating just under the permitting limit of 1000 animal units, this should be lowered to no more than 600 animal units.
Require feedlots with those permits to closely monitor their manure discharges to protect nearby groundwater and streams.
Set stricter limits on manure application to farm fields in vulnerable areas, like the heavily nitrate-polluted karst region in southeastern Minnesota.
Change how multiple small feedlots with the same owner are regulated. Currently, an owner of multiple feedlots, even feedlots right next to each other, can skirt stronger regulations by keeping them as “separate” operations, though the total pollution is the same as a large feedlot.
Require more rigorous reporting on manure transfers.
Make more manure managing data and mapping available to the public, including information about digesters and manure spreading plans.
Minnesota’s lakes, rivers, and groundwater have been getting more polluted every year. This is a chance to take a step in the right direction rather than continuing business as usual.

Hello MPCA,
Thank you for hosting regional meetings throughout Minnesota.
I would like you to consider these points that I think are important.
1. Fish kills
I have fished the same streams for almost 60 years and continue to fish. Every fish kill I have seen was a 3.5-5 inch downpour in a very short period of time. That is not something that is predictable and we can't regulate it. When I was younger, all trout streams were grazed and cattle stood in the streams during hot weather and pooped. There were no fish kills that I knew of or were publicized.
Today, we have more trout in the streams than ever before. Only 1-2% of fish kills are related to agriculture. Most are temperature elevation of water and stream bank debris. Streambank restoration may help. Let's not penalize agriculture for their minimal role in this problem.
2. Nitrates-Farmers are solely being blamed for nitrates but old septic systems and wells with eroded casings need to be checked as their leaks contaminate water as well. We should also be monitoring municipal sludge spreading practices to consider how they add to the nitrate and heavy metal contamination picture. In Lewiston we have had our municipal sewage pond develop a leak and disappear overnight.
3. Wintertime spread, storage pits, pad sites
Most young livestock are housed in manure packs in Southeast MN. As the packs thaw, they release ammonia in the sheds. The sheds need to be cleaned monthly starting at the end of January or the animals will have pneumonia problems.
We need to work with animal agriculture, like Europe does, to provide engineering plans, pads, or new buildings with financial help. If we don't, farms with under 1000 animal units will disappear due to the increased cost of operation. Dairy farms under 1000 animal units cannot afford this. Our profit margin is small. The cull price of calves have saved the day for the last 2 ½ years but that won't last forever and the milk price has not increased. Federal and state rules have already driven out most of the 50-250 cow sites in Minnesota.
The loss of one dairy cow means the loss of one acre of hay and pasture land. Those acres will be planted to corn and soybeans. We are moving in the wrong direction. We need more alfalfa and pasture for improved water quality.
Manure pads and liquid storage areas will cost 2-4 million dollars per dairy to meet the proposed changes. I asked at the regional meeting if funding from the state would be provided and was told, "Not at this time". Our family farm priced a manure storage pit in 2007 for 555 cows with 7 months storage. This would be 2 units containing 4, 712,591 gallons of liquid manure. The cost was over $800,000. With your proposals, we will need over 12 months storage for wet Spring conditions like we had in 2024 in our area. 3-5 million dollars will be needed for liquid and pen pack.
Exit will be the only option. There is no funding available. I have visited our NRCS and SWCD several times to confirm this.
The rural Minnesota economy will suffer the loss and food security will be at increased risk in the U.S. In 2017, each dairy cow returned $7000 to the local economy through machinery dealers, plumbers, electricians, veterinarians, nutritionists, agronomists, hardware stores, grocery stores, etc. The loss of dairy farms affects not only food availability but also the economic health of our communities.
4. No winter spread of manure also has serious implications.
• The cost of facilities for the manure will mean dairy and cattle farmers will need to sell their herds. The loss of hay and pasture ground to corn and soybeans results in lower

water quality.
• A wet spring would mean increased compaction due to repeated trips across the field to spread manure. Increased compaction reduces soil health.
• The need for more time spreading in the spring means a shorter window for planting and/or the use of shorter day crops, which would mean lower crop yield.
I have seen no study putting a smaller amount, like 3-4,000 gallons per acre, on chiseled fields in winter on fields with less than a 6% slope. In a winter like 2024-2025 (very little snow) all water melts into the chiseling and there is little runoff. With a spring like 2024 (excess rain, wet and saturated soil) there can be a great deal of runoff due to the unpredictable large rainfall.
A broad brush approach does not work. Weather forecasts are only about 50% correct and rainfall is the biggest predictor of runoff.
5. Distance between family farms
There should be no change. Farmers consider the distance between fields and an increased land base increases the opportunity for less manure per acre and less road travel with tankers and spreaders.
Each farm should have its own animal – unit base.
An exit from livestock production is very likely, going from 750 animal units to well over 1000 animal units will have different requirements. We were told not to worry if family members worked together.
6. Animal unit values need to stay the same as they are valued today.
Discharge per animal per day should be the standard, which was set-up by previous laws regarding animal unit total.
Our rural communities are already having difficulty meeting the challenge of school, fire, police, EMS, county taxes, and township taxes.
A loss of animal production will hurt rural communities. Loss of dairy/beef production will decrease alfalfa and pasture ground acres which will affect water quality.
There is no perfect style of farming. There are positives and negatives for everyone. We should encourage education of farming practices that will benefit water quality and provide an opportunity to change when it is affordable-Examples: cover crops, no till planting, manure management, fertilizer application, etc. Public cooperation helps us improve water quality. We can see changes in the last 10 years with adoption of several of these practices.
It will take time to see changes in water quality considering the time it takes for water to move through the soil. All changes will not work every year. Flexibility has to be built into the plan due to changes of rain and snowfall.
As a dairy farmer with the price of milk at $17 per hundred weight and the increased cost of production, there is not much left over for larger pits and stacking slabs.
Changing requirements will only leave 1000 animal unit facilities and rural communities will pay the price.
Thank you for considering these comments.
Attached is information about the costs and profit that is the reality that dairy farmers live with.

As a Minnesotan concerned about water quality in our state, I have gained some knowledge through different sources about the negative effects of farm animal feedlots on local water quality, including rivers, lakes. and ground water which leads me to urge

the MPCA agency to make feedlot regulations stronger than existing ones. Large areas of the state, especially in vulnerable regions like southeastern Minnesota, are struggling with water quality issues caused by nutrient runoff, to which feedlot manure is a big contributor. We owe it to our environment and to our future generations.
Continuing to become more knowledgable about Minnesota's precious resources. and learning how to respond.
Thank you for the work you do.
With appreciation,
Ann Beane

Comment on Feedlot Rules Update

I believe this work is long overdue and should be done in a shorter time frame in the future, in, perhaps 10 years. Confirmation of what a safe level of nitrates is, should be a priority. In 1962 it was set as 10mg/L. Is that still backed by current science?

Our lives depend on access to non-contaminated water. That’s the fundamental truth. We should protect our water quality with that in mind. As a water-blessed state, Minnesota should have a moral obligation to prioritize preserving our waters as move forward.

To begin with, we should widen the definition of operations that need to have their water runoff monitored and those who should be covered by this rule. 500 large animal units seems to be a fair number for reasonably requiring a need to periodically check outflow of water for nitrates, manure and bacterial content. I don’t know the frequency, but is should be scientifically sound. This of may inconvenience or cost the operators, but the public should demand this, as the water significantly affects the health of those who come in contact with it.

I see some research hinting at lower levels of nitrates than the present 10mg/L should be implemented. Prostrate cancer is a notable concern with minimally elevated nitrates, recent studies have suggested.

My profession as a provider of medical care in a rural setting, has me concerned that we are not being adequately aggressive in our water quality effort. Practicing in rural sw Minnesota, and prostate cancer and other cancers are elevated in their frequency out here. This at a time when the Minnesota River is seriously polluted. Farmers and non-farmers alike who are careless or under informed with their waste products need to be educated to the harm they are doing, and discouraged from doing it (lawn care).

Farmers and anyone using nitrogen fertilizers need to ensure that they are in compliance with other proven means (cover crops and reduction in application) to reduce the excess nitrogen proper timing of fertilizer application to insure the quality of our common public resource. “Water is life.”

I grew up on a farm. We didn't have 600 or 1000 head of livestock. Maybe if we counted the squirrels and birds in the trees. To pay for our land, Dad applied anhydrous ammonia to corn fields. Our daughter took SPRW water to Grandma and Grandpas, because we knew he had poisoned the well water at our rural church. I don't need to say anything about this issue, other than to remind us all, drinking water is pretty important to life. Millions of people drink water from our Mississippi River. Protect it. And protect the water in every farmhouse in the state.

I’m asking the MPCA not to change the animal unit numbers for turkeys. The current numbers work well and make sense for how turkey farms are actually run.
Raising turkeys doesn’t change much based on whether the birds are male or female, or if they’re slightly heavier or lighter. We feed them the same, house them the same, and manage their manure the same. Creating more categories based on bird size or sex would only make things more confusing without helping the environment.
Turkey farms already follow a lot of rules to keep water clean and manage manure responsibly. Adding more complicated rules about animal unit numbers without a scientific reason to do so won’t help and will only make it harder for farmers to understand and follow the rules.
Please keep the current animal unit numbers for turkeys. They’re simple, clear, and they reflect how farms actually work.
Thank you,
Mike Barber

so, I apply my manure in the fall so cover crops seeded in the late fall will probably not establish as far as reduced tillage I have an applicator on the back of the tank that uses a disk coulter the manure is buried right away the amount applied is controlled by a flow meter. I'm not too interested in a no till unit I still feel you need a well tilled seed bed.

My neighbor I sell manure to will not like the idea of having to fill out an annual report and the MPCA gets a transfer of manure from me the owner and I apply the manure to his land just as responsible as my own. I can agree we should be more responsible in sensitive areas, but I would like to point out that crop farmers don't report fertilizer applications at all it seems that everyone is after the livestock all the time it wouldn't make sense for a crop farmer to over apply but how do we know. As in past statements making winter application tougher could hurt the small farmers maybe make rules to stay away from sensitive areas which are probably in place already. the inspection of facilities is something the MPCA is supposed to be doing anyway not just when it is sold. I would like to point out that there are a lot of people pointing out all this pollution but don't seem to have any real evidence and it seems to me the urban area can pollute just as much. Farmers should not have the right to pollute, and I think we are all trying to do a good job to provide food, fuel and fiber for everyone.

As a Public Health professional I am concerned about the environment, and animal's and human's health and want to see regulations, which encourage practices promoting diversity and resilience and prevent further loss of biodiversity. Elevated nitrogen levels have been shown to cause cancer and neurological defects in infants as well as cause the dead zone Gulf of New Mexico and we need to remedy that. Twenty five per cent of Gulf of Mexico's dead zone is estimated to come from manure. I also would think we need to have family farmers help us come to good decisions for our futures, so we have strong rural communities. To promote the health of animals and prevent disease I think animals need a certain amount of space and access to fresh air in warm weather and to prevent the resistance to antibiotics they should not be given antibiotics unless sick. Manure should not be applied on fields in winter where it can run off and farmers should be given incentives for having cover crops and growing crops besides corn and soybeans. Keeping a continuous cover help promote soil health. I think all CAFOs should be regulated and certified since they have a cumulative effect and they need to be recertified in 5 years. Depending on the size of CAFO there should be a proportional amount in fees and if there is air or environmental pollution a significant fee should be charged, which increases with each incident. Standards need to be set for storage and disposal of manure and there needs to be system to enforce this, which the CAFOs pay for. Ideally say in 20 years manure would no longer be put on the fields but would be converted to energy.

As an independent turkey farmer in west-central Minnesota, I ask the MPCA to keep the current animal unit calculation for turkeys unchanged. The existing framework is straightforward and is the farmwork for how current turkey farm management was designed. Whether we raise hens or toms, our manure handling, housing, and nutrient management practices stay the same based on stocking densities that are appropriate for our barn, not based on the sex of the bird. Adding more animal unit categories based on bird size or sex would not provide any real environmental benefit.
What concerns me even more is the possibility of a one-size-fits-all approach that treats turkey farms like liquid manure operations. Turkey litter is dry, stored indoors, and cleaned out only once or twice a year. Any rules that overlook those differences could unfairly burden farms like mine with unnecessary compliance costs.
I also want to highlight the very real challenge of managing disease outbreaks like HPAI. Our farm has been directly impacted by HPAI, and it turned our entire operation upside down. During a disease event, we can't just move manure or clean barns when we want —those decisions are dictated by quarantine protocols from the Board of Animal Health and USDA. The updated rules must allow flexibility during disease outbreaks.

As someone who has made significant capital investments in our farm in recent years, the financial burden of meeting new regulatory standards is top of mind. Independent growers don't have corporate backing—we carry the risk ourselves. Every change in regulation impacts our ability to stay viable. I urge the MPCA to consider how any changes to these rules affect real farmers on the ground.
Minnesota's turkey farmers are already doing their part to protect water, soil, and air quality. What we need now is a regulatory framework that respects the work we're doing—and gives us the flexibility to keep doing it.

As someone who raises turkeys in Minnesota, I want to share my concern about any changes to the animal unit factors in the 7020 feedlot rules that were referenced during recent meetings. The current turkey animal unit factors fit industry standards across the country. Turkeys are not raised differently based on their size or sex, so there's no reason to create more categories - the current stocking densities are already based on current animal unit categories.
What's more important is that turkey manure is very different from liquid manure. Treating all manure the same just doesn't make sense. A one-size-fits-all regulation might work on paper, but it causes problems on farms.
I hope MPCA will stick with the current animal unit factors for turkeys and keep the rules practical for farms of all scopes and sizes.

Winona County's Pleasant Valley Creek and Beaver Creek were once listed by MPCA to be "Impaired Waterways" but were de-listed in 2024 due to strong conservation practices by landowners and farmers. This surface water success story will take time to trickle down to the aquifers – science says it may take 30+ years in some cases due to the Karst topography. The city of Altura, MN sealed its old city well in 2024 and partnered with the Winona County SWCD to create a video of groundwater flow. This video documents water flow between aquifers via old abandoned wells – the high-nitrate aquifer is directly contaminating the low-nitrate aquifers below. Historically, Minnesota's rural farmstead settlers dug shallow wells with shallow (or nonexistent) well casings. In the 1800's and early to mid-1900's underground cisterns were created in close proximity to outhouses (there were many decades without indoor plumbing). The nitrates generated by the outhouses leached directly into the underground aquifers via the adjacent well pipe. In this regard, and in response to EPA concerns, the MPCA has a duty to partner with MDOH to create a multi-faceted approach to reducing nitrate contributions from all sources. Abandoned wells need to be located and sealed. Out-of-compliant septic systems and old well casings and wells need to be brought up to code. These pollutant sources are regulated only by the MN Department of Health, but they are equal contributors to nitrate groundwater contamination. At the June 26, 2025 Chatfield MPCA presentation, MPCA's Steven Schmidt presented this scientific statement, "Hundreds to thousands of fish kills are reported every year in Minnesota. 9 out of 10 fish kills have NOTHING to do with agriculture." At the same meeting, MPCA's George Schwint referenced a 2014 Nutrient Reduction Strategy with online reporting of surface water nitrate trends from 2003 to 2022 with NO TREND DETECTED in SE MN.

40661 Minnesota Pollution Control Agency Request for Comments on Animal Feedlots Rule

Closed Jul 22, 2025 · Discussion · 168 Participants · 1 Topics · 194 Answers · 17 Replies · 55 Votes

NPDES or SDS permits should not be required for feedlots less than 1000 AU. UW Madison studies have shown the annual economic impact of one dairy dairy cow in a small community is more than $30,000 per cow. Minnesota needs all the cows it can get, especially if the goal is vibrant small towns with feed mills, repair shops, tractor dealerships, veterinary clinics, banks, schools, milk truck drivers, custom harvest crews, and etc. It should be noted that MN farmers are producing milk and meat commodities – Minnesota's dairy farms (98% are family-owned) must compete directly with Kansas and Texas dairy farms with 20,000+ dairy cows on the same farm, in a regulatory environment where those MN farms are not allowed to grow in size. SE MN topography has abundant Highly Erodible Land (HEL) classifications and very little Non-Highly Erodible Land (NHEL). Heavy rainfall events require contour stripping, grass waterways, cover crops, conservation tillage, and crop rotations that include alfalfa and perennial forages. Cows are the best tool for converting these forages into milk and meat. If the cows go away, then row crops will dominate the landscape, and the nitrate leaching will increase from 6.6mg/L to 22.3mg/L (SE MN Nitrate Strategies Collaborative Work Group) when alfalfa/corn is replaced with a corn/soybean rotation. Feedlots with less than 1000 AU should not be required to have 9 months storage unless tax dollars pay 100% of the cost (roughly $700 to $1000 per cow). The average Minnesota farmer is older than 55 years old – the smaller to medium sized farms will be unwilling to start over with nearly a million dollars in new debt that will provide them with zero Return On Investment (ROI) – this will greatly expediate vertical integration in the industry. Land application of manure on frozen or snow-covered fields should be allowed for bedding pack manure sources on NHEL fields. This is best for animal welfare. Feedlots under the same ownership in close proximity to each other should see no rule changes. Less than 3% of our family dairy farms survive until the 5th generation. As long as all sites are in full compliance, they should be left alone. After all, the farmers and their children and grandchildren drink the groundwater too, and none of them desire dead fish. "We lose 10% of our dairy farms each decade. And every decade, dairy farm size doubles" – Marin Bozic U of MN professor. More regulations on our dairy farmers will only accelerate this disheartening trend. Planting cover crops was unheard of 20 years ago. As mentioned earlier, two MN "Impaired Waterways" have been de-listed in the past two years - the new conservation practices are working! Science says that we need more time to prove it.

Farming is Everybody’s Bread, Butter, and Water. What I do on my farm truly affects the quantity and quality of water for all. CAFO feedlots greatly concern me because of the concentration of manure, nitrogen applications and water use. It is good to examine feedlot rules that are 25 years old.

There should be a statewide cap of 1,000 AUs per feedlot. I am concerned about having too many CAFO’s too close together for manure overload and water use. So, could there be a maximum density of an area using the watershed boundaries? That would take into consideration all the animal units, no matter what building site or farm business entity is responsible.

In karst geology, any feedlots over 300 animal units (AUs) need to have a water pollution permit. In non-karst, feedlots over 600 AUs need to have a water pollution permit.

In karst, feedlots over 300 AUs need to have any discharge to ground water monitored. In non-karst, feedlots over 600 AUs need to have ground water monitored. This includes drain tiles and any possible leakage from a manure storage structure.

Land application of manure should be stricter and monitored more closely, especially in karst. Manure application rates should not be allowed to exceed the agronomic rate in Vulnerable Groundwater Areas. Manure lagoons shall have cells and the cells should not exceed 250,000. Manure storage unit placements need to take into consideration the joints and fractures in karst, not just the sinkholes.

CAFOs should be responsible for any township road expenses beyond their normal expenses.

CAFOs should be responsible for any neighbor property values lost due to the CAFOs operation.
Air quality needs to be monitored on a constant basis, the monitoring equipment owned and maintained by the state. Procedures for violations of air quality be taken seriously, and be taken care of as soon as possible. Violators need a reasonable and fair amount of time to remedy the problem, but should not be allowed to have continued offenses of clean air.

Water is a resource we all need. And we should all have fair access to safe water. Because of my concern that CAFOs can take more water faster than the aquifers can recharge, I wonder about limiting the water any business or CAFO can draw. Setting a reasonable limit would take much work and consideration, but I think it could be done. Further, monitoring the water use of each CAFO would take more equipment, but if it protects the water usage for all of us, it will be a worthwhile expense.

We need to look at the permitting requirements of each CAFO site, and we need to also keep in mind the effect when numerous CAFOs are on the same watershed and aquifer. The accumulation of too much of anything anywhere can allow problems that either can’t be undone, or will take decades or more to remedy.

I was a dairy farmer for thirty years. We transitioned the farm and now I am a beef farmer. I understand that regulations, changing and adding rules can be onerous. Feedlot owners and managers may not like the needed time, effort and expense to work with additional rules. I know farmers are innovative and are very capable of adjusting and abiding by any rules put in place to clean up and maintain safe water above ground and underground for all of us. Farmers, families, livestock, and plant life depend on safe water for living and surviving. Feedlot rules are one of the places that affects our water. We need feedlot rules and protocols to protect our water, air, and neighbor’s basic needs.

Thank you for your attention to the feedlot rules in Minnesota.

I am for clean water and air, as a farmer I consume the water and air that surrounds my livestock farm. There is no need to open up and change the current 7020 rules, these rules have shaped the livestock production in Minnesota. If a famer has fewer than 1000 AU they can choose to get a NPDES permit, which offers them civil protections. As the way we handle and store manure has evolved over the years we are able to more precisely apply and incorporate the manure into our crop nutrient needs. Successful farmers are using “Best Management Practices” that work on their individual farms. On our farm we spring apply some liquid manure on certain fields because it is the best agronomic practice, not because of a Rule. Significant changes to the manure application and storage requirements will create many new challenges. The pure capital cost of additional manure storage is burdensome. MPCA needs to be service to the farmers of Minnesota not rule changers and enforcers. As I’m writing out these comments for a rule that is already comprehensive and scientific based it is taking away time from me spending time with my family because, there is farm work that needs to be done, oil changes, greasing equipment, and most importantly caring for the livestock we raise.

40661 Minnesota Pollution Control Agency Request for Comments on Animal Feedlots Rule

---

Gary Dukes · Citizen · (Postal Code: unknown) · Jul 20, 2025 1:08 pm
1 Votes

Minnesota prides itself on its pristine natural environment. However, this cherished identity is increasingly threatened by the unchecked proliferation and expansion of concentrated animal feeding operations, commonly known as CAFOs. These industrial-scale livestock facilities generate prodigious amounts of manure, posing a grave and escalating risk to the state's invaluable water resources. A moratorium on new feedlot construction and expansion in Minnesota is not merely a precautionary measure; it is a critical necessity to safeguard public health, protect aquatic ecosystems, and preserve the state's environmental heritage for future generations.

The sheer volume of waste produced by feedlots is staggering. While manure can be a valuable fertilizer, its immense quantity, coupled with increasingly industrialized agricultural practices, often leads to over-application on land. This excess manure, rich in nutrients like nitrogen and phosphorus, can then seep into groundwater or run off into surface waters, unleashing a cascade of environmental and health problems.

One of the most insidious hazards associated with feedlots is nitrate water pollution. Nitrogen, a key component of manure, readily converts to nitrate when it interacts with soil microorganisms. Nitrate is highly water-soluble, meaning it can easily leach through the soil and into groundwater, contaminating wells and aquifers that supply drinking water to countless Minnesotans. The problem is particularly acute in regions with karst geology, like southeastern Minnesota's Driftless Area, where porous bedrock allows contaminants to quickly reach groundwater and sensitive trout streams. Similarly, central sands regions are highly vulnerable. Furthermore, nitrate can naturally convert into nitrous oxide, a very potent greenhouse gas.

The health implications of nitrate-contaminated drinking water are severe, especially for vulnerable populations. The federal drinking water standard for nitrate is 10 milligrams per liter (mg/L), a limit primarily set to prevent methemoglobinemia, or "blue baby syndrome," a potentially fatal condition in infants under six months old where the blood's ability to carry oxygen is impaired. However, emerging research suggests that even nitrate levels below this federal standard, such as 5 mg/L or even 3 mg/L, are associated with increased risks of other serious health issues, including certain cancers (particularly colorectal), thyroid problems, and adverse pregnancy outcomes. For many Minnesotans relying on private wells, especially in rural areas, the threat of nitrate contamination is a constant concern, often requiring them to seek alternative, costly sources of clean drinking water.

Beyond human health, nitrate pollution wreaks havoc on aquatic ecosystems. Acting as a potent fertilizer in water bodies, nitrates fuel excessive algal blooms. When these algae decompose, they consume vast amounts of dissolved oxygen, leading to oxygen depletion and creating "dead zones" where fish and other aquatic life cannot survive. This can result in widespread fish kills, devastate sensitive trout populations, and fundamentally alter the ecological balance of lakes and rivers. Increased nitrates also stress adult fish, making them more susceptible to disease and impacting their reproductive success, and can reduce the availability of aquatic insects crucial for trout food.

The current regulatory framework in Minnesota has proven inadequate in addressing the

escalating scale and impact of modern feedlot operations. While large feedlots are required to obtain state and federal permits, the vast majority of Minnesota's feedlots are smaller and operate with less stringent oversight. Even for permitted facilities, challenges remain in enforcing manure management plans and ensuring that manure is applied appropriately to prevent runoff and leaching, especially with increasingly unpredictable and extreme weather events. Heavy rainfall can lead to overflows from manure storage basins or wash recently applied manure directly into waterways.

A moratorium on new feedlot construction and expansion would provide a crucial pause, allowing the state to thoroughly re-evaluate and strengthen its feedlot regulations. This time could be used to:

Update and enhance manure management rules: This includes stricter limitations on manure application in vulnerable groundwater areas, requiring more frequent and comprehensive monitoring of fields where manure is applied, and promoting practices that minimize nutrient runoff and leaching.

Invest in sustainable alternatives: A moratorium could incentivize research and investment in manure processing technologies that convert waste into valuable products, reducing the need for land application and mitigating pollution risks.

Support smaller, diversified farms: By slowing the trend towards industrial-scale operations, a moratorium could create a more equitable agricultural landscape that supports smaller, diversified farms with more sustainable manure management practices.

Assess cumulative impacts: The piecemeal approach to feedlot permitting often fails to consider the cumulative environmental impact of multiple feedlots in a watershed. A moratorium would allow for a comprehensive assessment of these impacts and the development of regional strategies.

Protect environmental justice communities: Feedlots are often disproportionately located in low-income and rural communities, leading to environmental justice concerns regarding air and water pollution. A moratorium would offer a chance to address these inequities.

It's crucial to recognize the significant externalized costs of current practices. The costs of environmental degradation, public health crises, and the need for expensive water treatment systems are ultimately borne by taxpayers and affected communities. Furthermore, sustainable, regenerative agricultural practices can offer long-term economic benefits by preserving natural resources and fostering resilient local economies.

In conclusion, the urgency for a moratorium on feedlot construction and expansion in Minnesota is undeniable. The pervasive threat of nitrate water pollution, the detrimental effects on aquatic ecosystems, and the inadequacy of existing regulations demand immediate and decisive action. A moratorium would not only protect Minnesota's vital water resources and the health of its citizens but also provide a much-needed opportunity to forge a more sustainable and responsible path for the state's agricultural future. The time to act is now.

small organic farmers

It is understood that water quality is paramount. It should also be understood that farmers do take care to preserve the environment, water supply, and resources as all of these are critical to the success of a farmer. Farmers do not want to negatively impact the assets used in the business and to do so would be contrary to the sustainability of the farmer.

There are different issues in different parts of the state due to geographical differences. Why would the entire state be forced to implement rule changes that are not relevant or appropriate in all geographical types? This approach is generally problematic and creates unintended consequences due to a blanket approach versus targeted plans for the various watersheds and geography.

While focus on agriculture is appropriate, why is there not also a focus on population centers and government entities related to water shed and flows? The Star Trib wrote an article that shared that rain gardens implemented in Minneapolis made the water quality worse and made the phosphorus issue worse. This is a small microcosm of metropolitan areas with the chemicals used on roads, lawns, households, industries, etc. Why is it that there is no shortage of water studies in rural areas and not in cities? We need to continue to work to enhance water quality and a question that needs answering is how much of the water quality issues come from farming and how much from cities? Are we focusing on the lowest hanging fruit to make the most change? With only part of the equation, we don’t know if we are being as effective as possible?

Additionally, why would the limit to N of 195 lbs apply only to manure, an organic matter material, and not to commercial fertilizer? Again, why is there such a narrow focus on agriculture and not population? Why is there a narrow focus on manure source N and not all fertilizer? Why is there not a wholistic statewide approach to understand where the challenges are? There have been multiple posts regarding draining city sewage treatment plants emptying into rivers which were approved by MPCA. It certainly feels as though it is a do as I say not as I do approach, and we need to better understand the why. Were there studies and or data points when the MPCA allowed cities to do this? Was there a measurement of the impact of doing so since the MPCA knew this would be done? Seems like a good opportunity to document the impact of doing so.

Regarding setbacks from water features this is something that farmers are concerned with. Farmers do not want to see manure go into waterways as they are concerned with the environment because they live and use water features in their “neighborhoods”. It is also economically foolish and therefore not motivation to do so as there is value in the manure as an organic matter nutrient. I do have concerns with changing the application rules to increase the distance as these rules are applied without consideration of the area, field, geography, time of year, application process. An example is we followed the setback rules for the placement of a hog barn even though there was a county road with no culverts in the area. Meaning, how will the manure rise to the level of flowing across the road and then another 800 feet into a water feature? Additionally we are not in a flood or earthquake zone and the cement pit is sealed. So to leak would create some cataclysmic event where manure leaching would be the least of all of our problems.

Farmers understand rules, we are at a loss of words for complete lack of common sense and willingness to look at a situation to see if it is legitimately required. Another example is having to place a buffer between a water feature and the field when the water feature has a bank that is six feet higher than the field. Again, lack of common sense and willingness to look at the situation.

In organic farming we do not utilize commercial chemicals and fertilizers. There is a suggestion that N be limited to 195 lbs per acre which is problematic for organic farmers that use organic matter such as manure. Since it is organic matter, it takes time for the soil (microorganisms) to break down and release the N, which only 75% is useable the first year. By limiting this we will have smaller crops and not fully use the full potential of the land as well as create potential shortages along with higher prices for consumers. The UofM extension service I believe has recently updated their recommendation for N to 210 lbs / ac in relation to the advancement in farming methods and seed capabilities. With the addition of organic matter to the soil it enhances and improves the soil health. The use of manure has been an effective, betterment, ecologically sound practice that our farm has used for over 75 years.

As organic farmers we use manure which is best to spread in the fall when soil temperatures are 50º which allows the N to be stabilized and not move until needed in the spring. With a suggestion of not starting application until October 1st this will create problems with our Minnesota weather and winters. There are products that conventional farmers can use which allows application before this date and will hold the N so it does not move. If this rule were in place, it will significantly shrink the window of opportunity for application. Many farmers use professional applicators who know the rules and provide an ecologically safe and efficient process to apply manure. As organic farmers, we want to go when it is colder and therefore, we are at the end of the list for application. The last two years we were applying manure right before Thanksgiving. With this smaller window I am extremely concerned that we will not have ours applied until early to mid-December when the ground is too frozen to incorporate which means it would have to be surface applied. This is a less effective method for both the environment and effectiveness of N utilization. Our likely only alternative is to purchase our own equipment which is extremely expensive and not affordable for our small farm operation.

As human beings there are dishonest farmers out there as there are dishonest politicians, dishonest government employees, and dishonest environmentalists because we are all human beings. We do want to stop these individuals from continuing to hurt the environment, but we do not want to regulate based on the 1% exceptions that may exist and create problems. I know in my “neighborhood” the farmers understand that soil and water are the two most important aspects of the farm with the land being the single most capital-intensive asset. No farmer wants to apply manure or any other product on their land that will be wasted or ineffective. Farmers are some of the most protective of nature that I have found. We cherish it, we live in it, and we want to maintain our ability to have this way of life. Wasteful economic decisions do not contribute to the achievement of this way of life.

As a young turkey farmer I’m asking the MPCA not to change the animal unit factors for

turkeys. Changing the animal unit rules won't help the environment—they'll add layers of unnecessary beauracracy and burden for farmers.
Turkey manure isn't a liquid. It's dry and easier to handle than other types. The risks are different, so the rules should be too. Please don't include turkey farms in a system that wasn't made for us. I hope MPCA sticks with the current rules that are already working for turkey farms.
Thanks for listening.

As a Minnesota turkey farmer, I'm asking the MPCA to keep the current animal unit calculation for turkeys as it is. On turkey farms, we manage our birds—regardless of sex or weight—the same way. Our manure handling, housing, and nutrient management systems are based off of stocking densities from the current animal unit categories for turkeys, not whether we're raising hens or toms. Creating more animal unit categories adds complexity without improving the environment.
It's also critical that MPCA understands how different turkey manure is from other livestock manure. Turkey litter is a dry mixture of manure and bedding, and it's stored indoors during the flock cycle. Our current management practices minimize runoff risk. A one-size-fits-all rule designed for lagoons or liquid systems doesn't fit litter-based systems like ours and shouldn't be applied across the board.
Another major concern is biosecurity and disease outbreaks, which are unfortunately common in the poultry industry. During events like HPAI, farms are placed under quarantine, and we often cannot move manure or clean out barns on our regular schedules. The rules must allow flexibility for in-barn storage or delayed manure handling during these times. Disease response is coordinated with the USDA and Board of Animal Health, and any rule that ignores this would risk undermining emergency protocols and biosecurity.
Minnesota's turkey farmers care deeply about protecting water, soil, and air quality—but we need rules that are science-based, practical, and flexible. I hope MPCA will keep that in mind as they review the current 7020 rules. Thank you.

During the Chatfield informational meeting, the presenters pointed out approximately 90% of the fish kill events do not have a root cause identified. It makes more sense to put resources into figuring out the root cause before creating additional regulations that may not reduce fish kill events.

Comments on the MPCA list of questions:
1. no comment

2. no changes
I am a relatively small row crop farmer and have brought a small number of cattle back to the farm. Any new or additional permitting restrictions will make the cattle enterprise unviable, and the benefits of livestock to the soil health of my farm will be gone

3. The transferred manure should be managed according to the plan or requirements of the farm at the source of the manure. The source animals are covered by existing

regulations and that shouldn't change just because the manure is applied on another parcel.

Do not implement any of the suggestions in the last 4 bullets of this question. I strongly disagree with restrictions on application base on forecasted or predicted rain. The national weather service forecasts are generally good at predicting temperature for the next 2-3 days, but the ability to predict rain with accuracy is not here yet.

4. any changes regarding manure storage structural integrity should be applied statewide to all systems urban and rural. City septic and holding systems should be included and at the same level of scrutiny. If the Dept of Health and MPCA cannot agree on an item, then it should be discarded entirely.

5. No, smaller sites should not be held to the same requirement. The cost for these types of structures would put an end to small scale cattle enterprises.

One may counter that cost sharing is available for these structures. However, multiple contractors have stated that a project cost basically doubles when it is a government cost share project due to the extra documentation and time required to accomplish the end result.

6. No change. Encourage farmers to work with the local NRCS and Soil & Water Conservation offices.

7. During the Chatfield meeting, the presenter mentioned the current "rule of thumb" is if the distance between lots is more than 1/4 mile it is treated as a separate feedlot.

If more clarity is needed, use the 1/4 mile distance between lots and add a clause that if the property tax parcel identification number is different for the adjacent feedlots they are treated as separate feedlots.

8. Put resources into determination of the root cause before creating more restrictions. "Treat the cause, not the symptom."

9. As a farmer, the manure has value, it is not waste material, and it gets applied such that it provides the most value to my crops.

MPCA Comment letter
The Rock Nobles Cattlemen are a group of men and women working together to promote, advocate and support the cattle industry in our Rock and Nobles County. Certainly, we would like to begin our comments by thanking you for giving us this opportunity to express our thoughts about the 7020 animal feedlot rules in Minnesota. The thought of change and more regulations always brings a level of anxiety but by collecting a wide array of opinions and ideas hopefully a good plan can bring us to our goals. We appreciate your time and consideration on this matter.
First and foremost, we truly feel that the current 7020 rules go a long way in correcting and reaching our goals of reducing groundwater contamination. One of the biggest issues we see is the lack of education among farmers and ranchers regarding our current rules. Knowing when to haul manure, testing manure prior to application, and applying

correct amounts are some of the first topics that come to mind. When to haul and not to apply manure during those critical months is so very important and many producers simply do not know the rules. The current 7020 animal feedlot rules are adequate, there just needs to be more education and resources for farmers and ranchers. Funding, adequate labor force and time seem to be a problem in many faucets of today business, but this is truly the best investment of our tax dollars, not more regulations. We feel more regular farm visits with county soil and water officers and county meetings helping to understand that region's concerns and rules would see great benefits. More regulations without education only allow for a more severe penalty if enforced.

For producers that have moved from 999 AU to over 1000AU, the many extra steps are very eye opening to them. There seems to be a stigma in Minnesota that if a facility stays under 1000 AU there are no rules that apply, but this is not true. Proper management is included in the current rules. Education is very critical and providing the funding and personnel for this to be done at a local or regional level is of utmost importance!

We brought up the local control and regionalization with county SWCDs and we feel that this is an important topic. Minnesota is made up of very different landscapes and soil types. Regionalizing areas according to the soil types, climate, and areas of sensitivity reduces unnecessary regulations that can truly be a burden to those facilities that have a far reduced chance of pollution based on their specific region. Rock and Nobles County have excellent SWCDs offices and their knowledge of the area and what works for others is truly helpful on their visits.

Proper manure storage as application windows are narrowed is continually becoming a concern among feedlot owners. This is an area that MPCA must be aware of, and the economic resources needed if all we are met with are more regulation and no solutions. Offsite manure storage and transferring this valuable and sustainable resource must be considered. This is a heavy burden for our farmers and ranchers, and this should not be left to them to shoulder.

The Best Management Practices that have been voluntarily added among our farmers and ranchers are very noticeable. The use of cover crops to tie up nutrients and add species to a rotation, strip tilling and incorporating liquid manure directly into these strips and reducing the amounts needed are examples. Flow meters, scales and the use of GPS on application equipment allows very precise use of this valuable nutrient. Composting of solid manure is also becoming more common also. Focusing Minnesota's resources and education in this area will reap the greatest benefits to all our Natural Resources.

Over regulation can truly be a heavy burden to the animal agriculture industry. Financial burdens that lead to a decrease in our industry have a great effect on the state's economy. The industry has made great strides in reducing our impact on the environment due to runoff and leaching. Building higher organic matter soils, increasing water infiltration, reducing tillage, increasing the use of cover crops are just a few to be named. Let's keep building on these positive impacts by using the current set of rules that we currently have and provide education and funding to keep moving us forward.

Sincerely
Rock and Nobles County Cattlemen

Any industry or business that stores materials which have the potential to impact ground water quality have a requirement to do inspections, testing, and monitoring.
The storage of manure in amounts typical of feedlot operation is typically in semi-solid or liquid form in lagoons, pits, or tanks. Any storage of manure in these types of structures with capacities over 5000 gallons individually, or cumulatively within ¼ mile shall be required to have ground water monitoring plan approved by the MPCA. All ground water monitoring plans shall:
1. Have no fewer than 4 monitoring wells installed within 100’ of the perimeter of the outer boundary of the storage structure or container where manure would typically be present. The four wells should be installed in a manner that the well screen must be a minimum of 10’ long and spans the seasonal fluctuation of the water table at the Site. (Due to the uncertain direction of ground water flow at the time of installation and seasonal variations fewer than 4 wells are not allowed).
2. A permit from the commissioner (MDH) is generally required for the construction, deepening, and modification of monitoring wells, including at feedlot locations.
a. A single permit application can cover all monitoring wells on a single property used as release detection devices at a feedlot location.
b. Construction Standards:
i. Monitoring wells must be constructed according to Minnesota Rules 4725.6650.
ii. Casing: Must be steel or plastic casing meeting specific standards, including stainless steel or flush-threaded PVC under certain conditions.
iii. Grouting: The annular space must be grouted from near the screen to the ground surface, with specific requirements for at-grade installations.
iv. Drilling Fluids: Must comply with relevant standards, with an exception for free chlorine residual.
v. Screen or Open Hole: Specific requirements apply to monitoring wells constructed to monitor contaminants at the water surface across unconsolidated formation and bedrock contact.
c. Maintenance Permits:
i. Environmental wells (monitoring wells) constructed after January 1, 1990, that are not sealed within 14 months require an annual environmental well maintenance permit.
ii. These permits are required for all environmental wells, and a single permit application can cover those on a single property.
iii. The permit must be renewed annually until the well is sealed.
d. Sampling and Analysis:
i. Groundwater elevations must be monitored in all monitoring wells semi-annually.
ii. Groundwater samples must be analyzed semi-annually for nitrates, fecal coliforms, and total dissolved solids, and other parameters as identified by the MPCA.
iii. Results of each semi-annual water level elevation measurement and sampling event must be submitted to the MPCA within 90 days of the semi-annual measurement and sampling event.
iv. Laboratory data must be generated by MPCA-recognized certified laboratories.
v. Documentation of sampling events, including specific details about the well sampling

procedures, identification of the sampling personnel, and chain of custody for all samples are required.

I am writing here in opposition to any stronger regulations to feedlots under 1000 animal units. Any stronger regulations will cause more small farms to disappear. The economics are not there to force more regulations on these size farms. Farmers are constantly improving their practices to do a better job of protecting groundwater and making better use of nutrients for crops. They can't afford not to. New precision ag products are becoming available all the time and farmers will continue to use these as they become available but don't over regulate and create more paperwork. Soon you will cause more small farms (under 1000 au) to disappear and more small towns and businesses to not be able to survive. Farmers are good stewards of the land and the water, they have to be, because they live with it each and everyday!

I am writing to ask the MPCA Feedlot Rules update to include:
1. More rigorous groundwater monitoring requirements for National Pollution Elimination System (NPDES) and State Disposal System (SDS) permit holding feedlots.
2. More rigorous reporting for transferred manure, and including winter application regulations for new permits.
3. Lowering the threshold for feedlots to obtain NPDES and SDS permits to 600 animal units to prevent the common regulatory issue of feedlots being built right below the current threshold to avoid the more stringent requirements that come with permitting. This is an issue that has been recognized by the MPCA.
4. Changes to how a collection of small feedlots all under the same ownership structure is permitted. We are requesting that rather than being permitted individually, they are permitted collectively.
5. Updating the new manure management plan mapping tool to include more

information about spreading plans and manure infrastructure like digesters. This information should always be made available to the public, not just to potential permitees while they are creating their manure management plan.
I am making these suggestions to the MPCA as a farmer (we raise sheep on 55 acres in Fillmore County) and as a manager of a tourism-related business. These two industries, agriculture and tourism, greatly fuel the economies of Fillmore County, in the heart of Minnesota's karst geology and the most susceptible area to the effects of feedlots, manure, and nutrient management on our soil health and water health. As a graduate of the U of MN in sustainable agriculture, I was quickly taught and learned that agriculture is a human-made system, it is not perfect, and agriculture must constantly find ways to be sustainable for economic, environmental and social reasons. We have better science and collaboration in the last 25 years where we must make changes to the feedlot rules that are a balance to serve agriculture, tourism, human health, and livability. Please consider my suggestions above from the lens of a Fillmore County resident who farms, manages a small hotel, and chooses to raise my young family here. My, and so many of my neighbors', livelihoods and human health are directly tied to how we manage our feedlots and manure, and those effects on our soil, water, wildlife, livestock, and human health. We must balance these interests to ensure our delicate ecosystems in southeastern Minnesota continue to be livable for humans, plants, and animals; and we can continue to thrive.

Dear Rule Coordinator Addison Otto,

I understand that Minnesota animal feedlot rules have not been updated for 25 years. In that time the number of animal feedlots has increased many fold. Now is a critical time to rewrite these rules and stop toxic nitrate pollution in Minnesota's waters. I am very concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including

respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Linda Herron

There actually are not scientifically based levels for nitrate poinsoning. The truth is, if you lower nitrates too low in water systems, you will cause real toxic harm in the form of increased Blue green algae blooms and Methylmercury levels which WILL harm humans.

The Minnesota-based Institute for Agriculture and Trade Policy is pleased to submit the attached comment on the updating of Minnesota's Animal Feedlot rule. Much has changed since the rule was last updated 25 years ago. Thanks for considering these comments.

#1, how is the permitting process going to help reduce pollution? i think it will be zero.
#4, if winter manure application is prohibited, small farms will bear the brunt of the regulatory cost. Large newer CAFOs are built to hold large amounts of manure. Small farms typically are not. Do we want to keep small farms around or do we want to regulate them out of existence? Funding must be made available to build storage facilities for small farms otherwise we will only have large ones. In terms of application on saturated ground, the weather conditions take care of that point. When a soil is fully saturated, there is no way your are taking a manure applicator into that field. Unless the farmer enjoys getting stuck and compacting his land!
To your point #6, Lake in the Minneapolis & St Paul area have been closed do to e coli and there are no feedlots near those areas. Farmers always get blamed when they are

actually one of the smaller contributor to the pollution problem. Farmers value the nutrients they receive from field applied manure and do not want to lose any of it. They take precautions to assure this. COVER CROP: Farmers depend on ideal weather to grow and harvest their crops. No one can control the weather. It a cover crop requirement was implemented, it would be done after harvest and manure application. The crop has to be harvested in order to make money so that is the first priority, or there wouldn't be any farms!! The manure also has to be applied before the ground freezes so seeding a cover crop would have to be the last then done in fall. Then often times it would be too late in the year for that cover crop to grow and be of any benefit. It is just not possible and to expect a farmer to do that before completing harvest. It would be financially devastating. It would also put a huge burden on farners in the form of equipment costs, time spent, supplies purchased and labor costs. I feel farmers are an easy target to blame for water pollution and that is not fair. Municipalities have dumped massive amounts of raw human sewage into Minnesota waters. That is far worse than the small amount of cattle manure that may get in. I believe that implementing these changes because it "Might" improve water quality is not right. There need to be more proof that it is cattle manure causing the problem. The drainage ditch buffer strips imposed on famers has cost them money in maintenance and loss of productive land. I don't believe that was thoroughly thought out before hand and also that it has not improved water quality. These proposed MPCA changes will put an undo financial burden, especially on the small family farm. Think this through thoroughly and do not make it harder than it is to get into farmers by unnecessary regulations.

I have grown up in Agriculture. My family was raising livestock many years before I took over the family farm. We are raising our children on the farm, just like I was raised. The biggest goal of all livestock farmers is to make the lives better for the next generation. We do that by treating our animals humanely, taking care of the land, working hard, and following the rules. The MPCA has worked extremely hard to produce clear, comprehensive, and concise rules that are easy to follow by all livestock producers and manure applicators across the state. The current rules make sense for everyone and are easy to understand and follow.

Family farms work hard to be great stewards of the land. We go above and beyond the current rules when they are applicable and we always follow them. Just like most other farms, we adhere by the best management practices policy. We are very concerned about runoff and leaching, because it is bad for the environment and it cost us money. We have been using Nitrogen Stabilizers during our manure applications for over a decade to ensure the nutrients get and stay where they belong, in the soil for the crops. We make sure setbacks are observed and we only apply manure when the environmental conditions are appropriate. Fall manure applications allow us to have the biggest and best window for the most effective application of manure for the soil and the environment. If we are forced to apply manure in the spring, there are greater chances of accidents, spillage and runoff, and it will be a huge addition of workload and cost. During spring field work, our timelines are maxed out. We can barely get a crop planted. If we are forced to apply manure during that timeframe, there will be problems. There aren’t enough custom applicators to hire to spread manure and there isn’t enough time to both plant the crops and apply manure. There will be more instances of entire farms not getting planted, leaving fallow fields with manure applied to them causing more issues and financial hardships.

As farmers we constantly deal with hurtles and obstacles to make the lives better for our livestock, our families and our future. If significant changes are made to the rules, it will only make it harder for family farms like mine to exist. If there needs to be changes, please base them off of sound science and experience of industry experts. The new rules should be flexible enough to consider other management techniques and philosophies. Please make the new rules easy to follow, with options to allow for a diversified livestock industry to follow the best management practices. Farmers who work for the future need more tools in the tool box to keep the family farm alive.

These are excellent comments Todd. I hope the comments of people who are doing things well and following the rules will be given strong consideration. Operations like this do not need more rules!

It is always good to revisit ways for improvement. There is data that shows that the identification of water issues or fish kills is not identifiable. What is the causal data that is directly linked to farm operations? And the research has not identified if municipalities and cities are the problem either. Therefore, it is premature to suggest rule changes will correct a problem where the source of the problem has not been identified. Nitrates are problematic and what are the contributing sources and impacts of the source(s)?

We have concerns with the suggested idea of manure application date being October 1st or later. Due to fall harvest, weather, and capacity the ability to apply manure limits our window to complete this in the fall. With moisture and maturity dates this often is pushed into the November time frame which can freeze and limit or stop the ability to apply manure using best practices of incorporation.

The suggestion of limiting the N to 195 lbs is contrary to the efficiency and technology of farming now brings. The UofM Extension service is recommending N rates of 210 lbs based on efficiency of use and plant development and depending on the situation this may not be sufficient. Farmers do not want to over apply N as this is a waste of money. There is an economic and yield curve and farmers run their business for profitability and there is not an advantage to overapplying nutrients.

There are currently setbacks in place for manure application regarding water features. These setbacks can be maintained and when incorporating manure should not be an issue as currently set. Manure management plans are already required.

In reference to the suggestion that lagoons need inspections, currently livestock locations are inspected for compliance if they are 300 animal units. This is already happening.

Each geographical area or zone should be identified to separately solve problems if problems exist. If nitrate levels exceed the EPA standard of 10 ppm, enhanced efforts need to be made to keep the water quality safe. There are rules and regulations in place

and farmers do better than this as it is in their and their family's best interest.

The suggestion to apply manure on based on weather forecasts is problematic. As has been noted, relying on rain forecasts from weather apps and the NWS is at best 50/50 probability of being correct. That is why people joke that it would be great to be a weather forecaster because you can be wrong most of the time and still get paid. Please note, it is not their problem, that is how nature works. It is also problematic because the weather can vary five miles apart. Spring of 2024 there were literally farmers planting across the road from each other and one had to stop because of the rain and the other did not. How will any of this be documented to prove that the conditions were fit? Farmers do not want to work land if it is not fit and to do so is economically costly. Compaction of soil is the enemy and if the ground isn't fit this can create a one to three season soil health problem for the farmer.

Applicators are required to maintain manure samples. Farmers are required to have a manure plan. Farmers are required to soil sample to manage nutrient levels related to manure application. Farmers are required to inject manure into the soil or work in the manure within 24 hours of application. Creating more rules when it is not identified where the problem is not a solution. The MPCA has noted that 9 of 10 fish kills are not associated with agriculture, meaning 90% of the problem is not agriculture. We aim to be part of the solution but if we achieved a 0 ppm there will still be a 9 ppm problem and the result will be a significant to impact to the local family farm.

Response:

Don Buhl · Citizen · (Postal Code: unknown) · Jul 22, 2025 12:57 pm
These comments are extremely well thoughtfull and should be taken very seriously! Until MPCA has a handle on the causes of fish kills, no new regulations should be placed on people who are already following the rules and protecting the environment.

To: Minnesota Pollution Control Agency
From: Pat Troendle
Business Names: Full Circle Nutrition LLC, Duschee Hills Dairy LLC
Address: 23962 Grosbeak Rd, Lanesboro, MN 55949
Re: Comments on Proposed Changes to Rule 7020 – Feedlot Program
Greetings,
My name is Pat Troendle. I own and operate two agricultural businesses in southeast Minnesota.
Full Circle Nutrition LLC is a ruminant nutrition and biological fertilizer company. On the agronomy side, we work closely with producers throughout SE Minnesota and NE Iowa. Nearly every operation we support either generates manure or utilizes compost products to build biological activity in the soil. Regardless of operation size, manure is a resource —not a waste product.

Duschee Hills Dairy LLC is our 190-cow dairy farm located in Lanesboro, MN. We manage 560 acres across 92 different fields. Our crop rotation includes about 300 acres of corn and 260 acres of alfalfa, and we follow every corn silage crop with a five-species cover crop. We adhere to a manure management plan developed with our county feedlot officer and are very aware of our region’s environmental sensitivity.
I attended the MPCA meeting held in Chatfield this June. Although no final decisions were presented, it was clear that certain regulatory changes are under serious consideration. I'd like to share a few thoughts, mainly from the perspective of a ruminant livestock operation.

1. Animal Unit Threshold Changes

The idea has been raised to add a fourth regulatory category and increase the requirements under 1,000 animal unit (AU). While I understand the intent is to apply stricter manure storage and application requirements to more operations, it's important to acknowledge that most livestock farms already strive to manage manure responsibly. Ideally, they would have 14 months of storage and apply manure during a narrow window of perfect conditions—but that’s simply not the reality we live in.
If regulators move forward with creating this new category, it is critical to consider the large number of farms that would be newly impacted and the serious economic consequences that could follow. For many of these operations, especially small to mid-sized family farms—the cost of building additional storage, upgrading infrastructure, and complying with stricter application requirements would be overwhelming. In many cases, these improvements would be financially unfeasible and could ultimately force farms out of business.
Any new policy must carefully balance environmental objectives with the economic and operational realities on the ground. Without that balance, we risk accelerating the demise of independent farms and further consolidating the livestock sector, with long-term consequences for rural communities and food security.

2. Limitations on Fall Manure Applications (Soil Temp <50°F)

Restricting fall manure applications based on soil temperature (e.g., below 50°F) is impractical. On our farm, we apply manure after corn silage harvest to make room in our storage basins and to establish fall cover crops in a timely manner.
Fall manure application has key advantages:
• Timely nutrient placement
• Reduced spring workload
• Tillage and incorporation reduce runoff risk
• Freeze-thaw cycles help alleviate compaction
When managed properly, manure incorporated in the fall is a stable and effective nutrient source for the next growing season.
One important issue that wasn’t addressed is that all manure types appear to be treated the same under the proposed changes. However, there are significant differences between liquid manure, bedded pack, and compost. These differences affect not only nutrient availability to plants but also the potential for nutrient loss through runoff or leaching. Bedded pack manure—and especially compost—pose a much lower environmental risk due to their physical form and how nutrients are stabilized within the material.

3. March Application Ban

The suggestion to ban manure applications in March may sound reasonable in theory, but it is unrealistic in practice. March weather in Minnesota is highly variable—conditions can indeed be snowy and wet, making application inappropriate. But just as often, the ground is still frozen, fields are dry enough to support equipment, and conditions are

actually well-suited for responsible manure application. Prohibiting all March applications would force farmers to wait until April, compressing both manure application and spring planting into an already narrow and often unpredictable window. This not only creates significant logistical challenges but could also result in missed opportunities to apply manure under ideal conditions, simply because the calendar says it's too early._____

4. Infrastructure and Time Limitations

The above proposals to temperature and dates assume that farmers have access to unlimited time, labor, and infrastructure. The reality is:

• There is not enough infrastructure (storage, equipment, or labor) to meet such tight timelines.

• Building sufficient storage and logistics capacity would require billions in investment.

• Even with investment, time and variable Minnesota weather remain the biggest limiting factors.

Ruminant operations like Duschee Hills Dairy serve as environmental stewards by using crop rotations which include alfalfa to minimize soil loss and efficiently utilize applied nutrients. Practices such as vegetative buffers, grassed waterways, and low-disturbance manure injection are already used by many producers to mitigate runoff risk

We are not alone, many similar farms across Minnesota do the same. If these operations are regulated out of viability and replaced by continuous row crops or residential developments, the result could be declining soil health and even increased nitrate levels —the very issues these rule changes are trying to prevent.

If Minnesota is serious about improving manure management, then it must be equally committed to funding infrastructure upgrades—such as expanded storage, low-disturbance application equipment, and local composting capacity—so that farmers have the tools needed to comply

_____

5. Nitrate Levels and Blame

While misapplication of manure can contribute to water quality concerns, the nitrate test maps presented at the meeting appear to correlate more closely with population density than with confirmed agricultural sources. Without reliable source tracking, we must be cautious about placing the full burden of blame on agriculture. Are we asking farmers to solve a problem that we can't definitively trace to their practices—and that we currently don't have the tools to accurately measure?

Furthermore, there has been little detail provided about how the necessary infrastructure improvements will be built or funded. If stricter regulations are going to be proposed, there must be a realistic plan for implementation. Rather than focusing solely on manure application restrictions, we should also consider investing in broader water protection strategies—such as replacing old, shallow wells, which may serve as significant nitrate entry points. A more balanced, evidence-based approach would provide better long-term outcomes for both water quality and the farming community.

_____

Conclusion

Thank you for the opportunity to comment on these important issues. I support responsible management and environmental stewardship. However, the proposed changes risk placing unrealistic burdens on producers without the necessary tools or support to comply effectively. I urge MPCA to continue working closely with farmers to find practical, science-based solutions that balance environmental protection with agricultural viability.

As someone actively managing a ruminant operation in a sensitive area, I would welcome the opportunity to serve on any future stakeholder or advisory group working on practical rule development.

Sincerely,
Pat Troendle

RE: Comments on MPCA Rule Amendments Chapter 7020

Dear Mr. Moore,

My name is David Thier and I own and operate a feedlot near Rushmore in Nobles County. I am sending you comments in regards to the MPCA Rules Amendments.

I would first like to thank you for the opportunity to comment. I feel that we as an industry have made great progress in protecting our waters through manure management plans, buffer strips, and overall best management practices. I feel our continued efforts have made improvements. I would however, like to comment on what we cannot do.

Winter time hauling for outside feedlots in Minnesota isn't something we might do. It is a necessity. The prohibition of March hauling is already nearly impossible, let alone proposing a ban on all winter hauling. What, might I ask, should one do with the material (manure and snow) collected and piled during this time? Stockpiling is not an option. I've tried this firsthand, and the material which piled in the winter melts into a puddle of slop that seals the ground on which it sits, making it nearly impossible to manage.

The pollution potential seems much higher to me, than just managing it as we need through the winter. I would strongly urge you to reconsider your ban on March hauling, and continue to let us use best management practices, setbacks and flat slopes for winter application.

The tranferral of manure and its current requirements is also concerning to me. I feel that the state has gone too far in making the recipient of the manure subject to the feedlot owners MMP. While I first question its legality, I also wonder if this won't be enough for those neighbors who had previously purchased manure, to just say "it's not worth the hassle!" Through overly aggressive regulatory reach, we once again achieve a regressive result. Producers who once hauled on neighbors' ground, now have the same manure to apply on less acres.

My question to you, is what part does the livestock industry play in the overall picture of water quality? We are already one of the most regulated states for livestock production, and are at a comparative disadvantage to our neighboring states. Why is the livestock industry singled out as the sole culprit? Is it not possible that row crop operations,

municipalities and lawn fertilization of city residents, could also be a large contributor to nutrient runoff?

In summary, I feel we, as livestock producers and landowners, do a good job in land and water stewardship. We raise our families here, and want to preserve our home. Our operations are family owned and operated, yet we compete not just nationally, but globally. Through this lens, I believe Minnesota has no large livestock operations.

The state thinks that 1000 animal units is large, but in reality this is not so. If we continue to put burdensome requirements on our producers, the family farm will disappear. I struggle with whether I should advocate for my sons to return to the family's operation as 4th generation operators, or give up like so many others and say “you win.” The problem with over regulation, is that it is mostly carried out by those who have never produced. I truly hope that unlike my many other previous comments to MPCA, these comments will have some positive effect.

Sincerely,

David Thier

I raise pork, corn and soybeans in southern Redwood county. As I have pursued this endeavor for many years many changes have occurred that can help the environment. We sample our soils in small grids so as to apply the correct amount of nutrients while at the same time manure is applied at economical rates that help us produce a corn crop the next year. Manure is incorporated into the soil and manure is tested so the proper amount is applied. Manure is a valuable organic resource. Over application is avoided to protect water quality and prevent nutrient loss due to the weather. If necessary a minimal application of fertilizer is applied prior to corn planting. Also over application is very unwise for economic reasons.

Where we farm spring application is less than desirable as compaction will occur which will
lead to runoff. We use no till on some of our acres so as to help with water infiltration in subsequent years. We also practice limited tillage which leads to improved soil tilth aiding infiltration of water.

As I have built new buildings and remodeled buildings the feeders for pigs have been selected to limit water and feed wastage. New buildings are designed to aid in comfort for the pigs which helps with water usage and manure production.

I am not what one would call an environmentalist, but am very careful how I treat the land I farm. Hopefully I leave the land in good stead for the next generation.

I was born and raised in Karst Country and live in Fillmore County, Holt Township. I'm alarmed by policies that continue to allow more application of N than our crops can use, resulting in rising levels of nitrates in our wells.
Rule 7020 needs to be strengthened to adequately protect our groundwater. I support the comments from Responsible Ag in Karst Country (RAKC) and add that the cells of manure lagoons need to have double liners with leak detection systems that would indicate leakage and prevent further contamination of our drinking water.

I am a farmer's daughter, attorney and author of 'Dodge County, Incorporated: Big Ag and the Undoing of Rual America.' The long, enduring fight to force corporate restructuring of rural America started years ago—one corporate factory farm at a time—aided primarily with the assistance of Republican-aligned Farm Bureau. In 1993, the first area swine factory farm was installed in 1993 by the son of a Farm Bureau farmer. During the mid-90s, as area hog farmers delivered their animals to market at Hormel Corporation in nearby Austin, Minnesota, farmers noticed that wait times were taking longer and longer for local independent farmers, as semi-loads of hogs from area factory farms were rushed through the plant and given priority. 1998 was the breaking point for independent farmers, as they were no longer able to deliver hogs to market.

The multinationals cleverly reorganized the marketplace and created a pyramid scheme. Today, multinationals such as Hormel, Brazilian-owned JBS, Chinese-owned Smithfield, Tyson and others occupy the top tier of the pyramid. Integrators such as Christiansen Farms, Holden Farms, Schwartz Farms, Pipestone Systems, Prestage, Iowa Select, and others occupy the middle tier of the pyramid and own the supply chain and provide feed and veterinary services to contract growers at the bottom of the pyramid. Contract growers, once known as farmers, occupy the bottom tier of the pyramid. Forced to "get big or get out," famers were compelled to construct a large factory farm in order to compete and participate in this closed market. While thousands of independent farmers were forced out of the marketplace, that son of a Farm Bureau farmer built a second swine factory farm one mile north of our farm in 1998. Today, our family farm in rural Dodge County is surrounded by 12 swine factory farms in a 3-mile radius.
The act of forcing factory farms into rural areas is part of the coordinated, deliberate and intentional corporate effort to force corporatization of rural areas. Working with Republican-aligned Farm Bureau to cement corporate control of rural areas, industry giants used a combination of market power and political power to turn rural areas bright red politically with the blood of dead corporate animals. In the process, farm families have been pushed off the land, hollowing-out neighboring small towns desperate to survive.

This devastating hollowing-out is nowhere more evident than rural Minnesota. During my youth, my hometown, Blooming Prairie, was a bustling community, sharing an attitude of abundance and kinship. When bread was broken, there was enough for everyone. The town boasted two grocery stores, local banks, two drug stores, a dime store, several restaurants and implement dealers, a furniture store, two clothing stores, local barber shops, a doctor's office, a dental office, a liquor store, a pool hall, local accounting firms

and other businesses on the lively main street as local dollars circulated in the small community.

A healthy interdependence permeated the community as residents bought local products and supported local businesses—long before corporate giants constructed factory farms and extracted wealth from the rural area, divided the farming community and created a sick dependency upon industry giants. Succumbing to the corporate takeover that shuttered Main Street in a single generation, local businesses eventually closed their doors.

One-by-one they closed their doors—schools, churches, restaurants and stores.

In this void, dollars that once circulated in Blooming Prairie and other small towns have been stripped, the profit landing on the corporate balance sheet. Dollars have been funneled to multinational corporations which enjoy billions in corporate profits. Never content with corporate performance, “man is the only animal whose desires increase as they are fed; the only animal that is never satisfied.”

In the wake of this corporate takeover of rural areas, manure management of these large industrial operations has been shifted to contract growers at the bottom of the pyramid. One cannot help but admire the thoroughness of the contract that binds contract growers. Contracts frequently specify that growers are required to indemnify and hold the integrator harmless if any claim, cause of action, demand, or regulatory proceeding is commenced or if there is any loss to the integrator on account of manure storage, manure application, dead pig disposal, public or private nuisance, pit pumping and/or cleaning of the facility, operation of the facility or acts or omissions related thereto. Most contract growers have no idea how to manage the millions of gallons of manure that must be spread on the land.

CAFO manure is an uncontrolled environmental disaster. Some CAFO operators only own a few acres theirs CAFOs sit upon, so they enter into what are called "manure easement agreements" with area farmers who agree to take the manure to spread on their nearby fields. In Dodge County, the county is required to take input about feedlot proposals from the pertinent township officers before the pertinent public hearing. We discovered, however, that three township officers signed manure easements contemporaneous with approval of a large swine factory farm just 1/2 mile west of our farm. Something stinks in Dodge County and other rural counties, and it's not just the pigs. Not all bribes take the form of cash in brown envelopes passed under the table. They can take many forms: gift certificates, prepaid credit cards, free travel and entertainment, free meals, or other noncash transfers. Offering free manure to be spread on an elected official's land is an easy non-traceable method to encourage officials to fast-track factory farm approval. No checks. No bank wires. No cash. No paper trails. Just a trail of stench - and I'm not talking about the manure.

In the fall of 2017, I participated in fall harvest with my elderly father. For three consecutive days, neighboring swine factory farm operators spread manure immediately adjacent to our farm. No notice to neighboring farm families, while factory farm operators receive an exemption to spread dangerous levels of manure during pump-out, threatening the lives of neighboring farm families from the toxic gases emitted from these facilities. As my father worked long hours to finish fall harvest, manure spreading occurred within feet of the combine my father expertly maneuvered through the field. He was eventually overcome by dangerous hydrogen sulfide emissions. Forced to step off the combine to vomit, he was sick for days thereafter, likely due to hydrogen sulfide

poisoning.

That weekend, curious to see the manure-spreading activities up close, my husband panicked as a manure hauler nearly ran our vehicle off the road. That weekend, I personally received two visits from the Dodge County Sheriff's Department. Neighboring swine factory farm operators made bogus calls to the sheriff's department, not to report some infraction, but to put the heat on me and get me to shut up.

Over the years, my family has faced tremendous harassment and intimidation as we speak out against industry operatives, including bullet holes shot in the stop sign just hours after my brother and I pulled weeds from the neighboring bean field just feet away, soiled blue farm booties strategically planted every 100 feet or so from the neighboring swine factory farm to our driveway (a reminder that the industry is large and in charge), pure Roundup sprayed on the corn field which caused thousands of dollars in damage (the perpetrator hit the neighbor's field across the road, not our field), harassing phone calls in the middle of the night to my elderly father, and other heavy-handed tactics to silence my family.

My family is not alone, The tactics employed against my family are the same tactics that have been employed against other farm families across the Midwest. But, the industry will do whatever it takes to silence families like mine, including engagement of the Animal Agriculture Alliance, a pro-industry group that watches the activists.

My family has been on the frontlines for years fighting corporate agriculture. We know many of the games that are played by the industry, including (1) the spreading of manure during the middle of the night, as no one knows where and no one knows how much manure is spread on the land, which eventually seeps into the groundwater and area waterways; (2) double-pledging of land for more than one factory farm; (3) failure of local factory farm operators to file manure management plans with the local feedlot officer; (4) failure of factory farm operators to secure water appropriation permits, as these large industrial operations strip millions of gallons of water from the aquifers each year; and other infractions.

For years, we could not drink the water at my husband's family farm on the north end of Dodge County, while neighboring swine factory farms drink pristine water from wells dug over 400 feet deep. Nitrate levels at my husband's family farm and other neighboring farms increased to 24 mg/l, 25 mg/l, and 26 mg/l, far in excess of the safe threshold of 10 mg/l. Eventually, my husband's family had to install a reverse osmosis system at their own expense to strip nitrates from the water.

Just one mile north of my husband's family farm, there is a road which the locals refer to as "Cancer Road." On this one-mile stretch, every single-family reports extremely high nitrates and every single family has been impacted by cancer. The combination of high nitrates and cancer is no surprise to many, as the neighbors fought installation of a large swine gestational facility that is situated at the corner of Cancer Road (County Road B) and Highway 7. Several years ago, the neighbors fought installation of this large gestational facility, which serves as the hub for several area factory farms. Situated on sensitive karst topography, Dodge County officials (then part of the MPCA Delegated County Program) nonetheless recommended approval of this facility in this region known for limestone outcroppings, sinkholes, natural springs, fissures and other characteristic landforms.

Today's corporate agriculture system requires a complete overhaul, including (1)

imposition of steep fines on the multinationals at the top of this pyramid scheme for failure to attend to environmental cleanup from these large industrial operations; (2) imposition of steep fines for failure to file manure management plans; (3) imposition of rules which require factory farm operators to provide ample notice to neighboring farm families regarding the spreading of manure from these industrial operations; (4) reversing the exemption that is extended to factory farm operators during fall "pump-out;" (5) prohibiting local county and township officials from signing manure easements with area factory farm operators; (6) directing local county and township officials to immediately disclose all manure easements with area factory farm operators and the amount paid, if any, for the receipt of manure from area factory farms; (7) immediate review of the MPCA Delegated County program, including abuses associated with this program; (8) immediate re-installation of the MPCA Citizens Board; (9) immediate hiring of additional personnel at the MPCA and other regulatory agencies; and (10), other measures, as appropriate to arm the regulators with appropriate oversight and methods to secure compliance.

I welcome the opportunity to serve on the MPCA Citizens Board or similar board charged with oversight of industry giants.

In 2002 I was chief author of a bill that made the 2000 rules workable. This bill passed the Republican controlled House and the DFL controlled Senate and was signed by the Governor. Through the hearing process we heard time and time again how the rules would put smaller farms out of business. We probably slowed down the exodus of small farm but the bleeding continues.
Since I left the MN House in 2004 I have operated a cattle finishing operation that is permitted up to 300 AU. First thing I want to make clear is the banning up spreading manure in winter months is unworkable. The manure pack in barns has to be managed and that includes the removal of the pack. During time in the winter when you have warmups above 32 degrees the manure pack warms and gives off smell that causes respiratory infections in animals. The easiest way to avoid using drugs is to clean the barns and apply the manure to the field. It is not as simple as piling it until spring. Without a pad that is made to contain the runoff you accomplish nothing. And that is where a huge expense comes in that in todays markets is not financially doable. As we learned in the hearings in the MN House this type of rules puts the small operators at a huge disadvantage and will only speed up operators leaving the business.

Any additional rules the burden operators financially will cause a greater exodus from livestock farming. The average age of livestock farmers has them approaching retirement. I'm 67. We are not going to leverage our equity when we know our sons and daughters have no chance of making it with additional rules. It is just easier to let the big guys (that can spread the cost over more AU) have the headaches.
This is not to say that we do nothing. About 10 years ago I was one of the first to go through the MN Agriculture Water Quality Certification Program and met the requirements. Programs that work with farmers are far superior than ones that use a stick. Blaming farmers for all fish kills when most can't be explained is not fair. There are

groups out there that are using process as a way to destroy animal agriculture. We are not going to sit back and let that happen.

Regarding Animal Feedlot Rule, Minnesota Rules, Chapter 7020

Recommendations from Responsible Agriculture in Karst Country

Our citizen group (RAKC) was successful in 2018 in convincing our neighbors and state regulators to reject a large Confined Animal Feeding Operation from being constructed in our community, due primarily to concerns about water quality in our karst region of Fillmore County.

Our input to this feedlot rule will focus on the delicate and usually unseen dangers of karst landscapes. Strict investigations and rules must be enacted before animal feedlots are permitted and before manure disbursement takes place, in order to preserve the public health of all local citizens.

Rationale for Strengthening MN 7020 Rule Regarding Karst Vulnerability

The current Minnesota Rules Chapter 7020, while attempting to regulate animal feedlots and manure management, falls short in adequately protecting groundwater in karst regions like southeastern Minnesota. The core issue lies in the unique hydrogeology of karst, which facilitates rapid and direct pathways for surface contaminants to reach underlying aquifers.

Pervasive Karst Goes Beyond Just Sinkholes: Karst is often visually recognized by dramatic features like sinkholes and caves. However, these are merely the most obvious expressions of a much more pervasive geological phenomenon. Karst landscapes, especially in the Driftless Area of southeastern Minnesota, are characterized by soluble carbonate bedrock (often limestone and dolostone) that has been extensively dissolved by slightly acidic water over geological timescales. This dissolution primarily occurs along existing joints (fractures) and bedding planes within the rock. Karst features are often also found in overlying or underlying sandstone layers; the St. Peter and Jordan Sandstone are primary aquifers for the southeast region of Minnesota.

Near-Surface Joint Sets (Karst Lineations): Networks of bedrock fractures that extend upwards to within a few feet of the ground surface, are often lying beneath a thin soil cover. During dry periods, these joints allow plants to access moisture deeper within the bedrock, leading to patterns of denser, greener vegetation known as "karst lineations" or "crop lines." These lineations are not just curiosities; they are direct evidence of highly permeable pathways that bypass the filtering capacity of surface soils. Water, sediment, and pollutants can rapidly infiltrate through these subtle yet widespread features, directly into the underlying fractured carbonate and sandstone aquifers.

The Arbitrary Nature of Current Rules: The existing 7020 rules, with their fixed setback distances (e.g., 300 feet from a sinkhole) and quantitative triggers (e.g., 4 or more sinkholes within 1,000 feet), are insufficient because they do not fully account for this

pervasive, interconnected nature of karst. A contaminant traveling through a discreet joint or conduit can traverse hundreds of feet in a short period, rendering arbitrary linear distances ineffective. The real vulnerability lies in the hydrogeological connectivity which often extends far beyond visible features or simple numerical thresholds. We now have the knowledge and tools to investigate whether a feedlot or manure application area is vulnerable to excessive pollution of groundwater.

A well-managed presence of animals on the landscape, particularly through practices like rotational grazing and distributed manure application, can significantly improve soil health and water quality by building organic matter, enhancing infiltration, and cycling nutrients naturally. However, the rapidly increasing scale and concentration of confined animal operations (CAFOs) present a fundamentally different and more challenging scenario. These operations concentrate vast quantities of manure, creating an immense nutrient load within a limited geographical area. The old adage, "Dilution is the solution to pollution," holds a profound truth in this context. When pollution levels become too high – when the density of a contaminant source overwhelms the landscape's natural capacity to assimilate or filter – the only effective strategy to protect our shared resources is to decrease the density of the source itself. In the context of concentrated animal agriculture in a highly vulnerable karst environment, this means critically evaluating and, where necessary, limiting the concentration of animal units and associated manure within sensitive geographical areas. This document outlines a set of urgent, scientifically-backed recommendations to strengthen Minnesota Rules Chapter 7020, aiming to protect these critical aquifers for generations to come.

Therefore, strengthening MN 7020 is critical to transition from a reactive approach (addressing pollution after it occurs) to a proactive one (preventing pollution by recognizing and protecting all vulnerable karst pathways).

Recommendations to Improve the 7020 Rule

(1) Agronomic rates for manure applications should be customized for particular soil and geological types, highlighting sensitivity to nutrient-loss.

Relevance: The current understanding of "agronomic rate" often focuses solely on maximizing crop yield, which has demonstrably led to excess nutrient application and subsequent nitrate leaching into groundwater. This issue is critically amplified in karst regions where there is little natural filtration.

Reasoning for Public Comment: Scientific Necessity: Different soil types (e.g., sandy vs. clayey) and underlying geological formations (e.g., fractured limestone vs. thick till) have vastly different capacities to retain or leach nutrients. A "one-size-fits-all" agronomic rate fails to account for this variability.

Environmental Protection: Customizing application rates based on nutrient-loss sensitivity means applying only the amount of nutrients the crop can realistically utilize, given the soil and geological context. This minimizes the excess nitrogen available for leaching, directly reducing the load on vulnerable aquifers. In karst areas, this is paramount to prevent nitrate contamination of drinking water sources. Both manure and fertilizer applications need to be customized.

Economic Efficiency for Producers (Long-Term): While initially perceived as a burden, more precise nutrient management can reduce input costs over time by preventing the waste of expensive fertilizers that are simply lost to the environment. It shifts from

"insurance" application to "precision" application.

(2) Create a Karst Vulnerability Assessment for new or expanding CAFOs that will ensure karst sensitive regions are qualitatively and quantitatively reviewed.

Relevance: The current rule's reliance on arbitrary distances and sinkhole counts is inadequate for truly protecting complex karst systems. A comprehensive, scientifically rigorous assessment is needed.

Reasoning for Public Comment: Accuracy and Effectiveness: While a significant portion of southeastern Minnesota's aquifers is widely recognized as highly sensitive and vulnerable, the precise nature and degree of karst vulnerability is highly site-specific. This underscores the critical need for detailed, localized assessments. A comprehensive Karst Vulnerability Assessment would use multiple, state-of-the-art techniques (e.g., advanced remote sensing, geophysical surveys, detailed drilling, dye tracing) to qualitatively and quantitatively map the actual pathways of water flow to the aquifer. This moves beyond assumptions to data-driven decision-making.

Targeted Protection: By identifying specific "high-vulnerability zones" based on robust scientific data, resources can be more effectively targeted for protection, ensuring that the most sensitive areas receive the highest level of scrutiny and protective measures. This avoids over-regulating low-risk areas while under-protecting critical ones.

Proactive Planning: A karst vulnerability assessment allows for proactive land-use planning and siting decisions, preventing new pollution sources from being placed in extremely sensitive areas where remediation is difficult or impossible once contamination occurs. Existing feedlots of 300 and up AU should also be sent information about karst vulnerabilities discovered in the Karst Vulnerability Assessment.

(3) All Nitrogen sources must be considered in nutrient management plans (not solely manure, nor just synthetic fertilizers).

Relevance: Farmers apply nitrogen from various sources (synthetic fertilizers and manure). If only one of these sources is accounted for, the total nitrogen load applied can still significantly exceed crop needs, leading to leaching.

Reasoning for Public Comment: Complete Nutrient Budgeting: To truly manage nitrogen effectively and prevent excess, multiple forms of nitrogen entering the soil system must be accurately quantified.

Minimizing Surplus: By comprehensively accounting for N sources, nutrient management plans can ensure that the total available nitrogen aligns more precisely with crop requirements, minimizing any surplus that is highly prone to leaching, particularly in karst areas.

Environmental Accountability: This ensures that the environmental impact of nitrogen is considered holistically, promoting a more responsible and sustainable approach to nutrient use that directly benefits groundwater quality. Drinking water supplies will be better protected as well.

(4) Place a cap on animal units within a geographical area, within state-defined and recognized sensitive regions. This will aim to cap and/or lower the density of animal units to decrease the source of nutrients that are leaching into groundwater.

Relevance: Even with stringent management practices, a very high density of animal units in a highly vulnerable karst landscape generates an immense volume of manure and associated nutrients, increasing the cumulative risk of groundwater and surface water contamination.

Reasoning for Public Comment: Source Reduction: This measure directly addresses the source of potential pollution. By capping the density of animal units such as in defined sensitive karst regions, the overall nutrient load (nitrogen and phosphorus) being generated and potentially applied to land in these vulnerable areas is reduced.

Carrying Capacity of the Landscape: Every landscape has a finite carrying capacity for nutrient assimilation, especially in karst where natural filtration is limited. This rule acknowledges that some areas are simply too sensitive to safely accommodate very large concentrations of animal agriculture without incurring unacceptable health and environmental risk.

Preventing Future Cumulative Impacts: This proactive measure would help prevent the exacerbation of existing groundwater quality issues and protect currently unaffected areas from future degradation due to an unsustainable density of nutrient sources.

(5) Monitor air quality, to ensure standards are met, using instruments the state pays for and has access to.

Relevance: While water quality concerns are paramount, feedlots are also significant sources of air pollutants (ammonia, hydrogen sulfide, particulate matter, volatile organic compounds) that impact public health and can contribute to environmental degradation.

Reasoning for Public Comment: Public Health Protection: Feedlot emissions can negatively impact the respiratory health and general well-being of nearby residents. State-funded and operated monitoring provides independent, unbiased data to assess compliance with air quality standards and protect public health.

Accountability and Transparency: State-managed monitoring ensures transparency and accountability, providing objective data for regulatory enforcement and informing community concerns about air quality impacts from feedlot operations.

(6) Cap well size usage for feedlot operations to discourage aquifer overuse (drawdown).

Relevance: Large-scale feedlot operations, especially those with many animal units, can have substantial water demands for drinking, waste flushing, and cooling. Excessive groundwater pumping can lead to aquifer drawdown, impacting other well users nearby, increasing pollution infiltration rates, and may reconfigure groundwater flow direction, thereby expanding the reach of contaminated water to previously unaffected wells and communities.

Reasoning for Public Comment: Sustainable Water Resources: Minnesota's aquifers are a shared public resource. Putting a cap on well size or, more broadly, limiting annual water appropriations for large feedlot operations helps ensure the sustainable use of groundwater for the larger impacted region, preventing excessive drawdown that can deplete aquifers and impact domestic wells, municipal water supplies, and connected surface waters.

Shared Responsibility: This measure ensures that large industrial agricultural operations contribute to the responsible management of water resources, just as other large water users are regulated. It encourages water conservation practices within feedlot operations.

(7) Restrict Liquid Manure Storage Areas to smaller 250,000 gallon cells, within geologically or environmentally sensitive regions.

Relevance: This directly addresses the risk of catastrophic failure of large liquid manure storage areas (LMSAs) in highly vulnerable karst settings, where a rapid loss of stored manure can have devastating, immediate, and widespread environmental and health consequences both above and below ground.

Reasoning for Public Comment: Mitigation of Catastrophic Failure: While sinkholes or liner failures cannot be entirely prevented, limiting the volume of individual cells within a manure containment area dramatically reduces the magnitude of pollution released in a single event. A 250,000-gallon spill, while still serious, is significantly more manageable and less environmentally damaging than a multi-million-gallon release.

Increased Containment Potential: Smaller spills are more amenable to rapid containment and remediation efforts, reducing the spread of contaminants into the broader environment and aquifers.

Risk Management for Sensitive Areas: This cap specifically targets geologically and environmentally sensitive regions (like karst), where the consequences of a large-scale failure are most severe due to direct aquifer connectivity. It prioritizes the protection of vital drinking water sources. Additionally, the line between groundwater and surface water is blurred in karst geology, and such failures can (and have) had major impacts on trout streams which are of huge importance to the local economy and environment.

(8) Polluters pay: Confined Animal Feeding Operations are point sources of pollution, and they are private businesses. They should play by the same rules as every other business if they pollute waters of the state. They should be held accountable for property values of neighbors, road destruction, etc.

Relevance: This principle seeks to shift the financial burden of environmental damage and community impacts from the public and affected individuals back to the polluting entity.

Reasoning for Public Comment: Economic Justice and Fairness: The "Polluter Pays Principle" is a widely accepted environmental and financial tenet. If a private business, regardless of sector, causes harm to public resources (like water or roads) or private property (like neighbor's land values), they should bear the cost of remediation and compensation. This prevents the externalization of costs onto taxpayers and affected communities.

Accountability for Environmental Damage: When CAFOs contribute to nitrate contamination of drinking water wells, they should be held financially responsible for providing alternative safe water sources or for remediation efforts. This aligns with accountability for violating water quality standards.

Addressing Broader Community Impacts: Studies have consistently shown that CAFOs can negatively impact nearby property values due to odors and aesthetic concerns.

Additionally, the heavy truck traffic associated with large feedlot operations can cause significant damage to rural roads, imposing substantial repair costs on local governments and taxpayers. Holding CAFO owners accountable for these documented impacts ensures that the full societal cost of their operations is recognized and addressed.

Respectfully Submitted, Responsible Agriculture in Karst Country

MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.

MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution.

MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.

MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

As someone who drinks and swims in Minnesota water, I want the MPCA to enforce safer and stricter policies of animal feedlots to prevent any pollutant runoff. This will not only protect the health of people, but the health of the animals who eat at the feedlots and the health of the watershed. We need healthy animals and healthy ecosystems for us to be healthy too, because all our health is connected.

We are NOT opposed to rules and regulations for feedlots in Minnesota. What we ARE opposed to, are rules that are high risk and low reward, meaning the results are projected but not achieved, and they can threaten the existence of animal agriculture in Minnesota. The fact that livestock operations have gotten bigger is not a scenario where “factory farms” have gobbled up small family farms. It is the same economic driver that has caused the loss of the small-town grocery stores, hardware stores, banks and more. It is the economy of scale and size that bring the efficiencies that make them competitive. As costs go higher, farmers need more units to spread the cost over. It doesn’t matter if it is animals, grain, fruit or vegetables. I’m a small farmer and I feel the pinch.
We need common sense rules that have achievable results. We need to keep focusing on the gains that we have achieved, to reach our goal. I live on the farm I run. I’m proud of what I do. It disheartens me when so many people disconnected with agriculture bash an industry that helps provide the safest, most abundant, and lowest cost food supply in the world. Most of the regulations people are proposing here will just aid the demise of the small farmers we have.

The Minnesota Department of Natural Resources supports the MPCA's rulemaking action updating its feedlot rules to address water quality and avoid fish kills. We look forward to reviewing preliminary rule language and are happy to provide information and assistance to the MPCA throughout its rule development process.

Thank you,
Melissa Kuskie

I run a small, family-owned cow-calf grazing operation in Fillmore County's rolling blufflands, which are known for livestock operations. Much of the pastureland in this area is hilly, and highly erodible land, but perfectly suited for grazing. We raise alfalfa and small grains in rotation with corn and soybeans. We have a small (unnamed) stream that meanders through many of our pastures. It would be impossible to fence this; it

stretches miles, and it wanders through sharp hills and sections of solid rock. It will also create many isolated pockets of pasture that cannot be connected -- and without water supply. (Fillmore County has few if any natural ponds, unlike the majority of the state, so livestock have used streams as primary water sources, historically. A blanketed stream fencing mandate will end our cattle operation.

If the state acts to create these barriers, we will be forced to put the land, highly erodible pasture and hay ground, into row crop production. This will be much more detrimental to the Minnesota environment erosion-wise, chemical-wise, fertilizer-wise, pesticide-wise and carbon-wise, compared to the alleged impact of cattle. MPCA has stated that the loss of pastureland, small grains and hay are a loss to the state in terms of environmental impact and in terms of revenue. Please don't impose blanket regulations that will increase this loss and also put small farms out of business.

The MPCA must adopt appropriate rules that limit the maximum size of feedlots for permitting purposes. The rules must not allow any feedlots to be permitted in karst regions or other sensitive areas (e.g. fens). In addition, the rules must consider that feedlots are non-point sources of pollution. Thus, the MPCA must require sufficient monitoring of feedlots and stringent water quality standards to protect surface water and groundwater resources. It is not sufficient for the MPCA to merely consider point source discharges from feedlots. Similarly, the MPCA must require water monitoring to include parameters that fall under MN Rules Chapter 7050, including all classes, including drinking water. Thank you for considering this and all other comments.

Thank you for providing this venue on such a vitally important topic on the 40661 Minnesota Pollution Control Agency Request for Comments on Animal Feedlots Rule. I write to not only support fundamental changes including -
More rigorous groundwater monitoring requirements for NPDES and SDS permit-holding feedlots.
- More rigorous reporting when it comes to the transferring of manure.
- Lowering the animal unit size threshold for feedlots to obtain NPDES and SDS permits to 600 animal units.
- Changes to how a collection of small feedlots all under the same ownership structure is permitted.
- Updating the new manure management plan mapping tool to include more information about spreading plans and manure infrastructure like digesters. This data should be made available to the public, not just to potential permitees while they are creating their manure management plan.

Alternatively to developing additional regulations which will require more cost for the farmer it is vital to look into composting methods as a mean of handling manure in a way that can reduce costs, provide biologically viable inputs that integrates high nitrogen manures that is has high organic matter and improves soil health. In addition to regulation we have provide farmers incentives to find genuine alternatives to address

the needs of the region.

Having served on the Winona County Board of Adjustment for several years, I have had the opportunity to to review the history, the science, and the evidence of the nitrate pollution problems in the karste geography in SE MN. From this experience, I have learned that many farmers want to do the “right thing” in protecting our ground water, but not been supported to be able to bring their practices in line with the preventions necessary. The Feed Lot number is only the tip of the iceberg. In addition, we must offer support through education and resources to make the transition to organic regenertive practices. Focusing only on the Feed Lot numbers without tranforming the practices of chemical uses conventional farming uses will not proving a lasting solution. Helping farmers learn how to, for example, use composting as the foundational product for healthy soil and increased productivity will also remediate our present water pollution. With this effort, we must keep the whole scenario in focus. We must “fix” it, not just reduce it.

Theresa Keaveny · Citizen · (Postal Code: unknown) · Jul 22, 2025 10:03 am

I urge MPCA to update the feedlot rules to limit the number of animal units per feedlot to 600 under National Pollution Elimination System (NPDES) and SDS, and to establish a more robust monitoring and enforcement system that protects surface and groundwater of the area. Also, the cumulative effect of livestock feedlots in an area needs to be better assessed before new feedlot permits are allowed, to reduce run off and leaching of pollutants. The consent agreement with MPCA, EPA and MDA offers an opportunity to substantially improve state requirements. It would be helpful to offer incentives to farmers to transition from manure-intensive feedlots to regenerative practices such as managed grazing and pasture-based animal feeding. And, offering free well testing to residents near feedlots, with support to repair or replace wells that are affected by feedlot run off, is long overdue. Thank you for the opportunity to comment.

40661 Minnesota Pollution Control Agency Request for Comments on Animal Feedlots Rule:

As a Minnesotan concerned about water quality in our state, I appreciate the MPCA’s work to update the animal feedlots rule and urge the agency to make it MUCH stronger. Large areas of the state, especially in vulnerable regions like southeastern Minnesota, are struggling with water quality issues caused by nutrient runoff, to which feedlot manure is a big contributor.
This is affecting people in this area, but much overlooked perhaps is that this is also causing a great risk to our “other than human” neighbors. Birds, deer, squirrels, etc., and especially fish and other species living in the water world, need clean water too. They do

not have a choice of filtered water but must drink directly from our streams and rivers, lakes and wetlands.
Several millions of species of teeming life are now under the care of one species – humans. We must have the moral and ethical imperative to value these species as something with a claim to existence in their own right and to ensure their right to thrive and survive into the future.
I ask that the MPCA take the following steps:
• Lower the size for a feedlot operation to be required to apply for a water pollution permit. Currently, many feedlots skirt greater regulation by operating just under the permitting limit of 1000 animal units, this should be lowered to no more than 600 animal units.
• Require feedlots with those permits to closely monitor their manure discharges to protect nearby groundwater and streams.
• Set stricter limits on manure application to farm fields in vulnerable areas, like the heavily nitrate-polluted karst region in southeastern Minnesota.
• Regulate multiple feedlots owned by one owner as a unit not as separate operations. Currently, an owner of multiple feedlots, even feedlots right next to each other, can skirt stronger regulations by keeping them as “separate” operations, though the total pollution is the same as a large feedlot.
• Require more rigorous reporting on manure transfers.
• Make more manure managing data and mapping available to the public, including information about digesters and manure spreading plans.
Minnesota’s lakes, rivers, and groundwater have been getting more polluted every year, this is unacceptable, and we completely rely on the MPCA to protect these resources for all Minnesotans. This is a chance to take a step in the right direction. The present response remains, if not completely negligible, very far from adequate. It is far past time to no longer rely on “business as usual” decision making. It is time to rise to the occasion and take the bold steps needed within this decade.

MPCA 7020 Feedlot Rulemaking

No additional restrictions are needed. According to the MN Extension, farmers have reduced manure and fertilizer rates and are now much in line with their recommendations. Farmers are already required to follow setbacks and with the new buffer laws in place adding more rules makes no sense. You still must consider all the problems that do not come from farmers such as wildlife and other people. A lot of the nitrates come from decomposing grass, leaves and other materials and farmers are given the blame.
No, current rules for 1000 AUs are in place. Smaller farmers already must have a manure plan and do manure and soil testing and follow BMP. So, there is no need to reduce the number from 1000. There are current rules on the books and recommendations for fall application of manure. For many of us we must inject the manure and wait till temperatures are below 50 degrees. Let’s all use common sense and please do not strangle us with red tape.
We recently opened and cleaned out a hog manure pit that had been holding manure for 38 years. It was in great shape and showed no signs of cracking. If the engineer does a good job designing the holding structure and checks the quality of the cement or other lining they are using, then there should not be any need for you to make rules on this

matter.
Excessive rules forcing small farmers to pay for long-term storage without the help of the state will force a lot of farmers out of business.
The WRAPS have documents that blame farm livestock for the high nutrients and bacteria in water, but I have seen large flocks of geese as well as other water fowl in the water and along the banks in which you can find a lot of manure that they leave behind as well as the four legged wildlife that visit the streams for a drink.
If a feedlot has a different address, it should be considered a separate facility whether owned by the same person or not.
Fish kills are rare and being caused by a farmer is ever rarer. Promote and encourage farmers to use cover crops when feasible as well as BMP at all times. Many of the fish kills are caused by municipalities flushing out their sewers.
You will have a lot of people making comments and many of those people have never step foot on a farm or ever know a farmer. It is good to get opinions from everyone but please be considerate that it is the farmers who must live with all the new rules, and quite often the rules are not needed, they are written to make a few people feel good. I just read an article in the Star Tribune that stated the Green Gardens that were started in the Twin Cities are showing that a lot more nitrates and extra phosphorus are being generated and going into the storm sewers. It is the exact problem they thought they were going to eliminate. It did help filter out some of the lead and other pollutants, but it increased the nitrate problem. In another story that was just published, migrating birds landed in some dead trees around a lake in the Twin Cities area and they dropped over ten thousand pounds of manure. The local people complain about it but no one has common sense to do anything about it. They say this type of bird only sits in dead trees. All they needed to do was remove the trees but now their nice lake is dead, and they can’t even blame a farmer.

I am writing to strongly request that MPCA feedlot rules are significantly strengthened. The fact is that Minnesota already has a nitrate problem that is killing babies. Groundwater in SE Minnesota in particular is already impacting the health of Minnesotans and without stronger regulation, monitoring and consequences, that part of our state will turn into a sewer that cannot support life. We must do better. I am not a scientist or specialist. I am an average Minnesotan who cares about the livability of our state and the legacy we are passing to ALL our children. The particular rule sections I support changing are as follows (and have been commented on by others):
MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.
MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.
MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.
MPCA rules should stop merely trusting that animal feedlots and manure applications are

“no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.
MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.
MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.
MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Thank you.

As a livestock farmer in Northern Minnesota I have concerns with the new feed lot proposed rulings. I attended the meeting in Detroit Lakes MN on June 4th and appreciated the open discussion we had. We not only raise beef but we raise our families here we also want safe wells and waterways as well . We have been committed in implementing practices over the years to be compliant with current rules. Our farm is not close to any waterways and we have buffers in place when we spread our manure and till it in right away We also use cover crop on any land we pasture even during the winter which helps with the water infiltration into the soil during rain and snow events and thus less runoff .We feel that changing the feedlot rules will make it more expensive for younger and smaller farmers being profitable in farming. We also feel that any feedlots that are over half mile apart regardless of ownership should be able to maintain their own identities because in the reduction in the concentration of the manure. Being a fifth generation farmer we are stewards of the land that we use to be able to preserve it for the next generation with having blanket restrictions being applied. Thank you for your consideration on these rulings. Blair Hoseth

I am very concerned about water quality in our state, especially in the Karst region of SE Minnesota where nitrate contaminates wells and vulnerable trout streams. I appreciate the MPCA's work to update the animal feedlots rule and urge the agency to protect the public's health and the health of aquatic ecosystems by strengthening them. Nutrient runoff from feedlots are a major contributor to the high levels of nitrates in SE Minnesota. It should be obvious that the current rules are not working.
I ask that the MPCA take the following steps:
Lower the size for a feedlot operation to be required to apply for a water pollution permit. Currently, many feedlots skirt greater regulation by operating just under the permitting limit of 1000 animal units, this should be lowered to no more than 600 animal units.
Require feedlots with those permits to closely monitor their manure discharges to protect nearby groundwater and streams.
Set stricter limits on manure application to farm fields in vulnerable areas, like the heavily nitrate-polluted karst region in southeastern Minnesota.
Change how multiple small feedlots with the same owner are regulated. Currently, an owner of multiple feedlots, even feedlots right next to each other, can skirt stronger regulations by keeping them as "separate" operations, though the total pollution is the same as a large feedlot.
Require more rigorous reporting on manure transfers.
Make more manure managing data and mapping available to the public, including information about digesters and manure spreading plans.
Minnesota's lakes, rivers, and groundwater have been getting more polluted every year. We lost a champion for protecting our trout streams and drinking water this year with the death of Jeff Broberg whose private well became increasingly polluted with nitrates over the years. Please honor his legacy by following the science and strengthening the rules on feedlots.
Thank you,
Veda Kanitz

Dear Sirs and Madams,

MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.
MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.
MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.
MPCA rules should stop merely trusting that animal feedlots and manure applications are “no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.
MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.
MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.
MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Thank you very much for your help!

I wish to comment on the proposed changes. Fall application is essential to properly utilizing manure nutrients for crop production, avoiding compaction and protecting the environment which is a high priority for us. Fall application allows us to choose a time to apply manure when the soils are cool and in good condition to accept and retain the nutrients applied. Mandated spring application would force producers to compromise because of the time pressure of a short planting window. This would be likely to harm the environment because of increased compaction,increased runoff and the absence of a freeze/thaw cycle after application to condition the soil for crop production. We have had an NPDES permit for many years and have followed the regulations and reporting rules and have preserved our environment.We test our manure and our soils and apply manure in appropriate amounts to raise a crop. We do this on our own land and with the manure we transfer to other landowners. The proposed changes would do nothing to inprove on how we are protecting the envoronment. These changes would only make it harder for us to handle our manure in a way that utilizes the nutrients in a way that protects the enviroment. They may look good on paper, but in the real world this could be a real mess.
Thank you for considering my comments.

I support changes to the animal feedlot rules and believe the MPCA should update the animal feedlot rules to continue protecting MN groundwater and waterways.
I live near a creek in rural southern MN which is polluted with fecal matter and nitrates to the point it can't be enjoyed for wading or fishing. This sort of degradation of water quality points to the critical nature of updating rules to be relevant to current agriculture practices and to the demands of American consumers and ag trade.
These are the ways the rules should be updated:
1 - More rigorous groundwater monitoring requirements for NPDES and SDS permit-holding feedlots.
2 - More rigorous reporting when it comes to the transferring of manure.
3 - Lower the animal unit size threshold for feedlots to obtain NPDES and SDS permits to 600 animal units.
4 - Change the way a collection of small feedlots all under the same ownership structure is permitted.
5 - Update the new manure management plan mapping tool to include more information about spreading plans and manure infrastructure like digesters. This data should be made available to the public, not just to potential permittees while they are creating their manure management plan.

Throughout Minnesota we can see ways in which improved monitoring and reporting will improve quality of life for our children, our neighbors and the animals. Additionally, by shifting the balance of animal unit thresholds to reduce pressure on our soil and waterways, we will sustain a strong agricultural system and a healthier environment. The MPCA can take steps now to protect many generations in the future.
Thank you for doing this work to improve our great state.

I am writing to oppose further regulations on Minnesota feedlots.
Feedlots already follow setbacks for land application and building of new lots.
Farmers deserve the freedom to operate and are diligent in their practices. Using precision agriculture practices farmers are able to apply manure at prescribed rates according to soils samples. Manure is a valuable natural resource used to fertilize crops.
We live where we farm and ensure safe manure practices to keep our family healthy.
Rules now in place are adequate and should stay the same.

To whom it may concern,

As a multi-generation family farming operation in Southeast Minnesota, the possible changes being considered to the 7020 rules are concerning and are very pertinent to our family's operation.

- As a hog, cattle, and cropping operation, we have manure that we spread in the spring and the fall. We inject most of our hog manure in the fall and do some in the spring. However, we apply the least we can in the spring because spring manure application is harder on crop yields, increases soil compaction, decreases seedbed quality, reduces planting timeliness, and crop evenness. Additionally, bigger rains and wetter soil are much more common in the spring than in the fall. If the rules were to change or narrow the application window in the fall, it would be very tough for our custom manure dragline crew to be able to serve all their customers in that small window.

- Our family uses multiple BMP's to protect the environment and water quality. We apply low amounts of manure over our acres, incorporate our manure into the soil to increase nutrient retention and prevent runoff, vertical tillage to improve nutrient retention and water holding capacity while reducing erosion, water ways to hold and slow water running in big rain events, crop rotation, cover crops, and we are very efficient with our total nitrogen use ratio.

- Separate sites owned by the same farmer should not be merged into one feedlot permit. This will lead to some farmers being put above the 1,000 animal unit threshold, leading to large increases in cost and regulation to be up to feedlot permitting code/rules. Another way to look at it is if there are two farmers that spread manure on their fields, and one farmer decided to retire and sell his farm and land to the other producer. Then there will be the same amount of land and manure, just under one producer. Additionally, farmers owning multiple sites lets them spread out their manure over more acres.

- Another possibility that was brought up was increasing runoff control and making new requirements for feed storage. Feed storage is very expensive, and is not really an upgrade that can cash flow or increase revenue for a farm. Furthermore, feed storage

runoff is a very minor source of nutrient runoff.

- Animal units should not be changed, as they are based on science and have been the same for many years. Additionally, livestock feed and water efficiency has greatly improved over the years, so if anything the animal unit rate could be decreased rather than increased.

- Only 1-2% of fish kills in the state of Minnesota are attributed to agricultural runoff, so farmers should not be blamed or burdened with being the major cause of fish kills.

- Agriculture is not the only source of nitrates and phosphorus in our water sources. The MPCA should also look at other sources of nitrate contamination such as out-of-date septic systems, urban sewage, bad well casings, etc.

- It was brought up that the MPCA may consider reducing livestock access to streams. Depending on how this would be implemented, it would lead to great cost in fencing and drilling a new well with a cost of $40,000 (if there is already an electrical supply available).

In conclusion, we recommend that the MPCA base their recommendations on proven science and the economic impacts on farmers and their communities, not on opinion or emotions. We also recommend that if the MPCA looks at implementing new rules, that it be local to the geography and features of the land, rather than a blanketed rule across the whole state. Farmers have and will continue to better our practices to conserve natural resources and the land we farm for generations to come. When we take care of the land, it takes care of us.

Please work with farmers and give flexibility to help continue the viability of livestock operations and communities in Minnesota.

Thank you,

Sauer’s Valley View Farms

Creighton Sauer

Minnesota Environmental Partnership (MEP) thanks the Minnesota Pollution Control Agency for working to update the state's Animal Feedlots Rule. Our scientific understanding of the impacts of these feedlots has advanced significantly in the 25 years since the rule was last revised, as has the scale of challenges to our clean water and climate. With both surface waters and groundwater increasingly impaired and our climate warming, Minnesota should use this opportunity to better steward our natural resources with improved feedlot standards.

Please see our specific recommendations, submitted on behalf of our coalition and 18 supporting organizations, in the attached file.

As MPCA considers revisions to the 7020 rules, I ask that you consider the relative costs and benefits of these changes as well as unintended consequences. Each year weather gives us a limited and uncertain amount of time each fall for manure application. Our current storage, application systems, and BMPs such as nitrogen stabilizers have been designed to take this into consideration. Our industry's capacity to responsibly complete fall application in a timely manner is already maxed out. We cant just build new storage if winter comes early. Any new requirements that shorten this window will result in the

need for winter application, which is extremely counter productive to proper nutrient management. Adding bigger equipment, more storage, and more labor are very expensive options that would be necessary to accommodate shorter application windows. This is an example of costs and possible consequences of just one factor, absolute soil temperature thresholds for manure application, but it also applies to any other practice or metric you consider. As you consider making any changes to the rules, please consider the costs and consequences as well as benefits.

Minnesota is blessed with incredible amounts of surface water. However, our water quality is terrible in many lakes and rivers. Frankly, this is an embarrassment to the state and a danger to humans and wildlife. Progress needs to occur. The quality of the water is being severely degraded by several sources, but a major one is agriculture. Accordingly, I support the following:

1) MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.

2) MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.

3) MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.

4) MPCA rules should stop merely trusting that animal feedlots and manure applications are “no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.

5) MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already

polluted) waters, and prevention of degradation in waters that are not polluted.

6) MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

7) MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.

8) MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

As a mother, it makes me upset to see that the Minnesota Department of Health has concluded that nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths. Every mother deserves access to clean and safe drinking water for their kids. No mother should have to go through the pain of losing a baby to nitrate contamination. Because of this, I am asking that MPCA consider the following recommended rule changes:
-MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.
-MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.
-MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.
-MPCA rules should stop merely trusting that animal feedlots and manure applications are “no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.
-MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.
-MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.
-MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions

resulting from climate change that increase winter runoff.
-MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Thank you for your time and thoughtful consideration.

On behalf of Schwartz Farms, thank you for the opportunity to comment on the proposed amendments to MPCA Chapter 7020. We appreciate the agency's outreach and willingness to engage with those impacted by these rules.

Our company believes the existing Chapter 7020 rules are effective, practical, and were developed with a rigorous process and extensive research based on sound science, protecting Minnesota's water quality while supporting responsible livestock production. These rules were built on thorough data, thoughtful stakeholder input, and balanced environmental stewardship, and have only become more robust over time with expanded permit requirements, environmental review processes and county level zoning.

We are concerned with, and do not support expanding the scope of farms required to have additional operating permits. Such oversight is not supported by clear evidence of need and may introduce unnecessary complexity without measurable environmental benefits. Similarly, expanding the size of farms required to submit Manure Management Plans (MMPs) and land application records is not reasonable. The agency currently has authority and ability to review these records on-farm. Requiring submission of proprietary business information subjects farmers to unnecessary breach of privacy.

We also urge caution against adopting rigid manure application timing restrictions that do not account for weather, field conditions, and rural infrastructure constraints. Minnesota's climate and geology varies widely across the state, as well as within short distances. We support science-based BMPs for flexible, site and localized, condition specific management to support environmental stewardship and agricultural productivity.

As it relates to additional soil nitrate testing, current language in the 7020 rules allows for such testing. As shown at the community listening sessions as part of this process, nitrate levels have remained stable or are declining in many areas, demonstrating the effectiveness of the existing 7020 rules. Additionally, it is imperative to recognize the complex nature of nitrate presence, sources (not just from livestock) and the naturally occurring cycle to avoid misinformation and well-intentioned rules that have negative, unintended consequences.

Minnesota's livestock producers share the agency's commitment to protecting water resources, and Chapter 7020 has enabled continuous improvements in environmental protection while maintaining the viability of family farms and local food systems.

We appreciate your consideration of these comments in protecting Minnesota's

environment while supporting a practical, science-based approach to regulation.

Thanks for the opportunity to weigh in on the changing of the 7020 rules. I am a consultant working with farms across MN of all sizes. Farms with more than 1000 AU have sufficient regulations in place. Nutrient management plans and annual reporting are required by MPCA. Daily, weekly and monthly inspections of water lines, manure levels, and perimeter tile lines are required by NPDES or SDS permit holders.

More is not better when it comes to manure applications. Providing the crop what it needs works best for all. That is what we recommend to our clients, and they see and understand the benefit of that. There is a cost to applying manure. Applying more than needed drives up the cost and is not economical.

Farms in the 300 - 999 AU are required to have nutrient management plans. Improvements can be made by asking them to take manure samples yearly. This could benefit the farms by not underapplying or possibly overapplying nutrients. Farms under 1000 AU could be better informed on feedlot rules. This is an opportunity for MPCA and counties to further educate farms. Farms that have resource concerns in the 300 - 999 AU range generally are required to "fix" those issues to the standards of those over 1000 AU. Making rules too restrictive will force some to close their operations. Farms should be given time to adapt to new restrictions. Farms looking to upgrade storage facilities to comply with any new rules should be given priority in funding for any cost share programs. Improving the environment should be a high priority for these programs.

Rules should allow for regional and soil type differences. What works in Rock County may not work in Roseau County. "One size fits all" can make things worse. Mandating only spring application of manure would be disastrous. Many acres would go unplanted with this scenario. The application season is generally three months long in the fall. Forcing spring only application would spread the spring only application season to July or even August well past the planting season. This would be and environmental and economic disaster.

MN farmers generally do a good job in managing their nutrient applications. Good custom applicators take pride in applying nutrients as close to the plan as possible. Adaptation of technology allows farms to do this.

At two of the public information meetings, I attended it was brought up as to what is being done to regulate private homeowners and golf courses on nutrient application. One citizen reported a friend of his was putting the equivalent of 1500 lbs of nitrogen per acre on his lawn. If a farm had applied that much to a field there would be serious consequences.

In response to The Minnesota Pollution Control Agency (MPCA) proposing to amend existing Minnesota Rules Chapter 7020 governing animal feedlots, everyone can agree water quality is important to this state. Commenting one is for or against amendments to 7020 is not indicative of a someone's commitment to stewardship or concern for water quality. Increasing a slew of regulations is a slippery slope that might have unintended affects on state industry, income and ecological orders.

Groups such as the Land Stewardship Project (LSP) want a return 'traditional' agriculture, which no one seems to define, yet they also demand 'modernity.' There is cry for "sustainability" and livestock manure application is 100% part of a farm's economic and environmental sustainability, yet for "big farms" it's evil, but for small or family farms it's forward-thinking and innovative. In one breath this group, like others, say they promote "vibrant rural communities that are places of belonging and opportunity for everyone," yet they also "work within a broader movement that is fighting for justice and positive change." So, does that mean farmers, currently within rural communities, are neither considerate stewards, nor "inclusive" enough? Farmers tend to be highly concerned about best practices, land and water stewardship, and proper usage of chemicals/herbicides/pesticides. Sadly agriculture, like any industry, is not immune to mishaps, accidents, or occasional bad apples, who misrepresent the entire industry wrongly (and sometimes dangerously) to consumers.

The MPCA states as background on its website https://www.pca.state.mn.us/get-engaged/animal-feedlots that since the last major revision of Minnesota feedlot rules took place in 2000, there have been "many notable changes" in part due to changes in agricultural practices technology. This must be explained and data quantified. From an agrarian perspective that would be more untrue than true. Are we examining 7020 just because it seems due, or have stewardship practices actually advanced at warp speed? Perhaps there is an agenda couched within that blanket statement. MPCA language comments that the livestock industry has adapted to have "more feedlots with 500 or more animal units (AUs), many designed to be just under permit thresholds." Apparently producers are following rules, yet still being targeted? Is this because self-proclaimed "culturally and racially diverse rural and urban people" in groups like LSP are pushing amendments to Minnesota Rules Chapter 7020 as an act of expropriation because they believe there is "lack of access to land for all farmers [which] has created a consolidated system that favors corporations and the wealthiest landowners?" [LSP’s Long Range Plan: 2025-2030]

Several questions to weigh are: To what extent are "contaminates" [and which one(s) are even being perceived as problematic] seeping into water supplies? Which water supplies? What will be included as "waterways?" [Sackett v. Environmental Protection Agency] How will this be regulated and to what impact to our state budget? What variation is there in regards to this "problem" among counties, as some are more rigid with regulating waterways? How are non-livestock contaminants measured? How and to what extent is agriculture a greater offender than human sewage? How and to what extent are other industries restricted within the state, as far as their contaminant levels,

dumping/release of byproduct, or damage to waterways? What is the impact of loss of business/industry to the state? What incentives should be offered to producers/farms to make them compliant? What could result from pastures being left unused, and overgrown because of water usage restrictions--spread of CWD, encroachment of noxious weeds and/or pests and unwanted wildlife?

Until those questions are sorted, there is no way to understand the parameters of the problem and what meaningful changes could be made, let alone make more laws. In the court of public opinion it's easy to jab at agriculture because of a misnomer that farmers are rich, yet what the public doesn't understand is that commodities prices are sinking, input costs are rising, and livestock is a boon to operations, which translates into state revenue--a state that is facing a budgetary crisis. Regulation is taking a gamble and the greater Midwest is happy to take up our slack.

I am writing to support the MPCA actions to rewrite and modernize the feedlot rules. I can’t believe the existing rules are nearly 25 years old. Surely, our agriculture practices have changed a lot - it’s certainly gotten more “corporate”; I am concerned many ground water contaminations go undetected until too much damage has occurred. I am also concerned that my own well water is at risk due to increased animal feedlots along our beautiful riverways . Surely our water quality and environmental sciences have also advanced in 25 years! We can apply improved technologies and methodology to do better. We only have one planet.

I support new rules to: 1) require permits for feedlots with 300 to 999 animal units; 2) set a maximum size for feedlots and prohibit feedlots in sensitive karst areas; 3) set a stringent limit on nitrate pollution of surface waters; 4) monitor feedlots and manure-spread fields and require compliance with “no discharge” rules as well as surface and groundwater limits; 5) set rigorous requirements for manure storage and spreading based on current science; and 6) close loopholes and remove the exemptions that allow noxious and toxic air and water pollution. I don’t see why theses rules need to be a burden to farmers. I support listening to them too so they can be the best stewards of the waters we all depend on.

I an asking the MPCA to protect Minnesotans (and, really, all downstream waters!) from toxic nitrate pollution.

When evaluating changes to the 7020 feedlot rules, there are a couple key points that I think should be considered.
- Any significant changes to current manure application or manure storage requirements will create significant challenges and hardship for farmers. There is already a very limited time window for manure application. There is no repeatable evidence that making manure application more difficult for farmers will further reduce nitrates. One of the reasons for this is that nitrogen loss is heavily dependent on the weather/climate change. On our farm we use best management practices such as nitrification inhibitors and only applying when soil temperatures are below 50. We could add more

labor/financial/logistical burdens to farmers but at this time, there is likely little to no positive impact.
- We are already using common-sense practices to avoid run-off. For example, not applying to saturated fields and timing applications to avoid heavy rainfall. There is also significantly less winter application in all parts of Minnesota.
- Rule changes need to be based on demonstrable science, not just what feels like a good idea. Changes related to cover crops (at this time) will make any improvement in achieving nitrate goals. Cover crops can work in a few situations, but there are many, many situations where they unfortunately do not work in their current iteration. There is also a very significant cost to cover crops.

MPCA, I am a trout fisherman, camper, outdoorsman and have witnessed the devastating effects of agricultural runoff and groundwater pollution from feedlots. I'm extremely concerned by the lack of environmental protections the MPCA provides to the citizens of Minnesota. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable. MPCA rules should stop merely trusting that animal feedlots and manure applications are "no discharge" facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread. Provide the protections you owe the citizens of Minnesota. Thank you.

Thank you for the opportunity to provide feedback on the proposed changes to Minnesota Rule 7020.

As a lifelong Minnesotan and hands-on hog farmer managing manure application and row crop acres across West Central Minnesota, I want to express strong concerns about the direction this rulemaking process is heading.

The existing 7020 rules already provide a solid framework for responsible manure management. Like many modern farms, we use GPS-guided injection, digital recordkeeping, and real-time equipment tracking to ensure precision and protect water quality. Rather than layering on new mandates, the MPCA should recognize and support these advancements. Unfortunately, parts of the rule—especially around setbacks—are confusing and inconsistently enforced across counties. Despite injecting all of our

manure and maintaining compliant buffer zones, we're still asked to meet surface application setback distances. It's unclear how these rules interact, and it creates unnecessary regulatory gray areas.

I'm particularly concerned about the push to restrict or eliminate fall application. Fall is the safest and most effective time to apply manure: it preserves soil structure, reduces compaction, and allows nutrients to stabilize in the soil before spring planting. Forcing application into the spring window is impractical, and it risks damaging field conditions. I am not in favor of applying manure on frozen ground, but when soil temps are right and conditions are workable, fall application is the most responsible choice. Similarly, winter application bans should be based on slope and method—not broad assumptions.

Proposals like mandatory cover crops or universal spring application simply don't work on every farm. These choices should remain with the farmer, not dictated by statewide policy. Real-world timing, local climate, and operational scale must be considered. Rules should be flexible, practical, and based on science, not advocacy.

Ultimately, this rulemaking feels like a solution looking for a problem. The current system works when enforced properly. Overregulation risks harming family farms without delivering meaningful environmental gains. We all want clean water and healthy soil. I live here. I farm here. My kids drink the water and play in the fields we work hard to protect. We care. Just give us credit for what's already working, and don't let fear-based narratives write the next 20 years of ag policy.

We simply ask that our voices and experience be taken seriously in shaping rules that affect our livelihoods and stewardship.

My family's farm is now on its third generation of raising hogs and the row crops of corn and soybeans. We continue to strive and be stewards of the land because if we don't take care of it, we won't be able to make a living and be able to pass our farm to the fourth generation.

The MPCA has worked to create clear and concise rules for feedlot owners and custom manure operators. I feel it's important for the current rules to be enforced. We follow BMP's with all our manure applications. We have an agronomist which does soil sampling for us and provides us with recommendations on how many gallons of manure need to be applied in the Fall to obtain the yield we want to achieve the following year. We take samples of the manure every year to know the concentration levels of N, P and K. We don't over apply the manure because it is too valuable, and we want to spread it over as many acres of our crop land as possible. The manure from our hogs is better for the environment than commercial fertilizer which we still have to purchase.

I feel any changes to the 7020 rules need to be based on accepted scientific studies and practices. Consider the geology and topography of an area, when making rules. Buffer strips and setbacks are great tools, and farmers like myself need more tools available, not less.

I come from a farm family, but there's no denying that the dairy farm of my dad's childhood is a far cry from the current industrial feedlots. We need to adapt regulations to our current reality. As a parent, I'm incredibly concerned that unmonitored and unchecked pollution will ruin the water quality for my children. All kids (and all people) deserve clean water. At a minimum, MN needs to implement the following:
MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure. It just doesn't make sense to ignore a category of feedlots when they are cumulatively so important.

MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.

MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.

MPCA rules should stop merely trusting that animal feedlots and manure applications are “no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.

MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff. We all know winters and spring weather patterns are changing. Feedlots need to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

As a state, we pride ourselves on our lakes and rivers, but that means actively working to make sure that we are all doing what we can do keep those lakes and rivers clean. We can't afford to turn a blind eye to something we know is a problem.

Comments on the proposed MPCA Feedlot Rules.

I attended the session of the Feedlot rules in Morris at the WCROC. I left the meeting very concerned for the future of the livestock industry in Minnesota. Many of the other attendees there were like me, smaller livestock producers concerned about the impact that changes in these rules would have on our family farms. The current permit and regulation system is at least partly responsible for the growth of larger and larger livestock operations. The reporting and compliance activities required of large operations mean that special expertise is needed, and only operations large enough to hire someone to fill those roles can afford to be in the business. If these rules and reporting requirements are extended to smaller family operations, many of them will be forced out of the livestock business.
Question 2: Permits should address the land application rates of manure. There is a large body of research that shows what nutrient levels are needed for optimum crop production. Accurate tests are widely used by growers to test soil and the different types of manure applied. This should be the primary standard which should be used to set application rates. Crop removal is the gold standard for dealing with nutrients from animal waste. Setting limits on ownership structure or proximity to other livestock operations make no sense from an agronomic or scientific basis.
Question 3: The presenter at our Morris meeting mentioned the visual inspection possibility. Who would do that? Can the state hire people to drive around and watch manure be spread? Can the MPCA accurately predict the weather? The new NDAWN stations will be a good resource for those applying manure, perhaps consulting them might be part of the rules. However, there are very few days a year that manure can be applied under the current standards, further tightening them will lead to larger unintended consequences.
Question 4: If there are no violations reported with existing manure storage systems, it seems that that is perfect evidence that they are functioning.
Question 5: Here I get really concerned. Manure storage is expensive. A requirement of this type will drive small operations out of business, there is no margin for engineering and construction of storage. Further, most if not all of these smaller operations generate such insignificant amounts of waste that the environmental gain from these structures hardly justifies the cost.
Question 6: Programs from agencies like MDA and NRCS are available for fencing and watering livestock on pasture. The rules should encourage the use of these programs and best management practices. These issues are really not needed to be addressed in the feedlot rule unless the feedlot itself has access to a water feature.
Question 7: Why is there a need for MPCA to be involved in how a farm business is structured? As long as there is enough land for the nutrients from manure to be applied at crop removal rates, it should not matter who the livestock belong to or how close together the barns are.
Question 8: Another of the items mentioned at the Morris meeting that concerned me was the idea that manure transferred to third parties be subjected to the same regulations that the original operation has. This kind of restriction will discourage the use of manure on the appropriate number of acres and could have the result of over application on some acres. The MPCA should be encouraging the transfer of manure to as wide a geography as is practical to move manure to acres that need the nutrients and record keeping and nutrient tracking should be as simple and straightforward as possible.
Question 9: My son recently retired as a large animal veterinarian and attended the Morris meeting with me. Many of the attendees were his former clients. As we left the meeting, he said, “It looks like the MPCA is trying to drive the small family livestock

operation out of business." It is my sincere hope that is not the case. Livestock and manure are one of the key principles of soil health. It is my hope that changes to the feedlot rules are based on sound science including agronomy, soil science and livestock care. Thank you for the opportunity to comment.

First of all, I have worked with the 7020 feedlot rules throughout my career in agriculture. In fact, I worked closely with MPCA staff to ensure the rules were user friendly, understandable, and applied to our state's livestock farmers. Our state and MPCA staff have a very good handle on what is happening in livestock production. I hope that MPCA staff can continue to do so. I would also like to mention that when the 7020 feedlot rules were done in the early 2000's, our state lawmakers offered the needed funding to help our state's farmers be compliant with the new rules they created. I am thankful for that.
I am very concerned about the topics that were mentioned at the New Ulm session that were NOT addressed. It was discussed numerous times that our state's municipalities have older wastewater treatment plants that need attention. (I can think of several.) Our state also has wastewater treatments plants that are VERY close to the Minnesota River (St. Peter, MN and Henderson, MN, for example) and the wastewater treatment plants have experienced flooded when the Minnesota River, itself, flooded. Perhaps our state's money would be better spent closely examining the older, out of date, wastewater treatment plants. Above all, Brown County, Minnesota has a landfill next to the Cottonwood River. How many other landfills are close to a water of the state?
I am an appraiser by trade. I have seen more abandoned wells in our state than I should. Abandoned wells offer easy access to contaminate our water supply. I truly hope the agency takes a closer look at the abandoned wells in our state. I have heard the horror stories of junk, garbage and even oil dumped in abandoned wells. This is a statewide issue that needs more awareness and needs to be addressed. This, too, applies to gravel pits, earthen manure basins, and other open pits that have not been

properly closed after being abandoned.
I truly hope that MPCA will do 2 things as they reexamine the need for the 7020 feedlot rules. 1) Create and utilize an advisory/technical committee of people well-verse in agriculture and the environment to guide the re-writing or examining of the 7020 rules. (I have someone I would like to nominate.) 2) Use the proper science that is needed to grow food, care for the land, and raise our state's livestock. As a farmer, I know that our state's land grant university/agriculture university does NOT provide the proper soil nutrient guidelines for all corners of our state. Our state is so diverse, and the soil nutrient guidelines published are a "one-size-fits-all," when the guidelines should be more tuned into our state's diverse soils and topography. We have the technology to do so, but it is not being done. Nutrient guidelines that work well with thick, black, fertile soil do not work for sandy soils with a major slope.
Everyone likes a nice lawn, but are property owners properly testing their lawns for fertilizers and chemicals they are using? Are they closely examining what is needed vs. spreading them heavily to have an impressive lawn? Homeowners that over apply chemicals, fertilizers and more allow those products to leach into our city sewer systems and then to our municipal wastewater treatment plants. Our family soil tests and keeps record of applications to our farm soils, others should too, even if it is a small plot of land used for as a lawn and/or garden.
In Minnesota, non-livestock farmers purchase manure from livestock farmers to apply to their own farmland. In this case, manure is personal property that has been sold. I have heard rumors that MPCA would like the selling farmer (a livestock farmer) to oversee and manage the buying farmer's (non-livestock farmer) manure application. Since the non-livestock farmer opted to purchase the manure at his own free will, the non-livestock farmer should be responsible for his own manure management plan. If I sold a car (again, personal property), I would not tell the buyer to insure it or maintain it. The buyer needs to have the ability to do that for themselves, for example.
Please remember that Minnesota is an agriculture state and agriculture makes our state thrive. We need to keep the 7020 rules applicable, common sense, and viable to our state's farmers. Unfortunately, many forget NEVER CRITIZE A FARMER WITH YOUR MOUTH FULL OF FOOD. Our state's farmers make sure you have food in your month, clothes on your back, leather shoes on your feet, products in your home, and fuel in your car! They also work hard to care for the land, their farms, and our environment - they live here, too!
Thank you for your time and consideration. Please let me know how I can be of assistance to you as you move forward.

We have been involved with hog production on our farm since 1974. Over the years, we have totally changed how we raise hogs and handle manure. Going from outdoor lots and surface applying manure year-round, to confinement facilities and injecting manure so we can fully utilize the nutrients in the manure. Airial photographs from the last fifty years document the fact that there was visibly more uncontrolled manure runoff from far fewer animals fifty years ago. All farmers know the benefits of manure and do not consider it a waste product, rather a crop input to be managed and maximized. The changes we have made derive from fact-based decision making, considering environmental, economic, and animal welfare factors. The current 7020 regulations have proven adequate. The changes we have made have been management driven, not regulation driven. The current 7020 aligns those two fairly well as they are common

sense rules that we would follow anyway, even if there were no regulations in place. Increased regulations, while they are intended to target "factory farms" always end up hurting the smaller operations the most as it adds costs, time, and paperwork for those already tight on time and resources.
Farmers are arguably more concerned about water quality and environmental stewardship as we raise our families on this land. We want our land, water and farm to be in better shape when we pass it on, than when we started farming and we enjoy outdoor recreational and sporting activities as well.
I encourage you to use facts and logic when considering changes to these regulations. There are people out there who want to end animal agriculture, not just as we know it today, but end it completely, without regard to the millions of people who rely on our industry to feed their families.
We try every year to be better stewards of our little part of the world. To be more efficient with all our inputs, not just manure, and to keep our nutrients and soil where they belong, on our fields.

As a part owner in a multigenerational family owned and operated farm, I believe a time and/or seasonal restriction on manure application would be extremely detrimental to anyone in a similar situation as myself. Spring only application would not work, as we already have limited days to prepare and plant the fields. We have limited equipment and man power already, so limiting to spring application would be extremely hard on a small farm. We have had to spring apply in the past, but for whatever reason (compaction, time of application, etc.) the yields were substantially less than the fields that had manure applied in the fall. In our experience, a forced spring application would be extremely detrimental to the famers.
We have been applying liquid hog manure on some of our ground for over 50 years, and it produces at or above county yield averages continuously. We are required to soil sample and follow specific rules regarding the level of manure to be applied to each piece of land. I believe it is important to know the data on your fields and be able to spread the manure appropriately, but I believe limiting the time of application would be extremely hard on small farms.

Minnesota has always been proud of the fact that most farms are family owned, and provided the rules and limitations stay reasonable, this will be able to remain a factor for many years to come. I am proud to be able carry on my family's farming operation, and I

am very proud to be farming in a state that takes the farmers' opinions into consideration when adopting new rules and regulations.

I had the opportunity to attend the community meeting that was hosted in Marshall, MN and that it was insightful. As a hog farmer on the State of Minnesota, I want to thank you for the opportunity to provide feedback on the proposed changes to Minnesota Rule 7020. As the state prepares to make changes to its feedlot rules careful and thoughtful consideration need to be taken on many levels.

Minnesota already has rules that regulate feedlots extensively. Rules that regulate how, when, and under what conditions manure can be applied. If changes are made to these rules, they need to be done in a manor that is easy for livestock owners and custom applications can understand and comply with. Rules must be easy for livestock owners to understand without the need to hire expensive outside consultants. Keeping reporting straightforward and easy is part of this.

Our farm and others like us already operate utilizing management practices to ensure the best use of manure as fertilizer and ensure its done so safely. Every year we measure the nutrients within our manure, apply at a specified rate utilizing GPS technology, incorporating immediately for the upcoming growing season. All of this is done to minimize nutrient loss and movement.
Rule changes that would limit our ability to apply in the fall and/or only when soil has reached a specific temperature, could become very prohibitive. Fall is always a busy time of year. Weather issues only make it busier and more challenging. If the window of time was narrowed, it would make it even more difficult for farmers get manure hauled in safe and effective manor. Rule changes need to be based on science and the practices they require cannot be prohibitive or ineffective. For example, the blanket expectation that cover crops must be planted after manure is applied is likely ineffective. In many years, that cover crop will never have a chance to establish itself and carry no benefit.

I look forward to seeing additional information on the proposed rules and the ability to comment further as proposed specific rules are proposed. But as stated in the opening, be mindful and thoughtful of all parties involved.

Thank you,
Mike Boerboom

We support the following updates to Minnesota's feedlot rule:
• Require state feedlot permits for operations with 600 or more animal units instead of 1,000.
• Require feedlots with 300 or more animal units to prepare and follow a manure management plan approved by MPCA.
• Require that manure management plans are also followed by anyone who purchases or accepts manure from another operation.
• Prohibit manure application on frozen or saturated ground, or within 24 hours of previous or forecasted rainfall (50 percent or greater chance of precipitation according to National Weather Service).
• Set stricter limits on manure application and storage in vulnerable areas, including the karst region in southeastern Minnesota. This would include increased setback distances from lakes, rivers, streams, sinkholes, and drinking water wells.

Hello. I have a comment for consideration. Twenty years ago, our family worked diligently to do the needed upgrades our farm to be compliment with the 7020 feedlot rules and have zero discharge. To do this, we had an expensive loan, worked with our county feedlot officer plus MPCA, and FSA officials, enhanced our feedlots, and worked with a consultant to make sure everything was done correctly. We have maintained our farm's compliance and pass inspection when the feedlot officer/MPCA comes for renewal. If the 7020 rules are re-written, I am concerned our farm will no longer be compliant and our money was spent in vain. Thank you.

Greetings, Commissioner Kessler, Mr. Schwint, and Ms. Otto.

Living on the Saint Croix River in the area included in the 2024 list of impaired waters in Minnesota and having long experience living on a lake in Iowa vulnerable to pollution from CAFOs, I and my family find it very concerning that CAFOs in Minnesota are subject to few or in some cases even no restrictions and little or no monitoring by the Minnesota Pollution Control Agency. With concern for many manifestations of pollution from CAFOs, including fish kills due to excessive nitrates, e. coli bacteria from animal waste in water, blue-green algae blooms in shallow bodies of water, and increased nitrates in well water,

all harmful to humans and animals, the problems are insidious and dangerous.

Please rewrite the MN animal feedlot rules to stop toxic nitrate pollution and to establish strict rules for CAFOs, including their size and locations, and enforce close monitoring for accountability. Water Legacy has provided a well considered list of eight recommended rule changes for adoption by the MPCA.

1. MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.

4. MPCA rules should stop merely trusting that animal feedlots and manure applications are “no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.

5. MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

6. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

7. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.

8. MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

I and my family agree with each of these recommendations and think their adoption would go a long way to help with this currently serious and threatening problem. We ask you to adopt them for the well being of all. Thank you.

Sincerely,
Rebecca Myerly

Our farm well in southeast Minnesota has been contaminated by nitrates at a level 3 times the maximum allowed since 1989. We can't drink our water. So we are very concerned about the increasing number of CAFO's being proposed in the hog, dairy and poultry industries. I have several comments and will list them in as orderly a fashion as I can:
1) Neighbors and community members whose water, air, waterways, homes and quality of life should be notified of a proposed feedlot operation in their township and watershed BEFORE the entire permitting process has proceeded so far that the proposer and the MPCA staff have a powerful vested interest in the project moving forward. Folks who will be most affected by the proposed feedlot are left out of the process for too long.
2) Though I understand that the permitting process and the environmental assessment proceed together -- more emphasis should be on the environmental assessment with accurate information about local wells, homes, other feedlots of any size, so that the environmental assessment moves along with more urgency than the permitting process. If they are in lock step, both the proposer and the MPCA staff, again, have a strong investment in the project moving forward, often without adequate public input.
3) Minnesota needs to promote public health and public safety over private profit -- slowing down the permitting process to allow for in-depth study of the environmental issues will allow the state to make wise decisions for the greater good.
4)Reduce consolidation b y limiting feedlots to 1500 animal units. That will support small farmers and rebuild our countryside and our small towns with stronger economies.
5) Feedlot applications for feedlots above 500 animal units should be required to go through an environmental assessment. Any feedlot application for 1500AUs should require an EIS.
6) Create a data base that aggregates all manure application plans in a watershed, from the primary farmer owner and from all farmers to whom manure will be transferred so you know how much manure is being applied to that watershed and then you can trace the impacts by providing state-funded well-testing in those watersheds at regular intervals. Crop acres are already aggregated, certainly manure application acres can be, as well.
7) Listen to farmers about when to apply manure and help them do the best job they can

-- choice of season, soil temp, weather forecasts re: rain events, esp. Grants for better manure storage.
8) Manure application plans that include transfer of manure from the owner to a secondary farmer need to be as well recorded as required of the primary farmer. Bothe manure owner and manure recipient should submit manure application reports electronically immediately after the application. There should be no overlapping of manure application on land from different sources. Spills or over-application should be reported at once.
9) Before any CAFO is permitted, local wells in that watershed should be tested to provide a baseline of test results, followed by water tests at regular intervals.
10) Promote greater use of cover crops to provide nitrogen take up. Encourage increased pasture land, hay fields and other crops for nitrogen take up. Encourage bringing more livestock onto the land.
11) Work with the university to avoid increasing the fertilizer recommendations -- and with local elevator agronomists to resist selling just 20% more commercial fertilizer which too often is used on the same fields that manure is spread. Help make sense of the how much nitrogen is being applied from both sources. Then provide accurate data to farmers so they can make the best choices for the land they are working.
12) Insure that proper setbacks from homes, wells, ditches, sinkholes, waterways, streams, lakes, etc are described in manure application plans, especially when a farmer is unable to apply all their own manure to their own land.
13) Pay attention to what happened in Dodge County -- too much consolidation, too many hog barns, too many cancers.
14) Increase inspection of feedlots over 500AUs. Especially those enormous CAFO's with thousands of animals -- esp. dairies.
Thank you for the opportunity to comment on this important issue. In a way, our lives really do depend on it!

I have grown up on a family farm in southeast Minnesota. My wife and I now farm with our son and his wife and their 3 daughters. It is very important to our family that we have clean water. We raise hogs in Fillmore County and also raise corn, soybeans and hay. MPCA has implemented rules that all livestock producers must follow. There are some rules and setbacks that are exclusive to the karst region of Minnesota. These current rules make sense for everyone and are easy to understand and follow.

Family farms work hard to be good stewards of land, following many Best Management Practices, and follow many rules set forth in MPCA guidelines.
When it comes to BMP’s one size does not fit every farm. It’s important to have several options to fit a wide variety of farms. One example of this is that cover crops do not fit everyone. I think it’s important to have the option to use a nitrogen stabilizer instead.

The 7020 rules need to serve as a baseline for all feedlots in the state and be based on sound and accepted science and soil and geographic conditions. The rules should take into consideration other requirements like including riparian buffers as part of the setback distances and the required set backs from karst features in our corner of the state.

Thank you for the opportunity to comment
Dave Mensink

MPCA 7020 Feedlot Rule comments:
Regarding development of animal feedlot rules
-In general simple rules are easier to define and follow.
-Simplify the state rule 7020. Local feedlot offices should be allowed to determine the BMP for their regions based on state guidelines; including nutrient applications and timing of application.
Considerations for BMP:
-Manure is a valuable commodity in Agriculture. Cost of production and climate already limit the application process, to further limit this process would not only be detrimental to the BMP but also the economics of the individual producer. Timing should remain based on a start date and further determined by the individual producer and local offices BMP.
-Feedlot capacities of less than 1,000 AU are currently regulated by county feedlot offices and should remain under their guidelines. Utilizing local office reduced the burden on State MPCA officers and allows local offices to monitor regional changes more closely.
-MPCA enforcement of onsite visits should be limited to emergencies. Bio-security for livestock producers has evolved to protect the livestock from outside diseases and infections. Allowing outside personnel and vehicles would be a liability for both parties. “Onsite” visits could be completed with producer and MPCA approved technology.
-Many of the proposed questions to 7020 changes focus on increasing regulations on the smaller Agricultural producer further burdening the already diminishing local family farms. We need to focus on preserving the family farms not adding more reasons to resign to consolidation.

Agriculture is an ever changing and evolving industry. Providing producers modest but environmentally conscious guidelines and resources will allow the individual producer to make their best choices based on their individual situation.

Minnesota has comprehensive rules regulating feedlots. These rules are clear and concise so that individual feedlot owners and custom manure applicators can easily understand and comply with these rules. There is no need to change the current 7020 rules.
Farmers are stewards of the land, who will be passing this land and water onto our children and grandchildren. Why would we not comply with the recommendations for application rates?
With manure sampling, soil sampling and the modern technology used during manure application, we closely monitor the nutrients going into our soil allowing us the certainty that these nutrients are not wasted or unprofitable. We see our manure as a valuable natural fertilizer; therefore, we use it as such. We closely follow the U of M recommendations for the following crop year and follow those guidelines. If the manure is transferred to a neighbor, we have a vested interest in how the manure is applied, as it is a valuable commodity to us. Implementing more regulations, paperwork and expenses to the farmer or manure recipient, who values the land, and is already following the rules that are in place, is not the answer.
I strongly encourage the MPCA to look at other factors that may be contributing to the nitrate levels, and trust that those who have been caring for our land for generations.

Minnesota already has an incredibly comprehensive set of rules for feedlot owners and for custom manure applicators. A better course of action would be to enforce the existing rules, especially as farmers are already committed to operating within the existing rules. Any rule changes to be based on sound science and not be overly prescriptive. We need to incentivize farmers to do the right thing (which most already do) versus creating burdensome rules and penalizing. We differentiate our approach to soil health field by field, as similar to a classroom full of students with different backgrounds and needs, every farm is a little different and has different needs. Split application in spring and fall allows us to maximize the acres we're able to use the manure on and be strategic in that. Fall gives us the ability to apply when ground temps are cooler but gives us a window to get the right nutrients to the right acres. Spring has an incredibly short window for field work and if all manure application falls then it will further strain labor and time resources are family farms that are already at the limit. Giving the flexibility encourages more thorough approach and gives the time to be able to do it right. Our nutrients are expensive, the last thing I want to do is waste them but I only have limited space in the pit during the season.

Feedlots:
7020.0300 Definitions.
Subpart 1.
Expand the definition of feedlots to include areas that state agencies and departments, including the MN DNR, County and local jurisdictions and municipalities, develop, either intentionally or by accident, that attract and concentrate wildlife, at levels that are not natural, where the wildlife concentration causes animal waste accumulation and concentration to negatively affect public and private lands and waters and the quiet use and enjoyment of said lands and waters and where such wildlife activities are such that vegetative cover cannot be maintained where the wildlife have been attracted.
Subpart 23.B.
Intermittent streams should not include parts of farmland that support agricultural crop production and row crops are farmed through these areas where current farming and land management practices have removed the actual and observed presence of an intermittent stream.
7020.2002
The need for feedlot operators to notify the commissioner or county feedlot officer should be removed to be exempt from the ambient air quality standard. This is an unnecessary and undue burden on feedlot operators.
7020.2225
The current rules for land application of manure in general are acceptable, however, the following points need to be strengthened:
Subpart 3.A.1.
Current record keeping forms and online MPCA tools to not allow for deviations to the University Of Minnesota recommendations as allowed in this section for recommendations from another land grant college in a contiguous state. This option should remain in the rule and record keeping tools need to accommodate this exception. Also, the MPCA must accommodate the entire range of nitrogen recommendations published by the University of Minnesota and not arbitrarily select a value within that range and hold producers to one number as has been the practice of the MPCA in the NPDES permits. The MPCA is also bound to follow the rule and not make judgements on the university recommendations.
It must also be recognized that the correlation and calibration of university nitrogen recommendations were established with commercial fertilizer that has a precise nutrient content. Manure is variable by nature and availability factors used for the nutrients are only estimates and not hard and fast realities, therefore, a range of available nitrogen within 10-15 % of recommendations should be considered compliant.
Additionally, when new information is provided by the University staff responsible for recommendations issue statements that adjust their recommendations, this information must be considered a university recommendation even before it has been included in the bulletin, as was the case in 2017 when sweetcorn N rates where increased and it took several years for the University to update their recommendations.
Subpart 3.A.2.
This is an important part of the rule and the ability to apply remedial applications as guided by the university “Supplemental N needs worksheet” should remain.

Research shows that pollution from feedlot manure is a primary driver of algal blooms in our lakes, fish kills in our rivers and streams, and unsafe nitrate levels in our drinking

water. PCA is supposed to protect us from this kind of pollution, and they need to start doing a better job.

I spent the first half of my life in a rural community in southern Minnesota, and it's deeply discouraging to see the ways ballooning feedlots are impacting our residents, our economies, and our quality of life. It's shocking that there is not maximum size for feedlots, and PCA must create this cap now.

Equally bad is the lack of permitting at all for "smaller" feedlots, and PCA must also implement permit requirements for 300-999 animal unit sized operations.

With the nitrate pollution issues in our neighboring karst region, feedlots should be prohibited in these sensitive areas, and nitrate pollution of surface waters should be strictly limited in all other areas.

Existing PCA rules claim “no discharge” is allowed, but neither manure storage areas nor fields where manure is sprayed are monitored to detect polluted discharge, and no rule limits nitrates to protect fish and other sensitive life in surface water.

New rules must monitor feedlots and manure-spread fields and require compliance with “no discharge” rules as well as surface and groundwater limits, and set rigorous requirements for manure storage and spreading based on current science.

The loopholes and exemptions that allow noxious and odorous hydrogen sulfide air emissions as well as toxic water pollution need to be closed and removed as well.

I am a hog farmer from Kenyon, MN and would like to comment on the proposed rule changes.
Question 1 - For the most part I think the rules and regulations we have in place now are reasonable. We should have enforcement around the rules that we have now. I just did my feedlot inspection with my local feedlot officer. We identified a couple of items that I need to work on, but overall a very good visit, showing no issues for pollution from our farm. This was the first time in many years this had been done. If I did have a serious issue, it would have been documented and something would need to be done about it.
Question 2 - I want to caution adding regulations to small and medium sized feedlots. The reality of the economics in agriculture today is that additional rules and regulations cost money to implement. On small and medium sized farms like mine, we don't have the additional resources to implement large changes. We all want clean air and water, and are ensuring that for the next generation. But, additional regulations come at a cost. On our farm, I would like to be able to pass it down to the next generation if possible. If our farm is not economically viable, I see no way to make that happen. Additional regulation favors large systems in agriculture and push smaller and mid sized farms out. Large systems have resources and people dedicated to complying with added rules and regulations.
Question 3 - In terms of manure management, I would like to see us keep the flexibility that we currently have. I think the farmers know better than government when, where and how to apply manure in an environmentally sensitive, and economically feasible way. On our farm, we hire a commercial applicator to apply our manure. Increased

regulation and rules will cost more, and push some commercial applicators out of the business. This would lead to less choice and more cost for myself on our farm. It would also make it more complicated for scheduling and efficient application. Adding rules to fall applied manure would force more manure applied in the spring. Spring applied manure is challenging to got put on in a timely manner, again pushing the limits of the current system for application. Also, we have seen in many cases, fields with spring applied manure yield much less due to compaction and later planting. This puts an additional economic burden on our farmers.
4 - In my feedlot inspection, my manure pits were inspected. I feel that current regulation addresses this if actually carried out.
5 - Requiring additional manure storage, while a good goal, is a costly one. One that would absolutely put smaller and mid-sized farms out of business rather than spend the money to comply. This would further push consolidation and larger scale in animal agriculture in Minnesota.
6 - No Comment
7 - Farmers have played by the rules set forth for them by State and Local Governments. Changing the rules after they have put investment in seems like pulling the rug out from under them.

As a lifelong Minnesotan who has spent many of my Summers swimming in, floating on, and boating around many lakes in the Twin Cities metro area as well as numerous lakes in Northern and Southern MN, I have great concern for the water quality in our lakes, rivers and creeks. For several decades I've lived within a walk or short bike ride of the Mississippi River, Minnehaha Creek, Lk Nokomis, and Lk Hiawatha. I live two blocks from the latter, which is one of the lakes on the list of most polluted in the state due to e.coli and blue-green algae blooms. It's been sad to see swimming become basically a thing of the past in our lake due to downstream pollution, contaminants and feces from the many birds that pass through this flyway zone. Dogs can't safely drink from or swim in the lake, and surely the abundance of wildlife we have is negatively affected by this extremely poor water quality. We can't control the wildlife that utilizes these waterways

(as no one wants to see the wildlife harmed or displaced), but there is something we can do about the many waterways (as well as soil and air quality) affected by animal agriculture, which has a huge negative impact on our environment.

I attended a meeting with small family farmers from Iowa & MN about a decade ago and can clearly remember the words of warning shared by the Iowa farmers: Most of our lakes and streams are polluted due to waste from factory farms. The soil is contaminated. And the air quality so bad from these CAFOs, that some residents and small family farmers have had to move because the smell is so noxious, Don't let what's happened to our waterways in Iowa, happen in Minnesota.

Well, I'm worried that this is happening in Minnesota. With 23,000 current feedlots here, and these numbers increasing, the problem will continue to get worse if we don't intervene now.

Please rewrite the MN animal feedlot rules to include strict rules for CAFOs, including their size and locations, and enforce close monitoring as rules without effective monitoring are basically as good as no rules at all. Per the suggestions of Water Legacy, I suggest the following eight rule changes for adoption by the MPCA:

MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.
MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.
MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.
MPCA rules should stop merely trusting that animal feedlots and manure applications are “no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.
MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.
MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.
MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

When people think of Minnesota, they think of our amazing lakes and other waterways.

Environmental Working Group comments to the Minnesota Pollution Control Agency; request for comments on the Animal Feedlots Rule.

The Environmental Working Group (EWG) thanks you for requesting input about Minnesota's Animal Feedlots Rule. EWG offers the following comments on the rule.

EWG, a nonprofit research and policy organization with teams in Minneapolis, Minn., Washington, D.C. and Sacramento, Calif., has conducted research into agricultural pollution and farm policy programs for over three decades. Our expertise focuses on the environmental and climate impacts of agricultural practices, with a particular emphasis on water quality.

Additionally, we are deep experts in using aerial imagery to geolocate animal feeding operations and we have developed a peer-reviewed methodology[i] that allows us to calculate the number of animals produced in an animal feeding operation and the manure amounts that each feedlot produces in a year. We also have considerable experience modeling which farm fields near feedlots likely receive manure. We analyzed the number of feedlots and animals, the manure they produced, and modeled manure application to nearby farm fields in Minnesota in a 2020 report[ii] and then updated that report in May of 2025.[iii]

We recommend that MPCA makes these changes to the Animal Feedlots Rule:

- Require all feedlots with 600 or more animal units to get a National Pollutant Discharge Elimination System or State Disposal System permit.
- Require the largest feedlots with 1,000 animal units or more to monitor discharges to groundwater as well as discharges to surface water through drain tile.
- Ensure feedlots cannot avoid permit requirements by splitting feedlots.
- Establish stricter manure land application requirements and lower manure application rates in Vulnerable Groundwater Areas[iv]. These requirements should include requiring conservation practices like cover crops or diversified crop rotations if a farmer applies manure in the fall, and no liquid manure application to frozen or snow-covered ground, in Vulnerable Groundwater Areas. Additionally, manure application rates should not be allowed to exceed the agronomic rate in Vulnerable Groundwater Areas.

- Close the manure transfer loophole. Currently, transferred manure is exempt from tracking, so the application location, rate, and date of transferred manure are unknown. Tracking requirements of transferred manure should be established and enforced.

Justification for recommendations

Manure from feedlots causes significant damage to nearby water quality, especially in conjunction with synthetic fertilizer use. The manure these facilities generate are often applied to nearby farm fields as a fertilizer and can wash off farm fields, leach through soil into drainage systems that empty into nearby streams, or get into groundwater.

Nitrogen forms in drinking water as nitrate and consuming this water can increase the risk of birth defects and cancer[v]. This is a particularly widespread issue in Minnesota's Vulnerable Groundwater Areas like the Southeast karst region[vi] and the Central Sands region[vii]. The harm that nitrate in drinking water causes to communities throughout the state is a well-known problem[viii].

Manure runoff can also create potentially toxic algae blooms in recreational waters when nutrients are applied in excess of crops' uptake capacity. EWG has previously reported on algae toxins in bodies of water throughout Minnesota[ix]. When manure is applied to meet the nitrogen recommendation for crops, phosphorus is often overapplied. Algae blooms in recreational water sources can pose a health hazard for humans and pets, as well as the ecosystem harm.

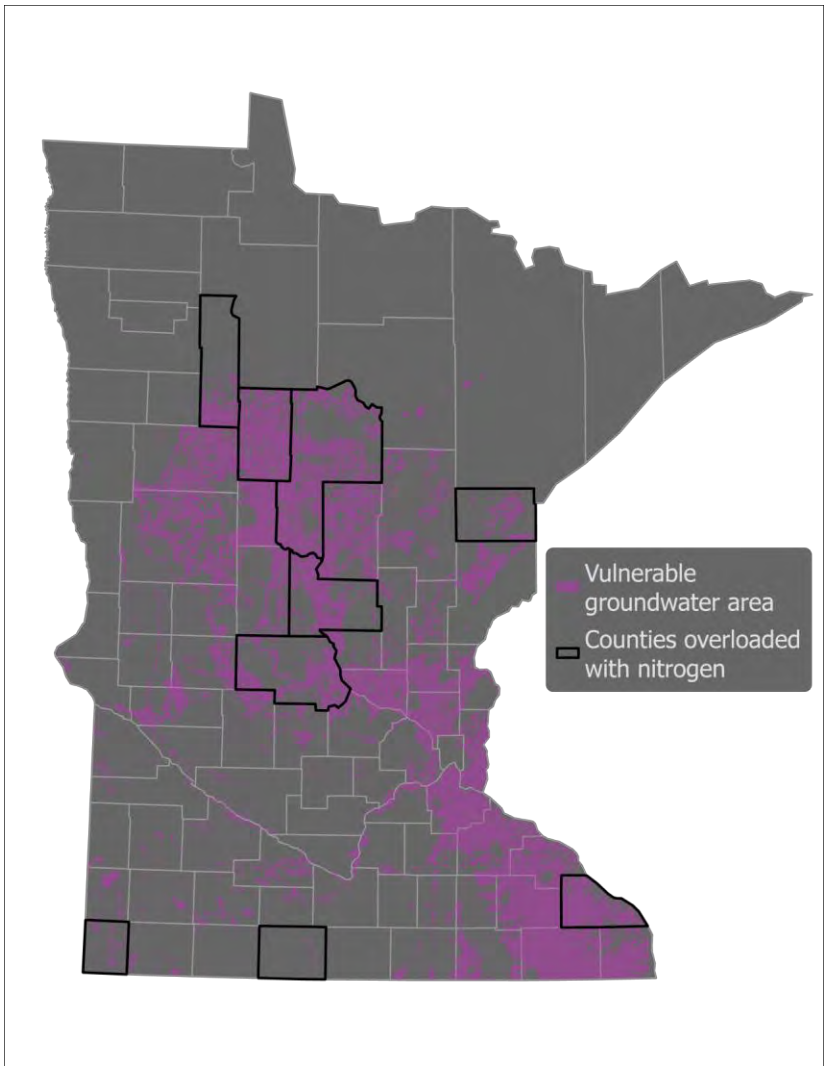
Over-applying nitrogen and phosphorus above crop needs from both animal manure and commercial fertilizer, as well as applying manure at high-risk times of the year such as fall when the ground is bare or winter when ground is frozen, leads to more nitrogen and phosphorus from manure ending up in bodies of water as well as groundwater sources.

In our report released in May of 2025, EWG analyzed which fields near feedlots likely received manure in 2024. The analysis found nine counties that are hot spots for nitrogen overload. This happens when nitrogen from manure, combined with nitrogen in fertilizer sold in the county, exceeds crop recommendations by more than 40 percent.

Nitrogen overload can be a particular problem in Vulnerable Groundwater Areas. In these areas, nitrate applied to farm fields through fertilizer or manure can easily get through soil and pollute groundwater. Many counties with nitrogen overload are within

the Central Sands and Southeast regions of Minnesota. These two regions have a high percentage of land with the MPCA Vulnerable Groundwater Area distinction. In 2024, 6,480 feedlots in the state were located within a vulnerable groundwater area, as can be seen in EWG's map below.

Minnesota counties and vulnerable groundwater areas at risk of nitrogen overload



In our analysis we also found that most feedlots in the state are small, but the medium and large facilities produce a disproportionate amount of manure. While 78 percent of facilities were small, they produced just 24 percent of manure in 2024. Medium facilities

made up only 18 percent of all operations but produced the largest share of manure, at 43 percent. Four percent of facilities were large but generated 33 percent of manure.

Because of the large quantities of manure that medium facilities produce, they should also be required to get a NPDES or SDS permit. In Minnesota, 983 facilities housed between 750 and 999 animal units in 2024 – just a few hundred units under the 1,000 animal unit level that requires stricter regulation. These facilities still produced a lot of manure, as they are 14 percent of all facilities in the state, but are hardly regulated. And among these, there were 374 operations that were between 950 and 999 animal units - just 50 animal units short of the large CAFO designation and more stringent permits. So almost 400 facilities are producing manure at levels close to the amounts from large facilities, but are not regulated in the same way.

We recommend requiring NPDES or SDS permits for all feedlots that house at least 600 animal units. According to our calculations, there were 2,316 feedlots with between 600 and 999 animal units in Minnesota in 2024, and these facilities produced 12,640,899 tons of manure. Of those, 329 feedlots were in a Vulnerable Groundwater Area.

In fact, out of the 6,480 total feedlots that are in a Vulnerable Groundwater Area, only 161 are above the 1,000 animal unit threshold, so most feedlots in these areas do not have many restrictions. A significant amount of manure is being produced by facilities that are not regulated stringently because they are not required to get NPDES or SDS permits.

A significant number of facilities, housing animals and producing manure, are also close to the Vulnerable Groundwater Areas while not being directly in the area. The above number only includes the facilities located directly within a Vulnerable Groundwater Area. Over 50% of all feedlots in Minnesota are either in a Vulnerable Groundwater Area or within 1 mile of a Vulnerable Groundwater Area.

In conclusion, we believe that MPCA should make the changes to the Animal Feedlots Rule that we have listed above in the recommendations section. Making these changes would significantly improve water quality and public health throughout Minnesota.

We appreciate the opportunity to comment.

RECEIVED
By: OAH on 7/15/2025

In developing the animal feedlot rule, the MPCA would appreciate comments on the following questions:

1. Are there parts of the current rule (Minn. R. Ch. 7020) that are no longer applicable or needed?

2. What specific changes to the current rules, including permit requirements (part 7020.0405), water quality discharge standards (part 7020.2003), all conditions here should be modified to reflect 100 animal units vs 1000 which is astronomical. No SDS permit should be allowed as well since it is ridiculous to assume any discharge would have some form of benefit to the water or organisms living there. location restrictions and expansion limitations (part 7020.2005), if someone from St. Paul were to come and smell the odor from any of these facilities they would understand that no facility should be allowed within 5 miles of any neighboring property and this requirement should be implemented as it will direct healthy free range type raising of animals. liquid manure storage area standards (part 7020.2100), or land application of manure (part 7020.2225) would provide improved regulations that prevent nitrate contamination to ground and surface waters and fish kills? Should any of the following bullets be considered? If so, at what size (in AU)?

• Operating permits (NPDES or SDS) for feedlots less than 1000 AUs. Yes

• Submittal of manure management plans and land application records for feedlots without operating permits.

• Monitoring of feedlots and land application sites for subsurface discharges of manure or nitrate to groundwater. Yes

• Additional restrictions on manure application rates. Yes, be around any field where this is applied in volume and understand the odor level and days of time prior to it diminishing.

• Soil nitrate tests prior to land application of manure. Yes

• Increased setback distance for land application of manure near sensitive features. Yes, dramatically increased as 300 ft is nothing

• Restricting land application of manure in areas with high levels of nitrate in waters or in areas with existing high densities of feedlot operations. Absolutely yes as this is so logical its sad it has to be asked if it should be implemented.

3. The State Disposal System (SDS) and National Pollutant Discharge Elimination System (NPDES) feedlot general permits apply to feedlots that currently have capacity, or are proposing to have capacity, for a total of 1,000 or more AUs (part 7020.0405). These permits include additional requirements as outlined in the following bullets. Should any of

these requirements or other requirements in the permits be incorporated into the rule to apply to facilities with less than 1000 AU capacity?

• Enhanced manure management planning and record keeping requirements for transferred manure. Yes

• Visual inspections of manure land application fields for signs of discharges.

• Additional best management practices for land application of manure during the months of September through November.

• Restricting land application of manure on frozen or snow-covered fields. Yes for liquid solutions due to the odor produced.

• Best management practices for land application of manure when there is a high probability of rain predicted. Absolutely yes

4. How should the MPCA address existing animal manure storage areas that have been used for a long period of time to determine structural integrity (part 7020.2100)? Any well driller now has the equipment to dig underground for multiple feet in a horizontal direction so soil samples can be obtained under such structures for contamination leakage.

5. Currently, feedlots with 1000 AUs or more are required to have 9 months manure storage capacity (part 7020.2100). Should smaller sites be required to have a similar requirement? If so, at what size (in AU)? 100 AU or greater

6. The MPCA has developed Watershed Restoration and Protection Strategy (WRAPS) documents for every one of Minnesota's 80 major watersheds. These WRAPS document high nutrient and bacteria levels in streams and rivers. The reports attribute this to livestock access to streams in many cases. How should the rules be amended to address this documented issue (part 7020.2015)? It makes zero sense to allow livestock of any form to have unlimited access to public waters for drinking purposes. This is not the developing country of the 1800's. Our public waters are under siege from all types of pollutants including this type and this can be easily identified and corrective action enforced.

7. How should the MPCA address feedlots under the same ownership in close proximity to each other? They should be considered as separate facilities How far apart must each feedlot be located in order to be considered a separate facility for the purposes of permitting and/or registration (parts 7020.0405 and 7020.0350)? Any distance greater than 300 ft.

8. State agencies are required to, whenever feasible, develop rules that are not overly prescriptive and inflexible, and rules that emphasize achievement of the MPCA's regulatory

objectives while allowing maximum flexibility to regulated parties and to the MPCA in meeting those objectives (Minn. Stat. § 14.002). How might the MPCA balance this need for flexibility for regulated parties while also addressing the issues of nitrate contamination and fish kills? Rules are rules. There is no such activity as request for a variance from them therefore IF an producer be it private or corporate there should be no acceptance of any rule being not followed to the letter since any other position will simply result in private or corporate representatives doing what they feel is justified and asking for forgiveness following breaking the rule.

9. Other questions or comments relating to the existing animal feedlot rules or this proposal to amend the rules. As I previously stated this in not the US in the 1800's with limited polluting contributions from other sources and the only way to even begin to get control to perhaps try to make some sort of improvement in water ways or sources is TO ENFORCE rules completely. There should be a complete reversal of the statement in 8 regarding allowing maximum flexibility since this position only promotes continued violations and perhaps corrupt behavior of employees responsible for monitoring being compensated for "allowing maximum flexibility" upon review of an identified issue.

Comments on MPCA Feedlot Rule Making Submitted by the Prairie Woods Chapter Izaak Walton League, Detroit Lakes, MN

Chapter Committee: Erika Gilsdorf, Sandy Gunderson, Lowell Deede, Matthew Davis, Willis Mattison, William Henke

The following comments pertain to the MPCA's planned amendments to the rules regulating Concentrated Animal Feeding Operations (CAFO's), MN Rules, Chapter 7020.

The Prairie Woods Chapter of the Izaak Walton League of America of Becker County, MN has been concerned about the implications of the statewide proliferation of CAFO's for several years. Because of the threat of these large industrial operations making their way into water rich Becker County, our chapter with the consent of the Becker County Board of Commissioners, completed a comprehensive and well researched report on the ramifications of these confinement operations. This report was submitted to Becker County and is on record as of August 2024.

Amongst the conclusions of this report, it is found that the industry model engenders industrial sized feeding operations aimed at maximizing profits resulting in the continuous loss of small family farms, contributes greatly to surface and ground water pollution, plays a major role in fostering the public health risk of ever increasing antibiotic resistance, has a significant negative impact on the economy associated with our small rural communities and dispels this industry's claims that manure produced is handled responsibly,

While the Prairie Woods Chapter feels that CAFO's are inherently a completely unsustainable model, a form of business that treats animals inhumanely, pollutes our waters with nitrates, phosphorus, fecal coliforms, chemicals and pharmaceuticals, and serves to stifle what could be a growing "local" agriculture economy that provides safe food sourcing, we understand the scope of the MPCA's upcoming task. As a result, we submit the following points for the agency's consideration.

LOCATION

1. Current MN rules do not restrict the location of feedlots except prohibiting them from shoreland. Even then, this does not take into account the hydrology of the site including slope, depth to bedrock/impervious surface, soil composition or inter-connectivity of waterways. This needs to change. The rules regulating location need to be very site specific and not "cookie-cutter."

BEST MANAGEMENT PRACTICES (BMP's)

2. No research has demonstrated effective BMP's. Therefore, a "prove-it-first" principle should be applied for both manure storage, manure transport, and manure application. Currently, use of manure application BMPs are largely voluntary and are not site specific. They must become more stringent, documentable, their use made mandatory, and they should be tied to the specific site. Effectiveness of BMPs depends upon site specific factors including climate conditions, soil type, and drainage system design. These factors must be considered when developing BMPs for a particular farm operation.

PERMITTING

3. One-size-fits-all by rule has proven to be the wrong approach. All permits should require plans and specifications should be site-specific.

4. Rules should apply to most, if not all CAFOs but certainly those below 1000 animal units. The industry's habit of seeking leniency by coming in under the 1000 animal unit limit per operation should not diminish the responsibility to protect water quality.

5. Permittees are not required to demonstrate their manure pits or lagoons meet the design standards. This is unacceptable.

6. To avoid overtaxing limited MPCA staff in reviewing and approving plans, professional engineers and licensed hydrologists should be required to "sign-off" on facility design and manure management plan ensuring performance. Failure of designed facility to perform to standards should threaten professional licensure.

7. The food industry sponsor, rather than farmer/owner, should be the permittee and should propose site-specific facility design and operation compliance plan.

MONITORING

8. Baseline ground and surface water assessment/monitoring is necessary prior to CAFO establishment and ongoing monitoring should be the indicator of compliance rather than documentation that planned BMP's were applied.

9. Monitoring of water to determine compliance should be done by a third party (certified laboratory or MPCA designee) whose certification is at stake for errors or false reporting. Testing valid water samples for the appropriate parameters is critical to ensure that degradation is not occurring. "Trust but Verify" is essential!

10. Water Quality standards should include nitrates, phosphorus and fecal coliform

for both surface and ground water including drain tile water.

DISPOSAL

11. The food industry (especially related to meat production and processing) has externalized the costs of animal waste disposal to the farmer/grower and to the public. The new rules need to internalize these costs to the top of the pyramid---the processors/packers that rule this industry. In addition, reparations need to be required of the industry when surface and ground water is polluted, wells of adjacent farms are degraded or when aquifers are depleted.

12. The current engineering "design" standard that allows manure storage pits and lagoons to leak at up to 500 gal/acre/day is unacceptable.

ACCOUNTABILITY

13. The food industry has successfully hidden behind the farmer/operator to escape liability for pollution, disease spread (ie. growing incidence of cancers in Iowa), and the increasing incidence of antibiotic resistance in not only animal husbandry but very much so in humans. Please note that agriculture use of antibiotics exceeds that in humans! The new rules must place the industry in the key responsible role for the negative consequences provoked by this harmful business model.

14. Pre-established water quality limit exceedance should trigger prompt remedial action.

15. Failure by violators to remediate contamination or operational violations within a pre-established timeframe should result in an immediate cessation of operations until full compliance is achieved. Enforcement of this cessation must be mandated and carried out by the state, with clearly defined penalties for non-compliance. The burden of enforcement should not fall on local residents, who often lack the resources and authority to compel accountability. The Minnesota Pollution Control Agency must ensure that oversight, compliance monitoring, and enforcement actions are fully supported and funded at the state level to protect public health, water quality, and community well-being.

Thank you, Minnesota Pollution Control Agency for considering the Chapter's concerns on this very important topic.

FRIENDS OF THE MISSISSIPPI RIVER

Protecting, restoring and enhancing the metro Mississippi River and its watershed since 1993.

106 W. Water St., Ste. 600 | St. Paul MN 55107-2032
(651) 222-2193 | fmr.org | info@fmr.org

July 18th, 2025

Office of Administrative Hearings
Attn William Moore, OAH
600 North Robert Street, PO Box 64620,
St. Paul, Minnesota 55164.

Greetings, Mr. Moore,

Thank you for the opportunity to provide written comments on planned amendments to Minnesota Rules governing animal feedlots (Chapter 7020, Revisor's ID Number R-04928).

Friends of the Mississippi River is a 501(c)3 non-profit organization dedicated to protecting and restoring the Mississippi River and its watershed in the Twin Cities. We believe it is time for the state to improve its efforts to prevent the unintended contamination of groundwater and surface waters from animal feedlots and the manure they produce.

As you know, it's been 25 years since Minnesota significantly revised the rules for animal feedlots and the manure they produce. We acknowledge that manure can be an important source of nutrients for Minnesota's croplands, and we want Minnesota's farm operations to be successful and sustainable. However, when improperly applied to croplands, manure can contribute to polluting our lakes, rivers, and streams. In addition, manure can contaminate groundwater, making our water unsafe to drink.

This is no small issue. Minnesota is home to more than 18,000 feedlots that, by some estimates, produce nearly 49 million tons of waste per year. This waste has potential consequences for Minnesota's water resources, including the Mississippi River. That's why addressing the impacts of pollution from feedlots and field-applied manure is included in high-level, multi-agency strategies for achieving clean and healthy waters in Minnesota, including:

- The Minnesota Nutrient Reduction Strategy
- The Great Lakes Water Quality Agreement
- The Minnesota Water Management Framework
- The Minnesota State Water Plan
- The Clean Water Council Strategic Plan
- The Minnesota Clean Water Road Map
- The Minnesota Water Sustainability Framework

- Multiple Total Maximum Daily Load (TMDL), Watershed Restoration and Protection Strategies (WRAPS), and Groundwater Restoration and Protection Strategies (GRAPS)

While improved feedlot rules will not resolve Minnesota's water quality challenges, it's equally clear that we can and must improve upon the status quo. Therefore, we respectfully request that the state consider the following amendments to Minnesota's feedlot rules (Chapter 7020):

1. **Permitting and environmental assessment**
    a. Require operating permits (NPDES / SDS) for all feedlots at or above 600 animal units. According to analysis from the Environmental Working Group, there were 2,316 feedlots with between 600 and 999 animal units in Minnesota in 2024, collectively producing more than 12 million tons of manure.
    b. Require operating permits (NPDES / SDS) for all feedlots at or above 300 annual units in vulnerable groundwater areas.
    c. Require monitoring of the largest feedlots for surface and subsurface discharges of manure, nutrients, and bacteria.
    d. Remove the potential for an ownership structure to split larger feedlots into multiple smaller operations for the purposes of permitting and/or registration. For example, the state might establish that feedlots under the same ownership structure located within a county, or within 25 miles but in an adjacent county, are not to be considered separate facilities.

2. **Manure management**
    a. Require all feedlots with 300 or more animal units to prepare a manure management plan and maintain land application records. Such records should be shared with the MPCA in a manner that allows the public to assess the efficacy of feedlot rules in protecting water quality over time.
    b. Require the largest feedlots to monitor the fields where they apply manure to ensure manure is not running off into waterways or seeping into groundwater.
    c. Consider strategies for prohibiting manure application on frozen or snow-covered ground or when there is a high probability of significant precipitation predicted. We acknowledge that this may require additional public cost-share for enhanced manure storage for some smaller facilities.
    d. When manure is transferred from a feedlot owner/operator to a third party for cropland application, require that the recipient also follow all relevant manure management plan requirements.
    e. Consider additional protections on manure application in vulnerable groundwater areas, including the southeastern karst region, the central sands region, and Drinking Water Supply Management Areas. These additional protections could include cover crops, diversified crop rotations, and strict limits on application that account for both manure and non-manure fertilization rates.

3. **Setbacks and livestock access**
    a. Require and enforce a 50-foot setback for land application of manure along certain waters. This includes rivers, lakes, and streams that are (i) impaired due to

excess nutrients or bacteria, or (ii) discharge into downstream waters that are impaired due to excess nutrients or bacteria.

b. Address the risks of livestock access to rivers, lakes, and streams. This includes the prohibition of livestock from a feedlot capable of holding 300 or more animal units from entering any waters that are impaired due to excess nutrients or bacteria, if it is determined that animal manure is a significant contributing factor to the impairment.

Thank you for your consideration,

Trevor Russell

RE: Minnesota Pollution Control Agency request for comments on animal feedlots rule

Comments submitted by Tom Salkowski, Buffalo, MN (teesalk@aol.com)

I am in favor of changes to the Feedlot rules and, more importantly, the need to overhaul the feedlot regulation system and devote far more time, human resources and funds to having the rules mean something beyond words on paper. With characteristic understatement, the public notice states that "Rule amendments are necessary to maintain regulations that are protective of human health and the environment." I live in south central Minnesota where most people get their drinking water from wells threatened by long-term pollution by outsized animal factories, and from pesticides and other cancer-causing chemicals dumped on farmland routinely.

In addition, I am very fond of and recreate in the Karst Region of Minnesota, and especially the pristine cold-water streams that are found there. The facts that several fish kills have occurred in streams there in recent years, and that it took prodding from the former federal EPA to get any real action from the MNPCA on this matter, is disturbing, to say the least. Worse, that no one has ever been held to account for poisoning these public waters is a damning comment on the fecklessness of current state programs. Since it has become clear that we cannot rely on the federal EPA to do anything to protect the environment for the next 4 years, it is imperative that the State of Minnesota step up.

Consider the hundreds of millions of public dollars spent on diluting, transporting and treating human waste before it is deemed safe to release back into the environment. Meanwhile, livestock waste, which is no less harmful than human waste (check the inoculations and meds given to livestock as well as the potential for pathogens), is generated in volumes at least ten times higher than human waste statewide. While there are regulations on paper, as a practical matter this livestock waste, especially as compared to the treatment of human waste, is mostly untreated and disposed of in ways which clearly harm natural systems and threaten human health. Paperwork, reports, plans and permits can serve some purpose, but if no one is ever punished for violating the rules, and virtually no one is regularly checking to see if the rules are being followed, the paperwork mostly punishes those who bother to comply. My primary comment is that the state must devote

considerable more resources to support for County Feedlot Officers and to enforcement and education, if rules changes are going to have any real impact.

I am personally aware that there are excellent County Feedlot Officers in Minnesota. But it is also true that there are County Boards who control budgets and employment that often consider environmental protection and regulating farmers very low on their list of priorities. Certainly, the decision by the MPCA years ago to foist as much of the feedlot regulation business as possible upon Counties resulted in some cases of the fox overseeing the henhouse. Water resources do not respect County borders, and there is plenty of justification for the MPCA to be more directly involved, especially in the Karst region. Farmers are no more fond of regulations than any other business operators, but most care as much about clean water and air as the rest of us. Most will abide reasonable regulations if they can be assured that they are applied consistently and fairly. The MPCA must become much more involved in feedlot permits below 1000 animal units, in my opinion down to 250 units, in order to ensure regulatory consistency. If the current system, of devolving all or most responsibilities to the counties which has been tried for many years, was working, then we would not have fish kills, nitrate polluted groundwater and rivers being degraded across the state.

In regard to other and more detailed suggestions, I also agree with the comments being submitted by Minnesota Trout Unlimited, though any thoughts offered herein are mine and do not represent Trout Unlimited. Beyond those, I believe that the recently revised manure application requirements that apply to State permitted sites should be applied to all operations with more than 250 animal units. Further, I believe that the determination of animal units should be based on the maximum number of animals on the farm on any day during a full year. Operators who register 999 animal units should not be able to game the system. Thank you for the opportunity to comment, and I look forward to seeing the results of the rulemaking process. Finally, I would like to repeat my primary concern, that the state must devote considerable more resources to the support for County Feedlot Officers and to enforcement and education, if the purpose of protecting our environment and public health is to be fulfilled.

Comments regarding protection of ground water quality – 21 July 2025

Robert Karls – Past President of Minnesota Ground Water Association

Any industry or business that stores materials which have the potential to impact ground water quality have a requirement to do inspections, testing, and monitoring. The storage of manure in amounts typical of feedlot operation is typically in semi-solid or liquid form in lagoons, pits, or tanks. Any storage of manure in these types of structures with capacities over 5000 gallons individually, or cumulatively within ¼ mile shall be required to have ground water monitoring plan approved by the MPCA. All ground water monitoring plans shall:

1. Have no fewer than 4 monitoring wells installed within 100' of the perimeter of the outer boundary of the storage structure or container where manure would typically be present. The four wells should be installed in a manner that the well screen must be a minimum of 10' long and spans the seasonal fluctuation of the water table at the Site. (Due to the uncertain direction of ground water flow at the time of installation and seasonal variations fewer than 4 wells are not allowed).
2. A permit from the commissioner (MDH) is generally required for the construction, deepening, and modification of monitoring wells, including at feedlot locations.
    a. A single permit application can cover all monitoring wells on a single property used as release detection devices at a feedlot location.
    b. Construction Standards:
        i. Monitoring wells must be constructed according to Minnesota Rules 4725.6650.
        ii. Casing: Must be steel or plastic casing meeting specific standards, including stainless steel or flush-threaded PVC under certain conditions.
        iii. Grouting: The annular space must be grouted from near the screen to the ground surface, with specific requirements for at-grade installations.
        iv. Drilling Fluids: Must comply with relevant standards, with an exception for free chlorine residual.
        v. Screen or Open Hole: Specific requirements apply to monitoring wells constructed to monitor contaminants at the water surface across unconsolidated formation and bedrock contact.
    c. Maintenance Permits:
        i. Environmental wells (monitoring wells) constructed after January 1, 1990, that are not sealed within 14 months require an annual environmental well maintenance permit.
        ii. These permits are required for all environmental wells, and a single permit application can cover those on a single property.
        iii. The permit must be renewed annually until the well is sealed.
    d. Sampling and Analysis:
        i. Groundwater elevations must be monitored in all monitoring wells semi-annually.

ii. Groundwater samples must be analyzed semi-annually for nitrates, fecal coliforms, and total dissolved solids, and other parameters as identified by the MPCA.
iii. Results of each semi-annual water level elevation measurement and sampling event must be submitted to the MPCA within 90 days of the semi-annual measurement and sampling event.
iv. Laboratory data must be generated by MPCA-recognized certified laboratories.
v. Documentation of sampling events, including specific details about the well sampling procedures, identification of the sampling personnel, and chain of custody for all samples are required.

Subject: Comments on proposed changes to Minnesota Rules governing animal feedlots Chapter 7020

To Whom it may concern,

Introduction

The Winona County Farm Bureau Ferderation in Southeast Minnesota is comprised of nearly 200 farmer members who represent farms of every size, structure and commodity found in our corner of the state. Winona County is in an area of the state with a robust livestock industry which supports hundreds of farm families directly while providing competitive markets for crop farmers in the region. The farm families who make up our membership have deep concerns over potential changes to the “7020” rules which govern nutrient management on farms below 1000 animal units. Any changes to Chapter 7020 must not be adopted without consideration for the economic viability of Winona County livestock farms. Failure to do so will result in serious financial stress and logistical concerns for producers and users of manure nutrients.

Poorly thought-out rules could incur burdensome expenses on farm families while hampering the use of manure by crop farmers in the region thereby favoring the use of chemical fertilizers.

Comments

- Winona County Farm Bureau members are particularly concerned about any rule change to lower the animal unit threshold where livestock farms would be required to hold a NPDES or similar permit. With an NPDES comes more stringent manure storage requirements, different rules for manure application and more stringent record keeping requirements. Smaller farms simply do not generate enough income to offset these additional costs. When faced with such requirements, farm families may choose to significantly expand operations to cover these costs or may decide to cease operations. Downsizing to an animal unit level where such requirements is also not financially viable as the farm may not generate enough income to support current family members and current capital costs.

- Winona County Farm Bureau opposes any modification to animal units which results in a greater animal unit value per head of actual animals (ie: raising a dairy cow from 1.4 au to 1.6 au). This could place many farm families over the 1000 au threshold potentially requiring them to comply with NPDES requirements without generating any more income to cover the expense.

- Winona County Farm Bureau opposes any rule that combines different feedlots owned by the same farmer into one operated under one permit. Purchasing other farm sites where non lactating cattle, or feeder livestock, are raised is a very common way for farmers to avoid the capital expenses of constructing new facilities while decreasing the concentration of manure at one location. Combining different sites could place a farm above the NPDES threshold causing significant financial stress for the business.

- Winona County Farm Bureau supports the responsible use of manure nutrients; however, we are concerned about new restrictions on winter time manure spreading and any increase of setbacks for manure application. No farmer wants to spread manure in the winter. However many farms began operating in a time when winter application was far more common than today Because of this, some family farms may not be able to store manure for long enough periods of time to get though the frozen months. Instead of a banket rule across the state, farmers should work with MPCA to identify times

throughout the winter when manure application presents little risk to water quality. Because of the geography of Southeast Minnesota, average field size can be very small and odd shaped. Greater setback requirements for manure application could render large number of fields ineligible for manure application requiring more acres for a farmer to meet the manure application requirements. Because some acres might be prohibited from manure application, greater use of commercial fertilizer could be expected.

Conclusion

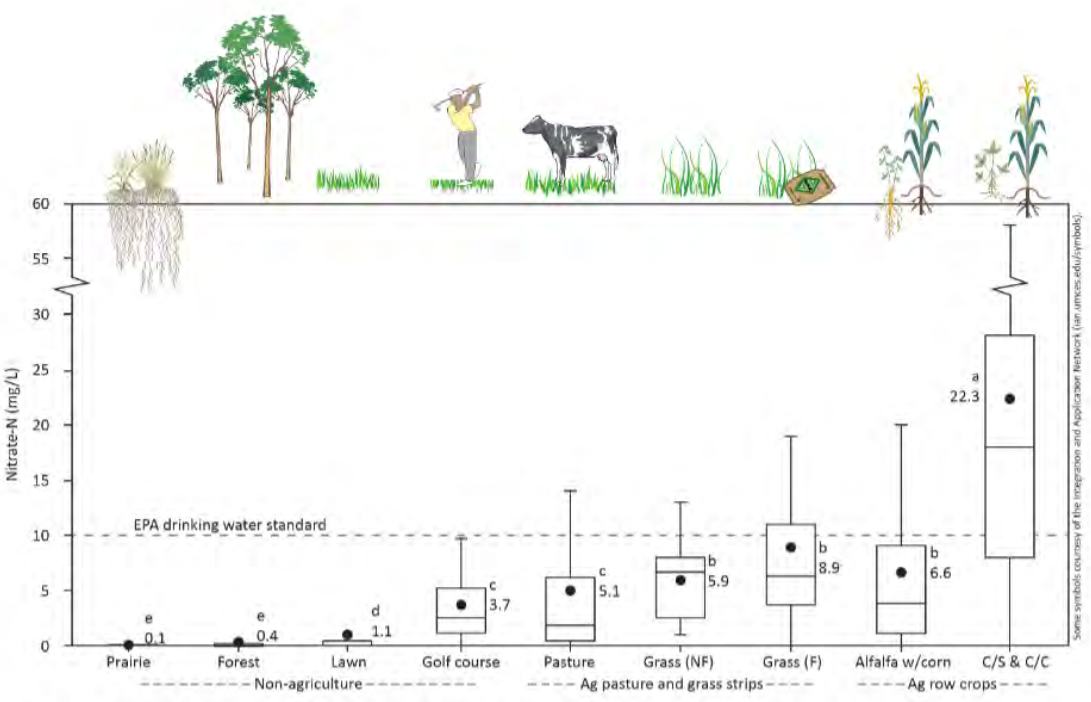
Winona County Farmers have a long history of land stewardship and share a conservation ethic that is unique to this part of the state. Farmers in our area have worked with conservation groups and voluntarily adopted numerous practices that benefit surface and groundwaters. The local livestock industry understands the importance of being good neighbors by keeping manure nutrients where they are to be stored and applied. Onerous rules that are financially impossible to comply with can, and will result in the decline of family owned livestock farms in Southeast Minnesota. Conservationists should be particularly concerned with the potential to lose cattle and dairy farms in the region. When the cattle leave, farm families often rely on the corn and soybean rotation to generate farm income. According to MPCA's own research (figure 1) grazing land and the alfalfa/corn crop rotation common to cattle and dairy farms reliably contributes water to our aquifers below the 10 ppm drinking water standards. Winona County Farm Bureau looks forward to staying engaged throughout the process of reviewing the 7020 rules and looks forward to collaborating to ensure a financially sound livestock industry while maintaining high water quality standards.

Sincerely,

Glen Groth

Winona County Farm Bureau President on behalf of the Winona County Farm Bureau Federation.

Figure 1



Data source: *Examination of Soil Water Nitrate-N Concentrations from Common Land Covers and Cropping Systems in Southeast Minnesota Karst* (Kuehner et al., 2020).

Graph summarizes nearly 3,000 soil-water nitrate-nitrogen samples collected from 50 suction-cup lysimeters, typically from a depth of four feet.
Black dots = average concentration; horizontal lines = median concentration; whiskers = ranges for top and bottom 25%, excluding outliers.
Land covers that do not share the same letter are statistically different at the 0.05 confidence level.

Abbreviations: NF = no fertilizer, F = fertilizer, C/S = corn/soybean rotations, C/C = continuous corn.

Re: Planned Amendments to Rules Governing Animal Feedlots, Minnesota Rules Ch. 7020, Revisor's ID No. R-4928, OAH Docket No. 25-9003-40661

Dear Honorable McKenzie,

The White Earth Nation appreciates the opportunity to comment on the proposed rulemaking for Minnesota Feedlot Rules (Chapter 7020). As stewards of the land and waters of northern Minnesota since time immemorial, we assert our responsibility to protect the health of the ecosystems and resources guaranteed to us by treaties, federal laws, and court decisions. These include rights reserved in the 1837, 1855, and other Treaties that affirm our ability to hunt, fish, and gather on lands and waters our ancestors ceded to the United States, rights that are increasingly threatened by the cumulative environmental impact of large-scale animal feedlots.

The fish, water, and wild rice that sustain our people are not merely resources, they are also our relatives. Our culture and our way of life is deeply connected to our ability to exercise these rights in relation with these resources. The presence of nitrates, phosphorous, bacteria, and manure runoff in surface waters directly harms fish populations, wild rice beds, and the ecosystems we depend upon for cultural survival, subsistence, and spiritual continuity. Fish kills, such as those increasingly reported following extreme weather events near manure storage lagoons as well as manure storage failures, undermine our Treaty Reserved Rights to continue to hunt, fish, and gather. Any degradation of these natural resources constitutes a violation of the Treaty obligations by the State of Minnesota and the United States federal government.

We support the MPCA's acknowledgement that agricultural practices and environmental understanding have significantly evolved since the last major feedlot rule update in 2000. These changes include:

- Increased use of liquid manure and high-risk seasonal land application;
- Consolidation of animal agriculture into fewer, larger operations (often just under permit thresholds);
- Growing reliance on manure pipelines and commercial application over long distances;
- Documented overapplication of nutrients, often exceeding crop needs by over 40%, especially in groundwater-vulnerable areas like the Central Sands and karst regions;
- Greater demands for real-time environmental data and digital reporting.

Given these trends, current regulatory structures are insufficient to prevent the contamination of drinking water sources, degradation of surface waters, and destruction of aquatic ecosystems. The White Earth Nation supports and urges MPCA to incorporate the following policy recommendations:

1. **Lowering the Permit Threshold to 600 Animal Units (AU) or less**
   This change would increase permit coverage from 4% to 14% of feedlots in Minnesota which will address a larger portion of the 49 million tons of manure generated annually in Minnesota. More feedlots under permit will mean more manure management planning and pollution prevention which benefits us all.
2. **Water Quality Monitoring Requirements for Large Feedlots**
   We urge the MPCA to require monitoring of discharges to groundwater, drain tile effluent, and surface water. Compliance cannot be presumed without data. Effective enforcement depends on accurate, transparent, and regular environmental monitoring.
3. **Air Quality Monitoring Requirements for Large Feedlots**
   We recommend monitoring of additional air pollutants for large feedlots. While the MPCA has set hydrogen sulfide standards for feedlots and enforces these standards, we suggest requiring the monitoring of ammonia, a significant contributor to PM2.5, as well as PM, VOCs, and greenhouse gases at large feedlots. This data will inform Minnesota of the impact large feedlots may have on climate change and human health and could help in the potential future development of feedlot emissions standards for these harmful air pollutants.
4. **Ensuring Compliance with Air Quality Rules**
   The MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.
5. **Stricter Manure Application Limits in Vulnerable Areas**
   Application rates in karst and sandy-soil regions must not exceed agronomic needs. We strongly support banning liquid manure application of frozen or snow-covered ground and requiring cover crops or divers rotations in fall manure applications.
6. **Prohibition of New or Expanded Feedlots in Vulnerable Groundwater Regions**
   The MPCA rules should prohibit new or expanded animal feedlots where groundwater is most vulnerable to seepage pollution such as karst geology areas or the central sands region of the State. There are no remediation techniques available for contaminated

groundwater. We cannot afford to contaminate our groundwater supplies and should be particularly careful in areas where the groundwater is vulnerable to seepage pollution.

7. **No Permit-by-Design for Large Feedlots**
   Feedlots should not be presumed in compliance based on planning documents alone. A "trust but verify" approach must be adopted. Regulatory enforcement should include frequent, unannounced inspections, a swift plan to come into compliance if non-compliance is found, and penalties for continued non-compliance.
8. **Require Environmental Assessments for Medium and Large Feedlots**
   The current regulations require Environmental Assessment Worksheets (EAWs) for proposed feedlots over 1,000 AU or over 500 AU in a sensitive area. We recommend requiring EAWs for proposed feedlots over 500 AU and over 250 AU in sensitive areas. Feedlots generate large amounts of manure and waste, which can lead to significant air and water pollution. Lowering the threshold for requiring EAWs ensures that potential environmental and public health impacts are evaluated prior to construction. This is especially crucial in sensitive areas where ecosystems, groundwater, or human populations are more vulnerable. Sensitive areas, such as those near water bodies, wetlands, vulnerable groundwater regions, are more prone to contamination. Requiring EAWs for feedlots over 250 Animal Units in these areas ensures that even moderate-sized operations are thoroughly assessed for risks. By lowering the threshold, the regulation becomes more precautionary which allows agencies and communities to identify and mitigate potential problems before they occur, rather than dealing with the consequences after the damage is done. Environmental impacts can occur even from smaller operations, particularly when clustered or located within sensitive areas. Communities are increasingly aware of these risks, and this adjustment aligns policy with both science and public concern. Requiring EAWs for more feedlots encourages better siting, waste management planning, and transparency. This leads to more sustainable agricultural practices that balance economic activity with long-term environmental stewardship.
9. **Limiting Feedlot Size and Animal Units to be Permitted within Each Local Area or Watershed**
   There are currently no limitations to the size of a feedlot or to the number of animal units allowed within a local area or watershed which allows feedlots and concentration of pollution impacts to increase. The MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

The White Earth Nation asserts that any regulatory framework that does not fully account for the protection of Treaty-reserved resources is fundamentally incomplete. Feedlot pollution has tangible and growing impacts on our waters, fisheries, and wild rice ecosystems. The new rules must reflect the science and ethics of our time. This means strong permitting, more monitoring, and applying the precautionary principle, especially in vulnerable landscapes and aquifers.

We ask the MPCA to uphold its duty to all Minnesotans, including Indigenous Nations, by ensuring that feedlot regulation meaningfully protects the ecosystems our people have relied on for generations.

Miigwech (Thank you),

Chairman Fairbanks (Jul 21, 2025 12:12 CDT)

Michael Fairbanks

RE: Comments on MPCA RFC for Amendments to Rule Governing Animal Feedlots: Minnesota Rules, Chapter 7020, Revisors ID Number R-4928, OAH Docket No. 25-9003-40661

Mr. Moore,

The Pennington Soil & Water Conservation District, as the delegated county feedlot officer for Pennington County, appreciates the opportunity to provide comments on the MPCA RFC regarding Minnesota Rules, Chapter 7020, governing animal feedlots. As the delegated county feedlot officer, we have direct experience implementing the state's feedlot program. It is important to maintain effective and practical rules to protect our natural resources and the environment while maintaining and supporting the success of the Minnesota livestock industry and operators across the state.

Information presented during the in-person meetings indicated an increasing trend in surface water nitrates at a couple of points in the northwest area. It was noted that an increasing trend did not mean exceeding standards. Looking at the same region, the number of registered feedlots continues to decline, which indicates other nitrate sources that should be reviewed. While animal feedlots may be a source of nitrates, it is one of many sources across the state such as the noted increasing use of sub surface drainage, increased use of synthetic fertilizers, city wastewater discharge, and more. As the MPCA reviews these rules and all available data, we encourage other sources to be taken into consideration and the rules, regulations, and enforcement are equal for all potential sources, not just animal feedlots.

The information presented during the in-person meetings also contained information on groundwater monitoring trends with very few data points in the northwest area, one being above the detection limit, located along a beach ridge. We urge the MPCA to reach out and compile as much information as possible prior to any rule changes. For example, Pennington SWCD has 20 years of lab certified well water testing data from their annual well clinics. With over 800 samples, only 3 samples have exceeded the drinking water standard. Please contact me if you wish to include our data set with your reviews. While nitrates in the groundwater are an issue in parts of the state and is an emerging concern, Minnesota is a large state with different soils, topography, and land uses. Rule revisions should be driven by science and data

for each region as necessary restrictions and corresponding best management practices should vary based on a site's soils, topography, and climate. As discussed in the Thief River Falls meeting, MPCA should consider creating different zones of the state as 'one size fits all' rules are not the best solution and do not provide the same benefits or protection across the state.

When reviewing land application rules, we again ask MPCA to consider utilizing zones when revising rules. As MDA has their fall restriction map for nitrogen application, areas of the state are identified as high vulnerability while others are climate excluded. Minnesota land and climate are different across the state and should be taken into consideration when revising the rule. Also, MPCA should recognize that changes to land application rules, limiting the amount, timing, setbacks, and locations will influence storage needs for existing and new facilities. New regulations regarding manure storage would need to account for the large financial costs to the feedlot owner and the timeframe it would take for owners to become compliant with new restrictions. Engineers, contractors, inspectors are already busy, increased demand from new regulations would create a bottleneck effect for survey, design, construction, installation, and certification of new storage areas that would be required before an owner could be in compliance with new rules.

While the MPCA reviews the current rules and considers changes, we ask the MPCA acknowledges that every region, county, city, site, and operation are unique and have differences. Keeping regulations and technical standards broad would be beneficial and the MPCA could allow, support, and supply the resources to the counties to update their local ordinances to strengthen their regulations as they see fit within their county's needs for restoration and protection of water resources. MPCA has Watershed Restoration and Protection Strategy (WRAPS) documents that could help guide each region in their local ordinances rather than a statewide rule as some areas document high nutrients and bacteria while other watersheds may have recent delisting of impairments. By referring to local WRAPS documents and Comprehensive Watershed Management Plans, it allows flexibility for each region to implement regulations that are needed in their area.

We urge the MPCA to carefully consider any proposed changes to animal unit (AU) calculations as these numbers are used for various determinations such local zoning, cost-share eligibility, manure management, land application, and soil and manure testing requirement thresholds. Small changes in these values could create large impacts to existing operations and feedlot program administration. MPCA should work closely with stakeholders and have a thorough understanding of the effects prior to any rule revisions to the animal unit calculations.

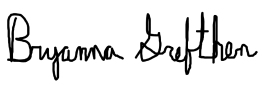
When considering any rule changes, we request the MPCA to consider practicality and balance flexibility and resource protection while also factoring the cost. New requirements could be costly and ultimately detrimental to the small operations that remain, especially in the northwest region. The livestock industry is important in the state and unjustified increased regulations could pressure small sites to close as financial assistance for these projects is very limited. Not only will new rules increase costs for landowners, but there will also be an increase in costs to administer the feedlot program.

With new rule revisions, there will be an increased need for additional outreach, assistance, education, inspections, and likely enforcement. The MPCA's Feedlot Program has very limited funding for administration and enforcement by both MPCA staff and funds distributed to delegated counties. MPCA will need to seek and identify additional funding for state and county staff to adequately and effectively educate feedlot owners and implement the new regulations. This increased financial hardship will be felt stronger in the counties that are minimally funded as the amount these counties currently receive is barely enough to administer the program.

There may also be a need to update the requirements of delegated counties. We support the need to update the rules to remove irrelevant wording and include the use of electronic systems for registrations, permitting, and manure management plans. However, MPCA should only add requirements that are necessary and can be directly tied to environmental protection and avoid creating unnecessary regulations that will only increase administrative costs of running the program. As stated above, the feedlot program is already working on limited funding and additional requirements could force counties to be undelegated, which is not desirable for individual counties and their feedlot owners.

Thank you again for the opportunity to provide comments on the proposed rule revision. Livestock operations are important as is the safety and health of the environment for all residents, tourists, and organisms. We support the MPCA's proposal to update the Chapter 7020 rules in a manner that is science-based, practical, flexible, maintain environmental protection, is region specific, and still preserve Minnesota's livestock industry.

Sincerely,



Bryanna Grefthen

Pennington County CFO

Re: Planned Amendments to Rules Governing Animal Feedlots, Minnesota Rules, Chapter 7020, Revisor's ID Number R-4928, OAH Docket No. 25-9003-40661

To Whom It May Concern,

The Lower Sioux Indian Community in the State of Minnesota (the "Community") submits these recommended amendments to Minnesota Rules Chapter 7020 that would assure minimum protections for tribal water systems in the vicinity of proposed feedlots. Chapter 7020 currently contains certain provisions applicable to a feedlot proposed near a drinking water supply management area ("DWSMA") approved by the Minnesota Department of Health. Those provisions should be amended to recognize similar areas designated by Indian Tribes located within the State of Minnesota.

Background

The Community is a federally recognized tribe with a reservation in southwestern Minnesota. As a sovereign nation, the Community possesses inherent authority over its drinking water systems, which are crucial to Community's health, safety, and welfare.

To ensure adequate protection of its water systems, the Community has developed a source water protection plan in partnership with the U.S. Environmental Protection Agency. A source water protection plan delineates a source water protection area, or a "land area that contributes water to the drinking water supply and where pollution from human activities or natural sources poses the greatest threat to source water quality."[1]

---

[1] U.S. Envtl. Protection Agency, *What is a Source Water Protection Area?*, https://www.epa.gov/sourcewaterprotection/delineate-source-water-protection-area.

Minnesota Rules Chapter 7020 currently includes specific provisions applicable to a DWSMA, which is similar to a tribal source water protection area. A DWSMA is delineated based on a "wellhead protection area," which is "the surface and subsurface area surrounding a well or well field that supplies a public water system, through which contaminants are likely to move toward and reach the well or well field."[2] A DWSMA is defined as the "surface and subsurface area surrounding a public water supply well, including the wellhead protection area."[3] A DWSMA, which draws a boundary around that area, is approved by the Minnesota Department of Health.[4]

Proposed Rule Changes

The Community recommends the following rule changes to ensure that tribal source water protection areas are afforded the minimum stop-gap protections that protect a DWSMA from inadvertent contamination. These amendments are not intended to place designation and administration of a tribal source water protection area under the purview of state law. Rather, the amendments would simply ensure that these areas are recognized and accounted for when a feedlot application is processed by the State or a county.

I. The Location Restrictions Applicable to a DWSMA Approved by the Minnesota Department of Health Should Also Apply to Tribal Source Water Protection Area.

Minnesota Rule 7020.2005 currently prohibits animal or manure feedlot storage areas from being located within 1,000 feet of a community water supply well or well serving a public school if it also would be located within a DWSMA.[5] The Minnesota Pollution Control Agency adopted location restrictions "to provide a minimum level of protection" that was "needed to protect human health and the environment."[6]

A tribal source water protection area is defined in the same way, and for the same purpose, as a DWSMA. In short, locating a feedlot within a tribal source protection area endangers human health and the environment in the same manner as locating a feedlot in a DWSMA. Accordingly, the Community recommends the following amendments to Minnesota Rule 7020.2008, specifically in Subpart 1.B.:

> **Subpart 1. Location restrictions.** A new animal feedlot or a manure storage area must not be constructed within a floodplain or within 300 feet of a sinkhole. A new animal feedlot or a manure storage area must not be constructed within the applicable isolation distance required by part 4725.4450 or 100 feet of a water supply well, whichever is greater. Except as provided in items A and B, a new

---

[2] Minn. R. 4710.5100, subps. 13, 24.
[3] *Id.* subp. 13.
[4] *See* Minn. R. 4720.5330, subp. 2.A.(2) (stating that the Department shall approve or disapprove "the drinking water supply management area boundary").
[5] See Minn. R. 7020.2005, subp. 1.B.(2) (prohibiting a new animal feedlot or manure storage area within 1,000 feet of a community water supply well or well serving a public school unless it is not within a DWSMA and not within 200 feet of the well).
[6] Minn. Pollution Control Agency, *Statement of Need and Reasonableness*, at 140 (Dec. 8, 1999) (hereinafter "1999 SONAR").

animal feedlot or a manure storage area must not be constructed within shoreland or within 1,000 feet of a community water supply well or other wells serving a public school as defined under Minnesota Statutes, section 120A.05, a private school excluding home school sites, or a licensed child care center where the well is vulnerable according to part 4720.5550, subpart 2.

. . .

B. A new animal feedlot or manure storage area may be constructed within 1,000 feet of a community water supply well or other well serving a public school as defined under Minnesota Statutes, section 120A.05, a private school excluding home school sites, or a licensed child care center if the following three conditions are met:

(1) the Minnesota Department of Health has approved a drinking water supply management area for the well under part 4720.5360 or an Indian Tribe has a tribally designated source water protection area;

(2) the animal feedlot or manure storage area is not within the drinking water supply management area approved by the Minnesota Department of Health or the tribally designated source water protection area; and

(3) the animal feedlot or manure storage area is not within 200 feet of the well.

It should be noted that the Community does not propose that a tribally designated source water protection area be referred to as a DWSMA in the rules, because there are specific requirements applicable to a state-designated DWSMA that may not be precisely the same as the tribal or federal standards that may govern a tribal source water protection area. There are eleven federally recognized tribes within the State of Minnesota, and some specific requirements or procedures may vary among tribes. As sovereign nations, tribes may each have their own processes and requirements.

The Community does not believe it is necessary to add a definition of the rules to describe a tribal source water protection area. However, if necessary, the term "tribally designated source water protection area" could be defined as "a geographic area, designated by an Indian Tribe, that contributes water to the drinking water supply of the Indian Tribe and where pollution from human activities or natural sources pose the greatest threat to water quality."

II. The Processing Requirements Applicable to a DWSMA Approved by the Minnesota Department of Health Should Also Apply to Tribal Source Water Protection Area.

The Minnesota Rules also require a county that is delegated feedlot permitting authority to forward certain permit feedlot applications for review by the MPCA.[7] The rule should be amended to include the forwarding of applications that may affect a tribal source water protection area.

[7] Minn. R. 7020.1600, subp. 4a.B.

As the Minnesota Legislature has recognized, the State of Minnesota has "a unique relationship with federally recognized Indian Tribes, formed by the Constitution of the United States, treaties, statutes, case law, and agreements."[8] State agencies have developed consultation procedures to further a productive government-to-government relationship.[9] Through the consultation process, the MPCA has developed relationships and experience working with Tribes on a government-to-government basis. Because of the status of Tribes as sovereign nations and the experience the MPCA has developed in working with Tribes, it would be appropriate for the MPCA to review applications in areas that Tribes have identified for source water protection.

To ensure effective implementation, a delegated county would first forward the permit application to Indian Tribes for a determination of whether the proposed permit would be within a tribally designated source water protection area. If an Indian Tribe confirms that, based on an existing designation, the permit would be located within a tribally designated source water protection area, then the permit would be forwarded to the MPCA for processing.

To implement these procedures, the Community recommends the following amendments to Minnesota Rule 7020.1600:

> **Subp. 4a. Permit application processing procedures.** The processing of permit applications by a delegated county shall be conducted according to the procedures in items A to F.
>
> > A. The county feedlot pollution control officer shall process permit applications and issue construction short-form and interim permits according to this part and parts 7020.0505 and 7020.0535, except as directed in item B. Upon receiving a permit application, the county feedlot control officer shall forward the permit application to all Indian Tribes located within the state to determine whether the proposed permit would be within a tribally designated source water protection area.
> >
> > B. The county feedlot pollution control officer shall forward to the commissioner for issuance all permit applications and all other applicable documents, comments, and recommendations for the following:
> >
> > > . . .
> > >
> > > (4) all facilities with 500 or more animal units that are within a vulnerable drinking water supply management area, as described on a Minnesota Department of Health approved wellhead protection plan or as described on an Indian Tribe's source water protection plan; ~~and~~
> > >
> > > (5) all facilities for which an application for a variance under part 7020.0505, subpart 6, is submitted; and~~.~~

---

[8] Minn. Stat. § 10.65, subd. 1(b).

[9] *See id.* subds. 2(1) (defining "agency"), 3 (describing consultation duties).

(6) all facilities for which the county has received a determination from the Indian Tribe that the proposed permit would be within a source water protection area designated by an Indian Tribe.

The Community recommends forwarding the notification to all Indian Tribes located within the state to ensure that the rule's requirements are clear and easy to follow. In some situations, a county may be unsure which Indian Tribe may be affected. Forwarding the application to all Indian Tribes is the simplest way to ensure that notification is received while relieving counties of the burden of determining where the application must be forwarded.

III. The Recommended Definition of "Indian Tribe" Would Include the Federally Recognized Tribes Located Within the State of Minnesota.

The Community recommends adding the following definition to Minnesota Rule 7020.0300, to ensure clarity as to tribally designated source water protection areas must be considered:

> **Indian Tribe**. "Indian Tribe" means the following federally recognized Tribes that are located within Minnesota: Boise Forte Band; Fond Du Lac Band; Grand Portage Band; Leech Lake Band; Mille Lacs Band; White Earth Band; Red Lake Nation; Lower Sioux Indian Community; Prairie Island Indian Community; Shakopee Mdewakanton Sioux Community; and Upper Sioux Community.

This definition is consistent with the definition of "Minnesota Tribal Government" that is used in Minnesota Statutes Section 10.65, which directs Minnesota state agencies to implement consultation duties with Tribes to address matters that have Tribal implications.[10] It is an appropriate definition for these particular rules because these are the Tribes that may have water systems located within the borders of the State of Minnesota.

Thank you for your time and consideration. The Community looks forward to continued dialogue and consultation on the feedlot rules.

Pidamayado,

Robert L. Larsen
President

Re: Minnesota Animal Feedlots Rules, chapter 7020, Revisor's ID Number R-04928
OAH Docket No. 25-9003-40661

Dear Commissioner Kessler, Mr. Schwint,

The comments below are submitted by WaterLegacy to request stronger Animal Feedlots Rules to protect water quality, fish, wildlife, and human health. WaterLegacy appreciates that the Minnesota Pollution Control Agency (MPCA) is seeking comments early in the process of developing new rules for animal feedlots.

Minnesota has more than 23,000 animal feedlots, also known as Concentrated Animal Feeding Operations (CAFOs). Manure and nitrate pollution from these feedlots flows down the Mississippi River and contributes to the Dead Zone in the Gulf of Mexico. Animal feedlot manure runoff, seepage, and spills also cause serious problems here in Minnesota:

- Fish kills result from byproducts of manure decomposition and depletion of oxygen levels in water due to excessive nitrates and algae blooms.

- Swimming is unsafe due to E.coli bacteria from animal wastes. More than 100 Minnesota waterbodies are listed under the Clean Water Act as impaired due to E.coli.

- Excessive nitrates result in blue-green algae blooms in shallow lakes and rivers, producing toxins (cyanobacteria) harmful to wildlife and humans.

- Increased nitrates in well water used to prepare infant formula can cause methemoglobinemia (blue-baby syndrome). The Minnesota Department of Health (MDH) has concluded that nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths in recent decades.[1]

[1] MDH, Nitrate and Methemoglobinemia, last visited July 20, 2025 at https://www.health.state.mn.us/communities/environment/water/docs/contaminants/nitratmethemog.pdf

Minnesotans are literally swimming in and drinking manure. WaterLegacy believes that existing MPCA Animal Feedlot Rules have significant deficiencies, including but not limited to the following:

- Existing rules only require water pollution permits (NPDES/SDS permits) for huge feedlots with 1,000 or more "animal units" (which can mean 3,000 swine, 10,000 sheep, or even 200,000 chickens). "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure[2]–require no permits.

- Existing rules set no maximum size for feedlots and no maximum number of animal units in a local area or watershed, allowing feedlots and concentration of pollution impacts to increase. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.

- Existing MPCA rules claim "no discharge" is allowed, but do not monitor or test manure storage areas or fields where manure is applied to verify what discharge in being released. In addition, despite compelling technical evidence since at least 2010 and multiple petitions for change, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.

- Existing MPCA rules do not apply modern science and technology to require containment of all manure within advanced liner systems. Rules allow application of manure to fields during the winter and under conditions where benefit to soil is unlikely and adverse effects to water quality virtually certain.

- Loopholes and exemptions allow noxious and odorous hydrogen sulfide air emissions as well as toxic water pollution. No existing rule requires a feedlot emitting noxious emissions and odors to demonstrate that at least 344 days a year, all air quality standards have been met.

WaterLegacy hopes that the MPCA will stand up to interested parties and substantially reform the way in which Minnesota regulates animal feedlots. We propose the following changes:

1. Require any animal feedlot with 300 or more animal units—rather than 1,000 or more animal units as currently stated in Minn. R. 7020.0405—to obtain a permit that complies with groundwater and surface water limits on pollution and non-degradation requirements as well as technology-based standards.

2. Define a "feedlot" for the purpose of requiring NPDES/SDS permits to include multiple feedlots with the same or overlapping ownership that are

---

[2] Environmental Working Group, Five years after EWG's first analysis, manure still overloads Minnesota, last visited July 20, 2025, https://www.ewg.org/research/five-years-after-ewgs-first-analysis-manure-still-overloads-minnesota.

within a specified distance of each other or affect the same sub-watershed. MPCA should also define what criteria should be used to set a cap or moratorium on additional feedlot animal units in a county or local watershed.

3. Prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that "stricter" requirements in existing rules prevent pollution.

4. State that MPCA will enforce "no discharge" requirements, compliance with all water quality and air quality limits, reduction of contamination in impaired waters based on compliance schedules and/or TMDLs, and prevention of degradation in waters that are not polluted. Increase the degree to which regulations are outcome-oriented to reduce the need to dictate or provide exemptions from specific practices.

5. In order to make the current "prohibition" of discharge from feedlots (Minn. R. 7020.2003) verifiable and enforceable, require monthly monitoring (and public availability of DMR data) for groundwater and surface water quality for every permitted animal feedlot. Monitoring should include boring beneath existing manure storage facilities (vertical or diagonal, if necessary) to determine whether contamination has leaked into groundwater.

6. Require monitoring (and public availability of DMR data) for groundwater and surface water quality at all land application sites where manure from permitted feedlots is applied. For accurate monitoring, MPCA rules should require that feedlot application plans submit tile system maps for all proposed land application sites.

7. Require soil nitrate tests prior to land application of manure and restrict land application in areas with nitrate levels that exceed groundwater or surface water quality standards or would result in "point source nitrate-nitrogen contamination" as described in Minn. R. ch. 1573.

8. Prohibit application of manure, whether wet or dry, in the winter. Land application must be regulated to consider unpredictable and extreme weather due to climate change and to benefit soil and living plants, not to allow cheap disposal for animal wastes.

9. Expedite adoption of surface water quality standards for nitrates, based on technical analyses performed in 2010 and 2022 to ensure prevention of fish kills and protection of endangered, threatened, and species of concern.

10. Set new technology-based standards applicable to all manure storage based on current knowledge regarding liners, leakage, climate, and hydrology. For example, require a synthetic liner system as well as concrete for storage of

liquid manure, a double liner system for manure stockpiles in use for 120 days or more, and verification that projected leakage limits are met. *See* Minn. R. 7020.2100, .2125.

11. Require that all permitted feedlots provide animals with drinking water pumped into tanks and prevent animal access to waters of the state. *See* Minn. R. 7020.2015.

12. Clarify burden of proof for exemption of permitted feedlots from ambient air quality standards so that MPCA on its own or on receipt of a complaint can enforce air emissions and odor violations if a livestock facility does not demonstrate that it has complied with odor and hydrogen sulfide standards a minimum of 344 days per year and has only exceeded standards when removing manure. *See* Minn. Stat. § 116.0713.

WaterLegacy appreciates the MPCA's consideration of the above recommendations. In an era where federal environmental protection is likely to be minimal, Minnesota's action to strengthen and enforce Animal Feedlots Rules to protect water, fish, wildlife, and public health becomes even more important.

Please feel free to contact us if you have any questions about WaterLegacy's comments.

Sincerely yours,

Paula G. Maccabee
WaterLegacy Executive Director and Counsel

COMMENT ON FEEDLOT RULES SUBMITTED BY MICHAEL D. MADIGAN

I appreciate the opportunity to submit comments on the proposed updates to Minnesota's feedlot rule (Minn. R. ch. 7020). Animal feedlots are a significant source of pollution. Without stronger regulations, manure runoff and groundwater contamination will continue to degrade human health, drinking water suppliers, and rural communities. While beyond the scope of my comments, the carcinogenic impact of nitrate pollution is well documented. https://progressreport.cancer.gov/prevention/chemical_exposures/nitrate.

Less well known are the devasting impacts of nitrate pollution to trout streams and the abundant life that they foster. Aquatic ecosystems are vital to Minnesota's outdoor economy, environmental health, and quality of life. Coldwater streams are among the rarest and most sensitive aquatic systems in Minnesota and require the highest level of protection. Anything less puts irreplaceable resources and the public's health at unacceptable risk. Feedlot pollution and agricultural runoff have already resulted in significant fishkills in the Southeast.

When revising the Rules I ask that you consider:

- **The true costs of a weak Rule:** Remediating polluted aquifers and restoring degraded streams is exponentially more expensive than proactively preventing nitrate pollution.
- **Manure and it's byproducts are toxic to aquatic ecosystems:** Nitrates reduce the size and potentially survival of trout populations and impact the macroinvertebrate populations trout depend on for food. Ammonia from manure is directly toxic to fish at even relatively low concentrations and has been tied to recent fish kills in southeast Minnesota.
- **Vulnerable Groundwater Areas must be prioritized:** Many feedlots are in the southeast Minnesota karst region, where groundwater moves quickly through cracks and sinkholes. Nitrate pollution from manure can easily seep into aquifers, threatening groundwater-fed trout streams.
- **Stronger rules help Minnesota mitigate and adapt to climate change:** Ensure resilient clean water supplies and trout streams for future generations and reduce nitrous oxide emissions.

I strongly urge the Minnesota Pollution Control Agency to amend the Rule to include the following:

- Require soil nitrate tests prior to all manure applications in Cass, Carlton, Morrison, Martin, Winona, Hubbard, Rock, Clearwater and Stearns counties which have been shown to be hot spots for nitrogen overload. (7020.2225 Subp.2)
- Require NPDE/SDS permits for feedlots with over 600 animal units. (7020.0405)
- Require robust nutrient management plans that minimizes nitrate loss to both groundwater and surface water for feedlots with more than 300 animal units. (7020.2225 Subp. 4)
- Prohibit manure application on frozen or saturated ground, or when rainfall is likely. (7020.2225 Subp. 6 add to Subp4))
- When manure is transferred for application purposes the transferee must also follow the requirements set forth in the permit. (7020.2225 Subp.5 D)
- Require expanded buffer zones and greater setback distances for feedlots located near trout streams, tributaries, seeps or springs flowing into trout streams, public waters, and public drinking water supplies. You cannot spread manure within 250 feet of a private well, 1000 feet of a community well, or 300 feet upslope or 100 feet downslope of a direct conduit to groundwater (sinkhole, outcrop). (https://cropsandsoils.extension.wisc.edu/articles/best-management-practices-to-use-on-karst-and-silurian-soil/) (7020.2225 Subp.6/8)
- Eliminate the option to delegate county level permit oversight and return oversight to the MPCA. (7020.1500)
- Animals of a CAFO or a facility capable of holding 300 or more animal units must not be allowed to enter waters of the state (7020.2015 Subp 1) Subp. 26.
- Manure and process waterwater application must not be allowed near trout streams and springs, seeps, and tributaries of trout streams. Specifically, I would suggest that manure and process wastewater not be applied land within 300 feet of a trout stream or spring, seep, or tributary to a trout stream or to land within 1000 feet of a trout stream with a slope of 6 degrees.
- Expand mandatory groundwater and surface water monitoring at all large operations, manure storage application sites.

- Consider the density and the maximum number animals units allowed in a particular watershed, with consideration to the vulnerable groundwater areas of the state including the Karst region. Using a cumulative spatial approach as used in the recent EWG report should be considered.

Healthy coldwater ecosystems need clean, cold water. Inadequate feedlot rules jeopardize the health of these precious resources. Recent, massive fishkills in the southeast attest to the failure and inadequacy of the current rules. I urge MPCA to act boldly and adopt stronger feedlot regulations that reflect the scale and urgency of this challenge.

Respectfully,

Michael D. Madigan

Minnesota Pollution Control Agency

July 21, 2025

Re: Minnesota's Animal Feedlot Rule

https://www.pca.state.mn.us/sites/default/files/wq-rule4-29a.pdf

The Institute for Agriculture and Trade Policy (IATP) appreciates the opportunity to comment on the Minnesota Pollution Control Agency's proposed amendment to Minnesota Rules Chapter 7020 governing animal feedlots.

It has been 25 years since Minnesota significantly revised the rules for animal feedlots and the massive amounts of manure they produce. As the MPCA acknowledges, much has changed since that time. Minnesota now has about 17,000 feedlots and those operations are getting far bigger and far more industrialized, storing much more manure in large waste facilities. We also have increased use of liquified manure systems that are leading to the over-application of manure on farmland and increasing the potential for runoff into waterways.

Our knowledge about how feedlots affect our water, climate, and public health has also improved. We have a better understanding of nitrate pollution and the number of impaired waters in the state.[1] Throughout the state, nitrogen loads in river systems are staying elevated or even increasing in some cases. Manure continues to be a major threat to water quality in the state. As the MPCA reports, the state is experiencing more extreme weather events that have affected the feedlot industry, including manure overflows.[2] The state has also seen a loss of small grains and accompanying grazing lands that could help improve water quality, even as the feedlot system has expanded.

According to a recent analysis by the Environmental Working Group, the state's feedlots house up to 1.03 million dairy cattle, 1.6 million beef cattle, 10.8 million hogs and 58.7 million turkeys and chickens, which together produced over 48.9 million tons of manure that year. Many of the state's feedlots are located near vulnerable groundwater areas. EWG found that almost 6,500 feedlots in the state are located in vulnerable areas.[3]

Facilities under 1,000 animal units do not need a water pollution permit under the EPA's NPDES or the State Disposal System (SDS, just a construction permit. For that reason, many

[1] https://www.pca.state.mn.us/air-water-land-climate/minnesotas-impaired-waters-list

[2] https://www.startribune.com/manure-pits-reportedly-overflow-at-16-large-feedlots-in-southern-minnesota/600376074

[3] https://www.ewg.org/research/five-years-after-ewgs-first-analysis-manure-still-overloads-minnesota

operators keep their animal unit numbers just below the 1,000-animal unit threshold to avoid having a water pollution permit. The EWG analysis found that 374 animal operations in the state had between 950 and 999 animal units in Minnesota in 2024.

We applaud the MPCA for updating the feedlot rule. Given the enormous changes over the last 25 years, we encourage the MPCA to take significant steps to protect the state's water and air. We recommend the following actions to strengthen the current feedlot rules.

1) The feedlot permit should lower the animal unit threshold for feedlots required to complete a NDS or SDS permit to 600 animal units. This simple step will greatly improve the effectiveness of the program by covering more feedlots.
2) The updated rule should include stronger limits on manure applications, including lowering manure application rates, best practice requirements for fall application, limits on winter application, and requirements for enough storage capacity to avoid winter application. These reforms are particularly needed in areas facing water quality problems such as the karst region and the central sands region.
3) Strong groundwater monitoring should be included in the permit. Permitted, large facilities should be required to monitor subsurface discharges, including where manure has been transferred to neighboring farms, to see how much nitrate ends up in water. There is currently no way to make sure these operations do not violate Minnesota's water quality standards.
4) Require permitted feedlots to create a risk-assessment plan to monitor their manure storage areas and land application sites for above-ground discharges to ensure feedlots are not polluting lakes and rivers. Such risk assessment plans should incorporate climate risk, including expected extreme weather events.
5) The state should make more manure managing data and mapping available to the public, including information about anerobic digesters and manure spreading plans. Communities near feedlots deserve to understand the impact of manure on their nearby environment.
6) Feedlots that include anerobic digester plants producing digestate should be required to have a specific digestate application plan to mitigate the unique risks associated with digestate that include higher concentrations of nitrogen and phosphorous, and the potential for PFAS and other chemical contamination.
7) IATP has signed onto and strongly supports a comment submitted in collaboration with other organizations, including the Minnesota Center for Environmental Advocacy, calling for the MPCA to include the regulation of greenhouse gas emissions for large feedlots as part of an updated feedlot rule. This action for greater reporting on climate impacts and mitigation plans aligns with the current Environmental Quality Board's Environmental Assessment Worksheet (EAW) and should include: monitoring and reporting provisions specific to GHG emissions; mitigation strategies to reduce emissions from manure management and livestock operations; and enforcement measures to ensure compliance with existing air emission plan requirements.

We hope the MPCA will consider the feedlot rule within the larger context of the climate crisis, increasing farmland consolidation and the loss of farmers in the state. New feedlot rules should be coupled with farmer-focused programs to support more sustainable, regenerative systems for raising animals that do not require the storage of mass quantities of manure.

William Moore

Office of Administration Hearings

600 N Robert St

PO Box 64620

St Paul, MN 55164

RE: MPCA Feedlot Regulations

Mr. Moore,

On behalf of Jax Dairy Farms Inc. I would like to provide a few comments on the proposed MPCA rule changes for feedlots.

1. Please consider the impact of placing limitations on the ability to haul pen pack/semi solid during the winter months. We place the utmost importance on animal welfare and proper husbandry. Depending on the amount of precipitation we receive during winter months, it is critical for us to have the ability to haul manure during this timeframe. We must be able to keep our animals clean and dry for the prevention of sickness.
2. The proposed time structure for hauling of manure in the fall would make it nearly impossible to be able to get all of our manure hauled. We currently hire a custom applicator to do this due to the high cost of owing and operating this type of equipment with the limited profitability of a family owned dairy business, it would be detrimental to the future generations of our family to continue the dairy operation if we had to invest in equipment to do our own manure hauling.
3. The current rules and regulations are taken very seriously by our ag sector. We find it to be our obligation to protect our water sources due to how critical they are to our livestock operations. The current regulations we follow we find to be fair and do what they are supposed to do by protecting our water sources. We are avid fisherman/hunters and take great pride in protecting our resources so they can continue to be enjoyed by future generations.

Sincerely,

Roger Jax

Sandstone, MN 55072

dairy_queen_shannon@hotmail.com

7/21/2025

Minnesota Pollution Control Agency

520 Lafayette Road North

St. Paul, MN 55155

To Whom It May Concern,

I am writing as a resident and stakeholder in the state of Minnesota in response to the recently proposed set of new environmental regulations. While I appreciate and deeply respect the Minnesota Pollution Control Agency's (MPCA) ongoing commitment to preserving the natural beauty and health of our state, I must voice my concerns and express my lack of support for these new regulatory measures. It is my hope that, by sharing my perspective and highlighting the potential implications of these regulations, my letter may contribute constructively to the ongoing dialogue surrounding environmental policy in Minnesota.

Appreciation for Environmental Stewardship

To begin, I wish to commend the MPCA for its long-standing efforts to maintain Minnesota's clean air, water, and land. Our state's rich natural resources are a source of pride and prosperity, and it is crucial that we continue to safeguard them for future generations. I recognize that robust environmental protection has been a cornerstone of Minnesota's reputation as a great place to live, work, and visit. Through the years, the MPCA has played an important role in upholding these standards and continually striving for improvement.

As a member of a family farm, I have witnessed firsthand the relentless effort required to remain both operational and compliant with MPCA standards. Our farm has worked diligently to meet every expectation, and we have appreciated the opportunity to

collaborate with MPCA representatives—particularly when facilitating dialogue with our neighbors to address concerns and dispel common misconceptions about animal agriculture. These conversations have not only clarified our commitment to responsible stewardship but have also helped foster understanding within our local community.

However, I am deeply concerned that further tightening of regulations could carry unintended consequences, ultimately discouraging the next generation from entering agriculture and jeopardizing the ability of current farmers to sustain their livelihoods and pass on their businesses. For many of us, farming is not just an occupation but a legacy, one that we hope to continue for years to come.

I am concerned that the proposed additional regulations will place a significant financial and administrative burden on family farms like ours. Increased compliance requirements often translate into higher operational costs—not only in terms of necessary equipment or infrastructural upgrades, but also through the increased time and resources needed to manage and document compliance. For many small- and medium-sized agricultural operations, the cost of additional paperwork and mandated procedures can be overwhelming, potentially threatening their long-term viability. These challenges could discourage new generations from continuing the tradition of family farming, ultimately impacting both local economies and our ability to provide fresh, sustainable food for Minnesota communities and maintain a diversified agricultural community.

As we evaluate these recommended practices, I urge the MPCA to recognize that effective regulations must be grounded in the realities of location, geography, and weather. While it is possible to regulate the actions of farms, we cannot control, nor reliably predict, the weather—an ever-changing variable that shapes every growing season. Flexibility in compliance will be essential for the longevity of Minnesota's farms.

In east central Minnesota, for example, we contend with a unique set of challenges due to our cooler climate, greatly influenced by proximity to Lake Superior. The short and unpredictable window for planting cover crops in the fall, compounded by the difficulties of spring forage removal, means success varies considerably from year to year. Some seasons, cover crops flourish; in others, they are simply not viable. This variability is not from lack of effort or care—quite the opposite, as farmers are consistently striving to do what's best for the land and their animals. These are the hallmarks of true sustainability, values at the very heart of family farming.

Moreover, as the state considers layering additional regulations, I ask that funding and support be made available to small- and midsize farmers to help them achieve

compliance. Financial assistance, technical guidance, and cost-sharing opportunities will promote shared success far more effectively than rigid mandates alone. Too often, the fear is not of change, but of being regulated out of common sense and, ultimately, out of business.

Farmers want nothing more than to be responsible stewards, preserving the health of the land and their herds for the next generation. I respectfully ask the MPCA to ensure that new regulations do not unintentionally undermine the sustainability of family farms like ours but rather empower us to continue our vital role in Minnesota's rural communities.

Respectfully submitted,

Shannon Watrin

By: OAH on 7/21/2025
Jill Nelson Attachment

To Whom It May Concern,

My name is Jill Nelson, and I am the President of the Brown County Farm Bureau. Recently, several of our members attended the listening session in New Ulm, MN. Following that meeting, we met to draw up comments on the proposed changes to Minnesota's feedlot rules on behalf of the livestock producers in our county. Our committee was made up of representatives from all species groups: dairy, beef, poultry and swine.

MPCA states that these updates are needed because "farming practices have changed over the past 25 years." We agree - but not with the conclusion you're drawing. Farming practices *have* changed - for the better. In fact, most of the changes made by farmers in the last two decades have significantly improved water quality and reduced runoff and erosion. This is evidenced in recent research done at the UM and statistics shown at the meetings put on by the MPCA. Adding additional regulations to farmers simply because of pressure from activist groups who work hand in hand with the EPA is nothing but playing into their hands. Hands that never come with real, unbiased science. The sole goal of these groups is to eliminate animal agriculture. It is our hope that the MPCA will be wise in their direction and focus on where the problems are.

Current Reality: Many farms have adopted conservation-based practices that were unheard of a generation ago:

- Manure is now managed through nutrient plans that prioritize timing, placement, and soil health.
- Many farms use buffers, minimum-till or no-till and cover crops to keep nutrients in the field where they belong.
- Modern equipment and technology have made it possible to reduce over-application of fertilizer (including manure) and avoid sensitive areas altogether.

Given this progress, I urge MPCA to consider the following points:

- **Don't punish progress.** These new rules seem to assume agriculture is stuck in the past, when in fact many of us have made voluntary improvements, often without government mandates. The new regulations should reflect and reward that progress, not pile on more restrictions.
- **Ease, don't increase, regulatory burden.** What we need now is simplification and flexibility, not additional permitting hurdles that treat all farms the same regardless of location, stewardship, or impact.
- **Base rules on current science and data.** If the MPCA has clear data showing that feedlot-related pollution is on the rise, it should be shared publicly. From what we've seen in our area and what the newest University research shows,

water quality has improved, not declined. This was also shown in the data presented by the MCPA at the early listening sessions.

- **Hold municipalities responsible.** Farms are constantly being asked to shoulder the burden of pollution control, especially in our MN waters. However, those rules don't apply to municipalities who, in many cases, are allowed to discard directly into lakes, rivers and streams, especially during weather events. Farms would be shut down for doing this. Also, fertilizer and lawn chemicals are applied ad-lib in towns with run-off going directly into the sewer systems and often to lakes, streams and rivers. Any laws applied to farms should also be applied to municipalities and those who live there. Acres upon acres of city lawns have fertilizer and chemicals applied several times each summer. Most often at rates far above what is recommended. Often those granules and sprays fall directly onto the street which are then washed directly into the sewer systems. This is **Direct Point Pollution** and should be the first thing addressed.
- **Test the water in the Mississippi and Minnesota Rivers in the Twin Cities area.** We have been told there are no test zones for the rivers which run through the twin cities and other large metro areas. Why is that, if not to avoid showing the municipalities contribution to the river pollution.
- **Tailor rules to farm size and type.** One-size-fits-all rules often hurt smaller farms that don't have dedicated compliance staff or the capital to completely overhaul existing infrastructure that is still working safely.

Inspection of old lagoons and manure storage – This is infeasible for any size farm. Most are never truly empty to a point they could be inspected. Our county feedlot personnel were told in training that a manure pit/lagoon is designed to last at least for 2 barn cycles. Most barns are good 40 years which means a pit wouldn't be suspect until 80 years of use. Also, we know that the soil seals up from the weight and pressure so any possible cracks in a cement or clay lined pit would seal up and not have water leaching into the ground.

Composting Manure – Research has shown the process of composting manure and other materials does not lead to contamination of the ground under the compost site or the ground where any potential rainwater flows to. Those who have been working with farms to develop compost sites encourage composting on ground rather than impervious surfaces because the compost process works better and faster and will result in less run-off. Manure needs moisture added periodically for the composting process to work. I can provide contact information for a man who is conducting on farm research into large scale composting with great success. I have seen firsthand how quickly a metal building built on top of a compost pile becomes completely corroded within a few years. Check with the city of Middelton, WI about their compost project. The building is like Swiss cheese.

Action plan for Composting manure

- Do not require impervious surfaces – this is unfeasible and works against the process
- Do not require covering – this is an unnecessary waste of resources and will quickly become ruined if it isn't outgrown first.
- Put manure composting under the jurisdiction of the Department of Agriculture for the entire process, not just the finished product
- Encourage more research and farm experimentation in this area – this could be a game changer for manure handling and hauling for farms of all sizes.

The Current Animal Unit Thresholds Are Outdated

Farming practices have improved greatly over the past 2 decades, but what hasn't changed in decades is how MPCA defines farm size under its permitting structure. And that's a problem.

MPCA regulates feedlots by animal unit (AU) size categories. But the thresholds have not been updated to reflect modern economic realities. Farming today requires larger herds just to cover rising input costs, sustain family incomes, and allow younger generations to return home to farm. Holding the same size thresholds year after year, while inflation and expenses climb, effectively penalizes farms for growing just enough to survive.

For example, the threshold for moving into a higher level of regulation (such as feedlots over 300 AUs) has remained stagnant, despite the fact that input costs, land prices, and equipment have all skyrocketed. It is time to **raise the base AU threshold for small farms to at least 500 AUs**, with an automatic annual adjustment based on inflation or USDA cost indexes.

Why This Matters:

- **Farms are growing out of necessity, not greed.** We aren't building mega-operations; we're trying to support family or bring the next generation into the business.
- **Current thresholds don't reflect stewardship.** A well-managed 500 AU farm using modern conservation practices can have less environmental impact than a poorly run 200 AU facility.
- **Staying "small" is becoming economically impossible.** When margins shrink but compliance burdens rise, more farms will close, especially family operations trying to pass the farm on.

- **Example for a small dairy (but similar for all species):** at 1.4 AU per mature Holstein cow. A farm is limited to just over 210 cows if they do not raise any young stock. This is below the level of milking cows that economists agree can sustain one family. This leaves the farm with few options:
    - have a 2nd farm for youngstock and replacements,
    - reduce the milking herd to under 140 milking cows and raise the replacements on site (unsustainable)
    - have a 2nd full time job to sustain the family since the farm can't make enough to cover basic family living costs
    - hope your neighbors and county will allow you to get a permit for higher AU
    - Give up milking cows and tell your farming kids to move on from their dreams.
- **Modern feeding strategies are making animals much more efficient**. In dairy, the huge increase in production per cow over the last 25 years has resulted in much less manure produced to produce the same amount of milk. This should be reflected in the regulations by decreasing the AU designated to a mature cow. The research in dairy cow efficiency is in its infancy and will only improve exponentially with new feeds being produced for this reason. Meat livestock are showing similar improvements in efficiency of getting animals to harvest sooner and with more meat in a shorter time. All of this leads to less waste produced for each food unit produced.

We Urge MPCA To:

1. **Increase the lower AU threshold from 300 to at least 500 AUs.**
2. **Establish a mechanism for annual review and adjustment based on inflation and farm income trends.**
3. **Reassess how environmental impact is measured—based on practice and management, not just headcount.**
4. **Permits for a CAFO should be good for the life of that farm. It is not feasible to invest in building a farm with the thought that the permit may not be renewed when the time comes.**

Nitrate Level

The research on what level of nitrates is dangerous for humans is far from established or clear with science. While nitrate reduction is a valid goal, pushing nitrate levels too low, without considering nutrient balance, can cause more harm than good.

- **Algae Blooms** - Low-nitrogen conditions often lead to increased toxic algae blooms due to a rise in phosphorus dominance. These cyanobacteria outbreaks pose serious risks to human and animal health and can make water unusable for recreation, drinking, or irrigation.
- **Microbial Activity** - overly strict nitrate limits can backfire in soil systems, reducing microbial activity, weakening crops, and accelerating erosion. Instead of setting arbitrary targets, MPCA should prioritize balanced nutrient management, not single-nutrient suppression.
- **Methylmercury Formation** - Another serious concern is the link between nitrate reduction and methylmercury formation. When nitrate levels in soils and sediments are driven too low, it encourages anaerobic microbial activity that converts inorganic mercury into **methylmercury, far more toxic compound.** Methylmercury builds up in fish and enters the human food chain, posing significant health risks including neurological damage, especially in unborn children. Ironically, well-intentioned nitrate reductions can unintentionally increase this far more dangerous pollutant.

Other

1. **There should be an active farmer from each major species represented on each of the committees formed to address the feedlot rule changes**
2. **Trying to regulate manure application by weather and temperature is not feasible on any level**
3. **Do not change the designation of animals units for variations in weight for any particular animal (large vs small turkey)**
4. **All of the issues outlined in the MPCA meeting can be attributed to both farms and cities/towns. From drain tiling (think house foundations) to animal and human waste. Just because it's easier to regulate farms doesn't mean it's the right thing to do.**

This is not about deregulation, it's about realistic, modern regulation that allows farms to evolve responsibly. Minnesota's farmers are not asking for a free pass, we're asking for rules that match the realities we live with every day. And we ask that every municipality is held to the same standards and measures.

Minnesota farmers are not standing still. We've already evolved. These proposed rules should reflect that, not take us backward with blanket regulations that disregard our progress and make it impossible to continue on with livestock.

Thank you for considering my comments and for allowing public input on these decisions.

Sincerely,
Jill Nelson

Re: Comments on Proposed Changes to Rule 7020 – Feedlot Program

Greetings,

My name is Pat Troendle. I own and operate two agricultural businesses in southeast Minnesota.

Full Circle Nutrition LLC is a ruminant nutrition and biological fertilizer company. On the agronomy side, we work closely with producers throughout SE Minnesota and NE Iowa. Nearly every operation we support either generates manure or utilizes compost products to build biological activity in the soil. Regardless of operation size, manure is a resource—not a waste product.

Duschee Hills Dairy LLC is our 190-cow dairy farm located in Lanesboro, MN. We manage 560 acres across 92 different fields. Our crop rotation includes about 300 acres of corn and 260 acres of alfalfa, and we follow every corn silage crop with a five-species cover crop. We adhere to a manure management plan developed with our county feedlot officer and are very aware of our region's environmental sensitivity.

I attended the MPCA meeting held in Chatfield this June. Although no final decisions were presented, it was clear that certain regulatory changes are under serious consideration. I'd like to share a few thoughts, mainly from the perspective of a ruminant livestock operation.

---

1. Animal Unit Threshold Changes

The idea has been raised to add a fourth regulatory category and increase the requirements under 1,000 animal unit (AU). While I understand the intent is to apply stricter manure storage and application requirements to more operations, it's important to acknowledge that most livestock farms already strive to manage manure responsibly. Ideally, they would have 14 months of storage and apply manure during a narrow window of perfect conditions—but that's simply not the reality we live in.

If regulators move forward with creating this new category, it is critical to consider the large number of farms that would be newly impacted and the serious economic consequences that could follow. For many of these operations, especially small to mid-sized family farms—the cost of building additional storage, upgrading infrastructure, and complying with stricter application requirements would be overwhelming. In many cases, these improvements would be financially unfeasible and could ultimately force farms out of business.

Any new policy must carefully balance environmental objectives with the economic and operational realities on the ground. Without that balance, we risk accelerating the demise of independent farms and further consolidating the livestock sector, with long-term consequences for rural communities and food security.

---

2. Limitations on Fall Manure Applications (Soil Temp <50°F)

Restricting fall manure applications based on soil temperature (e.g., below 50°F) is impractical. On our farm, we apply manure after corn silage harvest to make room in our storage basins and to establish fall cover crops in a timely manner.

Fall manure application has key advantages:

- Timely nutrient placement
- Reduced spring workload
- Tillage and incorporation reduce runoff risk
- Freeze-thaw cycles help alleviate compaction

When managed properly, manure incorporated in the fall is a stable and effective nutrient source for the next growing season.

One important issue that wasn't addressed is that all manure types appear to be treated the same under the proposed changes. However, there are significant differences between liquid manure, bedded pack, and compost. These differences affect not only nutrient availability to plants but also the potential for nutrient loss through runoff or leaching. Bedded pack manure—and especially compost—pose a much lower environmental risk due to their physical form and how nutrients are stabilized within the material.

---

3. March Application Ban

The suggestion to ban manure applications in March may sound reasonable in theory, but it is unrealistic in practice. March weather in Minnesota is highly variable—conditions can indeed be snowy and wet, making application inappropriate. But just as often, the ground is still frozen, fields are dry enough to support equipment, and conditions are actually well-suited for responsible manure application. Prohibiting all March applications would force farmers to wait until April, compressing both manure application and spring planting into an already narrow and often unpredictable window. This not only creates significant logistical challenges but could also result in missed opportunities to apply manure under

ideal conditions, simply because the calendar says it's too early.

---

4. Infrastructure and Time Limitations

The above proposals to temperature and dates assume that farmers have access to unlimited time, labor, and infrastructure. The reality is:

- There is not enough infrastructure (storage, equipment, or labor) to meet such tight timelines.
- Building sufficient storage and logistics capacity would require billions in investment.
- Even with investment, time and variable Minnesota weather remain the biggest limiting factors.

Ruminant operations like Duschee Hills Dairy serve as environmental stewards by using crop rotations which include alfalfa to minimize soil loss and efficiently utilize applied nutrients. Practices such as vegetative buffers, grassed waterways, and low-disturbance manure injection are already used by many producers to mitigate runoff risk

We are not alone, many similar farms across Minnesota do the same. If these operations are regulated out of viability and replaced by continuous row crops or residential developments, the result could be declining soil health and even increased nitrate levels—the very issues these rule changes are trying to prevent.

If Minnesota is serious about improving manure management, then it must be equally committed to funding infrastructure upgrades—such as expanded storage, low-disturbance application equipment, and local composting capacity—so that farmers have the tools needed to comply

---

5. Nitrate Levels and Blame

While misapplication of manure can contribute to water quality concerns, the nitrate test maps presented at the meeting appear to correlate more closely with population density than with confirmed agricultural sources. Without reliable source tracking, we must be cautious about placing the full burden of blame on agriculture. Are we asking farmers to solve a problem that we can't definitively trace to their practices—and that we currently don't have the tools to accurately measure?

Furthermore, there has been little detail provided about how the necessary infrastructure improvements will be built or funded. If stricter regulations are going to be proposed, there must be a realistic plan for implementation. Rather than focusing solely on manure application restrictions, we should also consider investing in broader water protection strategies—such as replacing old, shallow wells, which may serve as significant nitrate entry points. A more balanced, evidence-based approach would provide better long-term outcomes for both water quality and the farming community.

Conclusion

Thank you for the opportunity to comment on these important issues. I support responsible management and environmental stewardship. However, the proposed changes risk placing unrealistic burdens on producers without the necessary tools or support to comply effectively. I urge MPCA to continue working closely with farmers to find practical, science-based solutions that balance environmental protection with agricultural viability.

As someone actively managing a ruminant operation in a sensitive area, I would welcome the opportunity to serve on any future stakeholder or advisory group working on practical rule development.

Sincerely,
Pat Troendle

RE: Christensen Farms comments for the Chapter 7020 Planned Amendments to Rules Governing Animal Feedlots (Chapter 7020)

Thank you for the opportunity to comment on the amendments to the Minnesota Pollution Control Agency (MPCA) Chapter 7020. We appreciate the outreach and conversation held throughout this process to provide input from those who are impacted by changes to Chapter 7020.

Christensen Farms (CF) firmly believes that the existing Chapter 7020 rules are effective and reasonable in protecting the State's water quality. The strength of Chapter 7020 lies in the rigorous process behind its development. Around the new millennium, extensive data driven research, engagement, and thorough review were completed to ensure regulations balanced environmental protection with practical implementation. Since original implementation, regulations on feedlots have only become more stringent. Permit requirements have expanded, environmental review processes have grown more comprehensive, and county-level zoning rules have become more robust. For one to claim that feedlot regulations have remained unchanged since Chapter 7020 was implemented isn't just inaccurate, but a willful disregard of fact and reality.

While Chapter 7020 has been highly effective in protecting Minnesota's water resources, some now argue that facility size alone determines the environmental risk posed by a feedlot. This notion is fundamentally flawed and lacks any basis in sound science. The size of a feedlot is not a reliable indicator of environmental impact. In fact, the largest facilities in the state are subject to the most rigorous environmental assessments and must continually prove their compliance and low-risk status. In contrast, many smaller operations undergo far less scrutiny, even less than moderately sized sites. These smaller feedlots often have limited capacity to store manure before land application. The MPCA's stated goal to "prevent manure from entering surface and groundwater" is incomplete at best if it ignores these smaller facilities. Bluntly put, every gallon of manure, regardless of the size of farm it comes from, carries the same risk to Minnesota's water if mismanaged. Anything less than equal scrutiny across

operations of all sizes is policy by convenience, not protection.

The MPCA has stated that “the concentration of feedlots has resulted in concentration of manure generation volumes.” This statement is not only inaccurate, but it also reflects a concerning lack of understanding of the facts. Further, it reveals a potential bias within parts of the agency that must be addressed to ensure a fair and impartial review of the rules. When Chapter 7020 was originally developed, the landscape was characterized by a larger number of smaller, more widely distributed feedlots. These operations, despite their smaller size, could collectively generate comparable concentrations of manure nutrients and volumes, especially when land availability for application was limited given their smaller operations. In the swine industry today, feeding strategies have advanced significantly, reducing both the volume of manure and the nutrient content per animal. In many cases, today’s feedlots, even those that house more animals, produce fewer gallons and lower nutrient loads per head than in the past. CF maintains that the existing rules in Chapter 7020 were crafted to reflect practical realities, and the evolution of the industry only reinforces their continued reasonableness.

It is important to recognize that when Chapter 7020 was originally developed, it was thoughtfully designed to allow for the reasonable operation of livestock facilities while ensuring strong environmental protection. Some have recently argued that an increase in the number of feedlots over 500 animal units warrants significant changes to the rule. However, the presence of more permitted sites at or above that threshold does not inherently equate to increased environmental risk, and such claims lack supporting evidence. The State should not penalize or cast doubt on operations simply because they are permitted at certain animal unit levels. Feedlot owners carefully evaluate and understand the regulatory framework before making substantial investments, and they are committed to complying with those requirements. Maintaining respect for this permitting process is essential to ensuring fairness and continued environmental stewardship.

When it comes to manure transfer, one thing is clear: the agency has provided no evidence that transferring manure ownership increases environmental risk. Chapter 7020 has long permitted this practice, and it has proven to be an effective way to maximize the value of manure as a fertilizer while maintaining environmental compliance. By allowing manure to be transferred, feedlot owners can share its agronomic benefits beyond the land they personally own. In fact, increased manure transfers demonstrate that farmers are using manure more strategically, as an organic crop nutrient, thereby reducing the overall environmental footprint of agriculture. The current provisions in Chapter 7020 set reasonable, science-based requirements that ensure manure nutrients are applied for beneficial use.

It is a simple fact that the volume of liquid manure does not diminish the

effectiveness or reasonableness of Chapter 7020. In reality, liquid manure can often be stored, handled, and applied more efficiently. This represents continued improvements in feedlot operations and reinforcing the strength of the current rule. Chapter 7020 has enabled the adoption of advanced land application practices that have benefited both feedlot operators and the State's environment. Revising these rules without grounding changes in sound science would be unjustified. Practices such as the use of commercial applicators, manure pipelines and hoses, and transporting manure further from the source are all advancements that should be encouraged, not hindered, as they are under the current framework. Chapter 7020 supports innovation while maintaining environmental protection, and that balance must be preserved.

Some have suggested that a feedlot ownership structure should be a reason to amend Chapter 7020. CF firmly disagrees. Responsibility for each site is clearly assigned to accountable parties, and the form of entity incorporation has no bearing on environmental risk. This issue appears to be yet another example of bias that offers no real protection for Minnesota's waters and only serves to complicate effective regulation.

Extreme weather events have been considered in Chapter 7020 and the underlying Clean Water Act. The Clean Water Act clearly sets a level of reasonableness for the rules. There are specific standards of extreme weather that are acknowledged as outside the level of reasonableness.

Changes to sections 7020.0405, 7020.2003, 7020.2005, and 7020.2100 are unwarranted. The current rules are both reasonable and effective, and they have consistently supported strong environmental protection across the state. Importantly, no science-based, data-driven evidence has been presented to justify these proposed revisions. Without clear evidence demonstrating that the existing rules are failing, or that changes would improve environmental outcomes, it is neither necessary nor prudent to amend them. Regulatory changes must be grounded in measurable need and scientific justification, not assumption or perception.

For consideration by the agency, CF proposes amendments to Chapter 7020.0505.4D and 7020.2000.4, concerning public notice requirements, these sections add no value to the permitting process. Requiring yet another notice provides no measurable benefit to the public and merely creates a redundant layer of bureaucracy. The MPCA already maintains a well-established public notice system for all permits, and many counties also impose their own feedlot notification requirements. Repeating public notices for the same permit only increases the potential for confusion rather than improving transparency. Additionally, mandating communication methods, such as newspaper notices or mailed letters, directly contradicts the agency's direction of modernizing and streamlining permitting through electronic systems.

To support consistent and effective protection of Minnesota's water resources, CF proposes changes to the rules in Chapter 7020.2225.2 and 7020.2225.2A. In the interest of protecting all of Minnesota's waters and natural resources, one might suggest the agency give serious consideration to requiring manure nutrient testing from every registered feedlot in the state, regardless of size. Environmental stewardship is a shared responsibility among all livestock producers. Nutrients that are over-applied or improperly managed can impact water quality regardless of the number of animals on a site. Without consistent testing requirements across all feedlots, one might question how the Agency is able to ensure compliance or to confidently verify that manure is being applied at agronomic rates. To uphold its stated goal of protecting surface and groundwater, the agency should clearly explain and detail why the exemption for operations under 300 animal units remains appropriate and how it aligns with a comprehensive and science-based approach to environmental protection for all Minnesotans.

CF proposes an amendment to Chapter 7020.2225.6.B.2.a. to provide greater clarity around the definition of "intermittent streams." Specifically, it would be beneficial to limit this restriction to intermittent streams that exhibit a defined channel or channelized flow at the time of land application. Currently, some intermittent streams identified on maps may no longer exist or have been significantly altered since the maps were created. By clarifying that the restriction applies only to features with a visible channel or active flow, the rule can continue to provide reasonable environmental protection while allowing for the agronomic use of manure as a beneficial crop nutrient.

CF firmly opposes any requirement for additional operating permits, such as NPDES or SDS, for feedlots with fewer than 1,000 animal units. There are already mechanisms in place to permit and manage sites with pollution concerns, and no data has been presented to justify that expanding permitting requirements to smaller feedlots would result in measurable environmental benefits.

Similarly, requiring these feedlots to submit Manure Management Plans (MMPs) and land application records is not reasonable. Existing inspection and compliance procedures already provide the agency with authority and ability to review these materials on-site. Mandating submittals only adds to the regulatory burden without offering clear improvements to environmental protection beyond what current law already ensures.

Furthermore, the MPCA has not explained how it would meaningfully review or act upon the additional data submitted under these proposed rules. This raises significant concerns particularly since MMPs and land application records often contain proprietary business information. These privacy concerns have been raised with the agency as early as 2006 and have been repeated during multiple public comment periods. To date, the MPCA has offered no clear assurance to

feedlot operators or crop farmers that sensitive data will be protected.

Lastly, by requiring submittals exclusively through MPCA-provided forms, the agency imposes an unreasonable and unnecessary burden especially on producers without access to broadband internet or those lacking the technical skills to complete digital submissions. Flexibility in reporting format is not only practical but essential for ensuring fairness across Minnesota's diverse agricultural community.

Given the continued strength and effectiveness of Chapter 7020, changes related to groundwater monitoring at feedlots are not well-founded. No evidence has been presented to suggest that the current prohibitions on discharges to groundwater are inadequate or failing. Similarly, additional restrictions on manure application rates, particularly those that impose arbitrary or artificially limited thresholds, do not serve a reasonable purpose.

Animal manure is a valuable organic nutrient source that supports healthy soils and productive crop systems. It is both reasonable and responsible to allow manure application rates to be guided by crop nutrient needs and actual yield results, grounded in sound agronomic science rather than modeled economic assumptions. Importantly, Chapter 7020.2225.A.2 already allows for individualized nutrient management, acknowledging that the University of Minnesota recommendations are based on averages and may not reflect the advanced practices employed by many Minnesota farmers.

Notably, the MPCA's claim in its Nutrient Management Tool that such deviations are "limited" does not align with the intent of Chapter 7020, which recognizes the importance of flexibility, site-specific management, and the use of real-world data in supporting both environmental stewardship and agricultural productivity.

As it pertains to additional requirements for soil nitrate testing, subject matter experts have cautioned that changes do not align with sound science. Current language in Chapter 7020 already allows for the use of soil nitrate testing in accordance with science, that balances environmental benefit with practical implementation. It is important to recognize that nitrate presence in soil and water systems results from a highly complex cycle influenced by multiple sources, both anthropogenic and naturally occurring.

Available data indicate that nitrate levels have remained stable or are declining in many areas, pointing to the effectiveness of the existing Chapter 7020 framework. As the MPCA oversees numerous programs related to nutrient management, a comprehensive and transparent understanding of the broader nitrate item, including its sources and contributing factors, should be clearly communicated before introducing new regulatory burdens under Chapter 7020. Without this context, further requirements risk mischaracterizing the issue and undermine the progress that has already been achieved.

The Minnesota Department of Agriculture, members of the Minnesota State Legislature, and farm commodity groups have all placed a growing emphasis on practices that enhance soil health. CF shares the concerns of livestock producers who believe that increasing manure application setbacks in so-called "sensitive areas" would be both unreasonable and counterproductive to this shared objective. The current rules already support the responsible use of manure as a crop nutrient promoting healthy soils while protecting water resources. Proposals to restrict land application based on undefined "high densities" of feedlot operations undermine the benefits manure provides to soil health and represent a departure from science-based regulation. The agency must clearly define what constitutes "high density," and more importantly, provide evidence that restricting land application in such areas yields measurable environmental improvements.

Arbitrary or vaguely defined restrictions, especially those not grounded in sound agronomic science or reflective of actual farmer practices, impose unnecessary burdens on producers. The term "high density" offers no clear environmental rationale and instead appears to penalize regions where livestock and manure are responsibly integrated into crop production. Its use in the request for comments reflects a troubling pattern of bias that risks undermining trust in the rulemaking process and the agency's commitment to practical, science-based solutions.

CF has previously expressed serious concerns regarding the imposition of additional NPDES and SDS requirements on smaller livestock operations. We maintain that the existing framework under Chapter 7020 has proven effective in protecting Minnesota's water resources while remaining practical and workable for producers. At a high level, changes do not enhance environmental protection and instead place unnecessary regulatory and administrative burdens on Minnesota's livestock industry:

- Amendments requiring "enhanced" manure management planning and recordkeeping for transferred manure are excessive. Current rules already provide adequate safeguards to protect water quality.
- Mandating the submission of additional sensitive business information, without any demonstrated environmental benefit, is unreasonable and unjustified.
- Requiring more frequent visual inspections of land application fields is unnecessary, as existing rules already prohibit exceeding the soil's hydraulic loading capacity, ensuring proper manure application and environmental protection.

CF respectfully but firmly emphasizes that additional restrictions on the land application of manure are neither reasonable nor grounded in sound science. Agricultural production is highly variable, shaped by the unique characteristics of each field and the

unpredictability of localized weather conditions, factors that often do not align with rigid calendar dates. Imposing blanket application windows fails to account for this variability and does not necessarily lead to improved environmental outcomes.

Manure is a locally sourced, low-carbon fertilizer that not only supports crop production but also contributes to long-term soil health. Restricting its use in favor of commercial fertilizers would increase greenhouse gas emissions and undermine Minnesota's stated goals for improving soil health. MPCA has provided minimal data demonstrating that the proposed application timing restrictions would meaningfully reduce nitrogen loss. In fact, research previously cited by the agency has shown that timing alone is not a primary driver of nutrient loss.

Moreover, shifting manure application primarily to spring introduces significant logistical challenges, particularly for rural infrastructure. Spring road weight restrictions—enforced by both the State and local governments—limit transport capacity and would result in more trips, more fuel use, and increased wear on rural roads. While dragline hoses are a useful tool, they are not universally applicable. Factors such as the location of wind turbines, field distances, and required application rates can make their use impractical or impossible.

If the agency is committed to science-based regulation and practical implementation, it must account for these realities and reconsider restrictions that lack both evidence and feasibility.

CF urges caution regarding changes related to animal manure storage areas that have been in use for an undefined "long period of time." The current rules already establish reasonable and science-based requirements for the monitoring, operation, and maintenance of these storage structures. The term "long time" is inherently subjective and open to interpretation, which introduces unnecessary ambiguity into regulation.

It is not uncommon for well-constructed and properly maintained manure storage facilities to remain in service for many years without presenting environmental risks. In fact, there are documented cases where older storage areas have been voluntarily removed from service or upgraded for various operational reasons, demonstrating that the current standards are effective in protecting water quality. Additional requirements based solely on age, rather than on performance or condition, risk undermining confidence in existing rules that have consistently delivered sound environmental outcomes.

CF maintains that the current Chapter 7020 rules align with the requirements and intent of Minnesota Statutes 14.002. In contrast, several elements of the request for comment, as well as the use of seemingly biased terminology, appear to deviate from those statutory principles. Specifically, the MPCA has not provided evidence that would justify the need for significant regulatory changes. Claims suggesting increased environmental harm, such as a rise in fish kills tied to feedlot operations,

are not supported by available data. A review of the Environmental Quality Board (EQB) Monitor reveals no trend indicating an increase in fish kills attributable to feedlots.

Furthermore, the agency has not demonstrated that existing nitrate concerns are the result of current feedlot practices governed by Chapter 7020, rather than legacy issues stemming from practices that occurred prior to the rule's implementation. Without clear, data-driven evidence linking current feedlot operations to these environmental concerns, the rationale for revising Chapter 7020 remains unsubstantiated and contrary to the standards outlined in Minnesota Statutes 14.002.

Agriculture functions as an interconnected ecosystem, where the relationship between crop and livestock production creates important synergies, especially through the use of livestock manure as a local, organic fertilizer that promotes soil health and reduces greenhouse gas (GHG) emissions. This integration is critical to meeting Minnesota's long-term goals for both environmental protection and agricultural sustainability.

Changes to Chapter 7020 risk placing unreasonable burdens on feedlot operators without demonstrating a meaningful or measurable cumulative environmental benefit. For more than 25 years, Minnesota's livestock producers and permittees have operated under the current Chapter 7020 framework and have consistently demonstrated a strong commitment to environmental stewardship.

To date, the MPCA has not provided clear, data-driven evidence showing that the existing regulations under Chapter 7020 are contributing to environmental harm. Rather, the revisions appear to be a response to isolated concerns that fall outside the scope of what Chapter 7020 is designed to address. CF remains concerned that moving forward with these changes will add complexity and cost to livestock operations without delivering improved environmental outcomes.

Thank you for your consideration of our comments and concerns regarding Chapter 7020. If you need further clarification or have questions, please feel free to contact me.

Thank you

Minnesota Pollution Control Agency
520 Lafayette Road North
St. Paul, MN 55155
Submitted via: Office of Administrative Hearings Comments On

Re: Comments on Minnesota Feedlot Rule (7020) Review OAH Docket No. 25-9003-40661

Dear MPCA Staff,

The Minnesota Turkey Growers Association (MTGA) appreciates the opportunity to provide comments on the Minnesota Pollution Control Agency's (MPCA) review of the state feedlot rule (7020). As the representative voice of Minnesota's turkey farmers, and the nation's largest turkey-producing state, we represent 703 turkey farmers and supporting industry members. MTGA members support science-based, practical rules that safeguard water quality while supporting voluntary innovation for turkey farms of all scopes and sizes. The current 7020 rules work for Minnesota's turkey farmers.

Voluntary commitment to environmental stewardship:
Minnesota's turkey farmers are committed to protecting our state's land, water, and air. Many turkey operations already exceed regulatory requirements through voluntary adoption of nutrient management plans, annual soil testing, precision manure application, and use of grass buffer strips. We believe the 7020 rules should continue to enable and encourage voluntary stewardship and allow for innovation.

Turkey farms are distinct and must be considered separately:
Turkey farms operate with litter-based manure systems—solid, dry material mixed with bedding. Litter is stored indoors throughout the flock cycle and removed only during barn clean-out, typically twice per year. Therefore, regulatory frameworks should reflect these fundamental differences and avoid applying lagoon-based standards to litter systems.

Modifications to turkey animal unit calculations:
We urge the MPCA not to add complexity to the rule by modifying turkey animal unit calculations. In commercial turkey operations, male and female turkeys are raised in separate flocks, and manure management practices do not differ between the two. The existing permit framework already accounts for animal unit calculations based on standard weights, and modifications or additional distinctions would introduce unnecessary complexity without improving environmental outcomes.

Support for flexibility and innovation:
Any revision to the 7020 rules should promote flexibility in best management practices (BMPs), recognizing Minnesota's diversity in farm size, topography, and climate. One-size-fits-all approaches are not effective. Instead, the rules should allow producers to tailor BMPs to their specific conditions, incorporating modern conservation tools and precision technology. Farmers must be empowered to voluntarily adopt innovative solutions that enhance both environmental outcomes and farm viability.

MINNESOTA TURKEY GROWERS ASSOCIATION

108 Marty Drive, Suite 1, Buffalo, MN 55313-9338
Phone: 763-682-2171 **Fax:** 763-682-5546 **Email:** Info@MinnesotaTurkey.com

Biosecurity and emergency response considerations:
Turkey farms often face significant challenges from diseases like Highly Pathogenic Avian Influenza (HPAI). Movement of manure and clean-out schedules are sometimes restricted by quarantine and emergency protocols. Revised rules must allow flexibility for in-barn storage or delayed manure handling during disease outbreaks, in coordination with USDA and Board of Animal Health protocols.

Manure as a valuable resource, not waste:
Manure should be recognized as a vital contributor to soil health, not a waste product. When managed according to nutrient value, it supports soil structure, fertility, and water retention, reducing reliance on synthetic fertilizers and enhancing long-term productivity. Rules should reflect this perspective and avoid imposing unnecessary hurdles that disincentivize responsible manure use, like onerous manure transfer requirements.

Economic viability and practical implementation:
The cost of compliance must be considered. Small and mid-sized farms often face disproportionate financial burdens when rules are updated without regard to economic feasibility. Nearly 90% of Minnesota's turkey farmers are independently owned small farms. Any changes to the 7020 rules should align with achievable timelines, measurable outcomes, and clear guidance to avoid confusion and inconsistent enforcement.

The current 7020 rule works for Minnesota's turkey farmers. MTGA urges MPCA to maintain current environmental protections while fostering flexibility, voluntary innovation, and the long-term viability of Minnesota's diverse livestock farms—including our state's vital turkey industry.

Respectfully submitted,

Ashley Kohls
Executive Director
Minnesota Turkey Growers Association

Marlin Fay Attachment

We are NOT opposed to rules and regulations for feedlots in Minnesota. What we ARE opposed to, are rules that are high risk and low reward, meaning the results are projected but not achieved, and they can threaten the existence of animal agriculture in Minnesota. The fact that livestock operations have gotten bigger is not a scenario where “factory farms” have gobbled up small family farms. It is the same economic driver that has caused the loss of the small-town grocery stores, hardware stores, banks and more. It is the economy of scale and size that bring the efficiencies that make them competitive. As costs go higher, farmers need more units to spread the cost over. It doesn’t matter if it is animals, grain, fruit or vegetables. I’m a small farmer and I feel the pinch.

We need common sense rules that have achievable results. We need to keep focusing on the gains that we have achieved, to reach our goal. I live on the farm I run. I’m proud of what I do. It disheartens me when so many people disconnected with agriculture bash an industry that helps provide the safest, most abundant, and lowest cost food supply in the world. Most of the regulations people are proposing here will just aid the demise of the small farmers we have.

Minnesota Farm Bureau

July 22, 2025

Office of Administrative Hearings
c/o Administrative Law Judge Megan J. McKenzie
600 N. Robert St
St. Paul, MN 55164

RE: Planned Amendments to Rules Governing Animal Feedlots, Minnesota Rules, chapter 7020, Revisor's ID Number R-04928.

Dear Judge Megan J. McKenzie,

On behalf of the 31,000 members of the Minnesota Farm Bureau Federation (MFBF), I appreciate the opportunity to provide comments in response to the Minnesota Pollution Control Agency's Request for Comments on proposed amendments to Minnesota Rules Chapter 7020, which governs animal feedlots and manure management. MFBF is the largest grassroots, general farm organization committed to advancing the future of agriculture and rural communities in the state.

Minnesota's farmers and ranchers are leaders in environmental stewardship and have long embraced science-based practices to manage manure and protect water quality. Our state's regulatory framework has historically balanced environmental protection with agricultural productivity, and MFBF members are committed to continuing that legacy. As this rulemaking process advances, we encourage the Minnesota Pollution Control Agency (MPCA) to ensure that any revisions support practical, flexible, and outcome-driven approaches that reflect both environmental goals and the realities of livestock farming in Minnesota.

Question 1: Are there parts of the current rule (Minn. R. Ch. 7020) that are no longer applicable or needed?

Some parts of the current rule are outdated and could be updated to better reflect current practices.

Some transitional language and outdated references, such as those related to permit types used before 2000, still appear in the rule. These legacy references, like mentions of SW-A permits, no longer serve a practical purpose. Removing this outdated section would help simplify the rule and ensure it reflects the current permitting system.

The rule's requirement for feedlot owners to update registrations every four years may unintentionally create confusion, particularly when registration deadlines do not match up with other regulatory timelines or reporting requirements. As the MPCA and counties shift to more flexible, digital systems, the fixed four-year schedule could be re-evaluated to reduce confusion and streamline administrative tasks for producers, especially those who already maintain current records through other regulatory processes.

<u>Question 2:</u> What specific changes to the current rules, including permit requirements (part 7020.0405), water quality discharge standards (part 7020.2003), location restrictions and expansion limitations (part 7020.2005), liquid manure storage area standards (part 7020.2100), or land application of manure (part 7020.2225) would provide improved regulations that prevent nitrate contamination to ground and surface waters and fish kills? Should any of the following bullets be considered? If so, at what size (in AU)?

At this time, MFBF recommends not adding additional rule amendments, including the bulleted suggestions. The changes outlined here would disrupt the balance that the current rule strikes between environmental protection, regulatory flexibility, and economic impact. Justification as to why each bullet should not be considered is below.

- **Operating permits (NPDES or SDS) for feedlots less than 1000 AUs.**
  The existing NPDES/SDS permit has a threshold of 1,000 animal units (AUs) which aligns with the federal large CAFO permitting standards that were designed to ensure that regulatory resources are focused on operations with the greatest potential environmental impact.

- **Submittal of manure management plans and land application records for feedlots without operating permits.**
  Part 7020.2225, subpart 4, item A grants the MPCA and county feedlot officers the ability to access any feedlot's manure management plan (MMP) by request. Subpart 5 requires all feedlots 300 AUs and over to keep detailed records of manure application for a six-year timeframe. The same requirement applies to feedlots 100 AUs and over located in drinking water supply management areas (DWSMAs) with vulnerable aquifers. Mandating submission of every MMP to MPCA would increase administrative costs for the agency, increase staff workload, and slow targeted enforcement. Feedlot registration already requires current AUs, acreage, and location.

- **Monitoring of feedlots and land application sites for subsurface discharges of manure or nitrate to groundwater.**
  In responding to comments on the draft NPDES/SDS permits, MPCA laid out the challenges of water-quality monitoring near feedlots and also asserted it would be

unreasonable to require groundwater monitoring of every field in Minnesota. The same response details the robustness of Minnesota construction standards for manure storage areas, which far exceed those of the Natural Resources Conservation Service (NRCS). There are even more protections for storage of liquid manure and storage in areas with Karst geology.[1]

- **Additional restrictions on manure application rates.**
  Part 7020.2225 already limits nutrient application according to realistic nitrogen use rates on crops.

- **Soil nitrate tests prior to land application of manure.**
  The current rule already prescribes soil nitrate testing when a MMP is required (permit applications ≥ 100 AUs; all feedlots ≥ 300 AUs). Under part 7020.2225, subpart 4, item D, subitem (12) the MMP must include "plans for soil nitrate testing in accordance with University of Minnesota Extension Service recommendations." Part 7020.2225, subpart 1, item D states that manure transfer recipients must follow the MMP of the feedlot that generated the manure and complete the missing pieces of the MMP for application on their own land.

- **Increased setback distance for land application of manure near sensitive features.**
  Part 7020.2225 already provides reasonable restrictions on manure application near sensitive features. Subpart 4, item D, subitem (9) stipulates that a MMP must include protective measures for application of manure in special protection areas and floodplains.

  Subpart 7, item B requires all manure applied within 300 feet of open tile intakes to be injected or incorporated within 24 hours of application, or other agency-approved practices that demonstrate equal water quality protection. Similarly, subpart 8 prohibits manure application within 50 feet of wells, sinkholes, mines, and quarries. Manure applied within 300 feet of a sinkhole without diversions must be injected or incorporated within 24 hours of application. University of Minnesota Extension data shows that getting manure below the surface sharply cuts nutrient and pathogen runoff risk compared with leaving it on top.[2]

  The buffer law requires up to 50-foot perennial vegetation along public waters, providing an additional filtering strip. Buffer strips can remove approximately 50 percent or more of nutrients, about 60 percent of some pathogens, and about 75 percent of sediment.[3]

---

[1] https://www.pca.state.mn.us/sites/default/files/wq-f3-64.pdf See Common Issue #4 - Increased Water Quality Monitoring.
[2] https://extension.umn.edu/manure-management/manure-application-methods-and-nitrogen-losses
[3] https://files.dnr.state.mn.us/publications/waters/buffer_strips.pdf

- **Restricting land application of manure in areas with high levels of nitrate in waters or in areas with existing high densities of feedlot operations.**
  In vulnerable areas, Chapter 7020 already compels additional water protection measures for feedlots required to have a MMP. Under part 7020.2225, subpart 4, item D, subitem (9) MMPs must spell out protective measures for land application in DWSMAs with vulnerable aquifers and to soils within three feet of limestone bedrock.

  In addition, the Minnesota Department of Agriculture's Groundwater Protection Rule separately restricts fall and frozen soil nitrogen fertilizer applications in vulnerable groundwater areas and in DWSMAs with elevated nitrate, ensuring that those areas receive targeted nitrogen controls across all sources, not just manure. Geology, like the Karst Region in southeast Minnesota, strongly influences where nitrate reaches water, meaning a manure restriction or prohibition in "high nitrate" zones would likely prompt substitution with commercial nitrogen.

  Limiting manure application would not necessarily reduce nitrogen in the watershed, it would likely shift the nutrient source rather than reduce it, increasing costs for farmers without improving water quality. Restricting manure application based on feedlot density would result in more manure hauling or transfers and substituting manure with commercial fertilizer.

<u>Question 3:</u> The State Disposal System (SDS) and National Pollutant Discharge Elimination System (NPDES) feedlot general permits apply to feedlots that currently have capacity, or are proposing to have capacity, for a total of 1,000 or more AUs (part 7020.0405). These permits include additional requirements as outlined in the following bullets. Should any of these requirements or other requirements in the permits be incorporated into the rule to apply to facilities with less than 1000 AU capacity?

- **Enhanced manure management planning and record keeping requirements for transferred manure.**
- **Visual inspections of manure land application fields for signs of discharges.**
- **Additional best management practices for land application of manure during the months of September through November.**
- **Restricting land application of manure on frozen or snow-covered fields.**
- **Best management practices for land application of manure when there is a high probability of rain predicted.**

Generally speaking, the additional requirements found in NPDES and SDS permits should not be incorporated into the base feedlot rule under Chapter 7020. These permit conditions are designed to address the higher level of risk associated with the largest livestock operations, typically those with 1,000 animal units or more. As such, they include more detailed management,

recordkeeping, and application restrictions that go beyond what is necessary for smaller and mid-sized operations.

Chapter 7020 is intended to serve as a baseline standard for feedlot management across the state. It provides consistent, science-based protections without imposing the full set of requirements needed for large-permit holders. Incorporating permit-level requirements into the general rule would undermine the flexibility that smaller operations need and eliminate the important regulatory distinction between basic compliance and enhanced permit conditions.

Maintaining this distinction ensures that the rule remains practical and proportionate for the wide variety of livestock operations in Minnesota.

To the specific bullet points outlined in the question, MFBF would caution against any mandated best management practices that are tied strictly to calendar dates or seasons since weather and temperature patterns can vary considerably year to year. There is also concern with imposing more limits on manure applications during the winter months when sufficient rules already exist.

Question 4: How should the MPCA address existing animal manure storage areas that have been used for a long period of time to determine structural integrity (part 7020.2100)?

Any potential issues should be handled on a case-by-case basis when inspected by MPCA or a county feedlot officer. As mentioned previously in response to Question 2, Minnesota regulates manure storage construction to a more detailed and conservative engineering standard than national baselines. Minnesota imposes numeric seepage performance limits plus minimum 5-inch reinforced concrete floors and detailed liner-penetration controls, all backed by mandatory engineer-stamped design plans, construction notifications, in-process inspections, and engineer certification reports to MPCA or the county feedlot officer. By contrast, the federal standard does not prescribe liner thicknesses or seepage rates. NRCS Code 313 provides design guidance but defers to state rules for karst restrictions, storage period, and seepage criteria.

Question 5: Currently, feedlots with 1000 AUs or more are required to have 9 months manure storage capacity (part 7020.2100). Should smaller sites be required to have a similar requirement? If so, at what size (in AU)?

While manure storage capacity is an important part of protecting water quality, MFBF does not support a blanket extension of the nine-month storage requirement to smaller feedlots. The current requirement in part 7020.2100 for feedlots with 1,000 AUs or more recognizes the scale and potential impact of larger operations, many of which already manage liquid manure systems where long-term storage is necessary.

For feedlot operations under 1,000 AUs, a one-size-fits-all storage mandate would impose significant costs and may not align with how those farms manage manure.[4] Many smaller feedlots operate with solid manure systems, seasonal cleanouts, or daily hauling, all of which can be low-risk if managed properly. Mandating nine-month storage for these operations could be unnecessary and economically unviable.

Finally, MFBF affirms its support for using the original animal unit determinations as defined in part 7020.0300 as the appropriate basis for any regulatory thresholds related to feedlot permitting or management standards.

Question 6: The MPCA has developed Watershed Restoration and Protection Strategy (WRAPS) documents for every one of Minnesota's 80 major watersheds. These WRAPS document high nutrient and bacteria levels in streams and rivers. The reports attribute this to livestock access to streams in many cases. How should the rules be amended to address this documented issue (part 7020.2015)?

Existing regulations prohibit uncontrolled, direct feedlot runoff to waters of the state and surface waters. As stated in part 7020.2015, animals from ≥1,000 AUs facilities are restricted from entering waters of the state. Even smaller feedlots are required to fence animals out of DNR-classified lakes. Much of what WRAPS flags as "livestock access" occurs in pasture or grazing settings, areas which are expressly exempt from the feedlot rule.

Of the 80 WRAPS documents that report high nutrient and bacteria levels, how many specifically attribute the cause to livestock access to streams? And which watersheds?

Question 7: How should the MPCA address feedlots under the same ownership in close proximity to each other? How far apart must each feedlot be located in order to be considered a separate facility for the purposes of permitting and/or registration (parts 7020.0405 and 7020.0350)?

The MPCA should follow the existing federal standard under the Clean Water Act for determining when feedlots under common ownership and located near each other should be considered a single operation. Under 40 CFR § 122.23(b)(2), the federal rule provides a clear and well-established framework: operations may be aggregated when they are under common ownership, located within one-half mile of each other, and share a common manure handling or land application system. This test is applied on a case-by-case basis and considers both physical proximity and operational integration.

[4] https://www.pca.state.mn.us/sites/default/files/wq-rule4-29d.pdf See slide 39 for average cost of manure infrastructure.

This federal framework is already integrated into Minnesota's NPDES and SDS permitting process and gives regulators the discretion needed to assess environmental risk appropriately. Creating a new aggregation rule within Chapter 7020 would be unnecessary, duplicative, and could create confusion for both producers and regulators. The existing federal standard is sufficient and should remain the guiding policy.

Question 8: State agencies are required to, whenever feasible, develop rules that are not overly prescriptive and inflexible, and rules that emphasize achievement of the MPCA's regulatory objectives while allowing maximum flexibility to regulated parties and to the MPCA in meeting those objectives (Minn. Stat. §14.002). How might the MPCA balance this need for flexibility for regulated parties while also addressing the issues of nitrate contamination and fish kills?

Chapter 7020 as it currently stands strikes a balance between achieving regulatory objectives and providing flexibility to farmers and ranchers. In addressing nitrate contamination, it is important to recognize that increased regulation alone may not deliver the outcomes sought by the agency. Fortunately, Minnesota already has a strong network of voluntary programs and cost-share initiatives that can support this approach while advancing measurable water quality improvements.

The Minnesota Agricultural Water Quality Certification Program (MAWQCP) shows how voluntary, outcome-based programs drive real reductions. MPCA analysis cited in the program's 2024 biennial report estimates certified farms have achieved up to approximately 45 percent reductions in modeled nitrogen loss.[5]

The Minnesota Department of Agriculture's (MDA) Soil Health Financial Assistance Program offers up to 50 percent cost-share for farmers, producer groups, and local units of government to purchase or retrofit soil-health equipment. In 2024, the Minnesota Legislature appropriated $2.375 million, plus an additional $495,000 for targeted southeast Minnesota counties. This investment supports practices like no-till planting and cover crops, critical tools for reducing soil erosion and improving nutrient retention, directly benefiting water quality.[6]

Another state program that assists farmers is the Agricultural Best Management Practices (AgBMP) Loan Program. The AgBMP Loan Program is a water quality program that provides low-interest loans to farmers, rural landowners, and agriculture supply businesses. The purpose is to encourage best management practices that prevent or reduce runoff from feedlots, farm fields, and other pollution problems identified by the county in local water plans.[7]

---

[5] https://www.lrl.mn.gov/docs/2025/mandated/250186.pdf
[6] https://content.govdelivery.com/accounts/MNMDA/bulletins/3aa8444?
[7] https://www.mda.state.mn.us/agbmploan

As the MPCA moves forward in this rulemaking process, it is important to note that voluntary practices and cost-share support from the state are strongly viable options that drive results when it comes to managing our nutrients. The MPCA should consider utilizing all available options to balance the interests of those impacted by future regulatory changes.

<u>Question 9:</u> Other questions or comments relating to the existing animal feedlot rules or this proposal to amend the rules.

Justification for Rule Updates:

The MPCA's Request for Comments (RFC) document emphasizes fish kills as a recurring concern throughout the proposed rule changes. It connects fish kills to manure runoff and land application, especially in sensitive areas like southeastern Minnesota.

The 2024 multi-agency report "Preventing fish kills in Minnesota's driftless region" found only four trout stream fish kill events in southeast Minnesota with confirmed pollutant causes since 2015. This incidence rate is too low to justify animal feedlot rule amendments aimed toward preventing fish kills. The report concluded many high-value prevention steps fall within existing authorities without the need for changes in rule or statute. While the report's recommendations contained some regulatory measures, it also contained many nonregulatory recommendations.[8]

How does the agency justify fish kills as an impetus for rule changes?

Advisory Committees:

MFBF believes it is necessary to convene advisory groups for vetting rule amendment areas. Given that these changes will directly affect how livestock and poultry farmers operate, it is essential that farmers and ranchers with on-the-ground experience are included as representatives or subject-matter experts on each advisory committee.

Producers manage the day-to-day realities of feedlot operations, manure storage, and land application. Their insight is critical to ensuring that any proposed rule changes are practical, science-based, and adaptable to diverse agricultural systems across Minnesota. Without meaningful producer representation, there is a risk that recommendations may lack feasibility or fail to reflect the wide variety of livestock systems in the state.

Moreover, we strongly recommend the creation of a dedicated farmer and rancher advisory committee to review and provide oversight on all rule recommendations before they are

[8] https://www.lrl.mn.gov/docs/2025/mandated/250186.pdf

finalized. This would ensure producers have a consistent, structured role in shaping policies that affect their livelihoods and environmental stewardship responsibilities.

Recognizing Progress:

It is important to recognize the significant statewide measures that have been adopted since the last major revision of Minnesota's feedlot rules. Mandates aimed at improving water quality have strengthened protections across the landscape. In addition, producers have taken on voluntary efforts to improve nutrient management, including precision application, cover cropping, and improved timing of manure application. As MPCA considers rule updates, it is essential that these changes remain focused on areas clearly within the agency's jurisdiction and not attempt to compensate for groundwater or surface water contamination that falls outside the scope of feedlot and manure regulation.

Here are key statewide measures adopted since the last major revision of Chapter 7020 in 2000, highlighting ongoing improvements in manure and nutrient management:

NPDES and SDS Permit Updates

Since the early 2000s, the MPCA has reissued and updated its National Pollutant Discharge Elimination System (NPDES) and State Disposal System (SDS) general permits for feedlots on a five-year cycle, with the most recent revisions made this past year. These updates incorporate changes to federal CAFO (Concentrated Animal Feeding Operation) regulations, clarify compliance expectations, and strengthen water quality protections for large livestock operations. The NPDES/SDS permitting system is distinct from the Chapter 7020 rule and applies to operations with 1,000 animal units or more or those with potential to discharge. These permits reflect a performance-based, site-specific regulatory tool that continues to evolve in response to science, technology, and environmental needs.

Minnesota Buffer Law

The Buffer Law (Minn. Stat. § 103F.48), passed in 2015, requires vegetated buffers of 50 feet along public waters and 16.5 feet along public drainage systems on agricultural land. This law plays a critical role in protecting surface water quality by reducing sediment and nutrient runoff from adjacent cropland, including fields receiving manure applications. Implementation is led by the Board of Water and Soil Resources (BWSR) and enforced locally. As of July 2019, approximately 98% of parcels adjacent to Minnesota waters are compliant with the Buffer Law.[9]

[9] https://bwsr.state.mn.us/minnesota-buffer-law

Minnesota Nutrient Reduction Strategy

First released in 2014, this statewide strategy outlines goals and timelines for reducing nitrogen and phosphorus loading to Minnesota's waters. It emphasizes both point and nonpoint source reductions, including manure, and promotes adoption of precision application technologies, improved timing and placement of nutrients, and soil health practices. A 2025 update is underway to reflect new research and emerging practices.

MDA Groundwater Protection Rule

Adopted under the Nitrogen Fertilizer Management Plan, this rule targets nitrate contamination risks in vulnerable groundwater areas. While it primarily applies to commercial nitrogen fertilizer, it has encouraged greater awareness and adoption of voluntary best management practices among livestock producers managing manure. This effort complements the nitrogen application standards already embedded in part 7020.2225.

These statewide measures demonstrate that Minnesota has made significant progress in environmental protection, nutrient management, and technological modernization since the last major revision to Chapter 7020.

Minnesota's farmers and ranchers remain committed to environmental stewardship and the high quality of our state's water resources. The existing feedlot rule has supported this commitment by providing a workable framework that encourages sound management while maintaining water quality standards. As the MPCA considers updates to Chapter 7020, we urge the agency to recognize the progress already made and avoid changes that would introduce unnecessary complexity or economic strain for farmers and ranchers. We appreciate the opportunity to provide comments and look forward to working with the agency throughout the remainder of the rulemaking process.

Respectfully,

Dan Glessing, President
Minnesota Farm Bureau Federation

Katrina Kessler
Commissioner
Minnesota Pollution Control Agency
520 Lafayette Road North
St. Paul, MN 55155

Dear Minnesota Pollution Control Agency,

We appreciate that MPCA is considering revisions to its Animal Feedlots Rule and urge the agency to draft a Rule that will address dangerous levels of nitrate, other nutrients, and bacteria in surface waters and groundwater across Minnesota. Everyone in Minnesota should have safe tap water to drink; and our state's many lakes, streams, and rivers should be safe for people, fish, and wildlife.

Specifically, we urge MPCA to consider the following changes:

- Require water pollution permits not only for the largest feedlots, but also for feedlots with 600 or more animal units.

- Add stricter limitations on manure application in areas that are particularly vulnerable to groundwater pollution, including the southeastern karst region and the central sands region, such as additional best management practices for fall manure application and lowering manure application rates.

- Prohibit application of manure on frozen or snow-covered ground, which creates a high risk of runoff.

- Prohibit the application of manure when there is a high likelihood of rainfall, which creates a high risk of runoff.

- Require permitted feedlots to create a risk-assessment plan to monitor their manure storage areas and land application sites for above-ground and below-ground discharges to water to ensure feedlots are not polluting lakes, rivers, and groundwater.

- Require anyone who receives manure from a feedlot with a manure management plan to follow the permit requirements and manure management plan for that feedlot.

With this rulemaking, MPCA has a critical opportunity to help address a serious and long-standing environmental and public health threat to our state. High levels of nitrate, other nutrients, and bacteria in our waters kill our fish, make our lakes unswimmable and unfishable, and put Minnesotans' health at risk. We ask MPCA to create a robust rule that addresses water pollution from feedlots and protects all of Minnesota.

RE: Comments on MPCA RFC for Amendments to Rules Governing Animal Feedlots: Minnesota Rules, Chapter 7020, Revisor's ID Number R-4928, OAH Docket NO. 25-9003-40661

Dear Mr. Moore:

Thank you for this opportunity to voice our thoughts on the opening of the Chapter 7020 Rulemaking process.

We are writing to first say that we are in full agreement that we need to do what we can to protect our state waters. We see the data. Specifically, the nitrate increases in our waters, and we wholeheartedly agree with MPCA that we, as feedlot owners, play a critical role in protecting our waters. In fact, being good stewards of our water sources and preserving the quality of the land we manage is the basis for all of our decisions we make on the farm.

However, we oppose any further regulation through potential changes to the MN Chapter 7020 Rules. We understand the need to update certain pieces of the rules to address technology advancements, such as online registration and applications, and we are in support of well-developed and user friendly technology to be created and implemented. We do not support MPCA creating further restriction or regulation to any of the current rules—instead, we believe we can do better with what we already have.

Mr. Moore, water pollution is not caused by a one-source pollutant. It takes a collective effort to create the pollution and a collective effort to clean up the pollutants. Can the MPCA affirm that feedlots are the one-source cause for the increase of nitrates in our waters, or are there other sources at fault for these increased levels?

The commercial fertilizer industry has very few regulations for applying nitrogen to crop ground. Commercial fertilizer is not required to be treated with a nitrogen stabilizer (although some retailers do this), like manure is. And individuals applying commercial fertilizer have very few, if any setbacks from waterways they need to follow during application. As feedlot owners, we have been following land application setback rules for years—20+ years (not to mention the additional setbacks we now have due to the Buffer Law). Where is the regulation on

the agronomy side of crop production? Why are we already distancing our land application of manure from waterways, but there is no regulation to be followed for commercial fertilizer application?

What regulation is in place for applying fertilizer to lawns in municipalities? Who monitors that application of lawn-specific nitrogen? In town, lawn fertilizer doesn't even have natural setbacks from the curb or buffer strips in place to slow the flow of nitrogen to the city sewers. Why are we not discussing this as a source of nitrate pollution?

Manure is not the only nitrogen pollutant in our state. And we would go so far to say that we are currently the most regulated piece of this high nitrate puzzle.

That said, the questions we pose to the MPCA and to you, Mr. Moore, is, do we need further regulation? Or, can we do better with our current set of rules?

Within the current 7020 rulebook, MPCA and delegated county feedlot officers are required to routinely inspect feedlots across the state each year. Of the 17,000 registered feedlot in the state of Minnesota, how many state-permitted feedlots and county-permitted feedlots are inspected on an annual basis? There is also opportunity for inspections to be conducted on manure stockpiles, on land application of manure, and on manure management plans. How many of each of these types of inspections get done on an annual basis for county-permitted feedlots and state-permitted (NPDES/SDS) feedlots? If we had these data sets, we could show how many feedlots are being inspected annually, how many are "in compliance" during inspection, and eventually, we could track all the feedlots returning to compliance (those that were found to have an environmental concern that MPCA or the County Feedlot Officers assisted in finding a solution to). From there, we can adjust our target number of inspections annually to improve our data sets, as needed.

If we do not have a good set of data that shows our feedlot owners across the state are doing what they currently need to be doing, then why are we even considering stronger regulation? And, why does it seem like we are the only group actively working on improving water quality through best management practices? What push back has MPCA had on other agencies to own their part in this situation?

While we would like to comment on each of the MPCA-suggested items on the Request for Comments PDF that was provided, we will, instead, address our concerns on what we feel could be the most impactful proposals.

<u>Land Application of Manure:</u>

In the Request for Comments PDF, under item #2., the MPCA asked: What specific changes to the current rules...would provide improved regulations that prevent nitrate contamination into ground and surface waters and fish kills? Should any of the following bullets be considered? If so, at what size (in AU)?

We do not support any of the suggested bullet points listed below #2 in the Request for Comments PDF (i.e. operating permits for county sites, additional restrictions on manure application rates, increased setback distance for land application of manure near sensitive features, restricting land application of manure in areas with high levels of nitrate in waters or in areas with existing high densities of feedlots) being required of any feedlot under 1000 AU.

We do not want our manure to wash into the creeks, waterways and field tile. The manure our livestock produce is our second most valuable commodity on the farm, second only to our livestock. The ability to apply manure is time sensitive, and further restriction will only make the decision making process of when to apply their manure more difficult for farmers everywhere. Moving all manure application to the spring is just not feasible. Some of our local Certified Commercial Applicators have 9-12 weeks of land application work (12+ hour days), and there is absolutely no feasible or safe way to fit that amount of work into a 4 week window in the spring—that's if we get four weeks of dry weather. We are already constantly questioning where and when we should apply the manure from our farms due to weather and these proposed ideas will only add to the stress we face in making on-farm decisions.

We would invite you to visit with our feedlot owners—from both our county-permitted feedlots and our state-permitted feedlots—to hear for yourself the value that having a working manure management plan on our farm has brought us, and also the knowledge we carry from working our land year after year. Every field we work, plant and harvest in has different needs. And there's no blanket research or blanket rate-of-application that will compare to the knowledge we have of these acres. In fact, there's been such advancements in technology and GPS capabilities in our farm equipment that we can now map our fields based on the soil testing we do and spot-apply the manure and manure rates as-needed, ensuring that we are never over applying! These discussions will be invaluable to your research and consideration of any further regulation.

We also do not see how a one size-fits-all land application of manure approach is appropriate for feedlots in Minnesota. We would suggest to the MPCA to consider using MNDOT's Seasonal Load Limit Zone Boundary Descriptions as a starting point for determining a more regional or zoned approach if any new land application of manure regulations are considered. This map was developed to follow roads across the state, frost and thaw dates across the state, and also partially considers soil profile across the state, as well. In speaking with representatives from MNDOT, there would also be opportunity to further split the zones they have by selecting a north/south road in each zone to compensate for easterly portions of the state thawing sooner than their western counterparts. You can view the seasonal load limit zone boundary description map here: https://edocs-public.dot.state.mn.us/edocs_public/DMResultSet/download?docId=15860170. Using a regional approach to manure application best management practices seems more applicable than requiring the whole state to follow the same rule.

In the Request for Comments PDF, under #3., the MPCA suggested restricting land application of manure on frozen or snow-covered fields. There is literally no amount of power that any of us have to stop livestock from producing manure during winter months. Furthermore, building four months of manure storage at every feedlot in Minnesota is not financially feasible.

We would like MPCA to further research and reconsider the current rule of not applying manure in March. It is extremely difficult to not apply manure in March. We understand that March is historically the month our soils thaw and that we are at an increased risk for runoff. The manure we scrape from our open lots in these late winter months is often mixed heavily with snow, making application rates less than a normal fall application. We are constantly monitoring the weather and field conditions. It is always our goal to land apply manure in the best of conditions, but perfect conditions happen far less than imperfect conditions.

Perhaps the MPCA could consider a March manure application permit, that could be applied for annually, that would allow feedlots to land apply manure in March, on a case by case basis—similar to the emergency application acres listed in every manure management plan.

Transferred manure:

In the Request for Comments PDF, under #3., the MPCA suggested an "enhanced manure management planning and record keeping requirements for transferred manure." This is in reference to NPDES and SDS permit updates from 2024 and suggesting this item should apply to county-permitted sites, too.

After the 7020 rules update in 2000, it was a requirement for all feedlot owners transferring manure to maintain documentation for who was receiving the transferred manure. According to MPCA, this practice eventually fell out of practice, and today, the only requirement for documenting where the transferred manure is going is via the manure management plan for each site. There is no enforced requirement for the recipient of the manure to maintain their own manure management plan, although it is loosely worded that MPCA may enact additional measures, if needed. With the updated NPDES/SDS permits, the permit holder must now maintain records on who is receiving manure AND the recipient must be applying the received manure according the feedlot owners MMP, all of which must be recorded by the permit-holder.

How does this even make sense? To go from almost zero documentation for transferred manure to the feedlot owner having to maintain records and dictate application rates and measures to take for the manure they sold when the feedlot owner has no knowledge of the manure recipient's field data? Furthermore, how will MPCA monitor any of this information? Who will be required to receive the documentation from these NPDES/SDS sites and verify that all rules are being followed? And, what sort of follow up will occur to ensure the new rule rules will be followed correctly? There are roughly 1,000 NPDES/SDS sites in the state, how will the MPCA monitor and follow up on any of these new rules if the 16,000 county-permitted sites are required to follow the same type of rules?

We would be in favor of documenting where that manure is being transferred to, but we do not feel it is our responsibility, or that it would even be legal for us to regulate how that recipient of the manure applies that manure to their land whether we have a state or county permitted feedlot.

Common Ownership:

On the Request for Comments PDF #8., the MPCA asks: "How should the MPCA address feedlots under the same ownership in close proximity to each other? How far apart must each feedlot be located in order to be considered a separate facility for the purposes of permitting and/or registration?"

We propose that the MPCA leave these questions up to the determination of each county. At this time, the Environmental Protection Agency (EPA) generally considers any feedlot within .25 miles from another feedlot with the same ownership "common ownership" and may be considered a multi-site location in need of an NPDES or SDS permit.

Our county is zoned as "Agriculture Preservation". Minnesota State Statute 40A.18 LAND USE. states that "Land within an agricultural preserve must be maintained for agricultural production. The average maximum density of residential structures within an agricultural preserve and the location of a new structure must conform to locally applicable plan or zoning regulations. Commercial and industrial uses are not permitted except as provided in subdivision 2 after the user is issued a permit by the local government. *The local government is responsible for enforcing this section*."

Every county is different in how they permit feedlots beyond the Chapter 7020 requirements. Do not muddy the water further by making it more difficult to build the family farm and bring our children back to the farm when they graduate. Leave distance between feedlots and ownership decisions up to each local government.

According to the USDA's Economic Research Service, there were nearly 6.8 million farms in the United States in 1936. Today, there is roughly 1.88 million. The average number of acres of land per farm is 466 acres. According to the 2022 Census of Agriculture County Profile for Nobles County, 95% of the reporting farms indicate that they are family farms. Just under 50% of the farms in Nobles County farm an average of 50 – 499 acres of land.

In today's economy, it is not feasible to bring any child back to the farm with only 466 active acres, which is why we've seen a steady decrease in total number of farms and an increase in overall number of acres owned per farm. This is also why we see an increase in number of livestock on these farms—because our kids want to come home and do what they love. However, this is a testament to how competitive it can be to build a family farm.

In order to bring our children home to the farm we either need to purchase more land to crop or diversify our farms to include livestock. Further federal or state regulation only hinders the ability of family farm to expand. Let our local governments determine how far apart our feedlots need to be and what ownership rules need to look like.

Pasture:

Finally, on the Request for Comment PDF, #6., the MPCA questions, "How should the rules be amended to address this documented issue (WRAPS documents indicating high nutrient and bacteria levels in streams and rivers)?"

We ask that the MPCA leave pasture ground alone and do not require pastures to be registered as documented feedlots in the future. Nobles County has just over 6,700 acres of land in pasture ground, according to the 2022 Census of Agriculture County Profile. Pasture landowners are generally not restricted from providing access to waters on their property to their livestock (Department of Natural Resources). We do not want our livestock to create any pollution hazard to these rivers and streams, but how does the MPCA propose we monitor how much the livestock manure is contaminating the rivers and streams in comparison to wildlife feces contaminating rivers, streams and lakes?

Again, this seems like another suggestion that MPCA is proposing that would be difficult to provide the means to monitor or verify is being done correctly. This is another topic that should be left to the individual counties to decide how to monitor.

Final Thoughts:

As feedlot owners, we want to protect our water sources and keep our land fertile and usable for the future generations—we truly want to leave both in better condition than how we found them. We also understand that rules and regulations are part of the process, that if we didn't have them, we'd be dealing with much larger concerns than we are today. We believe there is a balance between trusting us with the land that we've farmed for multiple generations, that we know better than you do, and creating a space to ensure that everyone is being good stewards of our land and water. We have the same goal: to ensure these natural resources are here and healthy for future generations.

As a state, we have to remain competitive with our neighbors, too. Have you noticed the explosion of dairy herds along I-29 in South Dakota in the last 10 years? According to the USDA, South Dakota dairy herds totaled 208,000 head as of January of 2024, up 70.5% since 2019. That means that South Dakota's dairy herd has added 118,000 cows over the past 12 years. That's not because they are competitively closer to feed, or to road systems that provide easier transportation access than we do here in Nobles County. Our county is a 60 mere miles from I-29 and closer to the feed than South Dakota farms are. Minnesota's feedlot regulations are restrictive and deter farm growth in the state, in our opinion.

We stand by our overall sentiments that there is a lot of opportunity for the MPCA to improve on what they already have in place for rules, instead of further regulating feedlot operations. Let's work on getting feedlots compliant with the current set of regulations via more inspections and monitoring data trends, instead of slapping together a new rule book with stricter rules for Minnesota feedlots to follow.

And, we must repeat our sentiments that there is also opportunity for MPCA (and feedlot owners themselves) to have further conversations with other state agencies, and press those agencies to look into what the Minnesota Department of Agriculture is doing to regulate the agronomy industry through the land application of commercial fertilizer and regulate homeowners/business owners applying fertilizer to their lawns in town.

Respectfully,
Nobles County Feedlot Owners
Nobles County Commissioners

6601 Auto Club Road, Bloomington, MN 55438

July 22, 2025

The comments that follow are submitted by the Izaak Walton League of America (IWLA) Minnesota Division and pertain to the Minnesota Pollution Control Agency's planned amendments to rules governing animal feedlots, Minnesota Rules, chapter 7020, Revisor's ID Number R-4928 - OAH Docket No. 25-9003-40661.

Statement of Qualifications and Standing

The Izaak Walton League of America is one of the nation's oldest and most successful conservation organizations. Founded in 1922 the "Ikes" have for over 100 years stood for the protection and restoration of the nation's fish, wildlife and natural areas and is especially focused on matters affecting water quality.

Wherever these comments refer to "the League" this reference should be understood to be the collective opinions of members of the Izaak Walton League here in Minnesota that include a wide variety of experts in the natural sciences, water quality, hydrology, agriculture, public health and regulatory governance. The League is especially well positioned to make these comments on feedlot rules because many of our members are retired agency professionals from the Departments of Agriculture, Natural Resources, Pollution Control Agency, Health, Transportation, Board of Soil and Water Resources, Soil and Water Conservation Districts, U.S. Army Corps of Engineers, U.S. Geological Survey, U.S. Fish and Wildlife Service, the U.S. Environmental Protection Agency and more. Many League members are or were academics researching or teaching in colleges and universities in these disciplines. Other members have doctorate degrees and have been practicing family or specialty medicine for years, while still others are active citizens in natural resource protection in the League and other advocacy groups and have dedicated extraordinary amounts of time studying these matters and developing organizational policies to address conservation, pollution and environmental degradation.

Scope and Perspective for Comments

In the agency's request for public comments the MPCA has stated that the agency's three main areas of focus for these rule amendments include:

1. Updates to address changes in livestock and poultry operations and business practices, new agency data services, and outdated language.
    - Permit and registration applicability;
    - Animal unit factors;
    - Clarity of definitions and requirements;
    - Legislative alignment; and,
    - Utilization of agency data services.
2. Land application of manure practices to address nitrates, bacteria, and fish kills.
    - Transferred manure requirements;
    - Nitrogen Best Management Practices (BMPs);
    - Setbacks;
    - Manure Management Plan (MMP) applicability;
    - Visual monitoring; and,
    - Compliance monitoring.
3. Technical standards to protect water quality and avoid fish kills.
    - Manure storage capacity;
    - Feed storage design and operation;
    - Existing Liquid Manure Storage Area (LMSA) integrity;
    - Ground water monitoring; and,
    - Livestock access to waters.

The agency then asks: "Should any of the following bullets be considered? If so, at what size (in AUs - animal units)?"

- Operating permits (NPDES or SDS) for feedlots less than 1000 AUs.
- Submittal of manure management plans and land application records for feedlots without operating permits.
- Monitoring of feedlots and land application sites for subsurface discharges of manure or nitrate to groundwater.
- Additional restrictions on manure application rates.
- Soil nitrate tests prior to land application of manure.
- Increased setback distance for land application of manure near sensitive features.
- Restricting land application of manure in areas with high levels of nitrate in waters or in areas with existing high densities of feedlot operations.

MPCA's Three Area of Focus

The League generally agrees that the MPCA's three areas of focus listed above are appropriate. But, of particular concern to our members is the first one in this list: the significance of "*changes in livestock and poultry operations and business practices".*

There has been dramatic shift in animal and crop agriculture toward larger industrialized models over the past few decades that are thought to be primarily the result of government subsidy and world trade policy. As profit margins narrow and farm land prices rise the response has been to increase production rates to maintain viability. As

costs of inputs increase, the income from production has not been keeping pace. To hedge financial risks, producers (both crop and animal producers) have taken advantage of hidden subsidies that externalizes a major cost of production at the expense of a public asset: *degraded water quality and quantity.* By maximizing fertilization of crops with commercial fertilizer and manure to boost production (as recommended by established "agronomic rates") producers are encouraged to gamble on having a bumper crop every year. And there is an understandable tendency to augment the production benefits using less of the of higher cost commercial fertilizer, with more of the lower cost manure. But this gamble depends on having ideal weather conditions every year, which seldom happens. The result is that total nutrient inputs on an annual average, almost always exceed uptake and removal by harvested crops. The excess application of both forms of fertilizer accumulates each year that a "bumper" crop is not realized. Soil testing will not detect either form of nutrients that has leached below the root zone. As the build-up of excess fertilizer either washes off or leaches down below the root zone, this fertilizer is "released" as pollutants to groundwaters, surface waters, or both.

Current best management practices, even deployed to their maximum capability, which they seldom are, have not proven sufficient to recover, treat or retain these excess applications or the discharges to surface and groundwater. Uncontrolled discharges, "releases" of pollutants by these means, should be prohibited by the new rules because they are intentional, measurable and preventable.

As the MPCA works to develop rules for feedlot operations that reduce or eliminate this avoidable source of water pollution, the agricultural community's hidden profit subsidy *(degraded water quality and quantity*) that depends on continued release of pollutants will be significantly threatened. Powerful political forces will push back claiming that regulatory over-reach by the MPCA is threating the economic viability of farming in Minnesota.

Special attention must be given to this predictable political argument well in advance of the agency's proposed new rules that will make this unwarranted subsidy clear to the public, to the agricultural community and to our elected officials. Failure to anticipate and successfully dispel this argument in advance would imperil the success of the new rules.

The League believes that the MPCA must work with social scientists and other experts to carefully craft an educational campaign that exposes this unwarranted subsidy and builds support for ending it. The current industrial models for both crop and livestock production are seriously flawed in this regard and there are viable alternatives. The League stands ready to work with the MPCA, other state agencies and our partner non-profits to develop and roll out this educational campaign.

Later in these comments we will propose a structure and cite the authority for assembling an expert advisory panel to assist the agency and cooperating entities in

developing and implementing this plan based on existing statutory mandate and an Iowa example.

MPCA's Bullet-Points

The next section of our comments is directed toward the several bullet-points the MPCA offered for considerations. These summary responses on those points will be followed by more detailed discussion of them in a later section.

Overall, it is the League's position that the amended feedlot rules must not only be effective at reducing feedlot pollution, but should eliminate it to the degree necessary to support all classified uses of the state's surface and groundwaters. This has been and remains the goal of the Federal Clean Water Act, and actually provides the name of the federal NPDES permits many feedlots and all other discharges require. NPDES is short for the National Pollutant Discharge *Elimination* System.

The business and operating models for industrial-scale livestock and poultry production is vastly different from the conventional, family-farm model, and its waste handling and disposal methods are largely experimental. The industrial model has outside entities called integrators that own the animals. The "farmer" landowner owns the buildings, manure storage and handling equipment, and only some of land needed for manure disposal. Liquid manure rather than dry storage became the norm due to technical advances in manure handling equipment, but this required retention or addition of water to the manure. This business arrangement tends to bifurcate the responsibilities and liabilities of manure ownership, complicates storage and disposal options, and tends to shield the animal owner from any responsibilities.

Conventional family farms had the farmer owning both the animals and the all the related capitol infrastructure and all the land needed for manure. Dry handling storage of manure, depending on site conditions, has less tendency for run-off or seepage pollution because the manure inherently had more bulk (i.e. added bedding such as straw) and less added water.

Our research reveals that the industry's adoption of a wide variety of recommended best management practices have failed markedly at protecting surface and groundwaters nation-wide, and thus cannot continue to be the basis for either the voluntary norms or the regulatory requirements for permitting. Our recommendations for rule changes are premised on this fact. Unproven methods for manure storage and handling should be deemed "experimental" by rule. And these experimental waste management methods should only be allowed on a trial-and-error basis with close monitoring, and have prompt, pre-determined correction, remediation and compensation measures built in (for harms to public or private water supplies).

The comments below and the findings and recommendations in the League's Prairie Woods Chapter's AFO/CAFO report (attached) on feedlots to Becker County[1] are each

[1] See attached report entitled: ADDRESSING AFO & CAFO IMPACTS IN BECKER COUNTY'S COMPREHENSIVE LAND USE PLAN, ZOINING MAPS & ORDINANCES – August 1, 2024.

offered as useful information in regard to the MPCA's rule revisions. That report details gaps or deficiencies in federal and state rules governing feedlots that the League recommended Becker County address in their revised comprehensive land use plan. We also refer the agency to a recent Iowa report entitled *"Currents of Change*" [2] and offer that report into the record by reference. The Iowa report is offered here because it fortifies the findings of the League's AFO/CAFO report. The MPCA is encouraged to review the findings of each of these reports and address the identified deficiencies.

Our experience in Becker County is instructive. The League and specifically the members of the League's Prairie Woods Chapter in Detroit Lakes have examined the pollution potential of industrial-scale animal feeding operations and manure disposal in depth and on a national scale. This was done in preparation for a large swine operation that was proposed for a western Becker County township that requires a conditional use permit and an SDS or NPDES permit from the MPCA (application to MPCA yet filed). When the League challenged the adequacy of the county's zoning ordinances as being inadequate to control pollution from the facility, the county opted to update its Comprehensive Land Use Plan and review its ordinances. At the conclusion of that year-long process, county officials concluded that they were relying on the MPCA's rules to protect water quality. The county viewed their role and ordinances as intended to prevent land use conflicts, not protecting water quality. This, they concluded, was entirely the purview of the MPCA.

Our chapter members prepared the referenced report to demonstrate the inadequacy of Minnesota's and other states feedlot rules nation-wide. The report references the MCEA, et. al., petition to EPA that led to the current proposal for rule-revisions. Becker County officials were not convinced that they were obliged to fill this gap and have proceeded to issue the county permit.

This, and the *Currents of Change* report from Iowa, are offered to point out that local units of government are relying on the state governments (MPCA) to not only provide needed regulation of the design and operation of feedlots to prevent pollution, but to also to help them apply appropriate land use controls to avoid locating large feedlots in sensitive or already degraded areas of the state.

Summary Responses to the MPCA's Bullet Point Consideration Questions:

The League supports that construction and operating permits be required for feedlots far less than 1000 animal units in size. We suggest that all permitted feedlots should have both manure management plans, and require not only manure application records be kept, but water quality monitoring records as well. Because there is no evidence that feedlots below a certain number of animal units should be exempted as a class on the

[2] Currents of Change – An Analysis of the Racoon and Des Moines Rivers in Central Iowa - Final Scientific Assessment of Source Water Research Report available on-line at: https://www.polkcountyiowa.gov/media/lixlchbz/ciswra-currents-of-change_final-scientific-assessment-of-source-water-research-report_jun272025.pdf

basis of their low pollution risk, we recommend that small operators should apply for site-specific exemptions (variances) instead of being offered blanket exemptions based on their being below a certain number of animal units. Such exemptions could be applied for with assistance and documentation provided by county Soil and Water Conservation Districts or County Feed Lot officers. Criteria for exemptions would necessarily have to be spelled out in the new MPCA feedlot rules.

For example, traditional family-farm-scale feedlots often use dry handling and stacking methods for storing manure before field spreading. As mentioned above, dry stacked manure has far less potential for runoff or seepage than liquid manure handling and storage systems. If suitable vegetated setbacks are observed, slopes are moderate to level and runoff deflection and detention berms are constructed these operations could be considered exempt by rule.

We suggest that all permitted feedlots (that are not exempted) be required to record not only manure application rates, but additional commercial fertilizer rates as well. Permits should require active sampling and analysis of both surface and subsurface discharges for specific pollutants associated with animal manure storage and disposal and for other polluting chemicals associated with large feedlot operations. Monitoring for nitrates alone is not enough and parameters such as bacteria[3], biological oxygen demand (BOD), phosphorus and any other chemicals or pharmaceuticals being administered at the site for example, should also be required. Rates of manure application should be dictated by the site-specific character of the lands used for manure disposal from each permitted facility. Removal of nutrients such as nitrogen and phosphorus, through crops and residue harvested from fields receiving manure should be documented and compared to combined commercial and manure fertilization rates to assure excesses are not accumulating or being discharged. Determining the need for additional restrictions on manure application are again, site specific and should be proposed for each unique facility by licensed engineers and hydrologists who are experts at manure management for water quality protection purposes.

Setbacks from any and all surface waters should also be determined on a case-by-case basis, because a setback that may function well in one location may be inadequate for others, depending on slopes, ground cover, soil types and other site-specific characteristics.

Land application of manure in areas that already have high levels of nitrates or other pollutants associated with feedlots in either surface or groundwaters, should not only be more restrictive, but manure production, storage and land application should be prohibited in these areas until remedial actions are successful at reducing these

[3] U.S. Department of Agriculture studies in Wisconsin have shown that bacteria from feedlot seepage into ground water can travel several miles from the source underground so bacteria should be a monitored parameter for both surface and groundwaters. See section entitled GREEN BAY WISCONSIN – ON LAKE MICHIGAN on pages 22-23 of Leagues AFO/CAFO Report to Becker County attached.

excessive levels to a predetermined point. The term "high levels" are parameter specific and needs better definition. But, to be preventative, nitrates should have a trigger level well below the drinking water standard of 10 mg/l. This margin accounts for the lag time between a pollutant's discharge and its detection in receiving waters by monitoring.

The fact that the MPCA has not yet promulgated surface water nitrate standards for all waters other than those used for drinking water, is now being drawn into the public spot light. While adopting new nitrate water quality standards is not up for consideration in the current rule-making for feedlots, the League strongly encourages the agency to move forward with that long-delayed, much overdue process.

Detailed Discussion of Summary Above and Other Comments

The League respectfully suggests that any attempts to specify technical standards that are protective or remedial practices for most animal feeding operations by rule, are unlikely to accomplish the agency's statutory mission to: *"enforce reasonable orders, permits, variances, standards, rules, schedules of compliance, and stipulation agreements, under such conditions as it may prescribe, in order to prevent, control or abate water pollution."*[4] Minnesota's landscape, topography, soils, ground cover and the state's surface and groundwater vulnerabilities are far too varied in aspects relating to pollutant movement, retention and processing to allow a single "one-size-fits-all" approach. It is the League's strongly held opinion that most if not all permitted livestock or poultry operations should be required (by rule) to submit site-specific designs that take into account the unique natural or humanly altered features of a proposed feedlot and accompanying manure application locations. This is because animal feeding operations at or below 100 animal units in higher risk locations have been found to be major sources of pollution.

A Proposed "prove it first" Policy

The findings of the Prairie Woods Chapter's AFO/CAFO Report and the Iowa *Currents of Change* report referenced above, demonstrated that the intensification (concentration) of animals in what has become the industrial model for producing meat, has created a high risk for water pollution. The report also finds that in many other states that have experience with this scale of feedlot operations, citizens, environmental NGOs and regulatory entities alike have concluded that the array of pollution prevention methods (best management practices or BMPs) currently being deployed (whether mandatory or voluntary) have been inadequate to satisfactorily prevent feedlot pollution from entering public waters.

Based on this finding, the League recommends that the MPCA adopt a policy that declares this intensified method of livestock farming an experimental, high-risk polluting enterprise that must demonstrate new and improved controls before qualifying for permits. This would in effect, place the industry representatives (permit applicants) on

[4] Minnesota Pollution Control Agency enabling legislation at: Mn Statutes Chapter 115.03 POWERS AND DUTIES Subd 1(5).

notice that they must prove they have solved the heretofore unsolved problems associated with this industrial-scale enterprise.

To provide this "proof" the plans and specifications for new or expanding animal feeding operations should be required to be prepared by licensed engineers and hydrologists qualified and experienced in this specialized field. Existing permits should have renewal (expiration) dates after which time they would be required to meet these new rules. The licensed professionals responsible for the siting and design of these experimental operations should be required to affirm that the plans and specifications they submit will, in their professional opinion "prevent, control or abate" pollution.

This should not be viewed as an unusual hardship on even the smallest feedlot operation, considering that individual homeowners in rural areas of Minnesota are required to have licensed professionals design and install on-site sewage treatment and disposal systems that are reviewed by qualified professional in permitting units of government.

Furthermore, this is equitable, because municipalities and other industries in Minnesota, by rule, must hire qualified and licensed engineers to prepare plans and specification for wastewater treatment facilities before they can be permitted for construction and operation. Effluents from these facilities must submit monthly discharge monitoring reports that demonstrate compliance with effluent standards specifically designed to protect the public uses of the receiving waters. By "signing off" on these plans and specification, the designing engineers and hydrologists effectively warrant, by peril of their professional certification, that the facility, when built and operational can and will meet the prescribed water quality standards.

Permits for feedlots should be required to have both a construction and operation permits to detail the specifications by which this unique kind of pollution will be controlled and problems remedied.

Establishing a Point of Discharge as Compliance Boundary

The League recommends that the agency adopt a "point of discharge" policy as a compliance boundary that identifies the soil layer below land applied manure that represents the uncontrolled release of agricultural pollutants. This point would be below the root zone of current or planned crops that could capture or recover nutrients and biologicals applied to the land. Detection of "released" pollutants should be provided by monitoring devices such as lysimeters installed prior to a facilities operation and at locations representative of the areas, included in a facility's manure management plans.

To show whether or not surface or groundwater pollution is or has been originating from an animal feeding operation the permittee should be required to submit pre-construction (for new or expanding operations) monitoring data from representative locations in the water table or aquifer both upstream and downstream of the existing or proposed operation. Where the groundwater flow paths are uncertain due to karst or other geologic character the monitoring plan should demonstrate schemes for collecting data

that does documents the rates, routes and reservoirs of feedlot pollutants escaping (discharging) from a facility and its associated manure application fields. If the groundwater regime proves too complicated to monitor, these facts should constitute grounds for permit denial. Lack of information or the inability to collect it should not be used to justify avoidable risks.

Plans for the groundwater water quality monitoring regime should be submitted to the MPCA for prior approval before the monitoring system is put into operation. The plan should include the professional hydrologist's opinion on whether the existing pre-construction water quality condition will be adequately characterized by the sampling locations, frequency and duration of sampling and the parameters to be monitored. Parameters to be monitored should reflect not only the nutrient and microorganisms that could be discharged from the facility, but all other "pollutants" used at the facility relating to the feeding and raising animals.

In areas having heavy clay soils that a design engineer has determined to be an adequate barrier to downward movement of "released" pollutants, any and all drainage systems serving these fields, including surface ditches, natural waterways or underground tile, should have sampling locations and methods identified to detect "releases" of feedlot related pollutants.

If pre-construction monitoring demonstrates that an existing animal feeding operation owned and or operated by the applicant has already contributed to surface or ground water pollution, the prospective permittee must submit a remedial action plan to be approved by the MPCA. This remediation plan should be successfully implemented before new or expanded animal feeding operation can be permitted. Here, successfully implemented would mean the pollution levels are reduced to comply with applicable surface or groundwater standards.

Available tools for early detection of existing degradation include the MPCA's Watershed Restoration and Protection Plans, coupled with the One-Watershed-One-Plan documents prepared by each county or watershed boards if they exist. These plans are intended to gather and survey existing data on surface and groundwater and identify contributors (stressors) on these water bodies. The plans often include remedial measure needed to address impaired waters. If animal feeding operations are identified as one of the stressors causing impairments, new or expanding feedlot permit applications should be reviewed in light of these findings. As existing permits come up for renewal, the new monitoring and discharge control requirements in the new rules should then apply to these existing lots with a compliance schedule.

Joint Permits for Industrial Model Feedlots

The industrial model for large feedlots often includes a three-layer pyramid of agreements between the land-owner (farmer) and the animal owners (called integrators) and the contracted industrial meat processors. The new feedlot rules must include ways to obligate each of these entities to the responsibility for compliance with permit limitations on discharges, and for financial assurance necessary for remediation upon

discovery of a release. The integrators and the meat processors have been attempting to place the farmer/landowner in the position of responsibility for manure disposal in an effort to protect themselves from this liability. The farmer is not likely to have the financial wherewithal to withstand the costs of remediation should the manure threaten or contaminate surface or groundwater. Faced with this problem, the landowner/farmer may declare bankruptcy leaving the state (taxpayers) to bear the costs of the pollution and remediations.

The need for joint permitting of the parent companies and the intermediate integrators, along with the farmer/land owner must be addressed in the new rules.

Interstate Transport of Manure

Large feedlot operators are generating such large quantities of manure that they may need to seek lands in neighboring state for disposal options. The new rules should anticipate the issues raised by these circumstances. A Minnesota feedlot operator disposing of manure in a neighboring state should be required to comply with rules for long-distance transportation of manure through Minnesota. It is unlikely that the MPCA would have control of that manure once it crosses state lines. However, there may be opportunity for interstate cooperative agreements that provide a seamless protection for water quality. On the other hand, an importer of manure from another state should be required to prepare manure management plans that include the same level of monitoring and release response required of a Minnesota operator. Interstate agreements may also be needed to alert the MPCA to planned importation of manure. The same level of joint permitting for land and animal owners as discussed above would seem appropriate for these circumstances as well.

Importation of manure raises another issue that may be outside the MPCA's authority but nevertheless requires regulatory attention. The interstate transport of manure carries the potential for spread of livestock and poultry disease. If other state departments have the authority to regulate the interstate transport of animal disease, the MPCA should work toward some interagency agreement to address these issues. The MPCA could perform this courtesy for neighboring states receiving manure exported from Minnesota.

Groundwater Supply Impacts

Private well owners in agricultural areas have little or no protection for their water supplies and seldom have their wells tested. When they do test, they may only get results for nitrates and coliform bacteria and they may be unaware of fluctuations in supply aquifer levels influenced by high-capacity wells such as those needed to supply large feedlots.

These are data gaps that the proponents of industrial scale agriculture must help fill. Published studies[5] from N.E. Iowa have shown that

[5] Juxtaposition of intensive agriculture, vulnerable aquifers, and mixed chemical/microbial exposures in private-well tapwater in northeast Iowa available on-line at: https://pubmed.ncbi.nlm.nih.gov/36657670/

"… contaminant exposure in unregulated private-well point-of-use tapwater (TW) is a recognized public-health data gap and an obstacle to both risk-management and homeowner decision making.

The current results address a critical lack of directly comparable data on broad contaminant exposures in TW in agriculturally-developed settings and document commonplace simultaneous exposures to inorganic, organic, and microbial contaminants of human-health concern.

Heterotrophic bacteria detections were near ubiquitous (94 % of the samples), with detection of total coliform bacteria in 28 % of the samples and growth on at least one putative-pathogen selective media across all TW samples. Health-based hazard index screening levels were exceeded frequently in private-well TW and attributed primarily to inorganics (nitrate, uranium). Results support incorporation of residential treatment systems to protect against contaminant exposure and the need for increased monitoring of rural private-well homes."

The Prairie Woods Chapter's AFO/CAFO report also cited studies in Wisconsin where manure pit related bacteria traveled over three miles to neighboring private wells. To assess potential impacts of a proposed feeding operation on both the quality and quantities of available groundwater supplies, the permittee should be required to submit appropriate assessments of these water supplies that identify other area users (both public and private) potentially impacted and what measure will be taken to ensure supplies will be adequate in quantity and quality to serve all existing and planned future uses of these waters. Once again, these assessments should be prepared by licensed professional engineers and/or hydrologists.

Permits for sites that have downstream private wells within five miles should be required to pay for well water analysis of these wells prior to beginning operation, to establish background levels of indicator pollutants. If indicators of agricultural pollution are found, more exhaustive sampling and analysis should be required to determine if other agriculturally related biologicals or chemicals, including pharmaceuticals, are present. Likewise, pumping tests on new water supplies for large feedlots should be required, with water level impacts on existing private wells within five miles being reported. If no existing wells are located within five miles, special monitoring wells should be installed temporarily to determine the zone of depression caused by the new well and neighboring property owners should be formally notified if the aquifer they may rely on in the future may be impacted.

If these requirements should exceed the MPCA's authority or expertise, the League strongly suggests that either a memorandum of understanding or other agreement be developed between the MPCA, the Departments of Natural Resources, Health and Agriculture, to assure this impact is adequately addressed. For example, some form of written commitment between agencies to prepare a joint discretionary environmental assessment worksheet (EAW) or an environmental impact statement (EIS) may provide the level of scrutiny and public comment this problem requires.

Reasonableness of Requiring Compliance With Discharge Standards

The current MPCA policies and rules and the similar laws and policies in other states nation-wide have allowed feedlots to discharge both directly and indirectly into both surface and groundwaters causing serious pollution and impairment of these waters in many parts of the state, and only required that feedlots employ "best management practices" to "minimize" the discharges.

The League's position advocating the agency strengthen its policies and rules is supported by provisions of the Minnesota Environmental Policy Act (MEPA) which, in Chapter 116.04 subdivision 6 states:

> ***"Prohibitions**. No state action significantly affecting the quality of the environment shall be allowed, nor shall any permit for natural resources management and development be granted, where such action or permit has caused or is likely to cause pollution, impairment, or destruction of the air, water, land or other natural resources located within the state, so long as there is a feasible and prudent alternative consistent with the reasonable requirements of the public health, safety, and welfare and the state's paramount concern for the protection of its air, water, land and other natural resources from pollution, impairment, or destruction. Economic considerations alone shall not justify such conduct."*

This is a powerful mandate and a provision in state statute that would appear to compel the MPCA to prohibit (by denying permits) feedlot operations that pollute, impair or destroy the state's waters. Should the agency decide otherwise, it is the Leagues pointed request that the agency provide its explanation for allowing such pollution or impairment in their statement of need and reasonableness for any proposed rule that continues to allow this pollution.

Economic considerations

As discussed above, the League recognizes that the economics of livestock and poultry farming may have influenced landowners to increase that scale of their operations in order to increase or even maintain their profit margins as market prices for their livestock varied. However, manure storage and management practices that routinely allow pollution also increase profit margins, but do so at the expense of our precious water resources, a public trust to be managed for the public good. We maintain that feasible and prudent alternatives to the industrial-scale CAFO model do exist, thus this MEPA policy requires the agency to apply far more stringent standards for those feedlots. It is not our intention in these comments to list or outline these alternatives but instead recommend the MPCA, in conjunction with other state agencies and universities fully explore the available alternatives and make them known to the farming community.

In the section of the League's AFO/CAFO report to Becker County entitled *Economic Impact of CAFOs on Rural Communities (*on page 13) we present the economic arguments based on the work of Dr. John Ikerd, who holds a PhD in Agricultural Economics from University of Missouri-Columbia, that this form of industrialized meat

production is by many indicators, detrimental to the economies of communities where large feedlots of this type exist.

The League is sympathetic to the plight of farmers who may lack the technical or engineering resources to choose a less polluting alternative to the industrial CAFO model. Another section of MEPA requires agencies to do some of this work. *Minnesota Statutes* 116D.04 subdivision 2 (1&2) to establish advisory councils and forums to consult with experts on such matters:

> *"Subd. 2. Duties. All departments and agencies of the state government shall:*
>
> *(1) on a continuous basis, seek to strengthen relationships between state, regional, local and federal-state environmental planning, development and management programs;*
>
> *(2) utilize a systematic, interdisciplinary approach that will insure the integrated use of the natural and social sciences and the environmental arts in planning and in decision making which may have an impact on the environment; as an aid in accomplishing this purpose there shall be established advisory councils or other forums for consultation with persons in appropriate fields of specialization so as to ensure that the latest and most authoritative findings will be considered in administrative and regulatory decision making as quickly and as amply as possible;"*

The League strongly recommends that the MPCA act on this legislative mandate to create a feedlot advisory council to provide independent and objective input not only on these rules but to develop information and the means for its distribution to farmers who need to explore alternatives to the prevailing industrial CAFO model. The past practice of the MPCA, the EQB and other agencies to appoint "stakeholder" panels that includes those with obvious conflicts of interest should be avoided. The statute citation above emphasizes that advisory councils be populated *"with persons in appropriate fields of specialization so as to ensure that the latest and most authoritative findings will be considered in administrative and regulatory decision making as quickly and as amply as possible;"*

We offer instead the example of the panel of science advisors involved in preparing Iowa *Currents of Change* report. The report lists the names, qualifications and an indication of the independence of those panel members that contributed to the report.

<u>Currents of Change Panel of Science Advisors as Listed in the Report</u>

Currents of Change's depth, breadth, and comprehensive interpretation are due to approximately 4,000 hours of analysis and assessment by CISWRA's science advisors—all respected researchers and experts across multiple disciplines. The County is grateful for the passion and commitment devoted to CISWRA on the part of the science advisors.

Dr. Larry Weber, IIHR—Hydroscience & Engineering, University of Iowa
Dr. Michael Weber, Iowa State University Mr. Calvin Wolter, Iowa Geological Survey, IIHR—Hydroscience & Engineering, University of Iowa

Request for On-going Public Participation

Finally, the League respectfully requests that the current comment period not be the only opportunity for the public to have input into the new amendments to the feedlot rules before the draft rules are published. We request that the MPCA hold regular update forums around the state to provide transparency into the direction the agency is going and to what extent any of the public's comments (including those of the League) are being taken into account by the agency.

The League thanks the MPCA for providing this opportunity to submit comments on the agency's plan to revise the state's feedlot rules. We look forward to working closely with the MPCA throughout this rule-making process and beyond.

RE: Comments on Planned Amendments to Animal Feedlot Rules – Minn. R. ch. 7020 (Revisor's ID R-04928)

Dear Ms. Otto and MPCA Feedlot Rulemaking Team,

Thank you for the opportunity to comment at this *early* and important stage in MPCA's review of Minnesota's animal feedlot rules. Minnesota Milk Producers Association represents dairy farm families of every size in every region of the state. Our members care deeply about water quality, soil health, community vitality, animal care, and the future of the next generation that hopes to farm here.

We appreciate MPCA's stated intent to modernize the rules to reflect 25 years of change in data systems, farm management, climate variability, and environmental expectations. We fully share the goal of protecting water resources and preventing fish kills. At the same time, we must be direct: **if this rulemaking proceeds primarily as a "stick" that layers expensive NPDES-style mandates onto smaller farms, it will accelerate farm loss without delivering proportionate environmental benefit.**

Minnesota's NPDES requirements are already viewed as a major regulatory and financial hurdle; many producers stay below 999 animal units *solely* to avoid those costs and risks, throttling natural business efficiencies and delaying environmental technology investments that scale with herd size.

Minnesota needs a rule framework that (1) protects water, (2) works in *all* landscapes, and (3) is economically, logistically, and technologically feasible for the smallest regulated farm — we suggest using a *10-animal-unit feasibility screen* for any new statewide provision. Larger farms already can and do go further through permits, market programs, and voluntary cost-share; but baseline rule text must not presume the capital, labor, engineering, or land base of a 1,000+ AU facility. That presumption is what drives the avoidance behavior we documented in prior comments.

The easiest way to define the rules may simply be to add a multiple to the thresholds for current rules at the NPDES/SDS level and various 7020 levels – as economies of scale have changed agricultural feedlots, permitting could save time, money and provide ecological benefit by simply ensuring we scale-up the size of operations in a manner that keeps them equivalent to what was begun in the year 2000.

We also urge MPCA to **build more "carrots" into the system**. Natural incentives will lower cost and improve compliance faster than using a punitive approach.
Recognize the dramatic progress in farm-level technologies since the late 1990s "feedlot war" era: dragline/direct-injection systems; GPS-guided variable-rate nutrient application; digital recordkeeping; remote soil, moisture, and weather sensors; and satellite imagery that helps time applications and verify residue cover. These tools deliver more nutrient where the crop needs it and keep more out of surface and ground water — yet current permit structures rarely credit those advances.

Finally, instead of having agency staff review permits individually, leveraging these effective conservation practices—either on their own or in combination with enrollment in the Minnesota Ag Water Quality Certification Program—can free up staff to concentrate on areas that need the most improvement.

Executive Summary of Key Concerns for Minnesota Dairies

Below are cost and feasibility flashpoints we ask MPCA to *exclude from mandatory rule text* or to implement only as **voluntary, incentivized best practices**:

- **Impervious pads for calf hutches** (capital outlay, grading/drainage, runoff collection) would be financially devastating to most sub-1,000 AU family dairies; siting is often fixed and difficult to retrofit — a regulatory risk we've flagged when future rules change after facilities are built. The economic benefit is minimal, and the requirement for 1,000+ AU dairies today is questionable.
- **Universal cover-crop requirements** ignore climatic windows, manure timing conflicts, and low establishment success documented in Minnesota research and farmer surveys; mandatory use could eliminate many transferee acres from accepting manure.
- **Mandated long-duration manure storage** (e.g., 9 months) for smaller feedlots would force massive capital expenditures, more engineered structures, and labor/custom pumping constraints that smaller dairies cannot meet. Surveyed producers already struggle to schedule applicators under current seasonal limits.
- **Expanded recordkeeping & transferee tracking** will deter non-livestock neighbors from taking nutrient-rich manure, pushing acres toward synthetic fertilizer and devaluing manure — the opposite of shared environmental goals. Discouraging manure use ultimately encourages the import of additional nutrients into Minnesota.
- **Weather-calendar rigidities (e.g., "vulnerable groundwater area" blackout periods)** fail to match real agronomic conditions across Minnesota's diverse microclimates and produce

costly storage, labor, and fertilizer work-arounds. The current NPDES rules eliminated daily hauling in Minnesota. Expanding this further to smaller animal unit feedlots would be devastating, impractical and only minimally environmentally beneficial in some areas of the state.

- **Expanded field inspection mandates** raise costs, biosecurity risk, and practical scheduling burdens; producers are already concerned there aren't enough inspectors, and we should use the technology incorporated over the past 25 years to replace the time and manpower spent in inspections.

Minnesota Milk Responses to MPCA's Nine RFC Questions

Q1. Which parts of current Minn. R. ch. 7020 are no longer applicable or needed?

Response: Remove or streamline provisions that presuppose large engineered systems for all facilities; clarify that site design elements built to prior code remain grandfathered unless a demonstrated discharge risk exists. Farms invest heavily in fixed infrastructure (feed centers, calf facilities) that cannot be economically re-sited each time rules shift — a "regulatory risk" that suppresses investment and herd growth. As dairies modernize, they build manure systems to last 40+ years. We will see advancement in this technology through voluntary adoption and lower public and private cost where it is needed without any new rules. Meanwhile, MPCA should look outside the Minn. R. ch. 7020 for cost-share opportunities for dairy farms – funding through the Minnesota Department of Agriculture, Board of Water and Soil Resources and Department of Natural Resources, along with federal programs, should be sending a singular message to farmers as to what the state agencies prefer in regulation.

Eliminate duplicative paperwork that replicates NPDES reporting for small or non-NPDES sites; excessive administrative overhead devalues manure exchanges and discourages participation by neighboring crop farms.

Q2. What specific rule changes (permit applicability, discharge standards, siting, storage standards, land application) would better prevent nitrate contamination & fish kills? Consider bullets in RFC.
Targeted, risk-based updates we *support*, if implemented flexibly and affordably:

1. **Acres are the single greatest limitation to compliance, and not taken into much consideration.** Rather than treating feedlots as riskier based on animal unit size, their contracted acres for manure application and yield potential (as an indicator of nutrient uptake) should be the main risk factor. Farms with a good animal unit to acreage ratio should be the lowest risk, and need the least additional work from MPCA to ensure a limited environmental risk.

2. **Outcome-based land application tied to soil temperature, crop uptake stage, and risk modeling — not fixed calendar dates.** Minnesota's diverse climates mean "average" weather station dates don't align with field reality; rigid seasonal bans trigger costly storage and increased spill risk while missing good application windows. When we draw county, regional or size lines, inevitably we leave some farms behind. Allow farmers always to find alternative ways to meet the spirit of the requirements without rigid rules. For example, if they've used an environmental planner or TSP to help create their manure management plan, could that overcome new requirements (in addition, consider MAWQCP as an incentive to replace inspection time)?
3. **Recognize & credit direct-injection / dragline systems** (including low-disturbance incorporation) with extended application windows and reduced setback needs where injection depth and soil conditions protect water. These technologies improve nutrient recovery, reduce odor, and lessen surface runoff potential — a clear environmental upgrade that current permits fail to credit. MPCA has never acknowledged the role of this significant change in the past 25 years, whereas numerous soil health specialists will agree that it is better than what we were doing 25 years ago.
4. **Allow nitrogen stabilizers, split applications, and temperature triggers (<50°F soils) as BMP alternatives** in sensitive areas instead of blanket prohibitions. Producers need these tools to match manure N availability to crop demand without building unaffordable extra storage.
5. **Do *not* mandate cover crops statewide as a nitrate control surrogate.** Research and producer data confirm inconsistent establishment, tight fall planting windows, manure integration conflicts, and likely loss of transferee acres if required.
6. **If MPCA considers increased setbacks or soil testing triggers, scale them by hydrologic risk.** Many transferee acres will simply withdraw rather than absorb compliance costs, pushing more manure onto fewer fields or into commercial fertilizer substitution.

Q3. Should NPDES/SDS permit requirements (e.g., enhanced planning, visual inspections, fall BMPs, frozen-ground restrictions, wet-weather BMPs) extend below 1,000 AU?
No. For the scale of the dairies we are talking about we don't believe these changes are practical nor reflect the environmental risk with the practices voluntarily adopted since 1999.

Q4. How should MPCA address long-used existing manure storage areas for structural integrity?
Use a **risk-screen matrix**: age, design, proximity to water, liner type, documented leakage, and storage *duration actually used*. But moreover, this is the only area where we believe a regional

focus makes sense. Find the highest-risk areas of the state and start there to help farmers find cost-share or other opportunities for improvement.

Many smaller dairies rely on short-term stacks, daily haul, or seasonal reception pits; forcing full engineering assessments on low-volume, short-duration storages will divert scarce capital from higher water-quality returns. Where rule changes create retrofit triggers, grandfather compliant legacy systems built under prior code; unpredictable retrofit mandates exacerbate the regulatory risk we've highlighted.

Q5. Should smaller sites be required to have 9 months storage (current ≥1,000 AU standard)? If so, at what AU?

We **strongly oppose** a uniform 9-month storage mandate below 1,000 AU. Seasonal climates, cash-flow limits, land base access, and custom pumping capacity already strain application windows; additional storage would require large capital builds and create cascading scheduling conflicts across regions. Producers report they would need *additional storage*, *new cover crops*, and *more custom applicator availability* if seasonal restrictions tighten — signals that a 9-month rule is economically unrealistic.

Instead, allow a **menu**: daily haul, short-term stacking with weather contingency plans, shared/co-op storages, or incremental expansion supported by cost-share. Tie longer required storage only to documented high-risk hydrogeology plus available funding. Education on manure and nutrient value will provide far greater return to the state and dairy farmers than forcing additional storage – which will put smaller farms out of business.

Q6. WRAPS show nutrient/bacteria issues tied to livestock access to streams. How should rules address this?

First, educate: Help farmers and farm organizations understand which areas of the state have the highest risk and current "issues".

Encourage site-specific exclusion + managed access systems (fencing with stabilized crossings or limited watering points) rather than categorical bans that ignore topography, herd size, or season. Provide cost-share and credit participation in MAWQCP and similar conservation certifications to satisfy rule intent. Many dairies already implement rapid incorporation and manure transfer strategies to minimize runoff risk; do not couple stream access fixes with broad unrelated mandates (e.g., universal cover crops) that will sour participation. Producer feedback indicates that when compliance burdens rise too high, neighbors exit manure agreements, reducing the very land base that buffers nutrient loading.

Q7. How to address multiple feedlots under same ownership in close proximity (aggregation / separation distances)?

Allow farmers to be flexible. MPCA has changed, revised, and then revised again these rules in effort to find a best path forward. In the end, each situation is different. Two unrelated feedlots

across the road from each other can be seen as separate, where as the “mileage test” might pull two feedlots that are very related but use totally separate manure systems into one permit. This causes problems triggering NPDES and unplanned requirements.

Moreover, the current size limits of today cause more issues than they solve, and we’d suggest looking more at animal units over acreage x yield potential versus animal units alone. MPCA does not regulate feedlots so much as they regulate where and how the manure from feedlots is applied. Stay consistent in this and create more measures on ratios of animals to land rather than animal units.

Use a functional-system test rather than a pure distance rule: Are manure systems integrated? Are animals managed as a single herd? Is storage shared? A rigid distance threshold will incentivize paperwork games and discourage reasonable expansions. Because many farms stayed just under 999 AU to avoid permit burdens, overly broad aggregation triggers could retroactively force NPDES complexity onto modest, dispersed sites.

Q8. Minnesota law directs agencies to avoid overly prescriptive rules and to allow maximum flexibility while achieving environmental goals (Minn. Stat. §14.002). How to balance flexibility with nitrate & fish-kill concerns?
Adopt a **performance + incentives framework**:

- Offer a **scaled SDS bridge** and **fee waivers for compliant operators** (e.g., MAWQCP certified; multi-year good compliance record). Incentives to increase participation and data quality, and some sort of protection similar to the litigation protection provided by NPDES permits would allow this.
- Credit **advanced technologies** (direct injection, GPS-logged application, stabilizers, digital records) with extended windows/setback flex, delivering equal or better environmental outcomes at lower cost.
- Provide **BMP “menus”** producers can choose from based on soils, crop rotations, and weather rather than one-size mandates (e.g., cover crop *or* multi-year perennial *or* delayed fall application). Producer data show that multi-year crops can substitute for cover crop nitrate control where seasonal windows fail.

Flexibility is necessary because calendar cutoffs derived from limited weather stations don’t reflect actual field conditions statewide.

Q9. Other comments on existing rules or proposal.

- **Do not expand field inspection mandates** that add cost, delay, and biosecurity risk; focus inspection resources on complaint-driven or high-risk events. Producers report insufficient inspector timeliness and disease-transfer concerns when multiple sites are visited in a day – technology can replace or enhance these inspections.

- **Recognize labor scarcity** in rural areas; additional paperwork, seasonal bottlenecks, and infrastructure builds will divert labor from animal care and environmental practices that deliver real results.
- **Economic ripple effects:** When rules drive up compliance costs, counties often face unfunded mandates and declining tax bases as farms exit or shrink; please include fiscal notes that reflect these community impacts.
- **Market alignment:** Many processors and downstream brands are now investing in carbon intensity (CI) scoring, data platforms, and sustainability premiums. Rules that devalue manure or discourage data participation (by overburdening transferee acres) undercut those market opportunities. Producers already worry that heavier data / recordkeeping loads will push neighbors to synthetic fertilizer, severing nutrient recycling loops.
- **Commercial applicator capacity is limited;** tightening fall windows will overwhelm available services and strand manure in storages, increasing overflow risk. Survey respondents in our NPDES survey work flagged this capacity gap if new seasonal restrictions take effect.
- **Truly exempt pasture, as required by law.** There have been several instances of pasture-based dairies being turned into “feedlots” and being pulled into the program. The MPCA should work to exempt all pasture areas, even with a feedlot attached, and focus only on the feedlot areas. If an animal is on pasture, that means the growing nutrients do well to eliminate risk in that acreage. If the ground is bare or it is impervious surface, it makes sense to regulate within the feedlot program.

  One easy qualification to this pasture rule, to help save time and confusion, is any USDA Certified Organic facility. Those facilities should be exempt from the rule altogether in the areas that are growing vegetation where animals graze. This eliminates confusion and dedicates resources to higher risk areas.

Recommended Guiding Principles for MPCA Rule Drafting

1. Statewide Environmental Goals, Local Agronomic Flexibility
Environmental processes cross township and county boundaries; baseline rules should apply statewide. Yet the *pathways* to reach those goals must flex with soils, crop rotations, and climate bands. Avoid region-only mandates that stigmatize certain areas and fragment compliance — a concern we’ve heard repeatedly from producers and neighbors.
2. 10-AU Feasibility Screen
Before codifying any new requirement, ask: *Could a 10-AU farm comply with minimal capital and record burden?* If not, move it to guidance, BMP menu, cost-shared tier, or permit condition rather

than baseline rule. The regulatory risk of retrofits to fixed facilities (e.g., calf housing pads) is real and expensive.

3. Incentives Over Penalties

Rebuild the SDS tier (300-999 AU) as a voluntary incentive-rich, lower-burden bridge that encourages data sharing and BMP adoption without the full NPDES cost profile.

4. Credit Proven Technologies

Direct-injection/dragline systems, GPS logging, stabilizers, rapid incorporation, and digital manure transfer tools all reduce environmental risk and should earn compliance flexibility.

5. Keep Transferee Acres in the System

Simplify downstream recordkeeping; otherwise, transferee fields will default to commercial fertilizer and the nutrient recycling loop will collapse.

6. Science-Based Alternatives to Blanket Cover Crop Mandates

Given documented establishment limits and survey data, allow perennial crops or other N-mitigation practices to substitute for cover crops in rule compliance matrices.

7. Practical Inspection & Biosecurity Protocols

Target inspections where risk warrants; producers fear inadequate inspector timeliness and pathogen transfer.

Voluntary Practices Widely Adopted Since 1999 (Support & Build Upon)

Minnesota dairy farms — large and small — have steadily adopted advanced nutrient stewardship practices without blanket mandates. These include:

- Site-specific Nutrient Management Plans (NMPs) tied to soil and yield goals.
- Manure injection / low-disturbance incorporation and dragline delivery systems that reduce surface loss.
- Routine manure nutrient testing; increasing use of mobile labs and rapid analysis to match crop needs.
- GPS-enabled variable-rate placement and auto-logged application records.
- Solid-liquid separation and composting that stabilize nutrients and reduce hauling burdens.
- Covered / lined storages (where feasible and funded) that improve runoff control.
- Adoption of multi-year perennials (alfalfa) as functional nutrient capture where cover crops are impractical.

These farmer-led improvements demonstrate why incentive-based approaches work — and why punitive, one-size mandates risk reversing progress.

Appendix A – Cost & Feasibility Screen for Potential Rule Elements (<1,000 AU Focus)

Impervious Calf Hutch Pads: High capital retrofit; limited environmental return when managed solids are scraped to fields per NMP; retrofit challenge documented where facility siting cannot be easily changed after construction.
Cover Crop Mandates: Low establishment success; conflicts with manure timing; risk of losing transferee acres.
Extended Storage (9 mo.): Drives need for new pits; survey respondents anticipate needing added storage and commercial applicator scheduling; significant capital outlay.
Expanded Transferee Records: Likely to push recipients to synthetic fertilizer; undermines recycling loop.
Seasonal Blackouts / Vulnerable Area Limits: Poor alignment with real weather; increases storage/labor costs; relies on incomplete statewide averages.
Expanded Field Inspection Windows: Producer concerns about inspector availability and biosecurity.

Appendix B – Incentive & Equivalency Concepts

- **Voluntary SDS Bridge Permit (300-999 AU)** with reduced fees and phased reporting to encourage voluntary enrollment and data sharing.
- **Fee Waivers / Reduced Administrative Burden** for certified MAWQCP farms or multi-year clean compliance records to keep manure moving to transferee acres.
- **Technology Credits:** Extended windows or reduced setbacks for documented direct injection, GPS-logged application, or rapid incorporation.
- **BMP Menu Substitutions:** Allow perennial stands in lieu of cover crops where agronomically justified.

Closing

Minnesota's dairy farmers want practical, science-based regulation that protects water and allows farms to thrive. The advances in nutrient management technology over the past quarter century — and the voluntary adoption we've achieved together — prove that **collaborative, incentive-driven pathways deliver results**. We stand ready to work with MPCA, sister agencies, counties, and community partners to co-design rules that achieve environmental goals *and* keep family dairy farms viable across Minnesota.
Please contact me with any questions or to schedule further discussion.

July 22, 2025

Minnesota Environmental Partnership (MEP) thanks the Minnesota Pollution Control Agency for working to update the state's Animal Feedlots Rule. Our scientific understanding of the impacts of these feedlots has advanced significantly in the 25 years since the rule was last revised, as has the scale of challenges to our clean water and climate. With both surface waters and groundwater increasingly impaired and our climate warming, Minnesota should use this opportunity to better steward our natural resources with improved feedlot standards.

MEP and our member organizations support the following updates to the rule to protect water quality and human and ecological health:

- Implement stricter limits on manure application to farm fields in areas where groundwater is especially vulnerable. These areas, including the karst region in the southeast, are struggling with the impacts of nutrient pollution linked to cancer, birth defects, and other conditions.

- Lower the number of annual units at which National Pollution Elimination System (NPDES) and State Disposal System (SDS) are required to 600 animal units. Currently, many feedlots skirt greater regulation by operating just under the permitting limit; lowering the threshold will enable more waters to be more adequately protected.

- Require feedlots with NPDES and SDS permits to closely monitor their manure discharges to protect nearby groundwater and streams. Permit conditions are only effective if enforced and can only be enforced with accurate information on discharges.

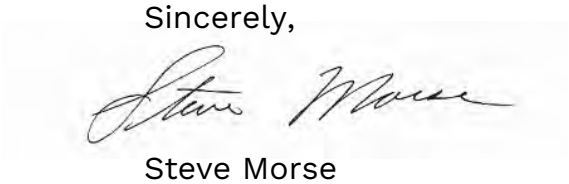
- Change how multiple small feedlots with the same owner are regulated. Currently, an owner of multiple feedlots, even feedlots right next to each other, can skirt stronger regulations by keeping them as "separate" operations, though the total impact is the same as a large feedlot. Minnesota's environment isn't protected by creative accounting measures, only by science-based standards.

- Require more rigorous reporting on manure transfers.

- Make more manure managing data and mapping available to the public, including information about digesters and manure spreading plans. Communities near feedlots deserve the opportunity to understand the impacts that manure uses may have on their nearby environment.

We appreciate the opportunity to share our views - and the priorities of our member groups and the thousands of Minnesotans they represent - during this comment opportunity. MEP will remain engaged on this important rulemaking process as it moves forward. We urge the MPCA to prioritize the health of Minnesotans, our waters, and our climate in the development of this rule.

Sincerely,



Steve Morse

MPCA Animal Feedlot Rules - Comment Requesting Stronger Rules to Protect Minnesota Waters

From Bryan Winget <imagemakersphoto@everyactioncustom.com>
Date Mon 7/21/2025 10:18 AM
To addison.otto@state.mn.us <addison.otto@state.mn.us>

Dear Rule Coordinator Addison Otto,

Now it's the time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Asa Laker, fisherman, and parent I am concerned about manure runoff in Minnesota waters resulting in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Bryan Winget

Dear Rule Coordinator Addison Otto,

Minnesota has water resources,a treasure to protect so it's critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure. As a public health trained professional I discern consequences of failure to regulate in people's health.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Mary Busch

Dear Rule Coordinator Addison Otto,

As someone who knows that clean water is necessary for the health of all life on Earth, and who cares about the quality of water in Minnesota, I am writing to express my concern about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

As someone has stated, "We are literally drinking and swimming in manure." Nitrates in manure runoff from Minnesota's 23,000 Concentrated Animal Feeding Operations (CAFOs), have even contributed to the Gulf of Mexico Dead Zone. Yet each year, these feedlots continue to get bigger, and the pollution becomes more concentrated.

In Minnesota, manure runoff waters result in fish kills. Swimming is unsafe due to E. coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning, which has likely
contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of

degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Thank you for the opportunity to comment. I urge you to remember that water if life and to please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Dear Rule Coordinator Addison Otto,

Feedlot response
Amy and Val Cordry
26006 County Road 9
Winona, Mn 55987

Nitrates in manure runoff from Minnesota's 23,000 feedlots, also known as Concentrated Animal Feeding Operations (CAFOs), even contribute to the Gulf of Mexico Dead Zone. But each year, pollution becomes more concentrated and feedlots get bigger in Minnesota. Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health.
Nitrates in manure runoff from Minnesota's 23,000 feedlots, also known as Concentrated Animal Feeding Operations (CAFOs), even contribute to the Gulf of Mexico Dead Zone. But each year, pollution becomes more concentrated and feedlots get bigger in Minnesota. Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths. Row crop agriculture is the main source of nitrate in southeast Minnesota. A comprehensive study completed in 2013 of nitrogen sources in the Lower Mississippi River Watershed in Minnesota (the basin covering most of southeast Minnesota) estimates that 89% of the nitrogen loading to surface waters originates from cropland, with a substantial portion moving downward through groundwater to surface waters.
Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health.
Safe drinking water is essential for the health and well-being of all Minnesotans. In southeastern Minnesota, approximately 300,000 people rely on 93 community water systems that all rely on groundwater as their source and more than 93,000 rely on private wells.
GENERAL RECOMMENDATIONS:

More living roots on the ground for longer periods.
Support alternative crops and land use
Support and increase implementation of nitrogen Best Management Practices
Education and outreach
Focus on sustainability for future generations.
Lift up locally driven community collaboration.
Outreach, education, and building trust are important components of making systems change.
Speak with one voice on the importance of testing wells and protecting health.
Use the best available science and data.
Agree that we have enough information about the causes of nitrate contamination to act.
Recognize solutions require both taking responsibility and supporting those willing to take risks in the interest of change.
Recognize that investment is needed at multiple scales for farming systems and markets to change.
Structure programs to be simple to use – remove red tape.
Embrace flexibility rather than a one-size-fits-all approach.
Make sure affected groups are at the table.
Drilling wells into deeper aquifers will not solve nitrate contamination in southeast Minnesota.
Additional approaches are needed to address the nitrate issue in southeast Minnesota.

SPECIFIC RECOMMENDATIONS:
a. Replicate programs like the Olmsted County Groundwater Protection and Soil Health Program model to other counties throughout the region. The program should have these core principles: locally led, flexible, streamlined implementation, and outcome-based/tiered payments.
b. Support federal and state programs that enroll more acres in conservation

Sincerely,
Amy and Val Cordry
26006 County Road 9 Winona, MN 55987-5922

Dear Rule Coordinator Addison Otto,

Ridgeway, a small community very near where i live in Winona Minnesota, has a community well. They had to drill a new one into another aquifer due to nitrates in the water. What happens if this aquifer becomes too high in nitrates? And why is this happening in the first place?? If we cant even have clean and pure drinkable water somethng is terribly wrong!!
Please stand up for clean drinking water for us, our children and grandchildren. That is YOUR job. Thank You.

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Dear Rule Coordinator Addison Otto,

Feed lot pee & poop should be captured and processed just like human waste is. Build mini sewer and treatment. Or truck it to human waste treatment plants.
This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or

compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Mr. Russ Erickson

Dear Rule Coordinator Addison Otto,

It is essential that the animal feedlot rules be rewritten to stop toxic nitrate pollution in Minnesota's waters. I am very concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Clean water is essential and manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure results in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. And manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. Let that sink in. It poisons babies. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths. That is beyond intolerable.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. It is essential that the MPCA address these dangerous impacts by developing strong rules. Therefore, I am requesting that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that the MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.

7. MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year. Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Thank you for the opportunity to comment. I urge you to take strong measures to protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. I am counting on you, and the State of Minnesota needs strong action from you.

Sincerely,
Judy Gronquist Grant

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure. Please do the necessary changes now!

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you. It is urgent that you rewrite the feedlot rules. Thanks.

Sincerely,
Seymour Gross

Dear Rule Coordinator Addison Otto,

Please act now to keep our water clean. As an avid outdoor adventurer of MN waterways, I can tell you how this is showing up, and it's terrible. The waters are full of every danger they've outlined such as algae blooms coating river surfaces and shores. My doctor and my vet confirmed that my dogs and I have both gotten infections from being near polluted water too long—this is in state parks!!!

Right now, is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. There are so few checks and balances and this is one within reach in order to preserve water quality. I am gravely concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. Please, we ask that you make the following changes to the Animl Feedlot Rules:

1. MPCA rules must require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules must set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules must prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules must state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of

degradation in waters that are not polluted.

5. MPCA rules must strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules must prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. Please, we are counting on you.

Dear Rule Coordinator Addison Otto,

I have been making personal choices to protect Minnesota water ways, one of them is refusing to purchase or consume meat. I do this for many reasons, but one is the protection of the environment from containments thats are a result of inhumane concentrated animal feedlots, particularly in water.

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

Dear Rule Coordinator Addison Otto,

As a natural resources professional I know this is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Sincerely,
Mr. Peter Leschak

Dear Rule Coordinator Addison Otto,

I thank you for the opportunity to provide comments on the MPCA proposed revisions to the Animal Feedlot Rules. I am submitting these comments through the personalized response provided by Water Legacy after repeated efforts to provide direct comments on your Website failed. Often, this effort ended in a "Website Time Out" message. This is no way to foster public comment. I'll begin with a bit of background information on myself. Much of this experience is based upon my work with MDNR. However, I wish to emphasize that in no way should my words be construed to mean that I speak for the MDNR; they are my own words based on my experiences.

I am a retired hydrogeologist with some 37 years of experience in the fields of limnology, hydrogeology and hydrology. I consider myself to be a field geologist; that is, most of my experience has been based on field observation. This work began in 1976 as a research scientist on the Regional Copper-Nickel Study. From there, I became the first DNR Area Hydrologist to represent NE Minnesota where I managed DNR's water permit program and assisted local governments in the development and management of their shoreland and floodplain management programs. Later, I helped lead in the development and management of the 1989 revision of the statewide shoreland management rules through a series of workshops across the state. Here is what I learned from Region V located in SE Minnesota that relates directly to the current issue.

As many know, SE Minnesota is part of the Driftless Area. That is, it was never covered by glaciers or glacial outwash. The native rock is composed largely of limestone where karsts and fractured limestone has led to sinkholes, but also the emergence of springs whose clear, cool water has resulted in many DNR designated trout streams.

Why is this important? Simply because improper placement or enlargement of feedlots can easily result in the pollution of these sensitive waters. It is of utmost concern in SE Minnesota, but also a concern anywhere feedlot runoff has the potential for polluting adjacent streams and wells. Therefore, I urge you to specifically address these issues in your proposed rules changes.

Sincerely,

Peder H. Otterson

Sincerely,

Mr. Peder Otterson

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure. Although concern for water quality in and near the Boundary Waters is widespread in Minnesota and beyond, that is a concern to maintain high quality water. Feedlots and their pollution are in important PRESENT concern that must be handled. We must deal with agricultural runoff NOW to prevent increased environmental degradation across all of agricultural Minnesota.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots

based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Dear Rule Coordinator Addison Otto,

Frankly, I am embarrassed. As a Minnesota citizen, I have seen the ongoing damage to our state's lands and waters, flora and fauna caused by manure spills and excess runoff from manure spread on farm fields.

Living in the land of 10,000 lakes, we should know better. Actually, we do know better.

It's time to take a stand.

As you work to rewrite the feedlot rules, please keep the destruction caused by runoff, seepage, and spills from animal feedlots foremost in your thoughts.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that “stricter” requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all

pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. The people of this state, nation and world are counting on you.

Dear Rule Coordinator Addison Otto,

It's past time to clean up Minnesota's waters so that we're not drinking and swimming in cow manure runoff and seepage. Do you think allowing such pollution is ok? Then please DO SOMETHING in your role with MPCA. It's past time to value people's health above corporate profit.

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming (hey, we're Minnesotans -- this is what we do, swim in our lakes and streams!) is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers (ugh), producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.

MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Dear Rule Coordinator Addison Otto,

We must, YOU must rewrite animal feedlot rules to halt toxic nitrate pollution in Minnesota's waters. I worry about the future and the very present when I read about the serious problems of runoff, seepage, and spills caused by animal feedlot manure. Size doesn't matter. Manure in any amount pollutes.

Manure runoff in Minnesota waters results in fish kills, makes swimming unsafe due to E.coli bacteria, leads to blue-green algae blooms in shallow lakes and rivers where it produces toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. I thought that happened only in third world nations. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Currently, Minnesota animal feedlot rules fail to protect water, fish, wildlife or human health. I urge the MPCA to address the following dangerous impacts by developing strong rules and enforcing them. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution, the rules must be enforced,

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or

compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide does have adverse health effects, including respiratory and neurological harm.

Thank you for letting me share my concerns. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. Minnesota depends on you to protect our waters, our precious life-giving resource.

Sincerely,
Doretta Reisenweber

Dear Rule Coordinator Addison Otto,

I am writing to urge the Minnesota Pollution Control Agency to rewrite and strengthen the state's animal feedlot rules to stop toxic nitrate pollution from concentrated animal feeding operations (CAFOs).

Current rules are failing to protect our water, wildlife, and public health. Nitrate and manure runoff from feedlots are directly responsible for:
- Mass fish kills,
- Toxic blue-green algae blooms,
- E. coli contamination that makes over 50% of southern Minnesota's lakes and rivers unsafe for swimming and recreation.

Nitrate pollution threatens rural Minnesotans who rely on private wells. It can make infant formula preparation dangerous, leading to blue baby syndrome which has contributed to at least 24 infant deaths over recent decades.

Minnesota's feedlot rules do not protect our water or health:
- No maximum size for feedlots;
- No permit required for medium-sized feedlots, which produce 43% of manure;
- No prohibitions in sensitive karst regions;
- No monitoring of manure storage or runoff from application fields;
- No enforceable nitrate limits to protect surface waters;
- No restrictions on antibiotics in feed, which harm aquatic life;
- No meaningful control of hydrogen sulfide emissions affecting nearby communities.

Even worse, our state's pollution contributes to the Gulf of Mexico dead zone.

I urge the MPCA to:
1. Set maximum feedlot sizes that will drastically reduce pollution;
2. Require permits for all feedlots, including medium-sized;
3. Prohibit CAFOs in karst areas;
4. Enforce nitrate limits for both groundwater and surface water;
5. Ban routine antibiotic use in livestock feed;
6. Require modern, lined manure storage systems;

7. Monitor storage facilities' and manure runoff from application fields;
8. Regulate hydrogen sulfide emissions.

Minnesotans deserve rules that prioritize clean water, healthy communities, and a livable environment. Please act accordingly.

Sincerely,
Mr. Wesley Sisson
21120 Shallow Lake Rd Warba, MN 55793-1634

Dear Rule Coordinator Addison Otto,

This is a critical moment to rewrite Minnesota's animal feedlot rules and put a stop to the toxic nitrate pollution threatening our waters. I'm deeply concerned about the serious damage being caused by manure runoff, seepage, and spills from feedlots.

In Minnesota, manure runoff leads to fish kills. E. coli from animal waste makes swimming dangerous. Excess nitrates from manure fuel toxic blue-green algae blooms in shallow lakes and rivers—harming wildlife and putting people at risk. When manure seeps into well water, it can contaminate the water used to prepare infant formula, leading to nitrate poisoning (methemoglobinemia or "blue baby syndrome"). Over the past few decades, nitrate-contaminated drinking water likely contributed to the deaths of 24 infants in Minnesota.

Right now, Minnesota's feedlot rules don't do enough to protect water, wildlife, or human health. I urge the MPCA to take meaningful action and adopt stronger rules. Specifically, I'm asking for the following changes:

Require pollution permits (NPDES/SDS) for medium-sized feedlots with 300–999 animal units—this group is responsible for 43% of all manure produced in Minnesota.

Set maximum limits on the size of individual feedlots and the total number of animal units allowed within any watershed or local area. These limits should be based on hydrology and the impact on ecosystems and public health.

Ban new or expanded feedlots in areas with karst geology, where groundwater is especially vulnerable. There's no evidence that existing "stricter" standards in these areas are actually preventing pollution.

Enforce "no discharge" requirements. Ensure all feedlots meet pollution limits, reduce contamination in already-impaired waters, and prevent degradation in clean ones.

Strengthen the minimum technology requirements for permitted feedlots. This includes modern liner systems and leak detection. Concrete or compacted soils shouldn't be assumed to prevent manure seepage.

Ban all winter application of manure, both wet and dry. Current rules don't account for increasingly unpredictable freeze-thaw and snowmelt patterns due to climate change, which increase the risk of runoff.

Require feedlots to comply with air quality rules at least 344 days per year. State law only allows 21 days of exemption annually, and that doesn't justify the health impacts of prolonged exposure to emissions like hydrogen sulfide, which is known to cause respiratory and neurological harm.

Thank you for the chance to comment. I'm asking you to act now to protect Minnesota's waters, wildlife, and communities from toxic nitrate pollution. We're counting on you.

Sincerely,
Thomas Sullivan

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure. While all of the following points are valid and important to Minnesotans, imagine what it would be like to walk into a cloud of airborne manure being spread over a field. It happened to me while riding my bicycle on a country road. The ag worker did not stop spreading manure until I was past or moderate his path even though the wind had caught up the noxious fumes. We nedd more rules tom protect our youth in the future!

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Ms. MaryAnn VandeVusse

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Tim Wallace

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Mr. Larry Bogolub

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Jaci Christenson

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Cecilia Dingledy

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Ms. Joyce Frohn

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Solo Greene

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Mr Norm Herron

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
arielle johnson

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Mrs. Pamela Martin

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Sophia Patane

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Riha Rothberg

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
DeeAnn Stenlund

Dear Rule Coordinator Addison Otto,

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Frank Verderame

Minnesota Pork Producers Association Comments on Planned Amendments to Rules Governing Animal Feedlots – Minnesota Rules, Chapter 7020

Revisor's ID Number R-4928
OAH Docket No. 25-9003-40661

Thank you for the opportunity to provide input during the scoping period of the 7020 Feedlot Rule review. On behalf of Minnesota's more than 3,000 family pig farmers, the Minnesota Pork Producers Association (MPPA) submits these comments to support a rules framework that protects water quality, sustains rural economies, and enables science-based, practical compliance by farms of all sizes.

Pig farmers in Minnesota care deeply about being good neighbors, good stewards of the land, and responsible food producers. A revised 7020 Rule should reflect shared values: environmental protection, regulatory clarity, and the flexibility needed to innovate and improve.

Anchor the Rules in Science, Practicality, and Flexibility

Rule revisions must be grounded in sound science, agronomic practicality, and a recognition of on-farm diversity.

Minnesota's 7020 rules are already among the most comprehensive in the Midwest and exceed the requirements in many neighboring states. This includes more robust permitting for feedlots over 1,000 animal units (AU). Any changes should modernize standards—not add unnecessary burdens—and continue to allow farmers to manage their operations in ways that protect water, land, and air while maintaining generational viability.

We urge the MPCA to preserve flexibility and avoid one-size-fits-all mandates that do not account for regional differences in soil type, cropping systems, and manure handling and storage systems.

Recognize Data-Driven Nutrient Management as a Best Practice

Farmers should be explicitly allowed to use actual farm-level crop data (3–5 year averages) to calculate manure application rates.

University of Minnesota recommendations offer a valuable baseline but do not always reflect the precision agriculture tools and management data available on today's farms. Feedlot rules should:

- Allow farmers to use their own data to match nutrient supply to crop removal.

- Recognize that data-driven management can improve nutrient use efficiency and reduce loss.
- Avoid imposing rigid regional rules that would complicate compliance and reduce effectiveness. Data-driven management will allow farmers to be responsible for their unique cropping and field features, without the need to physically draw lines and increase confusion for compliance and enforcement.

Integrate Existing Buffer and Setback Protections

Account for existing riparian buffers (103F.48 statute) and setbacks when considering additional manure application restrictions.

Current rules already require setbacks for sensitive features such as karst, wells, and water bodies. Farmers also comply with the 103F.48 statute requiring vegetative buffers along public waters and ditches. These should be acknowledged in the rules as contributing to nutrient management and water protection goals.

Adding additional buffer or setback requirements without crediting existing compliance would be duplicative and inequitable.

Expand and Diversify Best Management Practices (BMPs)

Broaden the menu of BMPs available to farmers rather than limiting or prescribing specific practices.

No two farms are the same. Feedlot rules should recognize a variety of BMPs that can achieve the same environmental outcomes. For example:
- Manure injection, variable rate application, and cover cropping can all enhance nutrient retention and reduce runoff.
- Allowing choice among effective practices encourages adoption and continuous improvement while leaving room for innovation and technology adoption.

Limiting options or prescribing a narrow set of BMPs would undermine flexibility and innovation. Farmers need adaptable tools to match local conditions and available resources.

Evaluate Practical and Economic Impacts of Proposed Changes

All proposed rule changes should be subject to agronomic, technical, and financial analysis, especially those involving infrastructure or timing constraints.

- Revisions that affect construction, application timing, or equipment needs may significantly increase costs with little environmental benefit. These should be avoided.
- Shortening application windows could exacerbate labor shortages during peak seasons, risking noncompliance or operational delays.

MPCA should conduct impact assessments and consult with farmers, engineers, and financial experts before finalizing rule language.

Support Education and Implementation Resources
Accompany rule updates with targeted education and training for feedlot owners and manure applicators.

Chapter 7020 applies to farms of all sizes. Effective implementation depends on clear communication, accessible training, and support materials that reflect real-world conditions.

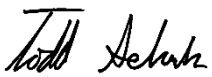
MPCA and its partners should:
- Invest in farmer-focused guidance materials.
- Offer timely workshops and re-education opportunities.
- Ensure that revised rules are not just enforceable, but understandable and achievable.

Collaboration builds trust and results in smarter regulations.

Minnesota's pig farmers are committed to protecting water quality, strengthening rural communities, and producing food sustainably. The 7020 Feedlot Rules are critical to that mission. We encourage MPCA to adopt revisions that reflect flexibility, data-based decision making, and a strong partnership with farmers.

Thank you for your leadership and for considering these comments. We look forward to continued collaboration throughout the rulemaking process.

Sincerely,



Todd Selvik
President, Minnesota Pork Producers Association

Re: Public Comment on OAH Docket No. 25-9003-40661
Planned Amendments to Rules Governing Animal Feedlots, *Minnesota Rules*, Chapter 7020

Dear Mr. Moore,

Thank you for the opportunity to provide public comments on planned amendments to rules governing animal feedlots under *Minnesota Rules*, Chapter 7020. Winona County Soil and Water Conservation District (SWCD) staff have participated in MPCA listening sessions and offer the following comments and recommendations for consideration:

Comments

1. **Cost of Compliance**
   Many producers are concerned about the financial burden associated with the planned amendments. Implementing feedlot improvements, manure storage and other best management practices (BMPs) is costly. Currently, state and federal cost-share funds - administered by SWCDs, NRCS, watershed districts and similar agencies - are limited. Without additional or dedicated funding, producers may be unable to comply with the planned feedlot rule changes.

2. **Limited Technical Assistance Capacity**
   Agencies like SWCDs and NRCS, providing technical assistance, lack the staff capacity to support producers in planning and implementing feedlot improvements, manure storage systems and related BMPs projects. Increased technical demand from these rule changes will further strain existing limited resources unless staffing support is expanded.

3. **Challenges for Small Operations**
   Small producers in the bluff regions of SE Minnesota face unique barriers. Limited labor, aging operators and difficult terrain make implementation of new practices challenging. For example, transitioning from winter manure hauling to long-term storage necessitates more spring application - coinciding with planting season. This may result in delayed planting or the need for hired labor, both financially burdensome.

   Producers unable to comply may leave livestock production which will reduce distributed feedlots and increase row crop acreage operated by renters. Renters are often less invested in conservation, leading to fewer BMPs, increased erosion and degraded water quality.

4. **Impact on the SE Minnesota Bluff Landscape**
   Rule changes could unintentionally encourage the consolidation of small contour strip fields into larger row cropped parcels using larger equipment - practices that increase erosion on sloped fields. Livestock declines also reduce hay and pasture acres, weakening perennial cover crucial for protecting fragile bluffland soils. Expansion of row crops in this area could further contribute to erosion, nitrate leaching and water quality decline.

Recommendations

1. **Expand Cost-Share and Loan Funding**
   Provide expanded state and federal funding for cost-share and AgBMP loan programs to assist producers in implementing practices meeting new feedlot rule changes.

2. **Revise the Animal Unit (AU) Cap**
   Adjust the current 500 AU cap to allow all affected producers - regardless of size - to access financial assistance for feedlots.

3. **Increase Funding for Technical Assistance**
   Provide increased funding to SWCDs, NRCS and private Technical Service Providers (TSPs) to expand capacity and support services for plan writing, design and engineering services.

4. **Implement a Stepped Timeline**
   Allow for phased implementation and flexible timelines so producers can reasonably adapt to new feedlot requirements.

5. **Retain Contour Strips and Perennial Vegetation**
   Prioritize support for producers in the SE Minnesota bluff region that utilize contour strips and perennial vegetation in their crop rotations.

6. **Offer Compliance Alternatives**
   Provide additional voluntary compliance pathways, such as participation in the Minnesota Agricultural Water Quality Certification Program (MAWQCP), to acknowledge producers who already implement conservation practices.

Please feel free to contact Winona County SWCD with any questions or requests for clarification.

Sincerely,

Amanda Gentry
Resource Conservationist
Winona County SWCD

Emily Wegener Attachment

At New Fashion Pork we are committed to raising our pigs and farming our land in ways that are better than the generations before us, utilizing modern methods and current technologies available in our industry. Doing more with less by embracing the natural processes nature provides. As pork producers it is our responsibility to protect and preserve our water resources. We actively embrace state and local requirements to safeguard and improve water quality. We implement and aggressively monitor water-conservation practices as part of our nutrient management plans. At NFP our goal is to be on the proven cutting-edge of new technologies that are relevant and applicable to the pork industry. We oppose greater regulations to Minnesota feedlots but rather a more logical approach.

Currently the manure recommendations are based off the University of Minnesota's maximum return to nitrogen (MRTN). We believe this recommendation is not best suited for the entire state and can be to variable based off of things happening in the economy. We believe application rate recommendations could be improved by basing them off field specific data.

First reason to change to a yield-based recommendation would be due to Minnesota having varying soil types and field landscape throughout the entire state. By basing the manure recommendations from actual field or county yield data this will better align with regional best practices without having to define specific regions. This may result in an increased nutrient balance and would better align with the surrounding states like Iowa and South Dakota who use this same approach for nutrient recommendations.

Secondly the MRTN is designed to optimize nitrogen application rates based on economics which is constantly changing each year due to comparing the value of manure to commercial fertilizer prices. Commercial fertilizer prices can change rapidly to things that may not be occurring in our region as well as change throughout the year due to supply and demand. Having a crop removal rate based on actual yield ensures replacing what the crop takes off to best capture the economic value of all nutrients not just

nitrogen. This helps better reflect the true value of the manure as it would be applied in line with field specific nutrient removal.

Lastly by following a crop removal recommendation based on actual crop yield data, encourages a data driven management approach and may encourage more precision or variable rate technology that increases plant nitrogen utilization. A targeted nitrogen removal rate can be used to allow for some consistency in nitrogen management. Data driven yield rates with anticipated nitrogen removal rate allows flexibility for those who may not have the most up to date technology.

Over time this helps maintain the soil test levels within optimal ranges for a balanced fertility management program. Manure is a very valuable asset that needs to be used to enhance and protect crop production, not restrain it, all while still protecting our water resources. We believe a science and data driven approach accomplishes this. Not all farms are the same, allowing flexibility and a variety of BMP's allows for options to choose what will be the most impactful for each field.

As equipment costs have increased there has been an increase in custom applicators applying the manure. Increased education to custom applicators would be very beneficial in ensuring the current rules are understood instead of just increasing regulation. This would be an opportunity for feedlot owners and custom applicators to stay up to date with any new research that the University of Minnesota is working on or has completed. Education should be led by the University of Minnesota, MPCA and watershed quality organizations. It is a collaborative effort to spread information and education to continue to improve water quality. Bridging the gap between all parties involved in the application of manure could help increase the efficacy of the current rules in place without creating new ones.

We don't believe there needs to be any changes to the current permitting thresholds. Regardless of what the thresholds are, producers are going to build their operations for what it is capable regardless of what the threshold is. Changing these thresholds will not accomplish any benefit to water quality improvements.

The opportunity to provide feedback is greatly appreciated.

CONSERVATION MINNESOTA

July 22, 2025

Minnesota Pollution Control Agency
520 Lafayette Road N
Saint Paul, MN 55155

Pollution Control Agency,

Minnesotans should be able to trust that the water we drink, swim in, and fish in is clean and safe. But pollution from animal feedlot manure threatens all of this—and Minnesota is home to 18,000 feedlots that collectively produce tens of millions of tons of manure each year.

We collected 415 signatures from Minnesotans who support strong protections from animal feedlot pollution. As you begin the process of revising the rules around how animal feedlot operators manage the manure they produce, these members would like to ask you to prioritize safe, clean water for all Minnesotans.

Members have signed on with this statement:

> "**I support strong protections from animal feedlot pollution. Safe, clean water for all Minnesotans should be our top priority.**"

Thank you for your consideration,

Nels Paulsen
Policy Director
Conservation Minnesota

Minnesota Pollution Control Agency
520 Lafayette Road N
St. Paul, MN 55155-4194

Disclaimer: The opinions expressed herein are our own and do not necessarily reflect the views of the Johns Hopkins University.

Dear Commissioner Kessler,

Thank you for the opportunity to comment on the Minnesota Rules Chapter 7020 governing animal feedlots (Revisor ID: R-04928).

We are researchers at the Johns Hopkins Center for a Livable Future (CLF), an interdisciplinary academic center at the Johns Hopkins Bloomberg School of Public Health dedicated to advancing equitable, resilient, and sustainable food systems through science and systems-based approaches. CLF has actively researched the public health implications of industrial animal agriculture since our founding in 1996.

As the Minnesota Pollution Control Agency (MPCA) begins rulemaking on planned amendments to the rules governing animal feedlots, we commend your efforts to gather new information, research and understanding regarding agriculture and the environment. In this comment, we first provide a brief explanation of the link between agriculture and public health as it pertains to feedlots and the application of manure to agricultural land. Next, we provide references to key research on manure application and water quality, including the health effects of high nitrate levels in surface and groundwaters.

1. Impacts of feedlots on environmental public health

Agriculture is a major contributor to the degradation of local community environments and water sources in the US. Research has shown that many of these communities located near large animal feedlots bear the undue burdens of poor environmental quality, poor health and poor economic conditions and that this is experienced disproportionately more by communities of color, low-socioeconomic status and vulnerable populations.[1] These conditions are emblematic of the environmental justice issues faced by many rural communities. We highlight this point as the MPCA has highlighted its commitment to environmental justice in decision-making. We urge the agency to consider this lens and the disproportionate impacts that revisions to the animal feedlot rules may have on already burdened communities in Minnesota.

The agricultural application of chemical fertilizers and manure are key sources of environmental and water pollution that compromise our environment and harm public health. Overapplication of manure and waste from these facilities can contaminate surface and groundwater with an array of health hazards.[2,3] For example, antimicrobial residues[4], pathogenic bacteria and antibiotic resistance genes[5] have been found in surface and groundwater near concentrated poultry feeding operations. One study conducted in the Chesapeake Bay watershed found higher levels of nitrates (a form of nutrient pollution) and antibiotic-resistant pathogenic *E. coli* in waterways

closer to poultry farms with larger numbers of animal[6]. Similarly, antibiotic-resistant *Salmonella* and *enterococci*, as well as fecal indicator bacteria[7], were detected in the surface waters where swine waste runoff occurs. Numerous studies have demonstrated that humans can be exposed to waterborne contaminants from livestock and poultry operations through the recreational use of contaminated surface water and the ingestion of contaminated drinking water.[8,9]

2. Additional resources on the application of manure and water quality

Given that the MPCA is seeking new information and research on the impacts of manure practices on water quality and public health, we strongly recommend that the agency review and incorporate findings from the following (and referenced) scientific studies and resources into its rulemaking:

- Jones, CS (2024). Water Pollution – Regional, National and Global Impacts. In J. Merchant & R. Martin (Eds.), *Industrial Farm Animal Production, the Environment, and Public Health*. Johns Hopkins University Press.

Specifically, regarding high levels of nitrate in surface and drinking waters:

- Exposure to elevated levels of nitrates in drinking water is associated with adverse health effects, including cancer[10,11] and birth defects[12].

Specifically, regarding nutrient runoff and the impacts of climate change:

- Nutrient runoff (including nitrogen and phosphorus) has also been implicated in the growth of harmful algal blooms which may pose health risks for people who swim or fish in recreational waters, or who consume contaminated fish and shellfish.[3,13] Exposure to algal toxins has been linked to acute gastrointestinal illness, liver damage, and other adverse health effects.[14,15] Harmful algal blooms and water contamination events are expected to occur more frequently due to extreme weather events induced by climate change[16].

We look forward to reviewing and further commenting on any forthcoming revisions to the Rule. Thank you for considering our comments.

Sincerely,

Sara Lupolt, PhD, MPH

• CHAPTER 2

Water Pollution—Regional, National, and Global Impacts

Christopher Jones

The increased commercial availability of macronutrients in the decades following World War II enabled farmers to decouple the production of commodity crops from livestock production. For example, use of nitrogen fertilizers derived from the Haber Bosch process of ammonia synthesis[1] increased 13-fold from 1945 to 1972.[2] As a result, farmers no longer needed to rely on nutrients supplied by animal manures or, in the case of nitrogen, biological fixation of atmospheric nitrogen by legumes in symbiosis with bacteria.[3]

As the demand for meat has continued to remain strong, especially in First World countries,[4,5] food animals have been concentrated onto fewer and fewer farms where efficiencies of production can be optimized. In the US state of Iowa, the number of farmers raising hogs decreased from 65,000 in 1980 to 10,000 in 2002 and to fewer than 5,000 at present.[6] However, the average number of hogs raised by an individual farmer has increased from 200 to 4,700 in that time span, while the total number of hogs in the state has grown from 13 million to 25 million.[6] Similar scenarios have played out with other farm animals. The number of egg-laying chickens in Iowa increased from 21.5 million in 1997 to 56.5 million in 2021, and an astonishing 19 of

20 Iowa chickens reside in operations that house 100,000 or more birds.[6] For beef cattle, the number of operations with greater than 500 head increased 82% between 1997 and 2017.[7] Clustering animals in this manner has occurred in other parts of the United States as well as the European Union, Eastern Europe, China, and many other countries.

Concentrating livestock animals in animal feeding operations (concentrated animal feeding operation [CAFO]) has meant more reliance on feedstuffs composed of corn (*Zea mays*) and soybeans (*Glycine max* [L.] Merr.) and less reliance on forage crops and small grains. Likewise, US Corn Belt farmers choosing not to raise livestock have been able to simplify their crop production systems to continuous corn, a two-year rotation of corn–soybean, or a two-year rotation of corn–soybean/wheat double crop in the eastern portion of the region. The introduction of soybean, which displaced not corn but rather crops like oat, alfalfa, clovers, and sorghum, correlates strongly with the use of commercial fertilizer for corn (Fig. 2.1).

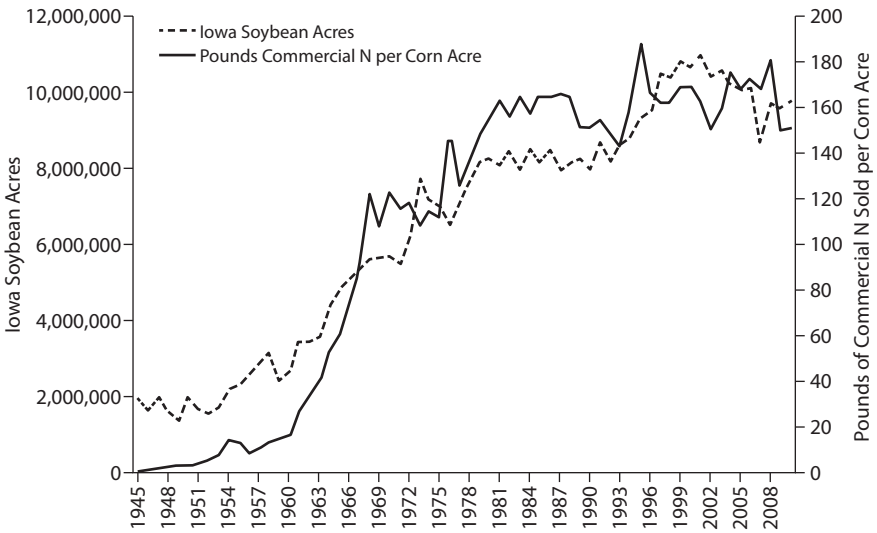

Figure 2.1 Area planted to soybeans in the US state of Iowa and the pounds of nitrogen fertilizer sold per planted acre of corn. *Data sources*: Census of Agriculture, National Agriculture Statistics Service.

Merchant_Health_int_1pgs.indd 17 03/06/24 3:14 PM

Concentrating animals on fewer and fewer farms coupled with the displacement of diverse crop rotations by soybean meant a greater reliance on chemical fertilizers. At the same time, the total number of animals continued to increase, and thus manure nutrients have also been concentrated into smaller geographical areas. This has had consequences for the environment in places where livestock production is intense: Iowa (hogs and chickens), Wisconsin (dairy and beef cattle), and the western Lake Erie basin (hogs, cattle, poultry), to name three.

Managing manure from concentrated livestock operations can be a colossal challenge. For example, the manure waste generated by a hog contains about 3 times as much nitrogen and phosphorus as a human being (8), and thus an Iowa operation raising the average number of hogs (4,700) is managing the nutrient waste equivalent of a community with a population greater than 14,000 people. When the volume of hog waste is considered, the challenge appears even larger. The waste just from Iowa's hog population exceeds that excreted by the human population by 20–30 times.[8] This waste is stored in belowground pits or surface lagoons for 6–12 months before it is applied to crop fields.[8–10]

In Iowa, large livestock operations are required to create a manure storage and application plan as part of the permitting process for CAFO construction.[9] This Manure Management Plan maps the fields where waste will be applied, along with the timing and amount of application. The amounts are weakly restricted by the yield goal formula for nitrogen (N)[11] and the phosphorus (P) index for that nutrient, neither of which has been shown to be protective of water quality.[12] The credibility of the 50-year-old yield goal formula (multiply the expected corn yield potential in bushels per acre by 1.2 for pounds per acre N application) has been questioned, if not wholly discredited, as a sound approach for optimum environmental and agronomic outcomes.[13,14] All available forms and sources of nitrogen need to be considered for efficient management of that nutrient and optimization of environmental outcomes. These include mineralization of soil organic matter

Merchant_Health_int_1pgs.indd 18 03/06/24 3:14 PM

(mobilization) and biological fixation in addition to synthetic products and manure. Immobilization of nitrogen within the soil matter also occurs as inorganic forms are incorporated into biomass through biological processes. Monitoring and managing these pools of nitrogen in synchrony can help align inputs with crop nutrient demands. Farmers, however, can be highly motivated to overapply manure because of economic considerations related to transport of the material, which is much less nutrient dense than commercial formulations (Fig. 2.2).[10]

Dissolved and solid forms of nitrogen (ammonia, ammonium, nitrate, nitrite, organic forms) contained within manure wastes can offgas to the atmosphere as ammonia (NH_3), nitrous oxide (N_2O), nitric oxide (NO), and nitrogen gas (N_2). Volatilization losses of N from both pit and lagoon storage are also difficult to control and minimize, and atmospheric deposition of N, usually ammonia (NH_3), ammonium (NH_4^+), and nitrate (NO_3^-), sourced to these facilities is a significant environmental consideration. There is evidence that much of the volatilized N is deposited within 1 km of the confinement operation,[15] and McGinn et al.[16] reported a 50% decline in deposition 200 m from a cattle confinement. In most circumstances, the farmer is not required to consider these inputs in their fertilization scheme, and Jackson et al.[9] concluded that in some scenarios, it makes clear economic sense for large livestock confinements to maximize N volatilization losses. Thus, in some circumstances, manure becomes a waste product and the practice of squandering manure nutrients is not necessarily economically wasteful.[17,18]

Effect of Livestock Production on Water Resources

The post–World War II transition from diverse, multispecies farms to operations devoted to cash crops like corn and soybean, with a subset raising livestock at high densities, has produced both efficiencies and negative environmental consequences. It has long been known that

nitrogen fertilization correlates with stream nitrate pollution in the US Corn Belt[19] with impacts on municipal water supply[20] and Gulf of Mexico hypoxia.[20] Nitrate is a regulated pollutant in the United States under the federal Safe Drinking Water Act and an important driver of eutrophication in both freshwater and marine environments. Infants consuming high-nitrate water alone or with that mixed with baby formula are vulnerable to methemoglobinemia, which impairs red blood cells' ability to transport oxygen throughout the body.[21]

Because nitrogen inputs to crops cycle through plant biomass and into and out of soil organic matter, and because of the time lag of pollutant transport to streams via groundwater pathways,[22] it is nearly impossible to trace stream nitrate back to commercial fertilizer, animal manure, legumes, or soil organic matter. Hence, many have attempted to gain insights on nitrate sources and pathways using nitrogen budgeting.[23,24] Similar approaches have been used for the other major

Merchant_Health_int_1pgs.indd 20 03/06/24 3:14 PM

macronutrient driving eutrophication, phosphorus.[8,25] Much of this and other research has shown that nutrient and other types of water pollution tend to be particularly bad in watersheds with a high density of livestock.[10,26–28] A few of these are discussed below.

Gulf of Mexico

Coastal Gulf of Mexico eutrophication driven by nutrient enrichment from livestock and crop production in the US Corn Belt draining to the Mississippi River basin has been observed and documented since at least 1974.[29] Waters off the coast of Louisiana become degraded as algae and phytoplankton exploit nutrient-rich water and bacterial consumption of their remains consumes dissolved oxygen (DO). Marine food webs are altered,[30] mobile species flee,[31,32] and immobile species perish[33] in areas where DO levels drop below 2 mg L^{-1} (hypoxic/hypoxia areas). Economic consequences include decline of commercial fishing and shellfish catches and recruitment failure of valuable species.[34] In recent years, harmful algae blooms requiring closure of beaches on the Gulf Coast have been blamed on nutrient pollution in the Mississippi River.[35] Livestock animal waste is the third-leading contributor of both phosphorus and nitrogen to the Gulf of Mexico, while commercial fertilization of crops largely grown to feed these animals is the leading contributor of both (Fig. 2.3).[36,37]

A consortium of state agencies, tribal governments, and federal agencies was formed in 1997 to address the issues of Mississippi River basin nutrient pollution and Gulf of Mexico hypoxia, with an objective of reducing the areal extent of hypoxia to the 1980–1996 baseline average by 2015. Seeing this goal would go unmet, the task force pushed back the goal date to 2035 (Fig. 2.4).[38]

Lake Erie

The shallowest of the five Great Lakes in North America, Lake Erie, has been plagued with algae blooms attributed to livestock, row crop

production, and point sources in both the United States and Canada (Figs. 2.5 and 2.6). Point sources are pollutants sourced back to the end of a regulated pipe discharge; nonpoint sources are disperse and not easily traceable from the stream to the source(s). Although water quality in the lake improved in the 1980s and 1990s following the implementation of the US Clean Water Act, which regulated point source discharges, a "re-eutrophication" has occurred over the past 20 years linked to unregulated nonpoint sources of nutrients from agriculture.[39] Degrading amounts of N and P from productive agricultural land in Ohio, Indiana, Michigan, and Ontario drain to the western basin via rivers such as the Maumee, Raisin, and Thames, impairing the lake for recreation, aquatic life, and municipal drinking water.[40,41]

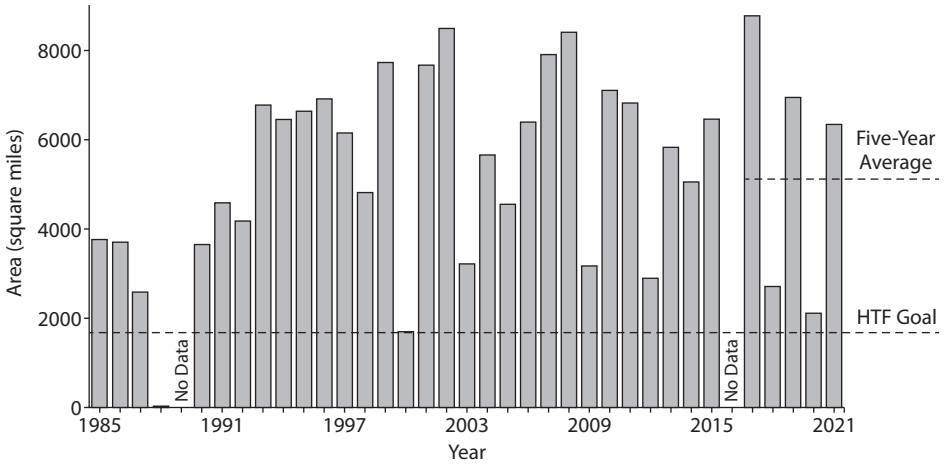

Figure 2.4 Gulf of Mexico hypoxia area. Also shown are the Environmental Protection Agency–led Hypoxia Task Force (HTF) improvement goal, along with the 5-year running annual average.

Unlike marine eutrophication in the Gulf of Mexico, where nitrogen is limiting,[42,43] anthropogenic sources of phosphorus are thought to be the main driver of eutrophication and degradation in Lake Erie.[39] The farmed landscape left level by glacial advance 2.5 million to 11,000 years ago requires constructed drainage in cropped fields to lower the water table, thereby drying out soggy soils and enhancing conditions for field work and increasing crop yields. This drainage consists primarily of networks of porous pipe (tile) installed to a depth of ~1 m that ultimately discharge to the stream network. Dissolved and particulate phosphorus, applied to or incorporated into the soil surface as manure or commercial fertilizer formulations, infiltrates to the tile via preferential pathways in the soil profile. Although commercial formulations have been found to contribute more than manure sources to the Maumee River, the proportion of applied manure phosphorus lost to Lake Erie is larger than the proportion of applied commercial P lost.[44] This is important since populations in the basin have increased since 2007, while the amount of commercial phosphorus application has likely declined since the 1970s.[45]

Chesapeake Bay

Land covering 64,000 square miles in six states drains to Chesapeake Bay, the largest estuary in the United States. Much of the land area in the Baltimore, Maryland, to Norfolk, Virginia, corridor is densely populated. The entire watershed is home to 17 million people, about 5% of the US population. By comparison, the area of the agricultural state of Iowa is only slightly less but is home to only 3 million people (Fig. 2.7).

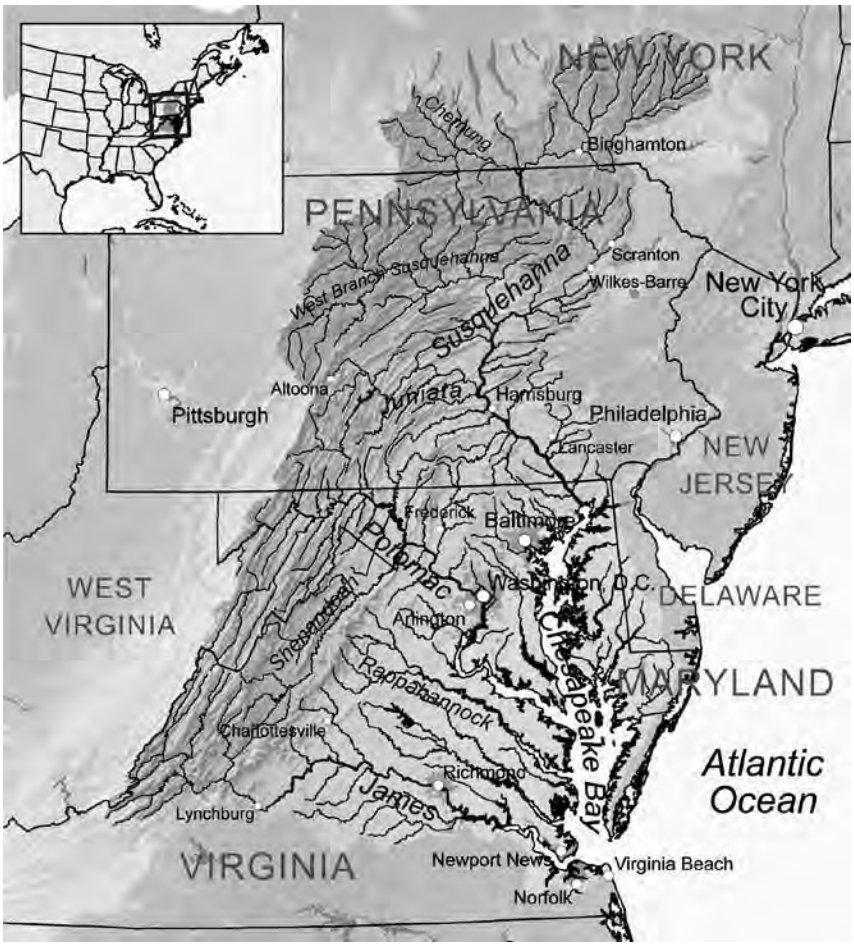

Figure 2.7 Chesapeake Bay watershed.

Merchant_Health_int_1pgs.indd 25 03/06/24 3:14 PM

Concern over degradation of water quality in Chesapeake Bay from nutrient and a myriad of other types of pollution was increasingly heightened during the 1960s and 1970s. The US Clean Water Act addressed many types of industrial and municipal discharges after its passage in 1972 but left nutrient pollution from nonpoint (disperse) sources mostly unregulated. Although only 22% of the land area is in agricultural production[46] (small compared to many areas of the US Corn Belt), these lands are disproportionately large contributors of both nitrogen (45%) and phosphorus (44%) to the Bay's feeder streams, which include the Potomac, Rappahannock, Susquehanna, and James rivers.[46]

Much of the Bay's nutrient pollution problems link to livestock production geographically decoupled from the production of the feed used to raise animals. As grain yields increased in the US Corn Belt and elsewhere with the widespread adoption of crop hybrids and chemical fertilizers following World War II, Chesapeake Bay livestock producers found it easier, more efficient, and economically prudent to feed their animals with grain formulations grown elsewhere. Import of animal feed also means import of nutrients (N and P) contained within the feed. Without adequate crop area to apply the excreted nutrients, nutrient imbalances result, and the excess enters the environment, which in this case means the Chesapeake Bay estuary. Areas draining to the Chesapeake Bay (Susquehanna, Rappahannock, Potomac, and James rivers, along with the Upper Chesapeake and Lower Chesapeake basins proper) are home to 1.2 million hogs, 2.4 million cattle, and 220 million chickens.[6] These animals excrete 138 million pounds of phosphorus and 560 million pounds of nitrogen in a year.[47] Our most nutrient-hungry crop, corn, needs about 25 pounds of phosphorus and 200 pounds of nitrogen per acre, meaning Chesapeake Bay animals excrete enough phosphorus and nitrogen to fertilize 5.5 million (P) and 2.8 million (N) acres of corn. Around 1.5 million acres of Chesapeake Bay land is committed to corn.[48] This illustrates the nutrient imbalances created by current configurations of livestock production in this region. These nutrient imbalances result in eutrophication of the estuary, reduced water

clarity and biodiversity, and degraded recreational and aesthetic qualities of this major water resource, and once-thriving commercial fish and shellfish industries have been severely degraded.[46]

Black Sea

The California-sized Black Sea is bordered by Russia, Ukraine, Bulgaria, Romania, Georgia, and Turkey. It receives freshwater from several major European rivers (especially the Danube), but Mediterranean Sea saltwater also intrudes through a hydrological connection known as the Bosphorus. Thus, Black Sea water is saltier than a lake but fresher than the ocean, producing a diverse ecosystem and productive fishery. Resorts along its shoreline have promoted Black Sea water as therapeutic for at least two centuries (Fig.2.8).

In the 1960s, USSR agricultural policy increased the use of chemical fertilizers. In addition, huge animal production systems were established in Soviet-bloc countries[49] (one Romanian CAFO had more than

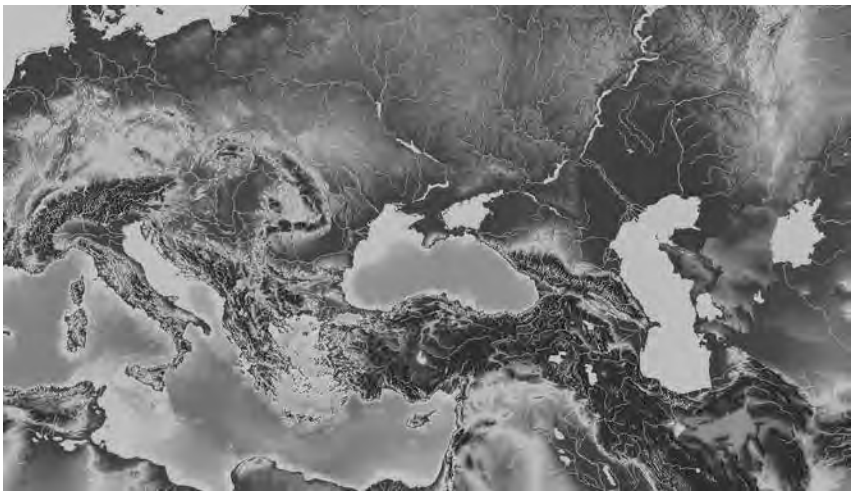

Figure 2.8 Black Sea is shown in the middle of this map. *Source*: By Kamel 15-own work, CC BY-SA 3.0, https://commons.wikimedia.org/w/index.php?curid=5623711.

a million hogs). By the 1970s, the Black Sea beaches of Ukraine and Romania were graveyards of fish, clams, and crabs doomed by a hypoxic dead zone in the Black Sea created by nitrogen and phosphorus pollution discharged by the Danube River. The excess of nutrients stimulated large blooms of phytoplankton, causing a collapse of the diverse brackish water ecosystem.

Following the collapse of the USSR in 1989, many of the huge CAFOs closed and use of chemical fertilizers declined. Only six years later in 1995, it was apparent that the Black Sea was recovering. By 2002, sensitive mussel beds were reestablished, and other ecological indicators were improving.

Baltic Sea

Of the world's 400 or so known "dead zones" (i.e., low- or no-oxygen coastal areas degraded by excess nutrients), the Baltic Sea may host the largest and may in fact have seven distinct areas of reduced oxygen. Although nutrients from agriculture are also a main driver here, industrial and municipal discharge have contributed, along with the collapse of the cod fishery, which has caused ecosystem disruption favorable to harmful algae.

Large-scale hog production in Denmark, Poland, and other countries has been a strong contributor of nutrients to the Baltic Sea.[50] At any given time, Danish farmers are raising 13 million hogs[51] within the 16,600 mi^2 country, a density that exceeds even that of the largest hog-producing state in the United States, Iowa. And some individual Polish farms raise more than 60,000 hogs.[50] Management of manure nutrients from confined animal feeding operations is a difficult task on many farms.

The Baltic Sea is similar to the Black Sea in that they both are surrounded by land, are minimally connected to the larger ocean, and have salinity levels between that of the ocean and freshwater. The Baltic has also warmed substantially with climate change, a condition favorable for the algae that contribute to hypoxic zone formation. Water turnover

Merchant_Health_int_1pgs.indd 28 03/06/24 3:14 PM

rate is naturally slow (~30 years), and intrusion of salt water is restricted by shallow areas known as sills.[52] These natural conditions, coupled with anthropogenic inputs of nutrients, have expanded the Baltic Sea hypoxia zones 10-fold over the past century.[53]

Iowa

The US Corn Belt state of Iowa has long been one of the country's leading producers of hogs, cattle, and poultry. Currently, Iowa exceeds all other states in egg and pork production and is fourth in production of feeder cattle.[6] Iowa has also been a leading producer of both corn and soybeans, frequently topping all other US states in harvested acres of these commodities.[6] To achieve this level of carbohydrate, protein, and vegetable oil production, nutrient inputs have been required that far exceed those present in the natural system that existed prior to European settlement. A consequence of this supercharged production system has been leakage of nutrients and other pollutants to the environment and especially the streams, lakes, and aquifers of the state (Fig 2.9).

Merchant_Health_int_1pgs.indd 29 03/06/24 3:14 PM

More than half of Iowa's corn is used to produce fuel ethanol, and most of the rest is used as livestock feed. Residuals from ethanol production—distillers dried grains (DDGs)—are also fed to livestock; in all, about half the calories contained within Iowa's corn crop end up in livestock feed. This is an enormous number of calories that nearly equals the caloric needs of the entire population of the United States. And an even greater percentage of the soybean crop is used in livestock feed.

While livestock production is geographically co-located with the growth of feed grain in a general way, most Iowa farms do not raise livestock; that is, most are committed solely to crop production. These crop farms do serve as end points for manure if a livestock producer has an inadequate crop area to dispose of the manure at rates that are allowed by Iowa rules. It has been found, however, that these rules do little to constrain farmers from applying manure and synthetic fertilizer nutrients far beyond recommended rates for crops.[9,10]

Livestock density strongly correlates with the nitrate concentration of adjacent streams in Iowa. Jones et al.[10] found that nitrate concentrations linked to total nitrogen inputs and generated manure but not with commercial nitrogen fertilizer amounts in nine Iowa watersheds. Manure nutrients applied to fields that were already fertilized with commercial nitrogen (implying a wastage of manure) created a surplus nitrogen condition that drives stream nitrate (Fig. 2.10).

Iowa has approximately 3,500 large concentrated animal feeding operations (CAFOs) as defined under the Clean Water Act[54] and several thousand smaller ones with even fewer regulations. CAFOs are operations that contain at least 700 dairy cows, 1,000 beef cows, 2,500 hogs, or 30,000 chickens. The state with the second-highest number of CAFOs, Minnesota, has only one-third as many (1,300). The neighboring states of Wisconsin and Illinois have fewer than 300. Livestock density in Iowa could explain why the state's stream phosphorus levels are two to three times higher than that of Illinois,

even though Illinois has a large urban phosphorus contributor (Chicago metropolitan area) and about the same corn and soybean crop area as Iowa.[55]

Leakage of excess nutrients from Iowa's landscape has had dire environmental consequences that degrade recreational opportunities, reduce biodiversity, and increase the cost of drinking water for the state's residents. The largest city (Des Moines) and its surrounding area require nitrate removal at the municipal drinking water treatment plant, a process that creates a pollution stream of its own. Also, around 6,600 private wells (most in rural areas) in the state have tested above safe limits for nitrate since 2000, and many more have been contaminated with bacteria.[56]

Iowa streams drain to the Missouri and Mississippi rivers, and the nutrients contained within ultimately discharge to the Gulf of Mexico (Fig. 2.11). Iowa has been identified as a strong contributor of both nitrogen and phosphorus, the primary drivers of the Gulf's hypoxic (dead) zone.[55,56]

Iowa area comprises 3.3% of the Missouri River basin while contributing 12% of the water and 55% of the nitrate. Likewise, the state comprises 21% of the land area while contributing 21% of the water and 45% of the nitrate to the Upper Mississippi River basin. Finally, Iowa comprises 4.5% of the entire Mississippi basin area (including the Missouri River basin) while contributing 5.9% of the water and 29% of the nitrate,[57] as well as 15% of the phosphorus.[55]

Clearly, livestock populations and the crop production system that supports it are large drivers of degraded water quality in Iowa and in states downstream. Both Denmark and the Netherlands have livestock densities on the scale of Iowa. As a result, both countries have in the past suffered environmental consequences similar to Iowa's, but both countries' governments have intervened in more forceful ways than Iowa's leaders have. Going forward, desired environmental outcomes in this intense production system will need to be reconciled with economic and regulatory considerations important to the agricultural industry.

Potential Policies for Improved Environmental Outcomes

The existing livestock production schemes in the United States and other developed countries did not happen by accident—policy, or the absence thereof (such as weak regulatory frameworks), incentivizes the concentration of production in places like Iowa and the Western Lake Erie basin. Industrialized farm animal production (IFAP), which here could be defined as feeding animals cash crop grains in confined or restricted living conditions, links closely to other agricultural systems. For example, the US renewable fuel standard guarantees a market for corn. DDGs are a by-product of fuel ethanol production and can be fed

to animals. Corn is a nutrient-hungry crop that can be fertilized with animal manure. Thus, ethanol production relates to mono-cropping corn (continuous corn versus corn–soybean rotation) and livestock production in indirect but important ways.

Efficiencies of production in concentrated animal schemes have influenced consumer prices. For example, the early stages of consolidation in the hog industry did reduce pork prices $29 per year for the average US customer.[58] These efficiencies can only be realized, however, when the costs of the externalities of water and air pollution and water resource depletion are distributed to the public at large and not to the farmers, packers, and retailers. This is where policy must intercede if improved environmental outcomes are to result.

What might these policies look like? Of course, this will depend on the type of production system. Incentivizing the return of cattle to pasture (from open feed lots and buildings) would be one first step. The renewable fuel standard catalyzed the conversion of pasture to corn crops and reduced available area for grazing.[59] Much of this converted land was marginally suitable for corn and thus more vulnerable to soil erosion and/or nutrient loss tied to corn production practices. Growing corn for ethanol also displaces forage crops like alfalfa, which could be grown without irrigation in much of the Corn Belt but require enormous amounts of irrigation water in the arid western United States (alfalfa/hay consumes the most irrigation water across all water sources).[60] This has had profound environmental and sociological consequences across the Colorado River basin and in fact most of the farmed western United States.[61] Likewise, corn grown for confinement cattle and fuel ethanol have helped to deplete the Ogallala aquifer in Kansas and other states to alarmingly low levels.[62] Around 6,000 years are required to recharge the aquifer naturally.[63]

Grazing cattle on pasture emulates the native grassland ecosystem that was grazed by bison and elk. Grazing would reduce the burden of manure management intrinsic to confined systems. Several existing policies help farmers construct water systems that enable them to restrict grazing animals from streams and eliminate or reduce stream

Merchant_Health_int_1pgs.indd 34 03/06/24 3:14 PM

degradation associated with animal wading. Programs of this sort, coupled with a retreat from the renewable fuel standard, could make meat production more sustainable.[64]

Recoupling livestock and crop production on individual farms could help farmers "close" nutrient cycling and avoid exporting grain to feed animals in distant areas that lack sufficient crop ground to utilize manure nutrients judiciously. Much of modern livestock production in the United States and elsewhere has been decoupled from crop production. Instead of grazing on forage crops, animals are fed with cash crop grains, mainly corn and soybeans, in a system designed for efficiency and rapid animal growth to market weights. This scheme requires large inputs of fossil fuel for nitrogen fertilizer, pesticides, grain drying, and equipment manufacturing, and other input costs, notably seeds modified with biotechnology, are also high. But because the renewable fuel standard guarantees a market for corn, these costs have become justified on lands that once were marginal for corn production but were productive pasture ground for grazing cattle. Thus, many Corn Belt farmers are indirectly incentivized to focus solely on crops, leaving a small minority to only raise livestock or link their own crop fertilization schemes to their animals' manure. The emergence of soybeans as a livestock feed helped that crop displace oats, alfalfa, and clovers, all crops with lower input costs and that degrade the environment far less than corn and soybean.[65] Return of Corn Belt land to alfalfa production could potentially reduce production of this crop in areas of the western United States where irrigation with dwindling water supplies is necessary. Feeding livestock with corn and soybean requires concentration of animals and subsequently has made manure management an enormous challenge, with consequences for both water and air.

A return of cattle to pasture would help diversify farms. Farmers are incentivized to crop marginally productive land when animals are confined and fed cash crop grains. These lands are often hilly and vulnerable to soil erosion, which increases losses of phosphorus to the stream network.[55] In the United States, federal cost share programs exist that help farmers set up fencing and watering systems that enable rotational

Merchant_Health_int_1pgs.indd 35 03/06/24 3:14 PM

grazing and restrict cattle from damaging stream banks and beds and defecating and urinating in streams. A return to these sorts of schemes very likely would reduce nutrient and other types of pollution. Likewise, a move away from the large hog confinement model and a return to hog production in pasture farrowing systems[66] would very likely increase the number of hog operations, bring diversity to farms, and make manure management less perilous to the environment. Animals can also be grazed in multispecies systems[67] that are more sustainable and humane environments for livestock.

Creative government policies favorable to these types of systems would produce positive environmental outcomes for the public. The transition away from these less intense production systems to the IFAP model was clearly made possible, at least in part, by the absence of regulations limiting CAFO pollution.

If animals are to remain in concentrated systems, laws that focus on and enforce measurable environmental outcomes could reduce the pollution inherent to these production systems. Such laws might include limiting the number of animals such that the watershed can meet water quality goals, government agency tracking of manure nutrients, aligning nutrient inputs to crops with their expected uptake, and prohibitions on manure application when the likelihood of loss from fields is high (i.e., winter, onto snow and frozen ground, just prior to expected storms, on steep slopes, near streambanks, etc.). Enforceable nutrient and pathogen standards for streams could force livestock facilities in those watersheds to suspend operation until they implement pollution-trapping or pollution-reducing methods. Stream nutrient standards have been used to help reduce phosphorus pollution of the Illinois River in Arkansas and Oklahoma.[68] The river and an impoundment on the river (Ten Killer Lake) are some of the most valuable and highly used water resources in Oklahoma. Poultry waste, primarily from concentrated broiler operations in Arkansas, is used to (over) fertilize pasture ground for cattle production, and its runoff seriously degrades the river and the lake.[69] Oklahoma sued Arkansas poultry producers in 2005 and

Merchant_Health_int_1pgs.indd 36 03/06/24 3:14 PM

ultimately won the case in 2023.[70] While the stream is improving, the limit of 0.037 mg/L phosphorus is still not being met at all times.[69] Similar regulatory frameworks that focus on air quality could also be developed in areas with high concentrations of livestock.

Many have considered anaerobic manure digesters as a means of making manure waste more manageable.[71] These also present the opportunity to reduce greenhouse gas emissions (CO_2 and methane-CH_4) from manure waste.[72] Methane has about 80 times the warming power of CO_2 and animal agriculture generates 32% of worldwide emissions.[73] Manure biogas systems (anaerobic digesters) potentially reduce emissions by capturing methane and then using it to displace the use of fossil fuels, namely, natural gas. This solution is intuitive, and in fact, the US federal government has tried to incentivize this strategy.[74] Digesters concentrate most of the manure nitrogen and phosphorus into a liquid that can then be used to fertilize crops. Solids are then usually applied as a soil amendment to farmed fields. This solution does have detractors, mainly because digesters do not reduce the overall volume of waste and fail to address the main driver of livestock-related water pollution: overpopulation of animals in polluted watersheds and consequently quantities of manure nutrients that exceed crop needs. Digesters are not mechanically foolproof and require skilled operators, and those that malfunction can seriously degrade nearby waterways.[75] There are also questions surrounding worker safety related to these systems.[76] Expense is also a concern for many operators.

Demand for meat products ultimately drives the level of production in many societies. Availability seldom limits consumption of meat in most Western countries where meat consumption is high. Globally, meat consumption increased 58% from 1998 to 2018, and only half of this was due to human population increase.[77] The United States leads the world in per capita meat consumption (except for Hong Kong) at 128 kg/year,[78] an amount that has increased 45% since 1961. Total meat consumed in the United States has increased fivefold since 1909.[79]

Merchant_Health_int_1pgs.indd 37 03/06/24 3:14 PM

This demand for meat clearly links to the environmental consequences of livestock production. In Europe, total meat consumption, especially meat from ruminant animals, explains most of the country-to-country variation in the environmental footprint of food production.[80] In the modern era, the biomass contained within human bodies outweighs that of Earth's wild mammals 8:1, and when we add in our domesticated food animals, that ratio jumps to 23:1.[81] This last ratio must be enormous in places like Iowa and Denmark, where livestock production is intense, and where water quality and other environmental degradation is a serious concern.

Policymakers take great risks when they attempt to improve animal welfare and environmental outcomes by steering consumer choices toward alternatives. Attitudes about food and eating in general can be strongly held and are embedded within a myriad of religious, cultural, geographical, and economic factors. While meat rationing was common among countries during World War II, even then strong moral appeals were needed to convince people of the necessity of the policy.[82] It seems unlikely that this approach would be politically viable in the present day, especially in high-income countries. Certainly, some people are aware of the environmental consequences of meat consumption and feel those outcomes are unavoidable and a fair trade-off for the pleasure of consuming meat.

If farmers, food processors, and retailers were required through regulation to reduce the environmental pollution resulting from meat production, and those costs were passed on to the consumer, would meat consumption decline? The evidence is not clear. Modestly increasing the price of beef (£0.20 per meal) did not reduce consumption in the United Kingdom,[83] while another study in the same country showed consumption declining with price increases.[84] And it is a near certainty that many people would be unhappy with price increases linked to environmental objectives. These are difficult problems for countries to confront, but a reckoning will be imperative. Climate change, air and water pollution, increased wealth in developing countries, and

continued population growth may force societies into more sustainable food production systems.

Comments on Planned Amendments to Rules Governing Animal Feedlots
Minnesota Rules – Chapter 7020

We appreciate the opportunity to give our comments on the 7020 Feedlot Rule review here in Minnesota. As pig and cattle farmers in Goodhue County, we are proud to call Southeast Minnesota home, and environmental and land stewardship is something we take very seriously. Our family has been farming livestock and crops on the same land for nearly 140 years, and that has only been possible because of the dedication our family and so many other family farms across Minnesota have to continuously improve our farming practices and protect our natural resources.

The current MPCA 7020 Feedlot Rules originally implemented in 2000 have done a lot in the way of improving the farming practices of livestock farmers across the state of Minnesota. As this consideration for rule review takes place, it would be logical to first look at the ways the current 7020 Feedlot Rules are being enforced to see how we can continue to improve our environmental stewardship in agriculture within the boundaries that have already been set before seeking to add additional regulations.

As farmers in the bluffs and valleys leading to the Mississippi River, we work hard to implement best management practices (BMPs) that ensure water quality (both surface water and groundwater) is not compromised, the nutrients from manure applied onto our pasture and crop ground can be utilized fully by the plants they are intended for, and the varied topography of our ground will remain intact now and into the future. Having flexibility with our current liquid manure application windows in both fall and spring enables us to apply that natural fertilizer when the environmental conditions are most fit to do so. If manure application were to only be allowed in the spring – a season of high weather variability – the outcome would likely be more rushed application, corners being cut just to get the job done, and not following environmental indicators to determine the true best time to apply the manure.

We are proud to call ourselves farmers, but our goals are not so different from those of our rural neighbors. We live on the same ground, drink the same water, and breathe the same air as the people who live in our communities, and it is a farmer’s goal to leave their farm for the next generation better than how it was passed to them. In order for us to do that, we will steward our land well by continuously improving our farming practices, using science-based research as our guide. It is our strong suggestion that any changes or additions to the 7020 Feedlot Rules be implemented and enforced only when that same sound science-based research agrees with and supports those modifications.

Once again, we appreciate the opportunity to provide comments on the 7020 Feedlot Rule review, and we hope the current efforts of farmers across the state are fully understood and taken

into consideration before undue regulation is put into place that will likely have a very negative impact on livestock farms of all sizes and types.

Sincerely,

Brandon Schafer

RE: Comments on Amending Minnesota Ch. 7020 Animal Feedlot Rules

Dear Office of Administrative Hearings:

Socially Responsible Agriculture Project (SRAP) is a nonprofit 501(c)(3) organization. For more than 20 years, SRAP has served as a mobilizing force to help communities protect themselves from the damages caused by industrial livestock operations, and to advocate for a food system built on regenerative practices, justice, democracy, and resilience. SRAP offers free support, providing communities with the knowledge and skills to protect their rights to clean air, water, and soil and to a healthy, just, and vibrant future. Across the U.S., SRAP receives requests for help from communities on the frontlines of industries streaming from industrial livestock business. SRAP has worked with several communities across Minnesota over the last few years to help them protect themselves from industrial livestock operations, and SRAP submitted comments on the Minnesota NPDES and SDS draft permits issued in 2024. SRAP submits these comments regarding the first round of public comments for the Chapter 7020 rulemaking and SRAP also incorporates by reference the comments submitted by Yale, Minnesota Center for Environmental Advocacy, and Food & Water Watch.

MPCA's stated purposes of this rulemaking process are to address changes in livestock and poultry operations and business practices, account for new agency data services, modernize outdated rule language, amend existing feedlot rules to improve land application of manure practices to address nitrates, bacteria, and fish kills, and establish additional technical standards to protect water quality and avoid fish kills. SRAP's comments focus on: (1) size of feedlot operations; (2) ownership transparency; (3) cumulative impacts of feedlot operations; (4) surface and groundwater contamination; (5) restricting land applications; (6) anaerobic digestion.

(1) Chapter 7020 Revisions Must Address Industry Changes in Operation Size.

Minnesota's animal agriculture program regulates "large" operations (1,000 animal units "or more") via the NPDES and SDS permit program, and all other operations via the feedlot rules. Neither federal rules or Minnesota rules establish any upwards cap on the number of animals or animal units subject to regulation in the "large" operation category. And neither federal rules or Minnesota rules recognize mega factory farms' outsized environmental impacts. These gaps can be corrected through the Chapter 7020 rulemaking process; without MPCA taking action, industry will only be obligated to follow an inappropriately designed regulatory framework that is acutely inadequate to protect Minnesotans from environmental pollution.

According to public records, Minnesota currently has approximately 38,158 feedlots subject to Chapter 7020.[1] One of the critical questions MPCA is evaluating through this rulemaking process relates to the size of operations covered by Chapter 7020 and corresponding rules. Since MPCA promulgated Chapter 7020 in 1971 and updated it in 2000, across the U.S. significant changes have occurred in the industry relating to facility size. Livestock operations increased in size, creating "extremely large" operations colloquially called megafarms. USDA National Agricultural Statistics Service (NASS) data confirms that the number of "mega" factory farms in the U.S. has essentially doubled since 2000 for chickens, egg layers, dairy cows, and pigs.[2] Some examples of "mega" factory farms include, for instance: Blackshirt Feeders (Nebraska) (under permitting to house 150,000 head of cattle and 36 digesters);[3] Simplot's Grand

[1] MPCA datasets "Feedlots Minnesota annotated" (accessed July 6, 2025) available at https://gisdata.mn.gov/dataset/env-feedlots (some feedlots may be "inactive" or "not required to registered" but most of the more than 38,000 feedlots are required to actively participate in Chapter 7020).
[2] See, e.g., USDA NASS trend data summarized in Bolotnikova, M. and Torrella, K. "9 charts show US factory farming is even bigger than you realize: Factory farms are now so big that we need a new word for them." Vox (Feb. 26, 2024) available at https://www.vox.com/future-perfect/24079424/factory-farming-facts-meat-usda-agriculture-census

View (Idaho) feedlot (authorized to manage up to 150,000 head of cattle);[4] Innovative Livestock Solutions (Kansas) (recently permitted to operate a facility with a capacity of 88,000 head of cattle);[5] and in Coffee County (Georgia), community members are currently opposing a proposed 60-barn poultry operation that would confine up to three million chickens.[6] Minnesota is no stranger to the mega factory farm problem; MPCA has permitted Golden Oaks Dairy to house 43,385 dairy cattle, and Woitalla Dairy LLC to operate a facility with 48,446 cows.[7]

Operation size plays into all other problems in the livestock production industry, including for example over generation of manure, overapplication of waste, expansive reach of waste within and across watersheds, and the generation of methane and GHG emissions (see also Yale comments submitted for this public comment period). Mega factory farms significantly magnify these problems and their impacts on communities, including heightened risks of groundwater and surface water contamination, air pollution, and increased greenhouse gas emissions. Additionally, the logistics of storing, transporting, and disposing of such massive volumes of waste present an additional layer of environmental and regulatory challenges. At the most basic level, decades of using current regulatory frameworks for the "small", "medium", and "large" size CAFOs have already clearly demonstrated that existing rules are completely insufficient to protect the environment from the livestock industry.[8] It would thus be unreasonable for MPCA to take the position that pollution from mega factory farms could be eliminated, or lessened, or controlled by relying on the same rules. As part of the rulemaking review here, we strongly encourage Minnesota to conduct its due diligence and seriously consider at least the following points:

- How other states have *started* to respond to mega factory farms by proposing different regulatory and permitting frameworks, and consider those frameworks as the *floor* for what needs to be done to protect the environment.
- Whether there should be a baseline number of animal units or headcount at which a facility is categorically considered a "mega" feedlot, factory farm, or CAFO.
- Whether there should also be an upper cap on the total number of animal units allowed under a single mega facility, beyond which no new CAFO or feedlot may be permitted.

[7] https://gisdata.mn.gov/dataset/env-feedlots

[8] See, e.g., MPCA Enforcement Case Summaries for 2022, 2023, 2024 (identifying multiple feedlot rules violations over the years) available at https://www.pca.state.mn.us/trending-topics/compliance-and-enforcement

- How MPCA should improve current inadequate setback, manure management, and land application requirements, recordkeeping and monitoring requirements, and surface and groundwater protection measures to withstand the intensified increased risks posed by mega feedlots.
- How MCPA should improve its enforcement of Chapter 7020 rules, especially for mega feedlots.
- Mega feedlots must trigger a more rigorous permitting process, including mandatory cumulative impact assessments and full environmental reviews that go deeper into the basic framework provided in Minnesota's existing Environmental Assessment Worksheets.
- Mega feedlots must be categorically prohibited from being constructed over, and from land applying over or into sensitive groundwater areas or geologic formations such as karst terrain.
- Given the sheer volume of waste produced by mega CAFOs, additional considerations must be required to ensure the safe, transparent, and environmentally responsible storage, transfer, transport, and land application of manure (on-site and exported manure).

One simple starting point is to establish a modest, reasonable upward cap on the number of animal units allowed within a single feedlot (or in jointly owned feedlot operations) until Minnesota solidifies a protective regulatory framework that ensures all feedlots can meet existing rules, and mega operations do not pollute the environment.

We also suggest that MPCA's review of the animal units / animal number question try to address what is colloquially called the "one under" problem. In many states, SRAP regularly sees operations regulated under lower standards simply because they report on paper being "one (cow, chicken, pig) under" the next regulatory (more stringent) threshold. This practice intentionally subverts regulatory compliance, and we recommend that MPCA consider incentives to eliminate this practice in Minnesota.

(2) <u>Ownership Transparency.</u>

Another concerning trend SRAP is seeing across the U.S., which MPCA can address in its Chapter 7020 rule review, relates to ownership transparency. Here,

- Chapter 7020.0350(1)(B) (relating to registration) requires the disclosure of "all owners" of the feedlot or manure storage area. Chapter 7020.0505(4)(A) (relating to permit applications) requires the names and addresses of the owners. Neither provision requires disclosure of the owners of land application areas owned, or used, by the feedlot or permitted operation.

- Mega feedlots and mega operations are increasingly owned by multiple individuals, businesses, and partnerships in shared ownership models … which in turn may be owned by other business entities. The layers make it difficult for the public to understand the true interests of a registration or permit applicant.
- Update rules to prohibit field sharing and self-transfers of manure (see SRAP's September 2, 2024 Comments to MPCA on the NPDES and SDS permits, p. 3-5).

Additionally, SRAP has observed a growing trend of intermingled ownership between feedlot and CAFO owners and anaerobic digester investors and operators, which raises significant concerns regarding transparency, liability, enforcement abilities, and regulatory oversight. If OAH incorporates anaerobic digesters into the revised rule, SRAP recommends the following points relating to ownership transparency:

- Expand the definition of "owner" to include anaerobic digester owners. "Owner" should be defined as any person or entity with possession, control, or title to an animal feedlot, manure storage area, or an anaerobic digester.
- Update Chapter 7020 to accommodate for shared ownership structures where the feedlot or CAFO and the anaerobic digester operation are not owned or operated by the same party or parties.
- Bind both parties to regulatory conditions. The rule should make clear that both the feedlot or CAFO owner(s) and the anaerobic digester owner(s) are independently and jointly bound to comply with all applicable terms and conditions of either Chapter 7020, the SDS Permit, the NPDES Permit, and all other applicable laws.
- Require written formal public agreements between feedlot owner(s) and digester owner(s). The owner and the anaerobic digester owner or operator must enter into a written agreement that clearly affirms shared responsibility for compliance. This agreement must be signed by both parties or their legally authorized representatives. Signatures must follow the appropriate authority level, as outlined below:

    - Corporation: Signed by a principal executive officer (at least the level of vice president), or their designated representative, if the representative is responsible for the overall operation of the facility. Documentation must be provided to verify this authority.
    - Limited Liability Company (LLC): Signed by a managing member.
    - Limited Liability Partnership (LLP): Signed by a managing partner.
    - Partnership: Signed by a general partner.
    - Sole Proprietorship: Signed by the proprietor.
    - Municipal, state, or other public entity: Signed by a principal executive officer, such as a mayor.

This last requirement is important because for decades state agencies have allowed parties with little vested interest in a livestock operation's compliance to sign for the facility. With the combined increased risk of mega feedlots and anaerobic digesters, greater security for accountability is essential and the appropriate signature is the minimum way to establish this.

(3) <u>Cumulative Impacts</u>

Minnesota's Environmental Policy Act (Minn. Stat. 116D) and accompanying regulations (Minn. R. Chapter 4410) "promote efforts that will prevent or eliminate damage to the environment and biosphere and stimulate the health and welfare of human beings." Minn. Stat. 116D.01(2). MEPA further recognizes "particularly the profound influences of …industrial expansion." Minn. Stat. 116D.02(1). To address the increasing number of public health impacts stemming from feedlots in small geographic areas, in 2019 the American Public Health Association issued a precautionary moratorium on new and expanding CAFOs.[9]

We propose that as part of this rule review, MPCA require certain operations to complete the detailed environmental impact statement process, not merely the environmental assessment worksheet. The EIS process is appropriate when there is a "potential for significant environmental effects." Minn. Stat. 116D.04(2a) (2024, 2025 1st session). While the statute exempts some feedlots from environmental review (Minn. Stat. 116D.04(2a)(f)), the exemption only applies to operations < 1,000 animal units and feedlots that execute a "written commitment" to comply with MPCA feedlot rules. Id. at (f)(2). Given the impacts of large, and mega, feedlots, greater environmental disclosure and mitigation should be required through the EIS process.

Increasingly, the siting of feedlots is occurring in close proximity to existing, or other new feedlot facilities. The localized increased impacts of animals, waste generation and storage, land applications, and attendant activities (transportation of feed, waste) must be identified, disclosed, considered, and addressed through mitigation measures. While Minnesota's EAW Form can identify some cumulative impacts, we remain concerned that some of the following scenarios that we are seeing across the U.S. may not be identified through the current environmental review process or their cumulative impacts mitigated.

- **Neighboring feedlot concerns**
    - For example, feedlots across the road from each other, where they may or may not be under separate ownership, magnify and intensify the impacts on local communities.

[9] American Public Health Association, Precautionary Moratorium (Nov. 5, 2019) ("Over the last several decades, food animal production in the United States has shifted from an extensive system of small and medium-sized farms to one characterized primarily by large-scale industrial operations that concentrate large numbers of animals in small geographic areas.") available at https://www.apha.org/policies-and-advocacy/public-health-policy-statements/policy-database/2020/01/13/precautionary-moratorium-on-new-and-expanding-concentrated-animal-feeding-operations

- **Expansion rates of multiple feedlots in small areas**
    - For example, states like Georgia, Missouri, and Nebraska have recently seen a proliferation of new feedlots within small areas / similar watersheds. See, e.g., Missouri DNR's review of nine poultry applications within a small area of Southwest Missouri;[10] the Coffee County, Georgia, proposal to build 60 poultry barns on a 1,000 acre parcel;[11] the expansion of Summit pork swine CAFOs in Nebraska.[12]

- **Field sharing**
    - This occurs when a manure generator and/or recipient simply uses a different Field ID. This practice of field sharing occurs without MPCA or the public knowing. If Minnesota were to require at a minimum the level of information that states like Michigan require, Minnesota would greatly increase transparency, enabling the state and the public to ensure that the improper practice of field sharing is not occurring in Minnesota, and thus offer an additional opportunity to protect Minnesota waters. See SRAP NPDES and SDS Comments to MPCA p. 3-5 (Sept. 3, 2024).

- **Self-transfers of manure**
    - Under Minnesota rules, a CAFO's ownership of manure ends when the manure is physically transferred or relinquished to a manure recipient. The manure recipient then land applies the manure to its fields, or fields the manure recipient has access to. Manure recipients must follow the protective measures identified in the CAFO permittee's approved manure management plan to minimize the risk of surface and groundwater contamination from manure applications. See Minnesota R. 7001.0150. However, SRAP sees a practice occurring across the U.S. where CAFOs play a "shell game" of land ownership, trucking ownership, and/or manure recipient ownership. In those scenarios, manure is being treated as "exported" off site to another recipient, even though a CAFO may own or control the manure recipient, and the CAFO may own or control—through shell ownership or strawman relationships—the land where the manure is being applied. Similar to the first problem above, this practice can result in inaccurate nutrient balance tallies, surface and groundwater discharge, contamination problems, and excessive nutrient loading in Minnesota's

[10] Missouri DNR, Water Pollution Control Sites of Interest available at https://dnr.mo.gov/water/business-industry-other-entities/sites-interest/southwest-mo-concentrated-animal-feeding-operation-cafo-facilities
[11] See n. 6 supra.
[12] Investigate Midwest, "Pigs and Power" 2023-2024 series available at https://investigatemidwest.org/pigs-and-power/

watersheds. Without accurate land ownership and manure recipient disclosures, fields will be over-applied with amounts of waste that compromise water quality. SRAP encourages MPCA to develop rules and a Nutrient Management Tool[13] to account for this problem, so that a Nutrient Management Tool minimizes runoff and contamination risks of every field, and that does not consider waste "transferred" when in fact it is still within the permitted CAFO's ownership or control.

Lastly, we appreciate Minnesota's inclusion of GHG factors in the EA Worksheet, and note that there is additional room for improvement as raised in the Yale comments submitted during this public comment period.

(4) Surface and Ground Water Contamination Require Stronger Monitoring.

There is significant surface and groundwater contamination in Minnesota that is persisting and that MPCA must address through improved Chapter 7020 feedlot rules. The 2024 Minnesota Impaired Waters List is an indicator of significant water contamination in Minnesota.[14] In 2024, there were:

- 739 waterways impaired for *nutrients*
- 671 waterways impaired for *E. coli*
- 239 waterways impaired for *fecal coliform*
- 31 waterways impaired for *nitrate*

The majority of these impaired waterways occur in the southern half of the state, which is also where MPCA's Feedlot Nutrient Management Planning Map confirms the majority of Minnesota feedlots are sited.[15] State agencies,[16] and reports and studies, have repeatedly found[17] that feedlots have significant negative impacts on water quality in Minnesota.

---

[13] SRAP acknowledges MPCA has recently released its Nutrient Management Tool, which we intend to separately review for how it addresses this issue.
[14] Available at https://www.pca.state.mn.us/air-water-land-climate/minnesotas-impaired-waters-list (approved by EPA April 2024).

[17] See, e.g., Environmental Working Group, "Manure Overload: Manure Plus Fertilizer Overwhelms Minnesota's Land and Water." (May 28, 2020) available at https://www.ewg.org/interactive-maps/2020-manure-overload/; Hanson, M. et al., "The Debate about Farm Nitrates and Drinking Water." Choices: Agricultural & Applied Economics Association. (2016 Q1) (see Minnesota example highlighting feedlots as contributors to nitrate pollution) available at https://www.jstor.org/stable/choices.31.1.07.

Subsurface discharges of manure to groundwater from feedlots is a significant issue in Minnesota[18] and in the United States.[19] In 2016, MPCA found that between 44% and 59% of groundwater monitoring wells sampled in central Minnesota (Central Sands area) were contaminated with nitrates beyond the federal drinking water standard.[20] Feedlot manure contamination can occur anywhere, but vulnerable groundwater areas in the state as identified by the Minnesota Department of Agriculture's Vulnerable Groundwater Area Map[21] are particularly problematic. Other states (e.g., Washington, Wisconsin) with risks to groundwater contamination from feedlots, factory farms, or CAFOs require groundwater monitoring. During the Chapter 7020 rule review, we suggest that MPCA explore options for advancing and progressing groundwater monitoring requirements, and we look forward to participating in that process.

(5) Restricting Land Applications

Restricting land application of manure in areas with high levels of nitrate in surface or groundwater, and in areas with existing high densities of feedlot operation is vital to protect Minnesota's water resources. Land applications of feedlot manure contribute significantly to nitrate contamination in surface and ground water, and MPCA should update the Chapter 7020 Feeldot Rule to implement the following regulations for land application in vulnerable groundwater areas or in areas with high concentrations of feedlots, for example:

- Decrease current allowable quantities of manure land applied.
- Increase manure application setback distances from surface waters.
- Require groundwater monitoring.
- Strengthen soil monitoring
- Require soil moisture sensors.
- Strengthen visual inspection requirements.
- Eliminate practices such as field sharing and self-transfers of manure (see (3) above).

SRAP looks forward to further participation in this process and discussing land application proposals in more detail.

(6) Anaerobic Digesters

Anaerobic Digesters Are Industrial Fuel Operations, Not Livestock Facilities

The concept of a digester is not new. In Minnesota, the first manure digester was installed in 1990.[22]. The early, first-generation anaerobic digesters were designed primarily to manage manure from a single farm. Their key purposes were odor and fly reduction, generation of heat, and limited on-site electricity production. However, their indented scale has dramatically shifted over the last 30 years

In contrast, modern industrial anaerobic digesters are fundamentally different in scale, purpose, and environmental impact. These systems are engineered to process large volumes of input streams, including not only manure but also other waste materials such as food waste. Their primary purpose is the production of methane, which is then either converted into compressed natural gas (CNG) or liquefied natural gas (LNG) for off-site transport via truck or pipeline injection, or used to generate electricity. These facilities can potentially produce several megawatts (MW) of electricity, enough to power entire cities. The electricity generated can then be sold to utility companies and fed into the electrical grid, underscoring the industrial scale of these operations. However, currently, the technology and infrastructure to actually connect to grids is underdeveloped; in fact most anaerobic digesters SRAP hears about simply load explosive gas onto trucks and transport gas to utilities.

In Minnesota, six permitted anaerobic digesters are currently on big dairy farms drawing from 26,385 cows.[23] Of these farms, two use the energy onsite for cogeneration (generating both electricity and useful heat), three exclusively produce methane for CNG, and one sells electricity to the grid.[24] In the past year, the Minnesota Public Utilities Commission approved two more anaerobic digesters of manure facilities to serve Xcel and CenterPoint.[25]

The clear trend is a shift away from first-generation facilities toward building anaerobic digesters as fuel conversion facilities. In fact, MPCA has opted to classify anaerobic digesters as "fuel conversion facilities" under Minnesota Rules, part 4410.4400, subpart 5, which are subject to mandatory environmental review when processing 25,000 dry tons or more per year of input. This regulatory classification reinforces that industrial-scale anaerobic digesters are not agricultural in nature, but are instead large-scale industrial energy operations.

---

[22] MPCA, "Regulatory requirements for anaerobic digesters." (Document No. WQ-F8-54)" (Sept. 2023) available at https://www.pca.state.mn.us/sites/default/files/wq-f8-54.pdf

[23] EPA, Agstar Livestock Anaerobic Digester Database. Last visited Jul. 22, 2025. Available at https://www.epa.gov/agstar/livestock-anaerobic-digester-database

[24] Id.

[25] Citizen Utility Board of Minnesota. "PUC approves $55 million Xcel gas-decarbonization pilots." (Feb. 12, 2025) available at https://cubminnesota.org/puc-approves-55-million-xcel-gas-decarbonization-pilots

Thus feedlots that include industrial anaerobic digesters to produce methane should not be allowed to include the anaerobic digesters under the rubric of an NPDES or SDS General Permit or the Chapter 7020 feedlot rule, because anaerobic digesters are wholly separate point sources under 33 U.S.C. § 1362(14) and industrial activities separate from agriculture. Moreover, the trend in the anaerobic digester industry is now moving towards developing "hubs", facilities designed to generate methane gas for transport or injection into pipelines, or methane "refineries" flaring gas produced from waste. These activities are well outside the realm of the core operations of a livestock feedlot, such as housing and raising livestock, storing feed and manure, and land-applying manure, and are fundamentally different from anaerobic digestion and methane production that Chapter 7020 was designed to address. Unfortunately, the MPCA has missed the mark by misusing its permitting authority and shoehorning digesters—a completely separate point source—into the recently revised SDS CAFO Permit (MN450000) and NPDES CAFO Permit (MNG440000). The approach in the new SDS and NPDES CAFO Permits only confuses the issue. MPCA can use this rulemaking process to carve out digesters from feedlot rules, placing their management and oversight back in the "fuel conversion facility" domain where they belong.

By allowing anaerobic digesters to operate under a CAFO permit, the Minnesota Pollution Control Agency is impermissibly conflating two entirely different industries. Anaerobic digesters are not merely an accessory to animal agriculture, they are independent industrial operations and a significant source of pollution in their own right. However, OAH has the authority to correct this error and we urge OAH to exclude anaerobic digesters from the NPDES and SDS permits and the feedlot rules, and to explicitly clarify in Chapter 7020 that anaerobic digesters require separate and distinct permits that align more appropriately with industrial fuel conversion operations.

Anaerobic Digester Construction Should Constitute a Major Permit Modification

If an anaerobic digester is proposed after a NPDES or SDS CAFO permit has already been issued, or a feedlot has been registered under the Chapter 7020 rules, its addition should be considered a "major modification" of the existing permit or registration. Anaerobic digesters are distinct industrial operations that introduce new environmental, operational, and regulatory considerations, including additional point source discharges, air emissions, and off-site waste transport concerns. Their inclusion warrants a rigorous review process that should, at a minimum, require a life cycle analysis, a full environmental impact review, and meaningful public participation under the framework of a major permit modification. We ask that MPCA account for these impacts in revising Chapter 7020 and consider how the modification would be regulated under Minnesota Rules, part 4410.4400, subpart 5 as well.

Conclusion

Thank you for your consideration of the issues identified above. The emergence of mega factory farms represents a scale of industrial livestock production that current regulations were not designed to govern. Minnesota now has the opportunity to proactively address gaps in Chapter 7020 before these operations take further root in the state. By updating registration and permitting requirements, strengthening operation controls, recordkeeping and reporting mechanisms, environmental review, setting enforceable limits on scale and siting, as well as enforcement mechanisms, the state can move towards safeguarding its water, air, lands, and communities. We look forward to participating in the rulemaking process.

Sincerely,

s/ Elisabeth Holmes

RE: Planned Amendments to Rules Governing Animal Feedlots

Dear Mr. Schwint:

Riverview appreciates the opportunity to comment on the Minnesota Pollution Control Agency's (MPCA) proposed feedlot rulemaking process. MPCA and its staff have the important responsibility of regulating and safeguarding the well-being of our state's natural resources and environment. Riverview has been a participant in the feedlot permit program for over 50 years, and we strive to be responsible stewards of the natural resources that are essential to our state. As a regulated party that values collaborating and working in partnership with governmental agencies, we respectfully submit the following comments

1. **Have the "need" and "reasonableness" to undergo a rewriting of the feedlot rules been sufficiently established?**

   Minnesota's Administrative Procedures Act requires MPCA to issue a statement regarding the "need" and "reasonableness" of a proposed rulemaking[1]. The agency states that "the main purpose of this rulemaking is to address changes in livestock and poultry operations and business practices, account for new agency data services, modernize outdated rule language, amend existing feedlot rules to improve land application of manure practices to address nitrates, bacteria, and fish

[1] Minn. Stat. § 14.131

kills, and establish additional technical standards to protect water quality and avoid fish kills.[2]" However, Minnesota's existing regulatory and permitting framework is already comprehensive and robust. Feedlots from 50 to over 1,000 animal units have registration, permitting, and/or reporting requirements with MPCA[3]. And feedlots over 1,000 animal units are particularly well-vetted before construction and operation can even begin. These types of facilities are subject to a comprehensive environmental review process, and they operate under permits that are typically revisited every five years. The environmental review process allows the agency to determine if a proposed feedlot has the potential for significant environmental impacts. Similarly, periodically updating feedlot permits provides the opportunity to modernize requirements and standards to keep pace with changes and advancements in the livestock and poultry industries. Further, MPCA can also require feedlots to obtain Individual permits. These can be effective tools that allow the agency to address circumstances and challenges that are not expressly contemplated within the rules or the General NPDES or SDS permits. Individual permits give MPCA the ability to impose additional, more stringent requirements during feedlot construction and/or operation.

Given that MPCA is currently equipped with numerous flexible methods of reviewing and regulating feedlots, we would like to better understand the need to amend the feedlot rules.

2. What research is driving MPCA's rulemaking action?

MPCA has referenced research and how it is influencing the agency's decision to begin the feedlot rulemaking process. However, to the best of our knowledge, this research has not been specifically cited. While research can provide valuable insight, it seems that it should be specifically identified, reviewed, and understood by all interested stakeholders. Providing this research would be beneficial for agency staff and feedlot operators alike. Not only could operators review the information and evaluate its applicability, but the agency could also receive relevant feedback.

[2] Minnesota Pollution Control Agency. Request for Comments. Planned Amendments to Rules Governing Animal Feedlots, *Minnesota Rules*, chapter 7020, Revisor's ID Number R-04928. (wq-rule4-29a)
[3] Minnesota Pollution Control Agency. Feedlot registration. (wq-f4-01)

3. **What are the implications and costs for feedlot operators and other stakeholders?**

   Feedlot operations and the farmers that work with them will bear the costs to implement any new regulations. Furthermore, if the costs of compliance are disproportional to the identified need, any new regulations could be an unreasonable burden that reduces farm economic viability, discourages innovation, and stifles growth. Minnesota's dairy industry has seen particularly sharp declines in herd numbers over the last 70 years. The state's dairy herd size went from approximately 1.47 million cows in 1950 to around 460,000 in 2015, a 69 percent decline[4]. In addition to lower cow inventory numbers, this also represents a decline in economic activity and rural vitality. Rulemaking should not unreasonably interfere with feedlot viability and growth, and MPCA should consider the economic implications of new proposals relative to the identified need. However, to further assess the reasonableness of new rulemaking, we would like to better understand the probable costs of complying with any new rules.

Riverview has a long history of operating feedlots in Minnesota. We are committed to being stewards of and protecting our shared natural resources. We thank the MPCA and its staff for their work protecting and preserving our state's environment. The above comments are submitted with the hope that they will lead to substantive conversations and a more productive process for all stakeholders involved.

Sincerely,

Riverview, LLP

July 22, 2025

Dear Mr. Moore:

This letter is to provide Sierra Club North Star Chapter comments on proposed amendments to the state animal feedlot rules as requested by the Minnesota Pollution Control Agency (MPCA). Sierra Club's Minnesota North Star Chapter represents 50,000 members and supporters working to help our state's communities flourish through environmental protection. Our concerns include water quality impacts, manure management, environmental assessment of feedlots, feedlot size, regulatory oversight, and health impacts.

Water Quality Concerns

1. **Contamination of surface water**

Feedlots in Minnesota significantly impact surface water quality due to runoff from manure. This is especially true when it is applied on frozen ground or just before heavy rainfall. It also occurs when livestock have direct access to nearby water bodies or when there is excessive application of manure and fertilizer on croplands. If the crops cannot take up the nutrients, it will lead to runoff. These situations lead to several results that degrade or damage our surface waters.

- Create algal blooms due to runoff with excessive nutrients. The algae may produce toxins that are hazardous to humans and biota
- Causes eutrophication in lakes and rivers, which leads to oxygen depletion
- Increase turbidity with decreasing light penetration
- Causes fish kills that occur due to low oxygen and ammonia from spills and runoff.

Drainage systems and best management practices (BMPs) are designed and implemented to prevent, treat, and manage runoff and any contamination. BMPs entail techniques to maintain proper environmental conditions for feedlots, such as preventing contaminated runoff using well-designed drainage and treatment systems. They also

entail effectively managing manure via proper storage, handling, and application methods. The following activities can enhance feedlot water quality management.

A. All feedlots required to have feedlot permits should complete water quality monitoring at the edge of the fields where manure is applied, from any drainage structures that discharge to nearby waters, and within the body of water itself. This monitoring will assist with determining the effectiveness of drainage and BMPs in preventing, treating, and managing feedlot drainage and runoff.
B. Ensure proper timing and application techniques to minimize runoff and maximize nutrient uptake by crops.
C. Require the use of cover crops to reduce nutrient runoff and improve soil health.
D. As in the Southeast Minnesota Nitrate Strategies Collaborative Work Plan, utilize teams of experts, agronomists, water quality specialists, Soil and Water Conservation District staff. and well management experts, to go on-site to assess and consult with farmers and feedlot owners on their use of best management practices and provide recommendations on improvements and changes that would best prevent water quality impacts

2. Contamination of groundwater

In addition to surface water quality effects, feedlots can impact groundwater through poor manure management, causing the contamination of drinking water by nitrates, bacteria, and other harmful substances. Improper storage and handling of manure, both solid and liquid, can result in leaching and runoff into the surrounding environment and to groundwater. These contaminants contribute to health risks and cause the need for high-cost drinking water treatment, especially in the vulnerable karst area in southeast Minnesota, the Central Sand Plain, and shallow overutilized aquifers in northwestern Minnesota.

A. To help mitigate groundwater contamination, the same BMPs and management actions listed above under surface water contamination apply. Monitoring of groundwater for parameters due to feedlot runoff and leaching pollutants should be increased on a routine basis in areas where wells are used for drinking water, in the areas where feedlots are concentrated, and in sensitive areas where feedlots are located.
B. Assess and mitigate subsurface discharges such as leaking tanks and lagoons, improperly abandoned wells, landfills, and septic tanks.

Manure Management

1. Oversight of Manure Management Plans

The MPCA has excellent guidance and assistance for the development of manure management plans required for feedlots with 300 or more Animal Units (AU). Inspection and

follow-up to determine if the plans are being used and used correctly is needed. This includes the use of more frequent enforcement along with technical assistance such as recommended in the Southeast Minnesota Nitrate Strategies Collaborative Work Plan,

2. Spills and their Impacts

Spills are a continuing problem for facilities that utilize tanks, lagoons, and treatment of runoff. Spills of agricultural runoff and manure can lead to fish kills and surface and groundwater contamination. Examples are the Rush Creek in July 2022, Trout Valley Creek in July 2021, and Garvin Brook in September 2019. Effective prevention includes the use of secondary containment equal to the volume of the tanks or lagoons and development and implementation of spill prevention and response plans in the case of a spill, and these requirements should be mandated in a more complete way in future regulations.

3. Overload of Manure and Fertilizer Applied in Minnesota

The combination of the use of nitrogen fertilizer and manure on crops in Minnesota is likely overloading nitrogen in the cropland, impacting nitrate contamination in ground water and surface water. There are several areas in Minnesota documented by the Environmental Working Group most impacted by this overload, and this should be considered in the location and evaluation of new and expanding feedlots. Large, concentrated operations are a significant concern and threaten water quality. Feedlot size and location should be considered in new or expanding feedlot environmental assessment and permitting to prevent further overload and decrease the nitrate burden in Minnesota water quality.

4. Tile Drainage Treatment

Tile drainage systems, while beneficial for agricultural productivity, can contribute to the nitrate burden in Minnesota waters. Treatment of tile drainage resulting from croplands where manure from feedlots is used as fertilizer through treatment techniques such as saturated buffers, constructed wetlands, and bioreactors, requires further promotion in Minnesota. There is little treatment of tile drainage but there is a large contribution of nitrate to our surface and groundwaters, leading to documented, serious environmental and health effects.

Environmental Assessment

1. Feedlot Registration

A complete database of feedlots is essential to allow for research on their impacts to the environment and public health, which can be accomplished by requiring registration of all feedlots, existing, new, and any with new expansion, not only those with 50 or more animal units (AU) or 10 or more in the shoreland.

2. Environmental Assessment

New or expanding feedlots with a capacity of 500 AU or more should be required to complete environmental assessment before being granted any permit to construct or operate. In sensitive areas, such as shorelands, floodplains, or other sensitive areas (karst features, the Central Sand Plain, and shallow overutilized aquifers in northwestern Minnesota), and drinking water supply areas, all new or expanding feedlots should be required to complete environmental assessment.

Regulatory Oversight of Feedlots

1. **Need for increased oversight and use of enforcement authorities**

MPCA is responsible for regulatory activities of permitted feedlots including permit issuance, permit compliance, inspections, and enforcement. USEPA is also involved in feedlot permit compliance and will conduct inspections routinely. With the large number of feedlots in MN, MPCA cannot likely routinely inspect all those that are regulated, which is a form of effective deterrence. More frequent and routine inspections are the basis for enforcement. MPCA must review the agency's current staffing levels, inspection frequency, and enforcement protocols to promote compliance, act on violations of permits, and prevent the continued contamination of surface and ground water impacting both health and the environment.

2. **Continued and increased oversight of county activity in feedlot regulation**

Most feedlots (60%) are in delegated counties in Minnesota. These counties are responsible for feedlot permitting and oversight outside of shoreland of feedlots that hold 50 to 299 AU in their county. There are approximately 3000 registered feedlots in MN located outside of shoreland that delegated counties oversee. A review of the feasibility and effectiveness of this arrangement should be completed. There are reports of political influence affecting the management of feedlots in delegated counties leading to lack of enforcement and oversight.

Health Impacts Due to Feedlots

Feedlots are a source of health issues and concerns for the community. Without effective regulation, health impacts are a much larger concern and potential source of disease and public health risk. Examples include air quality, pathogens and other health concerns included in the comments below. Animal feedlots demonstrate a wide range of health impacts, and enforcing environmental regulations on these facilities protects the public health and informs policymakers on the need to mitigate negative effects of feedlots through regulation and adequate program funding.

1. **Air quality**

Sources of air quality concerns due to feedlots include dust and particulate matter, especially fine particles like PM2.5 that can infiltrate deep into lungs, affecting respiratory function and premature death. Gas emissions, including ammonia, hydrogen sulfide, and

methane due to breakdown of animal waste, can exacerbate asthma and bronchitis. Neighbors of feedlots note irritation of eyes, nose, throat, headaches, and nausea, which can negatively impact mental well-being and stress.

2. Pathogens

The organisms E. coli and Salmonella can contaminate water supplies, contributing to foodborne illness when crops are irrigated with water impacted by feedlot runoff. Dust due to feedlots can also contribute to this. Another concern related to pathogens is that when antibiotics are heavily used at feedlots, the bacteria can become antibiotic-resistant causing illness to be harder to treat, and is a public health concern.

3. Other Health Concerns

Health issues due to feedlots include an increased risk of death due to impacts to cardiac health when living close to feedlots. Birth defects are noted with exposure to nitrogen compounds due to feedlots, including spina bifida and anencephaly. Other health conditions associated with feedlots are increased rates of thyroid disease, kidney disease, tuberculosis, septicemia, and methemoglobinemia in infants.

The North Star Sierra Club appreciates your consideration of our comments as you move forward with changes and updates to the state feedlot rules and programs. Please feel free to contact us at 612-659-9124 or north.star.chapter@sierraclub.org.

Sincerely,

Margaret Levin, State Director

Darin Broton Attachment

July 22, 2025

RE: Revisor's ID Number R-4928 [OAH Docket No. 25-9003-40661]

Our farmers are dedicated to ensuring Minnesota's waters are protected for future generations while creating a healthy, vibrant agriculture economy for their families and communities. Although the agency's current feedlot rules were last updated nearly 30 years ago, they are considered concise, clear, and comprehensive.

In fact, Minnesota has some of the most thorough feedlot regulations in the country. Feedlots with fewer than 1,000 animal units are already developing and adhering to manure management plans, following the state's buffer law that protects streams and lakes from potential runoff.

As the MPCA determines its next steps regarding feedlot regulations and the 7020 rules, Minnesota AgriGrowth encourages the agency to consider the following principles and strategies.

Maintain flexibility and innovation

The 7020 rules must promote flexibility and innovation for agriculture. Best management practices evolve as new technologies and advancements in science become available. Minnesota farmers have been dealing with extreme weather and a rapidly changing climate for almost 20 years. Precision agriculture has experienced significant growth over the past 15 years, enabling the more targeted allocation of resources needed for crop growth and the reduction of nutrient runoff. Yet the agency's 7020 rules do not reflect those new realities. Agency regulations will never keep pace with new science and technology. That's why creating more flexibility and avoiding a one-size-fits-all approach must be considered in any changes to the 7020 rules.

Recognize and utilize farm-specific data

Today's farms operate with a wealth of data. While the University of Minnesota and other land-grant universities' research is comprehensive and offers a baseline of recommendations, it does not recognize the data-driven management that can improve the efficient use of nutrients and reduce possible loss to ground and surface water. Feedlot rules should allow farmers to use five-year average crop-level data to make informed decisions for their fields. This is a great opportunity for a working group of precision

agriculture experts to develop flexible and responsive rules that adapt to changing field conditions.

Incorporate existing protections

Minnesota farmers underwent an extensive process to incorporate buffer strips and setbacks to protect water quality. While state agencies have not provided clear data on how buffer strips have improved water quality, Minnesota's buffer law should be recognized in feedlot rules as a means of enhancing nutrient management and water quality.

Assess better alignment between federal and state definitions of animal units and animal numbers

The federal government's decision to use animal heads is inconsistent with Minnesota's use of animal units. Additionally, the calculation of animal units for various species in Minnesota can vary when compared to our neighboring states, including Iowa and South Dakota. The MPCA should convene a working group to examine the varying definitions and calculations and determine the best approach for Minnesota that ensures consistency with the federal government and neighboring states, while avoiding unnecessary complexity and unintended consequences for livestock farmers, including new permitting thresholds.

Raise the threshold for the NPDES and SDS permits

The decision to require feedlots with at least 1,000 animal units to acquire a NPDES and SDS permit was never based on science. It was a political decision by the agency and the legislature at the time. The MPCA's 1,000-animal unit threshold has created a regulatory environment in which many farmers are unwilling to expand their operations due to the additional obstacles posed by the construction and operating permit requirements. Instead, the state has a significant number of feedlots with 999 animal units, an unintended consequence of the current regulations.

If the agency considers new regulations for farms with less than 1,000 animal units, the MPCA should strongly consider raising the threshold to require a SDS permit. The 1,000-animal unit threshold does not reflect the current state of the livestock industry. The NPDES and SDS permits should only be used when a facility may have the greatest environmental impact. There is no evidence that a 1,000-animal unit operation has any greater impact on the environment than a 999-animal unit operation. We can strengthen the livestock industry by reducing regulatory burdens while ensuring the protection of water quality. This is another opportunity for a working group to establish a commonsense threshold based on best practices and science.

For full consideration,

July 22, 2025

RE: Planned Amendments to Rules Governing Animal Feedlots, *Minnesota Rules*, chapter 7020, Revisor's ID Number R-04928

As a sovereign Tribal government located in northern Minnesota, the Leech Lake Band of Ojibwe (LLBO) is taking this opportunity to comment on proposed rulemaking for Minnesota Feedlot Rules (Chapter 7020). The Leech Lake Band of Ojibwe has Treatment as a State authorities under Sections 106, 319, 401, & 303(c) of the Clean Water Act and holds usufructuary rights to hunt, gather and fish within the Leech Lake Reservation and 1855 Ceded Territory. Protection of the environment, water quality, and treaty protected resources in this region is of utmost importance to Leech Lake Band members for their spiritual and physical wellbeing.

A healthy environment is vital to supporting the Leech Lake Band of Ojibwe as well as our plant and animal relatives. Long before modern agriculture and feedlots, people in what is now Minnesota lived off the bounty of wild rice, fish, and other natural resources. Proper regulation of feedlots and manure is needed to ensure protection of the environment and our way of life.

We support the Minnesota Pollution Control Agency's (MPCA) proposed rulemaking to update rules governing animal feedlots. In response to the request for comments, we recommend MPCA consider the following policy recommendations when drafting a future rule:

1. Lower the threshold to require NPDES/SDS permits for large feedlots with 600 or more animal units.

2. Water quality monitoring requirements for feedlots with 300 or more animal units. This monitoring should include groundwater and surface water at feedlots and manure storage sites.

3. Require sufficient storage of manure that capacity is not exceeded during the period when manure cannot be applied due to frozen or saturated soil conditions. A double liner system with groundwater monitoring should be required for liquid manure.

4. Require manure management plans for feedlots with 300 or more animal units and online reporting of manure application amount, location, and date.

5. When manure is transferred, the owner of feedlot must report that transfer to MPCA or delegated county. Transferees must report to MPCA or delegated county the amount, location, and date of manure application.

6. Require soil and shallow groundwater nitrate tests prior to manure application in locations with known nutrient issues, such as the central sands region or the Karst region.

7. Prohibit application of solid or liquid manure to frozen or saturated soils, or when rainfall is likely.

8. MPCA should establish a limit to maximum feedlot size and a limit to animal units and manure application within HUC-12 watersheds to limit cumulative effects.

9. Include Tribal source/drinking water protection areas in setback requirements.

10. Animals must be restricted from accessing and entering public waters or their tributaries and feedlots should be fenced to prevent such access.

11. Require delegated counties to submit annual reports to MPCA and explicitly authorize MPCA to revoke or rescind delegated authority if a county fails to perform its duties.

The Leech Lake Band of Ojibwe would like to express our appreciation for the opportunity to comment on possible rulemaking for feedlots at this early stage. We look forward to continued engagement in this process. If you have any questions or require clarification please do not hesitate to contact me.

Sincerely,

Craig Tangren
Environmental Deputy Director, Leech Lake Band of Ojibwe

July 22, 2025

Dear Rule Coordinator Addison Otto,

It is past time to clean up Minnesota's waters so that we're not drinking and swimming in high nitrate cow manure runoff and seepage. May I assume that you think allowing such pollution in our waters is NOT ok? Then please DO SOMETHING in your role with MPCA. It's past time to value people's health above corporate profit.

This is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. Animal feedlot manure causes serious problems of runoff, seepage, and spills that not only are odorous and disgusting, but are unsafe for humans and damage the environment.

Manure runoff in Minnesota waters results in fish kills. Swimming (hey, we're Minnesotans -- this is what we do, swim in our lakes and streams!) is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers (ugh), producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.

MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Anne Reich

To: WaterLegacy

Dear MPCA

1. MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.
2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.
3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.
4. MPCA rules should stop merely trusting that animal feedlots and manure applications are “no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.
5. MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.
6. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.
7. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
8. MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

TO: Minnesota Pollution Control Agency

FROM: Jennifer Pearson, MD

4532 London Rd. Duluth, MN 55804

RE: Feedlot rules

I am a family medicine physician and medical school faculty in Duluth Minnesota. I am very concerned about the connection between environmental pollution/toxins and resulting deleterious effects to human health. I would like to comment on the Animal Feedlot rules, given the fact that Minnesota has over 23,000 feedlots: aka concentrated animal feeding operations (CAFOs). These feedlots generate manure and nitrate pollution that flow down the Mississippi River and are not only contributing to the worsening Dead Zone in the Gulf of Mexico but to environmental conditions that are hazardous to ecological and human health.

The current manure runoff, seepage and spills from animal feedlots cause serious problems in our state:

- Fish kills result from byproducts of manure decomposition and depletion of oxygen levels in water due to excessive nitrates and algae blooms.
- Swimming is unsafe due to E.coli bacteria from animal wastes. More than 100 Minnesota waterbodies are listed under the Clean Water Act as impaired due to E.coli.
- Excessive nitrates result in blue-green algae blooms in shallow lakes and rivers, producing toxins (cyanobacteria) harmful to wildlife and humans.
- Increased nitrates in well water used to prepare infant formula can cause methemoglobinemia (blue baby). In recent decades, even without a tracking system for these cases, the Minnesota Department of Health has concluded that nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Current MPCA Animal feedlot rules are inadequate to protect Minnesotans:

- Existing rules require water pollution permits for huge feedlots with 1,000 or more “animal units”. “Medium-sized” feedlots with 300-999 animal units (which contribute 43% of Minnesota’s total manure) require no permits at all.

- Existing rules set no maximum size for feedlots and no maximum number of animal units in a local area or watershed, allowing feedlots and concentration of pollution impacts to increase. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.
- Existing MPCA rules claim “no discharge” is allowed, but neither manure storage areas nor fields where manure is sprayed are monitored or tested to detect discharge and pollution levels. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.
- Existing MPCA rules do not apply modern science and technology to require containment of all manure within advanced liner systems. Rules also allow spreading of manure on fields even during the winter.
- Loopholes and exemptions allow noxious and odorous hydrogen sulfide air emissions as well as toxic water pollution. No existing rule requires a feedlot emitting noxious emissions and odors to demonstrate that at least 344 days a year, all air quality standards have been met.

Given these many concerns, I advocate that the following changes be made by the MPCA:

1. MPCA rules should require pollution permits for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.
2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.
3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.

4. MPCA rules should stop merely trusting that animal feedlots and manure applications are “no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.

5. MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired waters, and prevention of degradation in waters that are not polluted.

6. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

7. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.

8. MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year. Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

Thank you for considering my comment and concerns.

July 22, 2025

To: Minnesota Pollution Control Agency
Commissioner Kessler, Mr. Schwint, and Ms. Otto

Reference: Individual Comment / MPCA Animal Feedlots Rule

I am hereby submitting my comments to the Minnesota Pollution Control Agency (MPCA) regarding the need to rewrite animal feed lot rules and stop toxic pollution of Minnesota waters.

Feedlots globally, nationally, and in our own state of Minnesota are huge polluters and a menace to public health. Nitrates in manure runoff from Minnesota's 23,000 CAFOs contribute to the Gulf of Mexico Dead Zone. Manure runoff results in fish kills, swimming is unsafe in some areas due to E.coli bacteria from animal waste. The excessive amount of nitrates from manure cause blue-green algae blooms in shallow lakes and rivers, producing toxins that harm wildlife and humans. Increased nitrates in well water used to prepare infant formula can cause methemoglobinemia, a condition of elevated methemoglobin in the blood that can be fatal to infants.

I am a proud Minnesotan and know we, as a forward thinking and acting state, can do much better, and now is our chance to make the needed course correction to protect our people and the fish, animals, and lakes/rivers/streams that are being irreparably damaged due to unnecessary and unchecked pollution caused by loose or non-existent rules and requirements around the management of feedlots.

The existing rules are unrealistic and ineffective if they are meant to check water pollution, and the following steps must be taken to better protect our water resources, wild life, and human population:

Covering only the largest of feedlots (1000 animal units), these rules don't affect medium-sized feedlots, which can still be very large in nature with up to 999 animal units, and which are, in fact, responsible for over 40% of all manure.

1. **Recommended rule change**: **MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units.**

Existing rules lack caps in terms of the size of feedlots and the number of animal units they can hold in any given local area or watershed, allowing for uncontrolled growth and ensuring concentrated, run-away pollution in adjacent areas.

2. **Recommended rule change: MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in**

any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. **Recommended rule change: MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that "stricter" requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.**

While MPCA rules claim there is no allowance for "discharge", this rule is impossible to enforce as neither manure storage areas nor fields where manure is sprayed are tested or monitored. This lack of standard monitoring and reporting further contributes to the pollution of our waters and to the dangerous environmental hazards people living nearby are subjected to.

4. **Recommended rule change: MPCA rules should stop merely trusting that animal feedlots and manure applications are "no discharge" facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.**

5. **Recommeded rule change: MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.**

The MPCA rules as they exist today are archaic and in no way serve to curb the spread of toxins that reach our water and harm the health of residents living in the affected areas. New technologies using liners to contain manure runoff are not employed and the MPCA actually allows manure to be spread on fields throughout the year, including in winter months that causes harmful results during the spring thaw with toxic runoff.

6. **Recommended rule change: MPCA rules should strengthen minimum technology** requirements for all permitted **animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.**

7. **Recommended rule change: MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.**

Loopholes and exemptions allow for the emission of noxious and odorous hydrogen sulfide as well as toxic water pollution.

8. **Recommended rule change: MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.**

Thank you for your consideration.

Dear MPCA:

Just because our federal government is abandoning all health and safety regulations doesn't mean that Minnesota should do the same.

We need permits required of feedlots above 300 head, caps on feedlot size, prohibition of feedlots in sensitive karst areas, a stringent limit on nitrate pollution of surface waters, monitoring of feedlots and manure-spread fields for compliance with "no discharge" rules and surface- and groundwater limits, current/rigorous requirements for manure storage and spreading, and the elimination of loopholes and exemptions that allow SHIT in our air and water.

Thank you,

Dr. Kristina Boerger

From: Russ Erickson
To: info@waterlegacy.org

Simple suggestion:
Require animal manure and liquid waste be put through a treatment plant just like we do with human waste. Mini treatment on site or trucking to a treatment plant.

Why - I lived in an area in Iowa where the Fairfield town water was undrinkable due to surrounding farm practices. Although people did drink the nitrate laden water because there was nothing, they could do about it and we all needed water. I hope no one has long term health issues there.

Dear MPCA,

I hope you will revise rules for animal feedlots to more effectively protect Minnesota's surface waters and groundwater from additional nitrate pollution.

We need to reduce nitrates in our water, and feedlots are increasingly adding nitrates to our environment.

I have lived in Minnesota for most of my 67 years and grew up drinking well water and swimming and boating in our lakes and rivers. I am saddened at the degradation of our waters, knowing that much of Minnesota's well water is no longer good to drink and that many of our surface waters are impaired and contribute, eventually, to the so-called dead-zone at the mouth of the Mississippi River.

Animal feedlots and their pollution of our waters need to be regulated--including "medium-sized" feedlots.

We know that the condition of our waters has much to do with what we do to our land.

Animal feedlots should be treated essentiallly as a kind of industrial point-source for pollution; and spreading manure on fields, particularly in winter, should be considered a form of discharge and be regulated and monitored accordingly.

I hope you will act in the interest of Minnesota's waters, which belong to all of us. No one has the right to ruin them now or for future generatons.

Sincerely,
Tim Larson

From: Winston Kaehler
To: info@waterlegacy.org

It sounds like the MPCA needs to tighten rules for feedlot operations, especially in the karst region, where topsoil is such a thin layer, leading to groundwater pollution. It is high time for feedlot operations to be regulated to protect the general public. The MPCA has a duty to do that.

Re: Comments on MPCA RFC for Amendments to Rules Governing Animal Feedlots: Minnesota Rules, Chapter 7020, Revisor's ID Number R-4928, OAH Docket No. 25-9003-40661

Dear Mr. Moore:

The **Association of Minnesota Counties (AMC)** and the **Minnesota Association of County Feedlot Officers (MACFO)** appreciate the opportunity to **provide comments on the Minnesota Pollution Control Agency's (MPCA) Request for Comments (RFC) regarding proposed amendments to Minnesota Rules, Chapter 7020, governing animal feedlots.** As organizations representing county governments and feedlot officers with direct experience in implementing the state's feedlot program, we are committed to supporting effective, flexible, and practical rules that protect the environment while maintaining the viability of Minnesota's livestock industry.

Manure Management and Storage

Any proposed changes to manure application restrictions—such as expanded setbacks or application restrictions—must consider their impact on storage needs. Any new restrictions on manure storage should be accompanied by evaluations of manure storage feasibility, accounting for financial costs, and regional differences in climate and infrastructure.

To address the structural integrity of aging manure storage areas, we suggest developing practical inspection standards. The MPCA or county feedlot officers could provide checklists or guidelines to assist feedlot owners in assessing structural integrity. Any inspection requirements should clearly define who conducts inspections, whether owners, certified professionals, or state/county staff, assessing the capacity and costs to do this work, and outline documentation expectations to ensure consistency and clarity.

Feedlots Under Common Ownership

MPCA policy documents and local ordinances currently address facility size questions. State guidance could be clarified for "separate facilities" based on operational and physical separation rather than arbitrary distance thresholds that are not consistently applied. Having specific and consistent standards will assist livestock producers in planning for the future of their farm(s). Local governments do and should continue to set separation distances, as local thresholds are already established and reflect regional needs.

Technical and Minor Rule Revisions

We recommend reviewing certain existing provisions to determine if they remain necessary. The Open Lot Agreement may be outdated given changes in management practices and should be re-evaluated for relevance. Similarly, the certified letter requirement for pit closures is overly prescriptive; digital reporting or alternative verification methods may be more efficient and equally reliable.

Feedlot-related well setback rules should also align more clearly with the Minnesota Department of Health Well Code to eliminate confusion and streamline compliance.

Balancing Flexibility with Environmental Protection

To balance regulatory flexibility with environmental protection, the MPCA should take a data-driven and regionally sensitive approach. Providing multiple compliance options—such as MPCA-approved alternative manure management practices referenced in NPDES Permit 13.5—can accommodate the diverse operational realities across the state. Before adopting new regulations, the MPCA should present data on current inspection rates, compliance performance, and stockpile oversight for both NPDES/SDS facilities and smaller sites to ensure that any changes address true gaps in effectiveness.

Additionally, a cost-benefit analysis is essential to assess the financial impact on producers and the availability of cost-share support. Counties should also be permitted to implement alternative compliance methods, leveraging local knowledge to develop flexible and effective environmental solutions.

We urge the MPCA to carefully evaluate any proposed changes to permit thresholds and Animal Unit (AU) calculations, as these figures have wide-reaching implications. AU values influence local zoning decisions, eligibility for cost-share programs, manure management plan (MMP) thresholds, and NPDES/SDS permitting requirements. Even small changes could create significant impacts for feedlot operators and state and county program administration. We encourage the agency to work closely with stakeholders to understand any implications before proceeding with revisions in this area.

Finally, we emphasize that the delegated county program is minimally funded. Any rule changes that increase administrative responsibilities for counties must be paired with additional resources to ensure successful implementation. Without adequate funding, expanded mandates risk creating bottlenecks and undermining program goals.

AMC and MACFO support the MPCA's intent to modernize Chapter 7020 in ways that strengthen environmental protections while preserving the vitality of Minnesota's livestock sector. We urge the agency to pursue rule changes that are cost-effective, flexible, and grounded in current data and field realities.

We look forward to continuing collaboration throughout the rulemaking process, including direct discussions with MPCA staff to refine proposed changes. If you have any questions or would like to discuss these comments further, please contact Brian Martinson, AMC Policy Analyst, at 651-246-4156 or bmartinson@mncounties.org.

Sincerely,

Brian Martinson, Policy Analyst

RE: Planned Amendments to Rules Governing Animal Feedlots, Minnesota Rules, chapter 7020, Revisor's ID Number R-04928

The Minnesota Agricultural Water Resource Center is comprised of general farm organizations, crop, livestock and poultry producer associations, and trade groups providing services and support to Minnesota farmers. Our efforts focus on ensuring a prosperous future for farmers while fostering improved environmental stewardship.

We offer the following comments in response to the MPCA's proposal to amend the current Chapter 7020 Rules governing feedlots. As part of this comment and rulemaking process, we hope you receive comments from many individual farmers, and we encourage you to carefully consider their input as it comes from those who derive their livelihood from farming, and specifically in this process, livestock and poultry production. You will also hear from farmer groups providing representative voices for those farmers who may be uncomfortable providing input, some out of fear of reprisal. Their comments should also be highly valued.

As stated in the request for comments, "the main purpose of this rulemaking is to address changes in livestock and poultry operations and business practices, account for new agency data services, modernize outdated rule language, amend existing feedlot rules to improve land application of manure practices to address nitrates, bacteria, and fish kills, and establish additional technical standards to protect water quality and avoid fish kills." For input on operations, data management, and related issues, comments from farm groups and farmers are of utmost importance, as it comes from those most directly affected by the rule.

In the request for comments, you specifically ask for comments relating to several questions. Our comments focus on those questions most directly related to water quality and stewardship.

• Are additional restrictions on manure application rates needed?

No additional restrictions are necessary. The current rule is adequate. Ongoing research should be supported and the results disseminated to livestock and poultry farmers enabling continued improvement in manure use efficiency. As pointed out in the recently published Nutrient Reduction Strategy, manure and fertilizer application rates are trending closer over time to Extension recommendations, without regulation.

• Are increased setback distance for land application of manure near sensitive features needed?

Simply, no, the current list of sensitive features and required setback distances are adequately protective of water quality and should not be increased. MN Buffer Law requirements should be included when factoring setback distances. The law was intended to protect the state's water resources from runoff pollution. BWSR reports that compliance with buffer requirements exceeds 99%. MPCA needs to provide scientific evidence that the existing setback distances are inadequate.

• Should land application of manure in areas with high levels of nitrate in waters or in areas with existing high densities of feedlot operations be further restricted?

Manure applications are already in place for those feedlots required to have a manure management plan. Additional limits on manure beyond agronomic optimums would incentivize the use of other nitrogen sources. How would MPCA define areas as having "high" feedlot operation density? From a statewide mass balance perspective, commercial nitrogen provides approximately three times as much nitrogen for crop production as does manure. As economics and markets dictate, there is room for

significant expansion of livestock and poultry production in our state without environmental harm, and potentially significant water quality improvement due to benefits of manure to soil health as compared to commercial fertilizer.

• Should additional best management practices be required for land application of manure during the months of September through November?

The current rule requiring cover crops following manure applications in June, July and August for feedlots required to have a manure management plan is adequate. MPCA should support other agencies in promoting all identified improved manure management practices, including cover crops and nitrification inhibitors, on a voluntary basis. The MPCA should support an exemption to current requirements for pesticide applicator training for nitrification inhibitors applied with manure in order to increase adoption of this recommended practice. These voluntary, incentive-based activities represent our best efforts to protect water resources, as documented in MPCA's Nutrient Reduction Strategy.

• Should land application of manure on frozen or snow-covered fields be restricted?

Many small farms lack the storage capacity and/or equipment to eliminate winter spreading. Restrictions would result in undue economic hardship, possibly forcing some farmers to discontinue operations. When winter manure applications can't be avoided, University of Minnesota Extension recommends applying manure at the lowest necessary rate, on fields with flat slopes, in accordance with all applicable setbacks including waterways, and avoided before a significant snowmelt event (www.extension.umn.edu/manure-management/manure-timing).

• Should additional best management practices be required for land application of manure when there is a high probability of rain predicted?

In order to assist farmers in avoiding such situations, the MPCA should work with the Minnesota Department of Agriculture to increase awareness and assist farmers in utilizing the MDA's brand new, state-of-the-art weather network and other tools that equip farmers with technology to inform the implementation of best management practices.

• The MPCA has developed Watershed Restoration and Protection Strategy (WRAPS) documents for every one of Minnesota's 80 major watersheds. These WRAPS document high nutrient and bacteria levels in streams and rivers. The reports attribute this to livestock access to streams in many cases. How should the rules be amended to address this documented issue (part 7020.2015)?

This is very misleading. Some WRAPS address feedlots without specificity and few refer to livestock access to streams. For those WRAPS reports that do include discussion of livestock and manure management, most call for increased support for voluntary efforts and practice incentives.

• State agencies are required to, whenever feasible, develop rules that are not overly prescriptive and inflexible, and rules that emphasize achievement of the MPCA's regulatory objectives while allowing maximum flexibility to regulated parties and to the MPCA in meeting those objectives (Minn. Stat. § 14.002). How might the MPCA balance this need for flexibility for regulated parties while also addressing the issues of nitrate contamination and fish kills?

The agency needs to demonstrate, using data, that the current rules are inadequate concerning the impact of manure on nitrate concentrations in surface water and fish kills. Fish kills are unfortunate, but extremely rare, and fish kills associated with manure are rarer still. In contrast, this is an opportunity for MPCA to promote wider adoption of cover crops and use of the MDA's weather network to improve manure management and protect surface waters from contamination.

9. Other questions or comments relating to the existing animal feedlot rules or this proposal to amend the rules.

As noted by the agency as justification for initiating this rulemaking process, livestock and poultry production have changed. Rulemaking cannot keep pace with technology and often inhibits innovation. Best management practices such as split rate manure applications, low disturbance manure application equipment, variable rate manure application, on-the-go manure nutrient content testing, on-farm processing of manure to separate liquids and solids, and improved manure distribution utilizing draglines have improved manure management on livestock and poultry farms. Some of these practices are very recent innovations, while others have become relatively common. This evolution of manure management clearly demonstrates that voluntary practices, supported by science, will be readily adopted.

Through this rulemaking the MPCA has an opportunity to provide clarity and efficiency in its programs in order to protect and improve water quality in Minnesota. In recent decades many livestock producers have exited the industry, often citing regulatory requirements or the threat of additional requirements as a primary factor in their decision. The solution to improving manure storage, handling and land application practices lies in on-farm innovations supported by research and incentives for early adopters. Regulation should be the last option and provide a practical baseline that works for farms of different sizes, types and locations.

We look forward to working with MPCA in coming years as you work through this process.

RE: Response to Request for Comments, Feedlot Rulemaking, Chapter 7020, Revisors ID Number R-04928

Dear MPCA and Office of Administrative Hearings staff:

On behalf of Minnesota Famers Union (MFU), I write to submit our organization's comments on potential updates to Minnesota feedlot rules. We appreciate the opportunity to share our thoughts and hope that they, along with comments from farmers across the state, help inform your work. We understand that changes to the 7020 rules could have consequences for our members of all sizes and production types. And we look forward to engaging with you and helping ensure our members are informed throughout the rulemaking process.

First, and broadly, promoting water quality is a fundamental value for all Minnesotans, including our members. And we recognize that—along with other programs and technical assistance—clear, practical, and science-based rules for feedlots help ensure farmers are doing all they can to protect the environment.

Second, and as a matter of our grassroots policy, our members support a graduated approach to regulation wherein permits are required for the largest facilities. We also recognize that, as you've worked to make clear, the 7020 rules apply to all sizes of livestock operations across a broad range of production types.

With that, here are some comments that come from conversations with our members about these potential changes:

- **Protect the viability of family farms** – as you note in the request for comments, the structure of agriculture is changing and with small farms leaving production. For example, between the 2017 and 2022 Census of Agriculture, Minnesota lost 40 percent of our dairy farms, while the overall number of cows remained largely the same. We believe that is a loss not just for those families, but also for our rural schools, main streets, and communities.

  We believe strongly that Minnesota is better for having more distributed, independent, livestock producers. Our Department of Agriculture (MDA) and others have led in supporting generational farms and helping new farmers build a life in agriculture. Policies across state government, including the 7020 rules, should promote the continued sustainability and viability of family farms across our state.

- **Promote livestock** – relatedly, we believe that livestock represent an important way that many farmers diversify their farm income, bring the next generation to their operation, and improve the health of their soil. Livestock also does a great deal to support local economies and provide value added markets for other farmers.

With that, any proposed rules should recognize the value of manure for soil health. It also promotes independence and resilience, allowing farmers to supply their own fertilizer rather than depending on the often-volatile market for chemical fertilizers produced outside the state.

- **Provide clarity** – farmers should be able to easily determine what rule changes apply to their operations, what is required of them, and on what timeline. In discussions with members about the potential rule changes, we encountered a variety of knowledge about current regulations and their applicability. Investments in outreach, farmer-facing materials, and other support is welcome. Clear rules are also important for training and retaining technical service and regulatory staff, who rely on working relationships with operators.

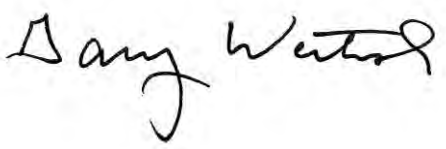
- **Ensure practicality and flexibility** – any rule changes should acknowledge and incorporate the complexity of farming and the decisions that farmers make across their operations from year to year depending on conditions. Any changes to the rules should ensure that farmers can meet the new requirements, and that there are tools and resources available to help them implement any changes.

  Any rule changes should also recognize—as you have in your request for comments—that farmers are always innovating with the goal of lowering costs, improving efficiency, promoting environmental outcomes, and otherwise improving their operations. From technology like variable rate application to practices like winter bale grazing, farmers of all sizes and production types are working to incorporate and inform the latest available science. Rule changes should allow farmers flexibility where supported for promoting water quality.

- **Leverage voluntary, incentive-based conservation programs** – recent years have seen significant investment in and adoption of voluntary and incentive-based conservation programs. These programs, including the Minnesota Agricultural Water Quality Certification Program, the Soil Health Financial Assistance Grant Program, various programs offered through Soil and Water Conservation Districts and the Board of Water and Soil Resources, as well as many private sector and non-profit organization run programs, offer a variety of options for farmers to add cover crops, reduce tillage, and implement edge-of-field practices which promote soil health, water quality, and biodiversity. Any updates to 7020 rules should leverage and be informed by these programs and their boots-on-the-ground technical staff. Continued investment and promotion of these programs is also an important strategy for reaching state soil health and water quality goals.

Thank you for your attention to these comments and your efforts to travel across the state and connect directly with farmers who will be affected by changes to 7020 rules. And to communicate the scope and potential impact of proposed changes. Please count on us as partners in this process going forward. If you have any questions, please contact our Government Relations Director, Stu Lourey, at stu@mfu.org or (320) 232-2047. Thank you for considering the needs and perspectives of our members and for your important work.

Sincerely,



Gary Wertish
President, Minnesota Farmers Union

Submitted Online via Office of Administrative Hearings Rulemaking e-Comments Website

Re: Comments on Planned Amendments to Rules Governing Animal Feedlots, Minn. Rules Ch. 7020, Revisor's ID No. R-04928

Dear Addison,

Food & Water Watch respectfully submit these comments in response to the request for comment on planned amendments to the Minnesota state feedlot regulations issued by the Minnesota Pollution Control Agency ("MPCA" or "the Agency") on February 25, 2025. We appreciate the opportunity for early input on a rulemaking that is critical to safeguarding water quality, human health, and wildlife from feedlot pollution. Without much-needed revisions to the state feedlot regulations, underregulated livestock waste and other feedlot pollutants will continue to degrade waters of the state in contravention of state and federal law. As discussed in detail below and supported by scientific studies and other documents submitted as exhibits to these comments, we ask that MPCA redress adverse impacts caused by feedlots by ensuring that all discharging concentrated animal feeding operations ("CAFOs") obtain National Pollutant Discharge Elimination System ("NPDES") permits, codifying requirements to implement best

management practices proven to control feedlot pollution, requiring feedlots to attain effluent limits based on pollutant reductions attainable through advanced wastewater treatment technologies, and mandating effluent monitoring and reporting to ensure compliance with major regulatory requirements. Food & Water Watch also supports and incorporates by reference comments submitted by the Minnesota Center for Environmental Advocacy.

I. Feedlots Harm Water Quality and Public Health in Minnesota

Unlike traditional livestock rearing operations that raise animals on pasture according to the land's capacity to feed the herd/flock and assimilate the waste generated, feedlots confine large numbers of animals in crowded enclosures. Many feedlots are essentially livestock factories that operate much like sewerless cities.[1] These facilities generate, store, handle, and dispose of enormous quantities of pollutant-laden waste.[2] Though managing feedlot waste poses many of the same risks as managing human waste, most feedlots do not treat their waste using the advanced treatment techniques required of sewage plants or any equivalent treatments. Rather, feedlots are largely permitted to store untreated liquid waste in leaky liquid manure storage areas ("LMSAs" or "lagoons"), and to spray or spread this waste onto land application areas at rates that are not designed to safeguard water quality or public health. Feedlots also manage solids like compost and silage in ways that allow pollutants to seep, leach, and runoff into waters of the state. When feedlots discharge their waste to ground- and surface waters, pollutants degrade water quality, creating severe health and environmental consequences that Minnesotans are unfairly forced to endure and pay for. Clearly, the status quo is not working for Minnesota's waters or residents.

A. Feedlot Waste Contains a Slurry of Harmful Pollutants

[1] U.S. GAO, CONCENTRATED ANIMAL FEEDING OPERATIONS: EPA NEEDS MORE INFORMATION AND A CLEARLY DEFINED STRATEGY TO PROTECT AIR AND WATER QUALITY FROM POLLUTANTS OF CONCERN, GAO-08-944 at 18, 20 (2008), available at https://www.gao.gov/products/gao-08-944 ("[T]he amount of manure produced by [CAFOs] can exceed the amount of waste produced by some large U.S. cities.").

[2] *See, e.g.,* AM. PUB. HEALTH ASS'N, *Precautionary Moratorium on New and Expanding Concentrated Feeding Operations* (Nov. 5, 2019), https://www.apha.org/policy-and-advocacy/public-health-policy-briefs/policy-database/2020/01/13/precautionary-moratorium-on-new-and-expanding-concentrated-animal-feeding-operations; CARRIE HRIBAR, NATIONAL ASS'N OF LOCAL BOARDS OF HEALTH, UNDERSTANDING CONCENTRATED ANIMAL FEEDING OPERATIONS AND THEIR IMPACT ON COMMUNITIES 2–3 (Mark Schultz, 2010), https://stacks.cdc.gov/view/cdc/59792; DOUG GURIAN-SHERMAN, UNION OF CONCERNED SCIENTISTS, CAFOS UNCOVERED: THE UNTOLD COST OF CONFINED ANIMAL FEEDING OP 42 (Apr. 2008), https://www.ucsusa.org/sites/default/files/2019-10/cafos-uncovered-full-report.pdf

Feedlot waste contains numerous pollutants that harm human and ecological health when they enter the environment.[3] These pollutants include nitrogen, phosphorus, sediments, salts, and ions such as magnesium, sodium, potassium, and chlorides.[4] Feedlot waste also contains a hazardous cocktail of bacteria, pathogens, pesticides, pharmaceuticals, and metals.[5] Though feedlot waste is often referred to exclusively as manure, this characterization is misleading as feedlot waste contains many pollutants not found in non-feedlot manure, and feedlots also dispose of hair, feathers, bedding materials, cleaning products, mortalities, and other pollutants from non-manure sources.[6] These pollutants pose unique threats to water quality that threaten human health and the public resources MPCA is statutorily bound to protect.

Nutrients

Nutrients in feedlot waste include nitrogen, phosphorous, and potassium. Because naturally occurring nutrients in soil help sustain plant life, feedlot waste is often applied to cropland under the guise of fertilization. However, nutrients harm animal and plant life when unnatural quantities are added to ecosystems, particularly aquatic ecosystems. Animal agriculture is a major source of nitrogen and phosphorus to state waters. As a result, feedlot-dense watersheds often suffer severe water quality impacts from excessive nutrients that endanger human health and the environment.

High concentrations of nitrogen and phosphorus in water create low-oxygen dead zones where fish and other aquatic species cannot survive.[7] Both nitrogen and phosphorus spur eutrophication, the process by which excessive marine plant growth saps the water of oxygen.[8] The proliferation of algae and other plant life under eutrophic conditions "can harm or kill fish by clogging their gills. Algal blooms can also reduce the ability of fish and other aquatic life to

find food and can cause entire populations to leave an area or even die."[9] Hypoxic conditions and high levels of the nitrogen-based compound ammonia observed following feedlot discharges "have caused major kills of freshwater fish of all species … from minnows and gar to largemouth bass."[10] Waterbirds like the endangered horned grebe and amphibians like the endangered Blanchard's cricket frog are also susceptible to adverse impacts from nutrient pollution. The Minnesota Department of Natural Resources specifically attributes the horned grebe's habitat loss to agricultural pollution, explaining that "[s]everal serious threats to Horned Grebe habitat in Minnesota are the direct result of agricultural activities including eutrophication."[11]

High nutrient concentrations also create hazardous algal blooms that can be toxic to humans, pets, and wildlife that come into contact with impacted waters.[12] Exposure to toxic algae from skin contact or ingestion can cause serious symptoms, including rashes, headaches, coughing, and gastrointestinal distress.[13] These health risks—which are elevated for vulnerable populations like children and the elderly—lead local governments to temporarily close recreational waters throughout the state each year.[14] The economic cost of a single major harmful algal bloom can climb to tens of thousands of dollars.[15]

Nutrient pollution also causes dangerously high nitrate concentrations in Minnesota waters.[16] Bacteria in the environment convert nitrogen from manure into nitrate, a pollutant

associated with many dangerous health conditions. Ingesting water contaminated with nitrates is associated with various kinds of cancer, thyroid disease, birth defects, premature births, and methemoglobinemia (a potentially fatal condition commonly known as "blue baby syndrome").[17] Minnesota's standard for nitrates in drinking water (10 mg/L) was designed to mitigate the risk of blue baby syndrome; however, recent research demonstrates that significant health risks are associated with much lower nitrate concentrations.[18]

The Minnesota Department of Health reports that between 1994 and 2022, eight community public water systems in the state spent over $15 million on nitrate treatment and management plans, often at a cost of thousands of dollars per household.[19] Similarly, the Northeast Wisconsin Karst Task Force recounts "millions of dollars spent helping municipalities, farmers, and rural homeowners address [pervasive nitrate and bacteria contamination issues]," without any meaningful progress toward reducing the number of contaminated wells or the severity of the contamination.[20] Once drinking water sources are contaminated with nitrate, it is often impossible to reduce concentrations to safe levels within the ordinary human life span.

Minnesota's porous karst soils are especially vulnerable to nitrate contamination, and private well testing in the karst region has shown dangerous levels of nitrate in drinking water.[21] Over 4.4 million Minnesotans rely on groundwater for their drinking water, including over 1.1 millions residents who rely on private wells.[22] The Minnesota Department of Health has found that fewer than 20 percent of Minnesotans regularly test their well water for common pollutants,

meaning that hundreds of thousands of residents could be unknowingly drinking water polluted with dangerous concentrations of nitrate.[23]

Critically, the health risks associated with high nitrate levels are often compounded by the synergistic effects of pesticides like those used in cattle ear tags or on nearby fields monocropped with corn and other livestock feed inputs.[24]

Pathogens

In addition to containing dangerous levels of nutrients, feedlot waste is laden with fecal coliform bacteria and other harmful pathogens that threaten the health of humans, pets, and wildlife.[25] Zoonotic pathogens commonly found in manure include *E. coli*, *Campylobacter*, *Salmonella*, *Listeria*, *Cryptosporidium parva*, and *Giardia*, all of which can cause acute gastrointestinal distress, fever, and other dangerous symptoms in humans who drink or have recreational contact with contaminated water.[26] EPA has found that "[m]ore than 150 pathogens associated with industrial livestock production are also associated with risks to humans, including the six human pathogens that account for more than 90% of food and waterborne diseases."[27]

Livestock waste is a leading cause of bacteria in Minnesota's lakes and streams.[28] In the Minnesota River basin, feedlot density is so high that MPCA considers livestock waste—and particularly waste from unpermitted feedlots—a "high priority" that must be addressed to return

E. coli concentrations to safe levels.[29] Strategies MPCA determined were necessary to reach water quality goals in the basin include ensuring 100 percent regulatory compliance with the feedlot regulations (presumably through permitting), not increasing the current livestock inventory, and expanding livestock exclusions on tributaries.[30]

Pharmaceuticals

Feedlot waste also contains pharmaceuticals that can adversely impact humans and animals. Antimicrobials, including medically important antibiotics, are common constituents of feedlot waste, and have been detected in both surface and groundwater samples collected near feedlots.[31] EPA has found that 80 to 90 percent of some administered antibiotics end up in animal waste.[32] Antibiotics used to hasten livestock growth and combat disease in crowded, unsanitary confinements also promote the proliferation and dissemination of antibiotic-resistant bacteria in waterways near feedlots. These antibiotic-resistant bacteria make it more difficult to treat infections in humans, significantly increasing both the likelihood of hospitalization and duration of hospital visits.[33]

Hormones present in feedlot waste pose additional threats to humans and wildlife.[34] Heightened levels of hormones commonly administered to livestock have consistently been found in surface waters, groundwater, and spring water surrounding feedlots.[35] These hormones,

particularly synthetic hormones with longer half-lives, alter the reproductive biology and development of aquatic species in waters near CAFOs.[36] Changes observed include demasculinization and defeminization of fish, decreased fertility in female fish, and abnormal reproductive proteins in turtles.[37] One study that specifically examined the impacts of CAFO effluent on fathead minnows found that "[w]ild fish collected below a feedlot exhibited altered reproductive biology."[38]

Other Pollutants

Lastly, feedlots generate and discharge sediments, salts, heavy metals, semimetals, and other trace elements added to feed and eventually expelled by livestock.[39] Though impacts stemming from these feedlot pollutants have been chronically under-monitored and under-researched, each pollutant creates individual and cumulative water quality impacts. For instance, sediments carried to surface waters by erosion, runoff, and air deposition "may prove a significant stressor to a watershed as sediment itself or as a medium for the transport of other stressors such as nutrients, pathogens, or chemical stressors."[40] "Bottom sediments in manure lagoons or natural waters can serve as a very effective reservoir for pathogens" like fecal bacteria, which can survive for "weeks or months" in sediments.[41]

These pollutant contaminated sediments threaten Minnesota's wildlife. For example, Minnesota Department of Natural Resources listed lake sturgeon as a species of special concern after impairments caused in part by agricultural practices limited its natural habitat range and caused a catch rate decline of over 99 percent over the 20th century.[42] A multinational coalition of tribal and state governments have been working to restore a stable lake sturgeon population to the Red River Basin for decades.[43] In 2022, these efforts were rewarded with the first confirmed

natural sturgeon spawning observed in the basin for over 100 years.[44] This hard won success is threatened by feedlot runoff that contributes to poor water quality conditions that endanger sturgeon, as well as other fish and wildlife in the ecosystem.[45]

Salts, metals, other trace elements, and even carcinogenic PFAS in feedlot waste also pollute water while providing no benefit to agricultural lands. Livestock feed, and therefore waste, is known to contain many of the same elements found in sewage sludge, including "cadmium, chromium, copper, lead, mercury, molybdenum, nickel, selenium, and zinc," yet these pollutants are not regulated under the feedlot rules.[46] Because these compounds are not agronomically useful, they persist in feedlot waste, resulting in on-field accumulation and contaminated runoff.[47] In North Carolina, for example, accumulations of zinc and copper in areas with high concentrations of industrial animal agriculture have degraded soil quality to toxic levels.[48] Excessive salts in feedlot waste also adversely impact soil quality to such an extent that they can restrict crop establishment and growth.[49] In this manner, allowing land application of feedlot waste that has not been treated or even tested for PFAS, salts, metals, and other trace elements directly undermines plant growth and contributes to overapplication of manure, fertilizer, and soil amendments that further reduce water quality.

B. Feedlots Discharge Pollutants to Waters of the State

EPA estimates that approximately 75 percent of all CAFOs discharge pollutants to waterways[50] and, as discussed below, feedlots in a Minnesota are no exception. Feedlots

discharge pollutants to water through various pathways from both production areas and land application areas, leading EPA to conclude that animal agriculture is a "primary source of nitrogen and phosphorus" in groundwater and surface water systems.[51] As discussed in greater detail below, well-established discharge pathways include seepage through corrals, waste storage structures, and below land application areas; overflows from waste storage structures; and runoff from land application fields and production areas.[52]

1. Production Area Pathways

Production areas—even those constructed and operated in compliance with NPDES or SDS permitting requirements—inevitably discharge harmful pollutants into the state's surface waters and groundwater. LMSAs are a primary source of production area discharges. However, compost piles and other solid waste storage also pose significant discharge risks.

Storing large amounts of feedlot waste in LMSAs creates an ever-present risk that the "lagoons will fail or rupture and pollute surface waters or allow waste to seep into groundwater."[53] Such risks are only increasing as climate change makes extreme weather events—like more powerful and more frequent extreme rainfall—more common.[54] For example, in June 2024, extreme rainfall in Southwest Minnesota caused seventeen manure storage areas to overflow.[55] Inundation of surrounding fields limited the state's ability to effectively contain or disperse the contaminated waters away from surface waters.[56] The changing climate may also increase the frequency and/or intensity of freeze and thaw cycles that destabilize clay lagoon

liners and manure seals currently allowed under the feedlot rules, further increasing the likelihood of cracks and tears under the existing regulatory regime.[57]

Even intact LMSAs designed to the permeability rate mandated by the existing feedlot rules are not sufficiently protective of groundwater and hydrologically connected surface waters. Currently, the rules permit pollutants to seep from lagoons at a rate of 1/56 (0.018) inches per day.[58] While this rate may seem inconsequential, LMSAs often span an acre or more, allowing pervasive seepage to occur over the entirety of the subsurface area.[59] Numerous scientific studies demonstrate that pollutants such as ammonia-N and antibiotic-resistant bacteria seep from inadequately-lined lagoons into groundwater where they are then transported downstream.[60] This and other evidence has led multiple courts to conclude that even LMSAs constructed to permeability standards more stringent than Minnesota's leach pollutants into groundwater because the "the lagoons are designed to leak."[61] While depth gauges intended to prevent overflows may alert a feedlot operator to a catastrophic lagoon breach, they are not designed to notify operators about slow and steady—but still significant—seepage and leaking to the subsurface.

[61] *Food & Water Watch v. U.S. EPA*, 20 F.4th 506, 509 (2021) (quoting *Cmty. Ass'n for Restoration of the Env't, Inc. v. Cow Palace, LLC*, 80 F. Supp. 3d 1180, 1223 (E.D. Wash. 2015)). The permeability standard at issue in those cases was 1 x 10^{-7} centimeters per second, more stringent than Minnesota's 1/56 inch per day standard which equates to 5.29 x 10^{-7} centimeters per second.

Storing large amounts of liquid waste in open lagoons also allows pollutants like ammonia to volatilize and deposit onto surrounding land and water.[62] Volatilized ammonia can account for up to 70 percent of nitrogen excreted by confined livestock.[63] EPA has long recognized that aerial deposition is a significant source of pollution to surface waters, that feedlots discharge pollutants through aerial deposition, and that such discharges are subject to NPDES permitting requirements.[64] Atmospheric deposition accounts for an estimated 9% of nitrogen contributions to surface waters in Minnesota.[65] The rate of atmospheric deposition is highest is the southern and southeastern parts of the state, where agricultural and urban sources of nitrogen are more prevalent.[66]

In addition to manure, feedlots also store large amounts of other solid wastes, including silage and compost.[67] When stockpiled, these organic wastes release significant amounts of nitrate through ammonia volatilization and pollutant-laden leachate that can infiltrate groundwater or contaminate stormwater runoff.[68] Controlling leachate is critical, as researchers estimate the liquid

can be "40 times stronger than dairy parlor wastewater and up to 200 times stronger than raw sewage."[69] Because leachate contains such high nutrient concentrations, even seemingly negligible amounts can signify major nutrient losses that reduce the nutritional value of feed and contribute to water quality impairments.[70] In fact, "silage bunkers [are] one of the highest concentrated runoff nutrient loss areas on a farm in terms of loading per unit area."[71] Leachate from compost, which often includes mortalities on feedlots, contains similar pollutants of concern as well as elevated risks that pathogens will infiltrate groundwater.[72]

For decades, EPA has acknowledged that groundwater contaminated by feedlot pollutants is a "significant transport mechanism" for surface water discharges due to the prevalence of hydrologic connections.[73] Investigations in Washington and California show nitrates that seep into groundwater from feedlot lagoons can and do travel downgradient to surface waters.[74] During MPCA's recent feedlot permit update, the agency admitted that "a number of very site-specific factors" are used to determine whether a hydrologic connection exists between Minnesota's surface waters and groundwater underlying feedlots.[75] However, MPCA has not disclosed what these factors are or how the agency applies them to consistently protect surface waters from feedlot pollutants conveyed by groundwater.

2. Land Application Pathways

Land application areas also discharge pollutants to surface waters. Known discharge pathways from land application areas to state waters include runoff, infiltration to hydraulically

connected groundwater, and aerial deposition.[76] Overapplication of feedlot waste to nearby cropland leads to runoff and infiltration when a field is oversaturated or when conditions are such that manure cannot reach crop roots.[77] The potential for runoff and infiltration "increases greatly" when "continual applications are made year after year," as many manure management plans ("MMPs") allow feedlots to do.[78] Minnesota's extensive drainage system, including subsurface tile drains and aboveground irrigation ditches, act as direct conduits to surface waters.[79] Pressurized irrigation systems and other land application methods cause discharges due to volatilization and aerial deposition, faulty equipment, and imprecise application.[80]

The combination of polluting land application methods and the use of yield-maximizing—as opposed to pollution-minimizing—application rates, has made land application of feedlot waste a significant source of water contamination.[81] According to models examining the overapplication of nitrogen to cropland throughout Minnesota, there are at least nine "hotspot" counties where cumulative nitrogen from feedlot waste and fertilizer purchased in the county "exceeds crop recommendations by more than 40 percent."[82] The model showed that in

[82] Bahe, *supra* n.21; *see also* Food & Water Watch, Factory Farm Manure Is Overwhelming U.S. Counties (2025).

areas of concentrated livestock production, "almost all crop fields are needed to achieve safe use of manure produced by nearby feedlots."[83] Although the model found dramatic nitrogen overapplication in nine counties, it "likely *understates* the risk of this overload, because we assumed every field within 5 miles of a cattle or hog feedlot and 25 miles of a poultry feedlot is available to take manure, while in most real situations, manure does not travel that far."[84]

Accordingly, land application of feedlot waste in Minnesota is a major contributor to the nitrate crisis, especially in rural communities.[85] Other states have also recognized the risk land application poses; for example, California's State Water Resources Control Board recently acknowledged that land application of dairy waste "is responsible for the vast majority of dairies' nitrogen impacts to groundwater quality."[86]

C. Minnesota Is Especially Susceptible to Harmful Effects from Feedlot Pollution

Environmental quality in Minnesota is particularly susceptible to degradation from feedlot pollution due to the industry profile and the state's unique geography. Minnesota has one of the largest and most consolidated livestock industries in the country, second only to Iowa in terms of overall number of factory farms.[87] Cattle and swine feedlots dominate the industry, with these operations producing over 90 percent of manure in the state.[88] Swine and dairy feedlots are particularly damaging to water quality because they handle and store waste in liquid or slurry form. According to a soil scientist with USDA's Natural Resources Conservation Service, liquid waste "behaves like water,"[89] allowing pollutants to easily move through the environment and discharge to state waters.

Minnesota's feedlot industry is also increasingly consolidating, confining larger numbers of animals on smaller tracts of land.[90] For instance, the number of dairy farms decreased by 40

[90] Bahe, *supra* n.21.

percent between 2017 and 2022, even as the overall number of dairy cows remained relatively stable.[91] This consolidation causes pollution hotspots in feedlot-dense areas where cropland simply cannot assimilate all the nutrients generated in the vicinity and waterways are overloaded with feedlot pollutants that do not benefit agriculture at all.[92]

Minnesota is especially vulnerable to adverse impacts stemming from groundwater pollution because the state's geology and hydrology lend themselves to rapid subsurface pollutant transport. In fact, the need to address rampant groundwater pollution in Southeastern Minnesota is a primary impetus for MPCA's decision to update its feedlot regulations.[93] Southeastern Minnesota—where many of the state's feedlots are concentrated—is dominated by karst topography, a landscape defined by a layer of porous sediment atop highly fractured bedrock which creates high connectivity between surface water and groundwater.[94] Groundwater flows easily and unpredictably through karst geology, aided by the region's extensive network of tile drains.[95] Pollutants that enter groundwater in Minnesota's karst region can reach domestic wells located miles from the source of contamination.[96] Subsurface pollutant plumes from liquid manure storage areas that reach groundwater also travel to surface waters.[97] Permitting liquid

waste generating feedlots to operate atop karst landscapes therefore increases the risks feedlot pollution poses to state waters.

Pollution impacts are also elevated in the Central Sands. This region is characterized by widespread sandy soils which are especially vulnerable to groundwater contamination.[98] Nitrate contamination, in particular, is an ongoing concern in this region.[99] Of the nine "hotspot" counties where manure and fertilizer sales exceed crop recommendations by over 40 percent, four were counties in the Central Sands region, indicating a risk of continuing groundwater contamination.[100] Indeed, monitoring in the region shows nearly 10 percent of private wells have nitrate concentrations above 3 mg/L,[101] a threshold that is increasingly associated with elevated risks of cancer, suboptimal birth outcomes, and other health problems.

Widespread tile drainage in these vulnerable karst and Central Sands regions further increases the risk of groundwater contamination. Minnesota is the third most-extensively tile drained state in the country, with over 3,266,234 acres of tile drained fields[102] conducting excess nutrients and other contaminants to the state's waters.[103] Accordingly, fields receiving feedlot manure are likely outfitted with direct pathways for pollutants to reach surface waters.

II. MPCA Must Strengthen Its Feedlot Regulations to Comply with Federal and State Law and Protect Public Health.

Despite broad authority to regulate feedlot pollution under section 116.07 of the Minnesota Statutes,[104] MPCA's feedlot rules are failing to protect Minnesota's residents and our

Stat. § 116.07, subd. 4(b) (authorizing MPCA to adopt rules necessary to regulate solid waste—which includes any animal waste not used as fertilizer—in a manner that will prevent, abate, and control water, air and land pollution), Minn. Stat. § 116.07, subd. 2(a) (requiring MPCA to "improve air quality by promoting. . . waste disposal methods which produce or emit the least air contaminants consistent with the agency's overall goal of reducing all forms of pollution.").

invaluable natural resources. Further, MPCA's rules controlling the development and issuance of National Pollutant Discharge Elimination System ("NPDES") permits for feedlots do not meet the minimum requirements established by the federal Clean Water Act.

A. New Feedlot Rules must Expand and Clarify Permitting

Minnesota's feedlot regulations currently offer four permitting options: (1) state disposal system ("SDS") permits; (2) NPDES permits; (3) construction short-form permits; and (4) interim permits.[105] Which permit a feedlot is required to obtain depends on the size of the operation, whether a facility believes or admits it is discharging, and whether it has been labeled a pollution risk by the state.[106] Further complicating matters, MPCA measures the number of animals on a feedlot differently than EPA does under the federal concentrated animal feeding operation ("CAFO") regulations.[107] These complex and subjective permitting requirements have resulted in low permit coverage that leaves many large and polluting feedlots without much-needed MPCA and public oversight.[108] To ensure feedlots in the state are properly permitted, MPCA should update section 7020.0405 of the regulations to establish a rebuttable presumption that any facilities that exceed the federal size thresholds for a Medium CAFO discharge and therefore must obtain coverage under a NPDES permit.

A straightforward permitting requirement based on a rebuttable presumption of discharge is preferable to a permit structure based on the existing permit structure because the vast majority of feedlots that store and land apply liquid waste are designed to discharge through production area and land application area pathways. Under the current approach, many discharging CAFOs are evading regulation under NPDES permits. EPA has found that approximately 75 percent of CAFOs nationally actually discharge due to their characteristics and how they are operated. In Minnesota, that percentage is certainly much higher due to the state's prevalence of rivers, streams, and lakes; its groundwater-surface water interactions; and its many CAFOs using liquid manure management. Yet fewer than two thirds of Minnesota CAFOs have NPDES permits.[109]

[106] *Id.*
[107] *Compare* Minn. R. § 7020.0300, subp. 5 (defining "animal unit") with 40 C.F.R. § 122.23(b) (defining medium and large CAFOs according to number of animals).
[108] *See, e.g.*, EPA, NPDES CAFO Permitting Status Report National Summary, Endyear 2023 (May 2024) (showing approximately a third of Large CAFOs in Minnesota do not have NPDES permit coverage).
[109] https://www.epa.gov/system/files/documents/2024-06/cafo-status-report-2023.pdf

Allowing self-selection for permit coverage ignores the likelihood of undiscovered discharges, a category that encompasses many subsurface discharges and discharges resulting from human error or faulty equipment. Determining whether a feedlot is discharging is often outside the area of expertise of the operator who may lack knowledge about subsurface hydro-connectivity that could lead to a functionally equivalent discharge that requires an NPDES permit. Moreover, feedlot operators lack incentive to voluntarily subject themselves to regulatory controls that may undercut their bottom line. Establishing a presumption of discharge will help to resolve Minnesota's under-permitting problem.

MPCA should also require that qualifying feedlots get NPDES permits as opposed to SDS permits. The federal Clean Water Act requires discharging feedlots that meet or exceed the size threshold for a Medium CAFO under the federal rules to obtain coverage under a NPDES permit.[110] By streamlining permitting options for these facilities to include just NPDES permits, MPCA would reduce confusion about which permit a feedlot is required to obtain and help ensure Minnesota's feedlots are compliant with federal law. The contents of Minnesota's NPDES general permit and SDS general permit for feedlots are largely the same, so requiring feedlots currently operating under an SDS permit to switch to NPDES will have little impact on those operations. However, requiring unpermitted feedlots that are discharging to obtain NPDES permit coverage will subject those facilities to important pollution controls, monitoring, and reporting requirements that are necessary to ensure compliance with state and federal law and prevent pollution.

Additional permitting that will result from adjusting MPCA's permitting requirement from the existing 1,000 animal unit standard to a standard based on EPA's Medium CAFO threshold is necessary to combat pollution. At present, the majority of feedlot waste generated in the state (43 percent) originates on unpermitted feedlots with fewer than 1,000 animal units.[111] Many of these facilities are clustered just below the 1,000 animal unit cutoff, avoiding regulation while generating negligibly less waste than their permitted peers.[112] However, even feedlots well below the 1,000 animal unit cutoff produce waste in quantities that should undoubtedly be

[110] 40 C.F.R. § 122.23.
[111] Bahe, *supra* n.21 (Finding that while only 4% of Minnesota's feedlots have more than 1,000 animal units, those feedlots produced 33% of the total manure in the state annually).
[112] Bahe, *supra* n.21.

regulated via permit. For instance, a 500-animal unit mature dairy feedlot produces approximately the same amount of feces and urine waste as a city with a human population of 25,200 yet lacks any discharge permitting or monitoring.[113] A rebuttable presumption of discharge for all feedlots that exceed the Medium CAFO size threshold accounts for the significant pollution risks posed by facilities that handle such magnitudes of harmful waste, while allowing feedlots that can demonstrate they do not discharge to avoid unnecessary permitting.

Notably, adopting this requirement would appropriately obviate construction short-form and interim permits as they currently exist because facilities that would have been required to obtain those permits would be subject to NPDES permitting instead.

B. MPCA Must Mandate Updated BMPs for Land Application

Under MPCA's existing regulations, land applied feedlot waste is a major source of pollutants to waters of the state. This is largely due to the regulations' failure to prohibit common land application practices known to cause pollutant discharges. To remedy these discharges and improve environmental quality, MPCA should incorporate the following provisions to section 7020.2225 of the Minnesota Administrative Rules.

1. Replace the Agronomic Approach to Land Application Rates with a Pollution Reduction Approach

In regulating polluting entities like feedlots, MPCA's overarching duty is to protect and improve water quality.[114] Despite this clear mandate, the feedlot regulations overwhelmingly allow land application rates that are based on crop needs rather than what is necessary to safeguard water quality and protect public health.[115] As EPA and other state pollution control agencies have acknowledged, application rates that focus on maximizing yields rather than

[115] *See* Minn. R. § 7020.2225, subp. 3 (authorizing application rates within 20 percent of expected crop needs).

preventing excess pollutant runoff are insufficient to protect water quality.[116] To correct Minnesota's existing approach for calculating land application rates, MPCA must amend section 7020.2225 to require that application rates conform to realistic expectations about land's capacity to assimilate pollutants and adjust based on water quality impairments in receiving waters.

As a first step toward reducing nutrient pollution from land application activities, MPCA must develop land application rates that are designed to prevent discharges to surface or groundwater as opposed to maximize crop yields. While the ability of crops on a receiving field to uptake nutrients may be one factor in this calculation, it cannot be the primary or only factor. The University of Minnesota Extension Service's history of establishing maximum return to nitrogen ("MRTN") values (the primary basis for land application rates) demonstrates the fundamental mismatch between application rates designed to benefit crops and application rates designed to protect water quality. Since the feedlot regulations were last updated, the University has increased MRTN values multiple times.[117] As a result of these updates, recommended nitrogen application rates for corn have increased from 155 pounds per acre to 190 pounds per acre.[118] One of the two primary factors for the increase is increased precipitation causing higher nitrate losses.[119] In other words, higher application rates are being used to compensate for increased losses to the

environment.[120] If this process is allowed to continue, feedlot pollution from land application activities will only ever increase.

Ultimately, MPCA must use representative monitoring data to determine how much waste a receiving field can assimilate without causing or contributing to water pollution.[121] However, until such data is available, MPCA should, at minimum, prohibit land application of feedlot waste at rates that exceed receiving crops' phosphorus needs. Researchers have known for decades that "[e]ven under ideal conditions, with a well-planned system, there is still a significant risk of losses to the environment"[122] because land application of animal waste at rates recommended by state universities frequently overloads fields with far more nutrients than plants can uptake or soil can retain, creating serious water pollution risks.[123] This is particularly the case for phosphorous.[124] Because most crops require more nitrogen than phosphorous, nitrogen-based approaches to manure application are more common than phosphorous-based plans. This "presents a special problem because the N-to-P ratio in manures is lower than that needed by crops . . . [causing] excess P [to] build[] up to environmentally harmful levels in fields that received repeated applications."[125] This nutrient mismatch "invariably means [phosphorous] is overapplied relative to needs," and has led some researchers to conclude that nitrogen-based application rates "are much higher than agronomic requirements."[126]

Osei et al., *Environmental Benefits and Economic Costs of Manure Incorporation on Dairy Waste Application Fields*, 68 J. ENV'T MGMT. 1, 6 (2003).

Indeed, in an EPA study "designed to test the assumption that a well-designed and executed NMP is protective," the author concluded that only a highly conservative plan that treated wastewater prior to application to remove most of the suspended solid content and "depleted the soil organic reservoir . . . by applying only a fraction of" the crop's nitrogen needs actually minimized pollution.[127] In contrast, a "more aggressive" plan—like those currently allowed under MPCA's feedlot regulations—led to increased "leaching and contaminant migration."[128] While defaulting to phosphorus-based planning is not a panacea for pollution impacts from land applying feedlot waste,[129] it is a commonsense solution to widespread phosphorus contamination in feedlot dense watersheds.

Even with phosphorus-based application rates as a baseline, MPCA must also update the regulations at Section 7020.2225 to be directly responsive to site-specific land application area soil conditions and water quality impairments in receiving waters. At present, feedlots with more than 300 animal units are only required to test and report soil phosphorus levels.[130] At minimum, this requirement must be expanded to include nitrogen as well. Land applying feedlot waste to fields with nutrient levels that indicate a high risk of runoff or leaching should be outright prohibited. Similarly, MPCA should consider instating a conservative cap on land application of feedlot waste to fields that drain to waters that are already impaired for

2. *Impose Numeric Limits on Pollutant Concentrations for Land Applied Waste That Exceeds Water Quality-Based Application Rates*

Once MPCA has developed land application rates based on water quality considerations as opposed to crop needs, the Agency should develop numeric limits for any waste permitted feedlots intend to land apply. These limits should be based on pollutant reductions attainable through the use of advanced treatment technologies. For instance, Terra Blue (formerly known as Super Soils)[131] is a three-step system that processes liquid feedlot waste through (1) SLS

enhanced by a polymer (polyacrylamide, or "PAM") to encourage flocculation; (2) biological treatment to enhance nitrification (the chemical process by which ammonia is transformed into nitrite and nitrate); and (3) alkali chemical precipitation to remove phosphorus and destroy pathogens.[132] A 4,400-animal swine feedlot in North Carolina that installed and operated the system for a full year shortly after the consent decree was reached was able to remove 97.6 percent of suspended solids, 99.7 percent of biological oxygen demand, 98.5 percent of total Kjeldahl nitrogen, 98.7 percent of ammonia, 95 percent of total phosphorus, 98.7 percent of copper, 99 percent of zinc.[133] Notably, a majority of suspended solids, zinc, copper, and phosphorus were removed during the polymer-assisted solids separation portion of the process.[134] The researchers working on the demonstration project concluded that "the technology was technically and operationally feasible," and met the technical performance standards that define an Environmentally Superior Technology.[135] Since these initial tests, additional data have been collected from other feedlots that have installed versions of the Super Soils/Terra Blue system, verifying its capacity for significant pollution reductions.[136]

The Terra Blue system also redresses adverse non-water quality environmental impacts. Field studies of facilities employing the system have seen up to 100 percent removal of odorous compounds in liquid waste thanks in large part to denitrifying bacteria in the system's second step.[137] This means that Terra Blue has the capacity to significantly abate odor nuisances caused by swine CAFOs (and likely other CAFOs using liquid manure management) across the country.

Further, emissions reductions that would result from broad implementation of Terra Blue could significantly reduce the swine industry's climate footprint and local air quality impacts. Between reductions in ammonia (a precursor to nitrous oxide formation) and methane emissions, researchers estimate that facilities using Terra Blue can expect approximately 96.9 percent reductions in greenhouse gas emissions from manure management. These emissions reductions

are critical to combatting the existential threats posed by climate change, as well as improving local air quality to benefit frontline communities.

Even requiring land applied waste that exceeds water quality-based application rates to meet pollutant standards based on a single step of the Terra Blue process would have significant benefits. For instance, in slaughterhouse effluent (a waste with a similar pollutant profile to feedlot waste), full denitrification via biological processes and activated sludge has been shown to achieve "95 percent reductions in BOD, suspended solids, and reductions in ammonia nitrogen."[138] Several of these systems have been proven effective in treating swine wastewater for not only nutrients and conventional pollutants, but for antibiotics as well.[139]

Alternatively, chemical precipitation has also been proved to aid in removing phosphorus from feedlot waste. Chemical additives proven to remove phosphorus from CAFO wastewater include magnesium phosphate (struvite) in combination with ethylenediaminetetraacetic acid (70 to 80 percent effective at removing phosphorus from swine and dairy wastewater, 90 to 98 percent effective at removing phosphorus from poultry manure); lime (79.8 to 94.7 percent effective in removing phosphorus from pig waste); a combination of acid, hydrated lime, and organic polyelectrolytes (80 to 90 percent effective in removing phosphorus from poultry litter and swine waste); and metal salts like alum, aluminum chloride, ferric sulfate, and ferric chloride, alone or in combination with polymers (variety of phosphorus removal efficacies depending on the dose applied).[140]

3. *Codify Land Application Restrictions in Existing General Permit and Prohibit Application in Winter Conditions*

In its latest revision to the NPDES General Permit for feedlots, MPCA significantly updated timing restrictions on land application activities to account for increased risks associated with applying waste to warm soils, fields without cover crops, and frozen and snow-covered ground.[141] As detailed in the response to comment issued along with that Permit, MPCA has

[141] Feedlot General Permit at 9-12 (Section 13, Land Application of Manure - Timing).

thorough scientific justification for these restrictions. Accordingly, these provisions should largely be incorporated into the feedlot land application restrictions.

The one exception is that MPCA should entirely prohibit the spreading of feedlot waste on frozen, saturated, or snow-covered grounds. "Considerable research has demonstrated that runoff from manure application on frozen or snow-covered ground has a high risk of water quality impact." [142] The increased likelihood of runoff associated with application of manure to frozen, saturated, or snow-covered ground is widely recognized by agricultural experts, including agricultural extension program technical staff, state agencies, and EPA. Liquid or semi–liquid manure cannot easily permeate ground that is already saturated or that is frozen, and thus is much more likely to run off into nearby waterways, particularly when snow or frozen ground begins to melt.[143] EPA has collected considerable research documenting "extremely high concentrations of nitrogen and phosphorous in runoff" due to winter application of waste. [144] Per this research, winter application of dairy manure can result in a 1,480 percent increase in soluble phosphorus concentrations found in nearby surface waters, and up to 576 percent increases in ammonia-nitrogen concentrations. [145] One study of Vermont streams and lakes concluded that 40 percent of studied waterbodies experienced significant water quality impairments from the addition of just two winter-spread fields in their watersheds.[146] A Wisconsin study similarly estimated that 25 percent of annual phosphorous loading was directly attributable to winter spreading of animal wastes.[147]

Other authorities, ranging from the state level to international, have also recognized the harms likely to result from land application in winter months and on frozen ground. The International Joint Commission, an international organization created by the Boundary Waters Treaty (ratified by the United States and Canada in 1909), recommends that to protect Lake Erie, all adjacent states should ban the spreading of manure on frozen or snow-covered ground because of the likelihood of those practices polluting surface waters.[148] The Iowa State University Extension acknowledges that "[b]roadcasting manure onto frozen, snow-covered, water-saturated

soils increases the potential for nutrient losses with rainfall or snowmelt runoff to surface water systems."[149] Similarly, the Penn State Extension warns that "[s]preading manure in the winter is discouraged because it is a high-risk time period for nutrient losses and contamination of surface water,"[150] and the Ohio State University Extension advises that "[w]inter application should not be part of a manure management plan and it should only be viewed as a last resort."[151]

As such, NRCS advises that "[n]utrients must not be surface–applied if nutrient losses offsite are likely" and warns against spreading on "frozen and/or snow-covered soils, and when the top 2 inches of soil are saturated from rainfall or snow melt."[152] MPCA should abide by this regulation and prohibit land application to frozen, snow-covered, and saturated ground in its revision of section 7020.2225.

4. Prohibit Pivots, Guns, and Other High-Pressure Broadcast Irrigation Technologies

In general, MPCA's rules currently permit feedlots to use any method to land apply waste so long as applications comply with the facility's MMP and do not violate setback requirements for open tile intakes, sinkholes, mines, quarries and water supply wells.[153] The exception to this rule is land application within "special protection areas."[154] Special protection areas include any land within 300 feet of DNR-listed protected waters or wetlands and land within 300 feet of USGS-listed intermittent streams or ditches, excluding bermed drainage ditches and grassed waterways.[155] Applying feedlot waste with a traveling gun, center pivot, or other irrigation equipment that allows liquid waste to travel more than 50 feet in the air is prohibited in special protection areas. Though this restriction correctly acknowledges the pollution risks created by

these technologies, it provides insufficient protections to mitigate these risks. To better protect water quality, MPCA must amend its land application regulations to prohibit high-pressure broadcast irrigation methods outright.

High-pressure spray equipment like irrigation guns and center pivots are not appropriate for land application of CAFO waste because of the likelihood of discharge to waters.[156] The special protection area regulations attempt to mitigate this risk by prohibiting the use of some broadcast spray irrigation technologies within 300 feet of surface waters and some conduits to surface waters. For a number of reasons, these measures are not sufficiently protective. First, pressurized spray irrigation equipment is known to jettison volatilized pollutants up to 10 kilometers away from the source.[157] Thus, a prohibition on using these technologies within 300 feet of waters or pathways to water will not stop volatilized pollutants from depositing in surface waters. Second, even if 300 feet were a large enough setback, MPCA's designated "special protection areas" do not include all surface waters. For instance, special protection areas inexplicably exclude bermed drainage ditches, even though berms do nothing to prevent the discharge of volatilized pollutants. Further, because DNR's Public Waters Inventory maps do not include Type 1 and Type 2 wetlands,[158] existing protections also exclude seasonal and ephemeral wetlands despite the elevated discharge risks known to accompany application of waste to

[158] *See* Minn. Dep't Nat. Res., *Public Waters Inventory Maps*, https://www.dnr.state.mn.us/waters/watermgmt_section/pwi/maps.html.

saturated soils.[159] Third, prohibiting pressurized spray irrigation equipment based on proximity to the nearest surface water overlooks the risk that dry deposited pollutants will seep into groundwater and flow through the subsurface into surface waters. Finally, the existing regulations only bar the use of irrigation equipment that allows liquid waste to travel more than 50 feet in the air. It is not clear that this is an evidence-backed standard proven to reduce pollutant discharges, particularly if irrigation occurs during periods of strong wind.

In addition to reducing water pollution throughout the state, amending section 7020.2225 to prohibit high pressurized spray irrigation techniques would also serve the interests of justice by alleviating harm to frontline communities and benefitting family farms. Pollutants expelled by spray irrigation technologies include aerosolized bacterial and viral pathogens that create serious health risks when inhaled by neighboring residents or deposited on food crops.[160] Indeed, multiple studies have confirmed that communities situated near CAFOs suffer higher infection rates[161] and that farmworkers and CAFO employees bear the brunt of these unnecessary hazards.[162] Crucially, health harms attributable to spray irrigation technologies include significant mental and physical health impacts from unbearable odor.[163] Residents who work and live near CAFOs report experiencing stenches so foul that they "interfere with daily activities, preventing neighbors from opening windows, drying clothes, gardening, and hosting family and

friends."[164] Regulating pressurized spray irrigation more stringently would help to mitigate these environmental justice impacts.

Moreover, removing pressurized spray irrigation as a waste disposal option for feedlots removes a tool that the largest feedlots frequently abuse to their competitive advantage and to the disadvantage of smaller, family-owned livestock operations. Industrial broadcast irrigation technologies are generally employed by and primarily benefit large feedlots as opposed to smaller scale operations that do not generate enough waste to necessitate long-term manure storage and bulk disposal.[165] As such, use of these technologies on feedlots has contributed to increased concentration and consolidation of Minnesota's livestock industry—a trend that inherently increases pollution risks. Pressurized irrigation equipment also facilitates nighttime land application of waste, a practice that should be disallowed due to inadequate oversight and accountability as well as increased likelihood of pathogen transmission in absence of the neutralizing impact of ultraviolet radiation from the sun.[166]

Evidence of water pollution and air quality related health hazards supports a full ban on using high-pressure broadcast irrigation equipment to land apply feedlot waste. However, if MPCA does not prohibit these technologies outright, the agency must at least consider updating section 7020.2225 to include mandatory BMPs such as nozzle settings that ensure waste droplets meet minimum size thresholds, foregoing spray application when winds are above 5 mph, and limiting spray irrigation to the late morning and early afternoons to reduce odor and pathogen transmission.[167]

5. Require Liners for Stockpiles

Minnesota law prohibits fines for discharges of manure that is land applied or stockpiled in accordance with agency rule.[168] Given this restriction, MPCA's land application and stockpiling regulations must provide maximum protection against water pollution to ensure feedlot operators

are able to be held accountable for risky management practices that endanger the public interest. Yet, the current feedlot regulations allow for allow for a "temporary" manure stockpile to be maintained on bare soil for up to one year.[169] This allowance for temporary solids stockpiling, even with setback requirements, creates a significant risk of groundwater contamination because leachate release generally peaks within a few days.[170] Further, short term solids stockpiling areas are not subject to the same degree of clean water diversion requirements that permanent solid storage sites are, creating a risk of contaminated run-off.[171]

To stem the flow of production area pollution and reduce the risk of nitrate contamination posed by feedlots, MPCA should update the feedlot regulations to require liners and covers for all waste stockpiles, thereby closing the loophole for temporary stockpiling. The most effective methods for controlling leachate pollution generally consist of a liner and leachate collection system paired with covers and stormwater diversions to prevent contaminated runoff. Pollution reduction rates attributable to such a system depend on the material being stored and the composition of the liner. Silage leachate, for example, is extremely corrosive and can damage both concrete and steel.[172] MPCA should update the Feedlot Rule to prohibit the practice of stockpiling on bare ground, even for temporary stockpiles, and should include minimum standards for liner composition that better protect against groundwater contamination.

6. Mandate Incorporation Within 24 Hours for All Land Applied Waste

Although MPCA already requires incorporation of land applied feedlot waste under certain circumstances, significant losses from failure to timely incorporate land applied waste persist. According to data collected as part of Minnesota Department of Agriculture's Farm Nutrient Management Assessment Program, up to 60 percent of nitrogen in applied manure was lost to the environment and therefore not available for crop fertilization due primarily to feedlot operators' failure to incorporate manure within 24 hours of application.[173] As such, the agency should simply

amend Section 7020.2225 to mandate that all land applied feedlot waste be incorporated within 24 hours.

Numerous studies show that incorporating manure likely helps to conserve nutrients in soil and reduce nutrient runoff. During EPA's consideration of its CAFO regulations in 2002, the Agency recognized that incorporation and injection can reduce erosion and runoff, keeping nutrients and other pollutants on land application sites.[174] Incorporation has proven particularly effective at reducing off-field transport of phosphorus. For instance, modeling based on dairy feedlots in Texas indicated that incorporation of land-applied waste could achieve up to 45 percent reductions in soluble phosphorus losses to edge-of-field runoff.[175] Field studies confirm the phosphorus reduction potential of incorporation as a BMP. In a study of swine manure applied to Iowa cropland, total phosphorus concentrations in runoff from unincorporated fields were more than two times higher than concentrations in runoff from fields that incorporated manure after application.[176]

Incorporation can also significantly reduce nitrogen pollution. Mixing promotes conversion of organic nitrogen to plant-available inorganic nitrogen, increasing the percentage of nitrogen that is taken up by crops and reducing the nitrogen content of runoff.[177] According to a 2005 literature review conducted by USDA, incorporation significantly reduces nitrogen losses from land application fields for hog, dairy, poultry, and beef operations.[178] Part of this reduction in nitrogen water pollution is due to incorporation's ability to control nitrogen volatilization.[179] As discussed, deposition of aerosolized pollutants—and particularly ammonia—is a major pathway by which feedlots discharge pollutants to surface waters. Because incorporation has been shown

to dramatically reduce ammonia emissions,[180] feedlots that incorporate their manure can be expected to contribute far less ammonia to waters.

Replacing broadcast spray irrigation with injection of liquid waste may produce even greater pollution reductions than incorporation of solid waste.[181] One study examining land application activities in the Mid-Atlantic region found that replacing broadcast irrigation with low-disturbance injection reduced total nitrogen in the watershed by 19 percent and total phosphorus by 44 percent.[182] Similarly, experiments conducted in Pennsylvania showed phosphorus lost to runoff was reduced by 68 percent on fields that injected dairy waste in place of broadcast irrigation.[183]

Incorporation has also been shown to reduce hormone transport to surface waters and overall runoff volume, indicating incorporation may be effective in reducing the off-field movement of other feedlot pollutants.[184] Cumulatively, this research supports a requirement that all permitted feedlots incorporate land applied waste within 24 hours of application.

C. Best Management Practices for Production Areas

MPCA's feedlot regulations could also be improved by adding provisions that mandate compliance with science-backed best management practices for production areas where livestock is confined and wastes are stored.

1. Require LMSA covers

Allowing feedlots to store waste in uncovered lagoons is an outdated practice that should no longer be permitted under Minnesota law. Uncovered lagoons are more susceptible to overflows that pollute state waters. Moreover, lagoon covers reduce emissions of odors and other harmful airborne pollutants that plague frontline communities. In particular, covers help reduce emissions of ammonia, a pollutant that harms human health and travels through air to deposit on surrounding land and surface waters. Aerial ammonia deposition is a significant contributor to nitrate contamination in Minnesota.[185] The feedlot regulations do not currently require any sort of lagoon cover; updating the rule to require that feedlots managing liquid waste use this affordable best management practice will advance MPCA's water protection goals while simultaneously protecting the health and quality of life in farming communities.

While the current Feedlot Rule requires feedlots to maintain minimum capacity necessary to contain precipitation from 25-year, 24-hour rainfall events,[186] uncovered lagoons continue to overflow due to human error and severe storms.[187] Lagoon covers can prevent rainfall from overwhelming storage capacity and causing catastrophic overflows that contaminate waterways.[188] This feature is increasingly important for pollution control as rainfall events become heavier and more unpredictable due to anthropogenic climate change.[189] The highest annual rainfall events in

Minnesota have increased in size by 13% since the early 20th century,[190] and these trends are expected to continue in the future.[191] Clearly, the Feedlot Rule must include greater protections against precipitation driven overflows.

In addition to preventing catastrophic overflows, lagoon covers also help control odors and volatilized pollutants.[192] While the scope of emission reductions depends on the material used, covers can reduce odor emission by 40 to 99 percent.[193] Covers are also effective at reducing gaseous pollutants like ammonia, hydrogen sulfide, and methane.[194] According to the University of Colorado, manure slurry stored in covered lagoons can retain 3.5 times more nitrogen than slurries stored in open lagoons where nitrogen freely volatilizes.[195] Controls for odor and other air pollutants from feedlots are desperately needed to mitigate harmful impacts to nearby residents who experience disproportionately high rates of respiratory illness, high blood pressure, and psychological distress.[196] Moreover, lagoon covers provide more reliable methane emissions reductions than manure crusts, helping to mitigate the livestock industry's contribution to climate change.[197]

By controlling volatilized pollutants, LMSA covers also help mitigate aerial deposition of manure pollutants. Mandating lagoon covers is therefore an efficient means of reducing a significant source of nitrate contamination in Minnesota's waters, supporting the state's long-term goal to protect drinking water.[198]

2. Strengthen LMSA liner requirements

Subsurface seepage through LMSA walls is a significant source of pollution to groundwater. Minnesota's existing feedlot LMSA design specifications provide incomplete protection against these discharges to state waters. To better control subsurface lagoon seepage, MPCA must strengthen LMSA liner requirements for all feedlots that exceed the minimum size thresholds in the federal definition of a Medium CAFO. Updated liner requirements are also necessary to prevent permitted feedlots from discharging to surface waters via hydraulically connected groundwater in violation of CWA requirements that generally prohibit production area discharges, including hydrologic discharges are the "functional equivalent" of surface water discharges.[199]

MPCA's existing feedlot regulations include a complicated series of LMSA design specifications, delineated by feedlot size and site-specific features such as distance to bedrock. At present, the primary constraint on seepage from non-concrete-lined lagoons is the requirement that LMSA permeability not exceed 1/56 inch per day.[200] While requiring elevated protections in areas with elevated pollution risks is a logical approach, the existing regulations are under-protective because they do not account for all vulnerable areas. Further, merely requiring that LMSAs meet a specified permeability standard has not adequately protected groundwater because wear, tear, and improper installation or upkeep are often not apparent to the naked eye.[201]

---

[198] MINN. DEP'T OF AGRIC. ET AL., WORK PLAN: ADDRESSING NITRATE IN SOUTHEAST MINNESOTA (Jan. 2024), https://www.health.state.mn.us/communities/environment/water/docs/wells/waterquality/epaworkplan.pdf (last accessed July 10, 2025).

[200] Minn. R. § 7020.2100 subp. 3(C)(1).
[201] *See infra* nn.55–59 and accompanying text (Sec. I.B.1); *see also* MELANIE REDDING, WASH. STATE DEP'T OF ECOLOGY, MANURE & GROUNDWATER QUALITY: LITERATURE REVIEW 69 (June 2016) (". . . it has been determined that design permeability data do not adequately predict actual seepage rates."); Erickson Report**,** *supra* n.59 at 5.

Since MPCA last updated the feedlot rule, the Minnesota Department of Agriculture promulgated the Groundwater Protection Rule.[202] This rule was passed to "minimize[] potential sources of nitrate pollution to the state's groundwater and protects [Minnesota's] drinking water,"[203] and operates by restricting nitrogen fertilizer application in both Drinking Water Supply Management Areas and Vulnerable Groundwater Areas. Vulnerable Groundwater Areas include all areas with coarse textured soils, soils that are shallow to bedrock, and karst regions, all of which increase the likelihood of significant groundwater contamination.[204] Accordingly, these areas are deserving of maximum protection against feedlot lagoon seepage.

Double synthetic lined lagoons are currently the most effective practice advised for use at feedlots.[205] Double synthetic liners are composed of two geomembranes—high-density polyethylene, polyvinyl chloride, or low linear density polyethylene processed to certain specifications[206]—and often include leak detection and collection systems between the synthetic layers.[207] Double liners are necessary for feedlot lagoon liners because, as explained in a study that examined the efficacy of various landfill liners in controlling seepage of many of the same pollutants of concern in CAFO waste, simple composite designs limited to a single geomembrane over soil attenuation layer "should not be used" where frequent filling and emptying disrupt tensile stress on the geomembrane.[208] EPA has used the double synthetic liner requirement to abate groundwater contamination from feedlots in Washington State.[209] Further, Meat & Poultry Products (MPP) facilities use double liners to control chlorides—a pollutant also of concern in feedlot waste—that otherwise seep from evaporation ponds.[210]

[210] EPA, Response to FOIA 2025-EPA-04763 at 10.

To make MPCA rules consistent with MDA rules, simplify the feedlot regulatory regime, and protect groundwater and hydraulically connected surface waters, MPCA should update section 7020.2100 to prohibit the construction of new feedlot lagoons in vulnerable groundwater areas and require all existing lagoons in vulnerable groundwater areas to install composite double synthetic liners with leak detection. Additionally, in conjunction with the recommended updated monitoring requirements, *see infra*, Section II.D., the State should require that feedlots that show elevated levels of nutrients or fecal coliform pathogens in representative sampling of groundwater around the production area install a composite liner with double synthetic layers.

Mandating leak detection in coordination with synthetic liners would mark a significant improvement over MPCA's existing LMSA requirements by minimizing uncertainty. If a liner is breached, leak detection allows feedlot operators to take immediate remedial action that can prevent discharges entirely. Without leak detection or groundwater quality monitoring, enforcing a lagoon permeability standard is impossible, illegally undermining one of the pillars of the CWA.[211] Simply requiring double-lined synthetic composite liners with leak detection mechanisms would facilitate straightforward enforcement and provide a better safeguard against pollution that threatens Minnesota's drinking water and surface waters.

3. Liners for solids storage

To effectively control groundwater contamination from all production areas, the Feedlot Rule should include updated liner requirements for manure stockpile sites, feed storage areas, and compost areas. To stem the flow of production area pollution and reduce the risk of nitrate contamination posed by feedlots, MPCA should update the Feedlot Rule to require liners and covers for all waste stockpiles.

Both the Minnesota SDS and NPDES permits include similar requirements for permanent manure stockpile areas, which include manure compost sites, and feed storage areas.[212] Permanent manure stockpiles and feed storage areas must have a liner or base made of group III or IV soils,

[211] *See* 33 U.S.C. § 1251(e) ("Public participation in the development, revision, and enforcement of any regulation, standard, effluent limitation, plan, or program established [under the CWA] shall be provided for, encouraged, and assisted by [EPA].").
[212] Minnesota Pollution Control Agency, Authorization To Construct And Operate An Animal Feedlot And/Or Manure Storage Area Under The State Disposal System (SDS) Program MNG450000, 6.1-6.2, 7.1-7.5,18.1-18.4;19.1-19.5, https://www.pca.state.mn.us/sites/default/files/wq-f3-63.pdf; Feedlot General Permit at 6.1-6.2, 7.1-7.5,18.1-18.4;19.1-19.5, https://www.pca.state.mn.us/sites/default/files/wq-f3-62.pdf

asphalt, concrete, or other materials that "achieve a hydraulic conductivity less than 1 x 10^{-7} cm/sec."[213] However, the Feedlot Rules allow for a "temporary" manure stockpile to be maintained on bare soil for up to one year.[214] This allowance for temporary solids stockpiling, even with setback requirements, creates a significant risk of groundwater contamination because leachate release generally peaks within a few days.[215] Further, short term solids stockpiling areas are not subject to the same degree of clean water diversion requirements that permanent solid storage sites are, creating a risk of contaminated run-off.[216]

The most effective methods for controlling leachate pollution generally consist of a liner and leachate collection system paired with covers and stormwater diversions to prevent contaminated runoff. Pollution reduction rates attributable to such a system depend on the material being stored and the composition of the liner. Silage leachate, for example, is extremely corrosive and can damage both concrete and steel.[217] MPCA should update the Feedlot Rule to prohibit the practice of stockpiling on bare ground, even for temporary stockpiles, and should include minimum standards for liner composition that better protect against groundwater contamination.

4. Solid liquid separation

With the understanding that a portion of land-applied waste will be discharged to waters, EPA should consider imposing maximum pollutant concentrations for land-applied waste based on demonstrated reductions attained by solid-liquid separation ("SLS"). SLS reduces the organic load in feedlot wastewater, thereby decreasing nutrient and pathogen concentrations in liquid containment structures and land-applied liquid waste and reducing water quality risks.[218] The solids can then be composted either on or offsite to create valuable fertilizer without the heightened leaching risks associated with higher inorganic nutrient concentrations.[219] Meanwhile, SLS

Hjorth et al., *Solid-liquid Separation of Animal Slurry in Theory and Practice: A Review*, 30 AGRONOMY SUSTAINABLE DEVEL. 153, 155 (2010) (contrasting manure management in Asia with management in North America); MINN. POLLUTION CONTROL AGENCY, RESPONSE TO COMMENTS ON THE

improves the liquid fraction's nutrient ratio, total suspended solids concentration, and pathogen content for plant growth compared to unseparated slurry.[220] For many SLS methods, estimated dry matter, total nitrogen, total phosphorus, volatile solids, and pathogen indicators removal efficiencies have already been documented.[221] Thus, MPCA could easily develop maximum limits for these pollutants in land applied waste and check that feedlots are complying through regular manure testing and reporting requirements.

In addition to helping CAFOs achieve water pollution reductions, SLS has many non-water quality benefits that EPA must consider. For instance, removing volatile solids prior to long-term liquid waste storage reduces greenhouse gas emissions.[222] In fact, a 2017 study of dairy CAFOs concluded that SLS reduced methane emissions by 46 percent and overall greenhouse gas emissions by 44 percent, indicating it was more effective than anaerobic digestion in combatting emissions from manure storage.[223] Relatedly, solids suspended in liquid waste are a primary source of odors that plague residents near CAFO lagoons.[224] Removal of these solids can help reduce odors.[225] Finally, CAFOs that rely on flushing systems to remove manure from production areas can reuse SLS liquids, reducing dewatering of aquifers and waterways.[226]

To combat aerial deposition of feedlot pollutants and improve health and wellbeing in surrounding communities, MPCA should require the largest confinements to demonstrate compliance with ammonia emission standards. A variety of filters and scrubbers are available and effective in reducing ammonia emissions and other air pollutants from feedlot housing. Much like the composite liners recommended for use with liquid manure storage structures, the most effective air deposition reduction systems have multiple components designed to provide extra layers of protection. Filters and scrubbers use physical, biological, and chemical processes to trap or neutralize pollutants.[227] Removal efficiencies depend on the type of filter used, but data are available for a variety of designs and pollutants at various livestock confinements.[228] Notably, ventilation outlets with acid scrubbers can remove up to 99 percent of ammonia before air leaves a feedlot, while biofilters can remove up to 67 percent of ammonia while also providing significant odor mitigation.[229] Multistage scrubbers, such as those that use a combination of water, acid, and a biofilter, have been shown to achieve 90 percent reductions in particulate matter while also significantly cutting emissions of airborne bacteria.[230] Filters with gas permeable membranes or electrostatic spinning technologies have also been proven effective in removing particulate matter, bacteria, and viruses.[231]

Installing filters and scrubbers in feedlot ventilation systems will reduce air pollution in addition to improving water quality. Filters that reduce ammonia and particulate matter emissions can protect health outcomes of nearby communities. Many filters that target odorous ammonia and particulate matter also reduce emissions of hydrogen sulfide, an odorous and toxic gas that is responsible for many human and animal deaths in livestock facilities.[232] Due in part to this ability

to trap hydrogen sulfide, many filters are effective in reducing odor impacts on surrounding communities.[233] Lastly, filters and scrubbers installed at ventilation outlets in animal housing have the capacity to capture and neutralize pathogens and antibiotic-resistant genes that could otherwise wreak havoc on other animal feeding operations, wildlife populations, and even global human health.[234]

MPCA has broad authority to regulate air and water pollution from feedlots, including through emissions standards.[235] The agency should therefore refer to well-documented removal efficiencies and available data on per-animal emissions to establish standards that will effectively reduce air-deposited water pollutants like ammonia.[236]

D. The Feedlot Rule Must Include Representative Compliance Monitoring and Reporting.

The federal Clean Water Act requires that MPCA implement its NPDES program according to minimum federal standards.[237] Under that Act, all NPDES permits must include representative monitoring and reporting provisions sufficient to ensure compliance with the permit effluent limits.[238] Minnesota's Water Pollution Control Act largely mirrors the Clean Water Act's requirements and provides MPCA with the authority to impose monitoring requirements necessary to control feedlot pollution.[239] Publicly available compliance monitoring data are critical to ensuring permit compliance and holding violators accountable; yet MPCA's feedlot regulations lack specific monitoring and reporting requirements sufficient to measure compliance with all applicable water quality discharge standards.[240] To improve the feedlot rules, MPCA must codify monitoring requirements designed to ensure any discharges of feedlot waste to the environment are detected, sampled, and reported in a timely manner.

1. Land Application Area Effluent Monitoring

Feedlots discharge to state waters from land application areas via three primary pathways: (1) overapplication of waste to fields that results in runoff to tile drains, irrigation ditches, or other conveyances to surface waters; (2) seepage of land applied waste to groundwater below crop root zones; and (3) aerial deposition from high-pressure broadcast spray irrigation technologies. Thus, to detect and redress feedlot discharges, MPCA's regulations must include provisions designed to monitor each of these pathways.

MPCA recently added monitoring for runoff resulting from land application activities to the NPDES general permit for feedlots. There, MPCA included a provision requiring feedlot operators and anyone land applying feedlot waste to visually inspect "downgradient field edges and any other potential discharge locations such as sensitive features, tile intakes, ditches, or other conveyances to waters" after land application.[241] MPCA should codify this monitoring requirement as it is necessary to detect feedlot contributions to water pollution and evaluate appropriate measures to mitigate adverse impacts. Further, MPCA should update the regulations to mandate that feedlots immediately sample any effluent discharged to a water of the state; test the sample for total nitrogen, nitrate nitrogen, ammonia nitrogen, total phosphorus, *E. coli*, five-day biochemical oxygen demand (BOD5), total suspended solids, pH, and temperature, and any other pollutants of concern in the watershed; and report the results of such testing to MPCA such that they are publicly accessible.

While all feedlot discharges should be monitored and reported to protect water quality and inform better regulation, it is particularly important for enforcement purposes that MPCA collect information sufficient to determine whether a discharge is the result of noncompliance with a facility's MMP. The NPDES general permit currently requires that equipment used for land application be calibrated such that actual application rates "are known."[242] However, there is no requirement that this information be submitted to MPCA to ensure compliance with MMPs—one of the primary pollution controls applicable to feedlots.[243] Modern irrigation

[241] MPCA, AUTHORIZATION TO CONSTRUCT AND OPERATE A CONCENTRATED ANIMAL FEEDING OPERATION UNDER THE NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM (NPDES) PROGRAM (MNG440000) at 12 (permit section 14) ("Feedlot General Permit).
[242] NPDES
[243] *See* Minn. R. § 7020.2225, subp. 5.

equipment is capable of monitoring and recording the amount of waste used during an individual application. To enforce overall application rates as well as timing restrictions,[244] MPCA must require that these records be submitted to the agency shortly after the application rather than cumulatively as annual totals once a year.

Critically, MCPA must also monitor for subsurface discharges from land application areas. EPA specifically recommended that MPCA institute subsurface discharge monitoring requirements to deal with Minnesota's nitrate crisis and, as California's State Water Resources Control Board recently acknowledged, land application of dairy feedlot waste "is responsible for the vast majority of dairies' nitrogen impacts to groundwater quality."[245] This is because existing application practices (e.g. agronomic rates) are primarily a waste disposal method with "secondary benefits of fertilizing crops, rather than a method of crop fertilization that may have incidental impacts to groundwater.[246] Difficulties in accounting for the precise water demands of crops, other sources of plant available water beyond irrigation, and preferential flow paths in soil that allow feedlot wastewater to bypass the root zone all impede the ability of MMPs to minimize surface and groundwater contamination.[247] Nutrients from land-applied waste that seep below a crop's root zone cannot be appropriately utilized,[248] indicating the feedlot applying the waste is either not following its—a permit violation meriting enforcement action—or that the feedlot must revise its MMP (such as by lowering application rates or specifying operational practices to avoid cracks or other preferential flow paths) in order to comply with state and federal law.[249]

[244] *See infra* Section II.B.3 (requesting that MPCA incorporate the timing restrictions from the current NPDES general permit into the feedlot rules).
[245] CA DAIRY ORDER at 6.
[246] *Id.*
[247] BRADFORD, *supra* n.34 at 66.
[248] As discussed elsewhere in this memo, CAFO waste contains numerous pollutants that provide no benefit to crops at any application rate. Waste must be treated to reduce or remove these pollutants prior to land application.
[249] *See* Minn. R. § 7020.2003, subp. 1 (prohibiting discharges to any "natural or constructed channels that convey fluids to groundwater); 40 C.F.R. § 412.4(c) (requiring CAFOs to implement a nutrient management plan that minimizes nutrient transport to surface waters); *see also Cnty. of Maui,* 590 U.S. at 185 (explaining that discharges to groundwater that are "functionally equivalent" to surface water discharges are jurisdictional under the Clean Water Act).

To monitor subsurface discharges on land application areas and "assure compliance with permit limitations" as required by law,[250] MPCA must consider updating its regulations to require that permitted feedlots conduct representative subsurface monitoring of land application areas using readily available soil moisture probes or lysimeters installed to measure moisture below crop roots.[251] Again, the regulations should also specify that the results of such monitoring be reported to MPCA and made available to the public shortly after each land application activity. Monitoring and reporting soil moisture below the root zone would help safeguard water quality by providing regulatory agencies and the public with data necessary for EPA to effectively review and revise the ELGs going forward, as well as to facilitate enforcement against CAFOs that over- or mis-apply waste.

2. Production Area Effluent Monitoring

Subsurface monitoring is also necessary to detect, correct, and enforce against discharges to groundwater and hydrologically connected surface waters. EPA has pointed MPCA to the most recent NPDES General Permit for CAFOs in Idaho as an example of how to implement site-specific discharge monitoring at feedlots.[252] That permit requires all permittees to develop and implement a subsurface discharge monitoring plan that includes site-specific procedures for monitoring subsurface discharges from lagoons.[253] MPCA's regulations should make clear that subsurface discharge monitoring plans should include monitoring, sampling, and reporting requirements not only for LMSAs, but also for solid storage areas (compost piles, silage storage, etc.) and any other known subsurface discharge pathways in a facility's production area. MPCA should consider specifying that the baseline requirement for any subsurface discharge monitoring plan include at least two upgradient and three downgradient wells and routine sampling.[254]

Importantly, the Idaho permit includes an exemption to the subsurface discharge monitoring plan requirement for feedlots that can prove the land underlying their facilities has no hydrologic connection to a Water of the United States. To reduce regulatory burden, MPCA's regulations could contain a similar exemption. However, because Minnesota's definition of waters of the state includes groundwater, any such exemption in MPCA's regulations would need to be narrower and based on the conclusion of a professional engineer or hydrogeologist that the facility has no risk of discharging to groundwater, regardless of whether that groundwater is hydrologically connected to a Water of the United States.

Expert Opinion
David J Erickson, PG CPG
Idaho CAFO General Permit

Introduction

I, David J. Erickson, have worked in the Hydrogeology/Geology field for 35 years. I am currently the Principal/Founder of Water & Environmental Technologies (WET), a 130-person engineering firm started in 2000 that provides engineering, environmental, and remediation services in a 10-state region to a wide variety of clients including private, industrial, and State agencies based in Butte, Montana. I previously served as President of WET for 20 years. I am a registered Professional Geologist in Utah and Wyoming and a Certified Professional Geologist with the American Institute of Professional Geologists.

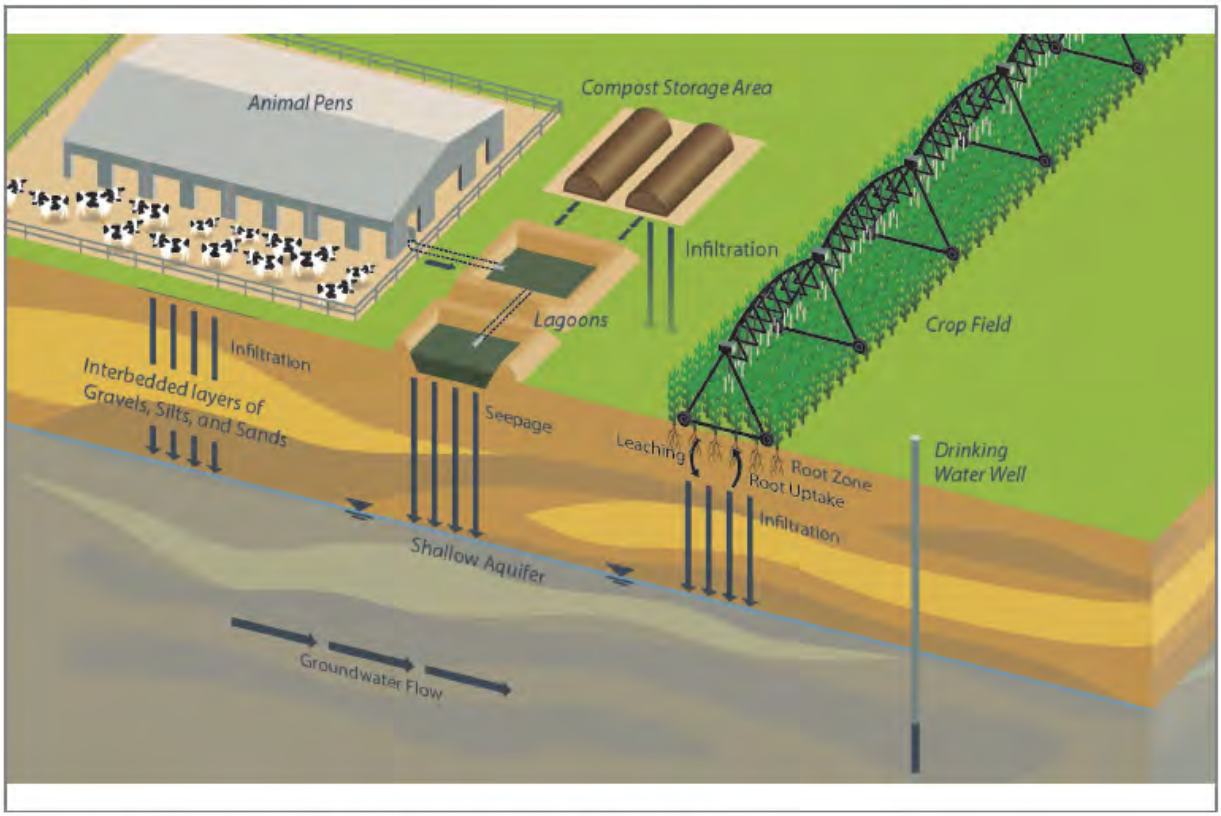
I received my Geological Engineering degree from Montana Tech in 1988. I worked in the petroleum industry in Houston for 1 year and later in the engineering consulting field. My technical focus has been on water related issues: investigation, development, remediation, permitting, litigation, and compliance. I serve as lead expert on several litigation issues as well as Project Manager/ Principal Hydrogeologist on complex remediation and investigation projects in the region including management of waste and water related environmental issues at coal fired generation facilities in Wyoming and Utah.

I have worked on more than 30 Concentrated Animal Feeding Operations (CAFOs) across the nation. I have successfully implemented long-term monitoring programs, lagoon lining projects, and management of CAFO facilities to minimize water quality impacts. Many of these projects are a result of litigation where I provided recommendations for the CAFO to achieve and maintain compliance. My full CV is attached as Attachment 1.

I started working CAFOs in the early 2000's in Montana and in 2013 in the Yakima, Washington area and currently work in several States investigating, characterizing and remediating the impacts to ground water, soil and surface water from these facilities. The principles, pathways and science behind the discharge of pollution by CAFOs is both simple and proven throughout industry. After completing an environmental investigation of more than 30 of these facilities, the sources of contributing contamination to the ground water and surface water include:

1. Lagoons designed to the standards mandated by the draft modified Idaho CAFO Permit (seepage rate of 1 x 10^{-6} cm/sec) leak and seep substantial volumes of process wastewater.
2. Manure applications to fields are both imprecise and often overapplied, intentionally and unintentionally.
3. Other sources, such as underground piping, compost areas, silage storage, cattle pens, and manure applications are potential sources of contamination.
4. Seepage, leaching, and surface discharges from these sources negatively impact water quality.
5. CAFO contaminated ground water flows toward and causes detrimental impacts to surface water.
6. Pollutants discharging from all areas of CAFOs are a significant threat to human health and the environment.

Figure 1, below, illustrates some of the ways that CAFO pollutants infiltrate or seep into ground water and then discharge to surface waters. Once in groundwater, pollutants will migrate in whatever direction the ground water flows.



Monitoring of groundwater, surface water, and soil conditions to assess a CAFO's pollution discharges does not require new or innovative technologies. These types of monitoring activities have been a well-established practice for decades. The only scientifically sound method of ensuring that a CAFO is not unlawfully discharging into jurisdictional waters is to: 1) monitor the places where the facility may discharge to surface water, and 2) monitor both groundwater contamination and migration. Such monitoring data are also essential to assessing the effectiveness of CAFO waste management practices and the relationship between precipitation, infiltration, ground water amount and quality, and surface water amount and quality.

CAFO monitoring plans must be tailored to individual facilities and land application areas, similar to how nutrient management plans are facility specific. These site-specific plans must be designed by a professional engineer or geologist with experience in monitoring methodology, systems, and analytical requirements (hereinafter, a "qualified professional"). All monitoring methodologies and systems must be documented in a Discharge Monitoring Plan and all resulting data must be included in publicly available reports, such as Discharge Monitoring Reports or their equivalent. The monitoring plan should be included as part of a CAFO's permit application and made available for public review and comment to ensure it can generate high-quality, representative data capable of demonstrating whether the CAFO has complied with the Permit's discharges restrictions.

Opinions specific to the modified Idaho CAFO General Permit

I. The construction and pollution management requirements in the Permit are not sufficient to prevent or detect discharges from CAFO production areas to surface water through ground water.

The water cycle is well documented and well understood throughout the world. Ground water almost always flows toward a surface water body, whether it be a stream, lake or the ocean. Many States have recognized this interconnection and limit ground water rights because it depletes surface water volumes.

Starting with the lagoon permeability allowance that is deemed protective by EPA, a simple analysis using Darcy's Law proves this position false. Darcy's Law is used to calculate the water movement through soil of a specific permeability. It is expressed as:

$$Q=Kia$$

Where:

Q= water flow (gallons)
K = liner permeability (cm/sec)
i = hydraulic gradient through the material (ft/ft)
a = cross sectional area where flow occurs (ft^2).

The table below provides a range of allowed seepage rates and volumes out of a CAFO lagoon that meets the requirements of the Idaho general permit because it does not exceed the permit's maximum seepage rate of 1 x 10^{-6} cm/sec. Per NRCS guidelines, the majority of lagoons hold approximately 9 feet of liquid manure. Most CAFOs have 2 to10 acres of lagoons, depending on several operational factors. Each 1-acre lagoon on a typical CAFO releases approximately 3,000,000 gallons of contaminated seepage per year or 8,313 gallons per day to the subsurface, clearly neither insignificant nor protective.

The table below uses the CAFO permit's allowed seepage rate times the different gradients based on the liquid level in the lagoon and calculates the seepage rate over a 1-acre lagoon. The highlighted row shows the seepage rate for the common allowed 9-foot depth of a lagoon. To summarize, the general permit allows 8,313 gallon of seepage per day or over 3,000,000 gallons of seepage per year per acre of CAFO lagoon.

Table 1. Typical Lagoon seepage rates

Permeability		Gradient	Q =Seepage per Acre per Day (Gallons)	Q =Seepage per Acre per Year (Gallons)
K (cm/sec)	K (ft/day)	i (ft/ft)		
1.00E-06	2.84E-03	1	923.7	337,159
		2	1847.4	674,319
		3	2771.2	1,011,478
		4	3694.9	1,348,638
		5	4618.6	1,685,797
		6	5542.3	2,022,957
		7	6466.1	2,360,116
		8	7389.8	2,697,276
		9	**8313.5**	**3,034,435**
		10	9237.2	3,371,595
		11	10161.0	3,708,754
		12	11084.7	4,045,914
		13	12008.4	4,383,073
		14	12932.1	4,720,233
		15	13855.9	5,057,392

Nitrate, the main contaminate from CAFO lagoons, has a very low partitioning coefficient, which causes nitrate to migrate quickly in the water and not sorb or diffuse into the soil. As a result, nitrate migrates very quickly through ground water and forms large ground water contamination plumes traveling long distances that can and do reach surface water.

CAFOs discharge contaminants from several areas of the operation; however, lagoon seepage and leakage cause large pollutant contamination including nitrate plumes in ground water that have a high likelihood of impacting surface water.

Construction requirements do not substitute for a leak detection system. Construction issues or mistakes result in leaks and the operator does not know if there is an impact to ground water or surface water without routine monitoring. Routine monitoring can be a set of monitoring wells downgradient of the system or a designed leak detection sump. These systems must be sampled on a routine basis to establish background conditions and sampled for the correct analytes to identify a wastewater discharge.

The Permit also requires visual inspections and routine cleaning. I have reviewed years of inspection data forms for lagoons in several States, and an inspector cannot visually see a leak below the liquid. The liquid is opaque and the leak rate would have to be catastrophic to be visible. As a result, these inspections are not effective in determining if a lagoon is leaking or seeping to a degree that will impact surface waters.

Also, the routine cleaning of manure solids results in excavation, erosion and liner damage over the life of the lagoon. A lagoon that meets the Permit requirement most likely will fail the requirements after the first cleaning. In addition, erosion of an earthen liner at the inlet is well documented and causes a liner breach resulting in a much higher leak rate than is documented above.

II. The liquid manure waste generated by CAFOs has a mix of contaminants that can cause impacts to human health and the environment. Pollution from CAFO wastewater harms the environment and endangers public health.

In addition to nitrogen contamination from lagoons, I have detected fecal coliform, hormones, bovine antibiotics, growth hormones, phosphorus, and chloride in the seepage and in the receiving ground water. These are all problematic contaminants in the environment; however, nitrate is the most mobile contaminant since it does not sorb to soil. These contaminants have known and recognized health effects to humans. Nitrate causes blue baby syndrome and other health effects, while the pharmaceuticals are known endocrine disrupters. Fecal coliform can cause severe gastrointestinal distress.

Data collected by EPA and WET in Washington State show a variety of contaminants are present.

The following table provides average concentration in CAFO wastewater from the Yakima Valley, Washington. These data were collected from sampling conducted by the EPA and WET.

Table 2. Contaminant concentrations in CAFO Wastewater

.pH	TDS	Chloride	Ammonia	TKN	Phosphorus	Calcium	Potassium
s.u.	mg/L	mg/L	mg/L	mg/L	mg/L	mg/L	mg/L

7.6	3100	230	330	1600	358	122	80

The following list of contaminants is directly from an EPA study of the Dairy Cluster in Yakima, Washington. These compounds have been detected in the drinking water aquifer and are a result of leaking lagoons and overapplication of dairy wastewater.

Table 3. Contaminants found in CAFO Lagoons and Drinking Water Wells, Yakima Washington

Nutrients & Minerals	**Antibiotics**
Nitrate Nitrite Ammonia TKN Chloride	Tylosin Enthromycin Lincomycin Sulfamethazine Tiamulin Virginiamycin Monensin Chlortetracycline Tetracycline
Hormones	**Pesticides & Herbicides**
Estradiol Androsterone Testosterone 7-a-estradiol Androstadienedione 17- β-trenbolone Epitestosterone	Atrazine Alachlor DEHP DEET Bentazon

These compounds are all linked to animal wastes and fall into the general categories of nutrients, antibiotics, and growth hormones. All compounds were detected in both the dairy lagoons and in the drinking water aquifer serving hundreds of residents in the Lower Yakima valley.

III. Pollution from CAFO impoundments and land application areas can reach surface water through ground water due to the hydrological connection between surface water and ground water.

Based on years of performing remedial investigations at industrial facilities and over a decade of investigating CAFOs, the contaminant migration pathway from the source to ground water beneath the facility, with migration to or toward surface water is almost always complete (*i.e.*, ground water almost always flows toward and recharges surface water). It is a natural part of the water cycle. While dilution changes the discharge concentration, the migration pathway is easily characterized using standard ground water investigation techniques. The disturbing data from

these facilities is that the nearby neighbor's drinking water well can be as high as 200 ppm nitrate and have a mix of bacteria and other contaminants.

Since nitrate is very conservative, as discussed above, ground water plumes from CAFO operations have been documented to travel several miles. An investigation I completed in Wisconsin showed nitrate traveling in ground water over two miles from the dairy CAFO and impacting Lake Petenwell with concentration above drinking water standard in many of the private drinking water wells along the flowpath. In Washington, hundreds of private water supply wells over a mile downgradient from the CAFO facility are contaminated above drinking water standards. Similarly in California, nitrate has migrated over 2 miles downgradient. Nitrate, the primary contaminant from CAFO waste, moves unattenuated with ground water, migrating to the next receptor: ground water withdrawal or nearby surface water discharge.

Since the Wisconsin site mentioned above was a detailed investigation, cross sections of the site are attached for reference as Attachment 2. These cross sections and data clearly show impacts from a manure lagoon constructed to NRCS standards with a concrete bottom and impacts from overapplication of both manure and chemical fertilizer to the land application areas. They also show a complete contaminant pathway to human exposure and discharge to surface water.

Given the conservative nature of nitrate contamination, a minimal setback from any surface water (100 to 300 feet) is not protective of surface waters. Both the mobility of nitrate and the size and volume of the sources easily cause plumes to migrate more than 300 feet. The Wisconsin site has nitrate migration in excess of 8000 feet through ground water.

Similar to other States, Idaho CAFO density is focused on large alluvial valleys where there is abundant water and large areas favorable for agriculture. These alluvial aquifers are permeable with relatively shallow water tables and fertile soils for crop growth. The areas around the CAFOs are generally rural, relying on ground water wells for drinking water supply.

Due to low precipitation, most of the facilities are open pen facilities that generate large amounts of stormwater runoff, pen scrapings and compost. Compost is a mix of wet manure and bedding that is windrowed in specific areas until the composting process is complete. The compost is moved out of the pens at >50% plus moisture and turned until the moisture is reduced to approximate 30-40% when it starts to heat up and compost. This material drains 40% of the moisture from the manure mix into the ground or the stormwater collection system, if one exists. In my experience, these compost areas are a significant source of soil and ground water contamination where the areas were not managed properly.

IV. Pollution from CAFO land application areas can directly discharge to surface water through a variety of pathways.

CAFO pollution from land application areas can reach surface water directly in several ways in addition to transport via ground water. If CAFO waste is overapplied it can runoff into nearby

surface water features such as ditches, canals, rivers, and streams. Also, If CAFO waste is applied on frozen ground or prior to a precipitation event there is a much higher probability of direct discharge to surface water. If waste application equipment malfunctions, for example if an irrigation center pivot malfunctions during application, CAFO waste can reach surface waters as runoff or directly. CAFO waste can also reach surface waters if an operator improperly conducts waste application, such as not observing setbacks, mis-calibrating application equipment, applying to saturated soil, or overapplying.

V. Effective and feasible monitoring techniques are available.

As stated above, the types of monitoring activities sufficient to determine a CAFO's water pollution impacts have been a well-established practice for decades. Below I outline select monitoring options that can be effective and feasible if implemented properly.

A. Ground water monitoring

Purpose: To determine if a CAFO has discharged pollution to surface waters via groundwater.

Available monitoring methodology/system: Groundwater monitoring is a simple and well-established process. Monitoring wells are placed upgradient and downgradient of the field or lagoon to be monitored. Typically, 1-2 upgradient monitoring well(s) and 2-5 downgradient monitoring wells are installed using standard drilling technology. If ground water flow direction and seasonality are already understood at the site, fewer wells can be used to effectively monitor each area (*i.e.*, upgradient wells for 1 field can be downgradient wells for the next field). Sampling is conducted quarterly or semiannually according to the SAP to establish seasonal fluctuation in ground water quality or quantity, to collect representative data, and to establish statistically significant background data. Semiannual sampling is typically sufficient for detection monitoring, with sampling occurring a high ground water and low ground water conditions or prior to application in the spring and after harvest in the fall. If other fluctuations that directly affect ground water flow and transport are identified, more frequent monitoring may be required.

Well drilling, sampling and analysis protocols are documented in both Idaho and EPA documents.[1] Data analysis requires statistical evaluation of the data to determine if upgradient water quality is different than downgradient water quality. A statistically significant delta between these two data sets establishes that the monitored area is contributing pollutants to groundwater.

Multiple regulations have been promulgated that are examples of effective groundwater monitoring regulations, such as 40 CFR 257.90-.98, which applies to Coal Combustion Residuals

[1] *E.g.* 40 C.F.R. §§ 257.91–.95; Idaho Dept. of Env't Quality, Statistical Guidance for Determining Background Ground Water Quality and Degradation (Mar. 2014), https://www2.deq.idaho.gov/admin/LEIA/api/document/download/4807.

("CCR") in landfills and surface impoundments. These regulations are relevant for CAFO waste management because they provided the basis for ground water monitoring and data analysis documenting the facilities impact to ground water. These regulations also detail construction standards to prevent discharges and corrective measure to remediate those discharges, if they occur. For example, 40 C.F.R. § 257.91(a)-(c) should inform monitoring of CAFO lagoons, silage storage, and manure composting areas and potentially land application areas:

> The groundwater monitoring system must include the minimum number of monitoring wells necessary to meet the performance standards specified in paragraph (a) of this section, based on the site-specific information specified in paragraph (b) of this section. The groundwater monitoring system must contain:
>
> **(1)** A minimum of one upgradient and three downgradient monitoring wells; and
>
> **(2)** Additional monitoring wells as necessary to accurately represent the quality of background groundwater that has not been affected by leakage from the CCR unit and the quality of groundwater passing the waste boundary of the CCR unit.

Groundwater monitoring system should be progressively more rigorous depending on the type of waste impoundment liner used.

1. Earthen liners with a constructed seepage rate of 1×10^{-6} require a full groundwater monitoring plan with 2 upgradient and 3 downgradient wells and routine sampling;
2. Synthetic liners with 2' compacted clay subbase require an abbreviated monitoring scenario (1 upgradient and 2 downgradient) and routine sampling; and
3. Double synthetic liner with leak detection or a sump and pump design would not require a groundwater monitoring system.

The monitoring well network in the monitoring plan must be developed by a qualified professional with knowledge of well network design and sampling programs.

The Sample analyte list for groundwater should be, at a minimum:

- Major Mineral: Alkalinity, Calcium, Chloride, Magnesium, Potassium, Sodium, Sulfate
- Nutrients: Nitrate, Ammonia, TKN, Phosphorous
- WQ Parameters: pH, Temp, SC, DO, TDS, total coliform bacteria.

B. Soil monitoring at land application areas

1. Soil sampling

Purpose: Detect nutrient migration through the soil column to identify nutrient leaching to groundwater.

Available monitoring methodology/system: Soil collected with hand auger or mechanical soil probe and analyzed for nutrient and other characteristics.

In order to obtain quality data that are representative, soil samples will be collected at a density of at least 1 per 20 acres of crop. Larger fields of 220-640 acres or fields with consistent soil types could be decreased. The table below presents a recommended sampling density. A minimum of 4 locations should be sampled across each application field. Samples must be collected in each soil type present in the field and should not be composited with other soil types. Together these data provide a representative dataset for the entire application area. The samples will be collected at depth intervals of 0-1', 1-2', and 2-3'.[2] Soil core collection methodology can include hand auger or mechanical soil probe.

Field Acreage	Samples Required
0-20	4
20-40	6
40-160	8
160-640	12

Soil samples should be taken before each application to facilitate proper nutrient application; sampling soil only annually or every three years is not representative and does not enable an operator to make responsible application decisions.

Analysis of the soils should include:

- Ammonia
- Nitrate as N
- Phosphorus
- Potassium
- pH
- Electrical conductivity
- Soil Organic Matter

2. **Soil moisture monitoring**

Purpose: To determine if soils are saturated above field capacity and causing nutrients to leach to groundwater.

[2] The additional depths allow determination of plant uptake of nutrients versus nutrients leaching past the root zone and contaminating groundwater.

Available monitoring methodology/system: Soil moisture probes are a simple but readily available technology that are easier to operate than lysimeters and provide faster, continuous monitoring.

A soil moisture monitoring program is easily implemented with existing data that the CAFO facility already should have in its Nutrient Management Plan ("NMP"). These can be simple devices that indicate when the soil moisture is above field capacity and leaching of nutrients is occurring. The soil moisture data, combined with routine soil nutrient sampling described above, provide a more accurate assessment of a field's ability to receive and retain CAFO waste. This data collection provides the operator with the information necessary to identify whether nutrients are leaching to groundwater.

Current soil moisture probe technology has data logging capabilities so the monitoring can continue without operator attention and the data can be downloaded at any time during the year to prevent overapplication that results in discharges to surface waters.

For each field that receives CAFO waste, each soil type present in the application area should contain 1 to 3 soil moisture probes as necessary to collect a representative sample of soil moisture. Operators must identify low lying areas of fields where liquid may pond and install at least 1 soil moisture probe in such areas.

Soil Type Acreage	Soil Moisture Probes Required
0-20	1
20-40	2
40-160	3
160-640	4

C. Above ground discharge monitoring for land application areas

Purpose: To identify surface water features and potential discharge points and monitor the quantity and quality of surface water discharges from a specific CAFO.

Available monitoring methodology/system: Visual monitoring that is representative of the land application area; in stream water quality sampling (up and down stream of a discharge point); and grab sampling of effluent discharges. Surface water sampling technology can be very simple, with grab samples collected by a sampling professional or a trained operator if a discharge point is accessible safely. The grab sample location should be permanently marked to allow collection in the same location over the monitoring period.

Surface water sampling can also be more complex. For example, an ISCO automatic flow proportionate sampling device could be considered, but these devices require experienced

operators. Similarly, an operator could use time- or event-controlled samplers such as Isco 6712 or 6712c.

Surface water sampling requires identifying monitoring locations that ensure collection of representative data. It is important to establish minimum requirements and standards, but due to the variability in where such monitoring locations will be for a given CAFO, a qualified professional should determine the correct location for representative sample collection to provide the necessary flexibility. The professional should also provide a monitoring plan that describes monitoring locations during and immediately following applications near surface water features. This assessment must be included in the facility's monitoring plan. This qualified professional must certify that the details contained in the monitoring plan are appropriately tailored to the specific CAFO and will generate representative data.

As discussed above, land application events can result in discharges to nearby surface water features. Land application often occurs over many acres, sometimes via largely automated systems such as pumps that deliver CAFO waste via pipes to irrigation center pivot systems.

Surface water monitoring must include, at a minimum,

- Frequency:
    - Visual monitoring to identify all pollutant discharges must occur during and after each land application event.
    - When a discharge occurs, analytical monitoring of both the effluent discharge and receiving water during the discharge event.
- Location:
    - For visual monitoring, operators must choose locations that are designed to produce data representative of the entire application area. This may require monitoring along the length of a downgradient edge of field, monitoring at the four corners of a field, or other set of locations tailored to the specific field's discharge potential. Visual monitoring must monitor for conduit discharges (e.g., tile drains) and sheet flow.
    - Grab sample at the point of discharge, if accessible safely.
    - For waters immediately adjacent to production or land application areas, 1 monitoring location immediately upstream of the CAFO and 1 monitoring location immediately downstream of the CAFO. If there are multiple discharge points, a monitoring plan may be able to collect representative data with 1 upstream and 1 downstream monitoring location, but if non-CAFO contributions are present operators should choose monitoring locations as close to the discharge point(s) as is practical to isolate the CAFO's impacts to the receiving water's quality.
    - Tile drain outfalls.
    - Furrows or other topographical features likely to discharge liquid from a field.
    - Application equipment must be inspected by a trained operator prior to each land application event.

The analyte list for CAFOs is provided below but EPA may require additional analysis to better characterize the surface water seasonality or local surface water variation.

Analyte List

- Major Mineral: Alkalinity, Calcium, Chloride, Magnesium, Potassium, Sodium, Sulfate
- Nutrients: Nitrate, Ammonia, TKN, Phosphorous
- WQ Parameters: pH, Temp, SC, DO, TDS, TSS, total coliform bacteria (e-coli P/A).

VI. The operation of multiple CAFOs in one concentrated area aggravates the impact of CAFO pollution on water quality.

Several States recognize cumulative effects from multiple facilities that discharge pollutants. This was especially evident in the Dairy Cluster Investigation completed by the EPA in the Yakima Valley (Lower Yakima Valley Groundwater | US EPA). The dairy cluster investigation identified leaking lagoons, overapplication in the fields and a general nitrate plume increasing from no detect to over 200 ppm nitrate in ground water. It also identified contamination of private drinking water supply wells above EPA Maximum Contaminant Levels (MCL) above which health effects are known and recognized in humans.

The increasing trend in nitrates along ground water flowpath are a direct result of cumulative effects from the multiple sources of soil and water contamination at the CAFO. In many investigations, the application fields are the major contributor to cumulative effects since they represent a constant nutrient load over each application field. The constant flux of nutrients from multiple sources at a single CAFO to ground water results in increasing concentrations along the ground water flowpath. Multiple CAFOs in the same area only increase the number of contaminant sources and result in increasing contaminant concentration along the ground water flowpath and subsequently in surface water.

The current knowledge base in the science of hydrogeology, hydrology and contaminants in the environment make clear that the Permit is not precluding the discharge of CAFO pollution to Idaho's surface waters. As these CAFOs continue to increase in size, the volume of manure generated becomes overwhelming and the facility is forced to become a waste handling operation. CAFO waste represents a highly mobile mixture of contaminants with known and recognized detrimental effects on human health and the environment, typically placed in an area with many human and environmental receptors.

To further illustrate this point, each dairy cow produces an estimated 140 pounds per day of waste and 22 pounds of produced milk per day per dairy cow. The waste to milk ratio is 6.36 lbs waste/ 1 lb of milk. At the same time the trend in the industry is less facilities confining greater numbers of animals. These data indicate that waste management issues at the CAFO are growing faster than actual milk production.

Dated August 23rd, 2023.

Subject: Comments on Proposed Amendments to Minnesota Feedlot Rules (Minn. R. Chapter 7020)

Dear Mr. Moore and the Minnesota Pollution Control Agency,

I am writing to provide input on the Minnesota Pollution Control Agency's (MPCA) rulemaking process to amend the animal feedlot rules (Minn. R. Chapter 7020), last significantly updated in 2000. As a sixth generation farmer, I am committed to ensuring these regulations balance environmental protection with the economic realities of modern agriculture. Given the 25-year gap since the last major update, I offer the following comments to ensure the rules remain relevant and effective.

The Future of Agriculture in 25 Years: If feedlot rules are updated only every 25 years, the MPCA must anticipate long-term agricultural trends. By 2050, I foresee precision agriculture dominating, with widespread use of variable rate technology (VRT), advanced nutrient management, and diversified rotations including specialty crops, and cover crops. Larger feedlots will increase manure production, requiring rules that incentivize innovations to manage nutrient runoff effectively while supporting farm viability.

Nitrogen Management and Efficiency: Minnesota's nitrogen regulations, such as the Groundwater Protection Rule, often rely on average application rates, which do not reflect the variability of high-yield operations or regional differences. In a commodity market, "average" performance risks economic failure. Minnesota's diverse agricultural regions, ranging from tile drained soils of the Red River Valley, lower yielding sandy soils of central and northern areas, and high yielding southern Minnesota require tailored nutrient management. In northwest Minnesota a 200-bushel corn crop may be a record-breaking achievement, whereas in south-central Minnesota, it represents a failure, reflecting the regions potential for 220+ bushels per acre. The nitrogen recommendation table (1) (e.g., 195 lb N/acre following group 2 crops at 200+ bushels per acre vs 145 lbs N/acre for <100 bushels per acre) highlights this variability, yet current rules often average nutrient standards across the state. This approach is invalid, as it may encourage farmers to over apply nutrients to meet high yield targets in a low yield area or penalizes south central farmers for underperforming relative to their potential. A recent study in Nature Communications found that optimal nitrogen fertilizer rates for maize in the US Midwest have increased by 33% from 1985 to 2018 (from 150 to 200 kg N/ha), driven by higher-yielding hybrids and improved practices, yet nitrogen use efficiency

(NUE) has remained stable or improved due to precision application (2). Compared to states like Iowa and North Dakota, which adjust nitrogen rates based on soil tests and crop needs, Minnesota's approach may disadvantage efficient producers. For instance, North Dakota's recommendations incorporate soil nitrate tests. Recent research also indicates high-yield soybeans may not provide the assumed nitrogen credit, as they consume more nitrogen than they fix, creating residue challenges rather than surplus nitrogen. Additionally, corn's nitrogen uptake is shifting later in the season, particularly with fungicides extending plant health. In-season manure applications, supported by stabilizers, are more efficient than fall applications, which are restricted in vulnerable areas. I urge the MPCA to adopt NUE metrics over flat caps, using tools like the University of Minnesota's nitrogen rate trials, regional yield data, and the Nature study's findings to guide manure application rates. Also, nitrogen rate studies should incorporate farming practices that include fungicide and in season nutrient applications. As plants stay alive longer in the season with fungicides, they require more nitrogen to "get to the finish line". A study from Pioneer (3) also shows that as yields go up, less nitrogen is getting remobilized in the plant, therefor requiring higher amounts of nitrogen. Following the current guidelines in the table over applications in a low yielding region could increase nitrate leaching, while in under-application in a high yielding region reduces crop health, both harming water quality and farm viability. MPCA should adopt a tiered nitrogen standard based on county level yield averages, soil productivity zones, and other data sources that follow the potential of the region.

Phosphorus Management and Variable Rate Technology: Phosphorus regulations often treat fields uniformly, despite variability in soil test levels. VRT allows precise application, reducing high soil phosphorus levels while building low ones, unlike blanket restrictions based on field averages. MPCA should incorporate a more detailed approach to manage P levels based on grid or zone testing, not whole field averages.

Setback Requirements: Minnesota's setback distances for manure application exceed those in other states which allows smaller setbacks for in-season applications due to lower runoff risks. Given that in-season applications align with crop uptake and reduce leaching, the MPCA should consider tiered setbacks based on application timing and soil conditions to balance water quality protection with practical land use.

Crop Rotations and Specialty Crops: Diversified rotations, including small grains and cover crops, can reduce nitrogen and phosphorus runoff by up to 70%, as demonstrated in Iowa's Nutrient Reduction Strategy. Encouraging these practices in feedlot rules could enhance soil health and nutrient cycling, especially in high-manure regions. The MPCA should offer incentives for operators adopting such rotations.

Nitrogen Stabilizers: Nitrogen stabilizers, like nitrification inhibitors, improve NUE by reducing nitrate leaching and volatilization. Given their effectiveness, the MPCA should incorporate stabilizer use into manure management plans, allowing flexibility in application timing and rates to reward innovative producers.

In some recent conversations with growers in Canada, they are surface applying manure in corn with 90-foot-wide booms with drop hoses to the ground, and they are experiencing a 50% reduction in nitrogen losses. The crop is immediately using the nutrients, and the nutrients are not subject to weather from fall until the crop needs it. Practices like this would be too restrictive with current setbacks, even though very beneficial for crop yields and water quality. In Europe, which is densely

populated and very concerned with farm practices, applies in season with top dress applications on wheat. Any in season application should utilize nutrients far better than up front applications. Ideas like these need to be considered in the next 25 years. As fertilizer prices are and will most likely remain high, we need to think of practices that are not currently used here to gain better efficiency.

The MPCA's rulemaking process, extending through 2027, is a critical opportunity to modernize feedlot regulations. I encourage continued public engagement through accessible sessions and clear summaries of proposed changes. By adopting science-based, flexible rules informed by studies like the Nature Communications analysis, the MPCA can protect Minnesota's water resources while supporting a competitive agricultural sector.

Thank you for considering my input.

Sincerely,

Cole Pestorious
Farmer, Owner, Frontier Family Farms

Nitrogen Recommendations

Crop Grown Last Year	Organic Matter	Expected Yield (bu/acre) <100	100-124	125-149	150-174	175-199	200+	Irrigated Sands
Alfalfa 2+ year old stand	low	0	0	40	40	40	40	150
	med/high	0	0	40	40	40	40	150
Alfalfa 1 year old stand	low	30	30	80	80	80	80	170
	med/high	30	30	80	80	80	80	170
Soybeans	low	100	100	150	150	150	150	205
	med/high	100	100	150	150	150	150	205
Edible beans, field peas	low	125	125	175	175	175	175	215
	med/high	125	125	175	175	175	175	215
Group 1 Crops: Clover, fallow, grass/legume hay, grass/leg, pasture, etc.	low	70	70	120	120	120	120	160
	med/high	70	70	120	120	120	120	160
Group 2 Crops: Corn, wheat, oats, potatoes, sugar beets, grass, rye, etc.	low	145	145	195	195	195	195	235
	med/high	145	145	195	195	195	195	235

(2) This highlights that over time increasing soybean yields are not giving the corresponding increase in nitrogen back to the corn crop since it's slope is greater than following corn.

Comment on Planned Amendments to Animal Feedlot Rule, Minn. Rs. Ch. 7020

I am writing to ask the MPCA to do more to protect our lakes, rivers, streams, and groundwater by revising the Animal Feedlot Rule to address the crisis of nitrate pollution in our state. Feedlots are a major source of nitrate pollution in our waters, and by adding stronger rules for the handling of manure, MPCA can help ensure that all Minnesotans' water at the tap is safe to drink.

I care about this because...

St. Paul, MN 55164-0620

Comment on Planned Amendments to Animal Feedlot Rule, Minn. Rs. Ch. 7020

I am writing to ask the MPCA to do more to protect our lakes, rivers, streams, and groundwater by revising the Animal Feedlot Rule to address the crisis of nitrate pollution in our state. Feedlots are a major source of nitrate pollution in our waters, and by adding stronger rules for the handling of manure, MPCA can help ensure that all Minnesotans' water at the tap is safe to drink.

I care about this because...

Clean water is non negotiable! Nothing is worth polluting them!

St. Paul, MN 55164-0620

Comment on Planned Amendments to Animal Feedlot Rule, Minn. Rs. Ch. 7020

I am writing to ask the MPCA to do more to protect our lakes, rivers, streams, and groundwater by revising the Animal Feedlot Rule to address the crisis of nitrate pollution in our state. Feedlots are a major source of nitrate pollution in our waters, and by adding stronger rules for the handling of manure, MPCA can help ensure that all Minnesotans' water at the tap is safe to drink.

I care about this because...

We need to take steps to protect our land + water

William Moore, OAH:

RE: OAH Docket # 25-9003-40661, Revisor # R-4928

My concern about the CAFOs is due to the impact on water quality because of the manure runoff that contaminates the adjacent soil, waterways, and impacts human health

The USFWS has documented reduced populations of aquatic invertebrates that are bioindicators of water quality, such as reported using the EPT index (Ephemeroptera, Plecoptera, Trichoptera) is leading to fish kills.

For the last few years I have heard farmers in many rural communities speak at legislative hearings about the nitrate levels in their wells from manure and fertilizers that are above what is considered safe drinking water. In addition, there are reports of blue baby syndrome and other birth defects, cancers and illness from bacterial contamination from E. coli.

This is more than enough evidence to require more feedlots to have water pollution permits, to require medium and large confinement operations to monitor discharges to groundwater and drain tiles, to enforce stricter land application requirements and to require lower application rates in especially vulnerable groundwater areas such at the Karst regions in southeastern MN.

In this state that has so many farmers in rural communities, growing food for us and for other countries, we need to be protecting them *and* our environment.

Please give this your serious consideration.

Sincerely, Margot Monson

Margot Monson, aquatic entomologist

St Paul, MN

Give us your comments on the
Animal Feedlots Rule

MINNESOTA POLLUTION CONTROL AGENCY

We want to hear from you!

The information that I share with you should not be shared with the public. This will make it harder for me to transfer manure to neighbors some of them will not want there fertility info and yield shared publicly.

With all reporting having to be done online many are going to have to hire someone to do it for them or just not do and then what are we going to do put them out of business.

Cover crop for all maybe is not the answer for all. Soil type and typography is more important then time of year. Weather and time in the Fall can make this hard to get done.

I have been doing it for the last few years

Use the back if you need more room.

3 ways to submit your comments:

Hand this card to an MPCA staff member

Send via mail to:
OAH Attn: William Moore
600 N Robert St.
PO Box 64620
St. Paul, MN 55164-0620

Scan the QR code to submit comments online

and if I get a good stand I need to to put more N on early into the year because the Cover Crop has all the N tide up and this is when the yield potential is being set, After the cover Crop breaks down later in the Season its ok but I have lost yield by then. Non Cover Crop field's allway out yield Cover Crop Fields, It comes at a cost of 40-50 ac to plant and kill.

Animal Feedlots Rule

MINNESOTA POLLUTION CONTROL AGENCY

We want to hear from you!

I am a hog producer in SE MN. There are several rules, standards, guidelines that we have to follow each year to be able to haul manure and are watched over closely by goverment officials.

Major rainfalls are hard to control. In MN 90% of reported fish kills are non agricultural related and I think that stat is imortant to share.

Comment on Planned Amendments to Animal Feedlot Rule, Minn. Rs. Ch. 7020

7 JUL 2025 PM 8 L

I am writing to ask the MPCA to do more to protect our lakes, rivers, streams, and groundwater by revising the Animal Feedlot Rule to address the crisis of nitrate pollution in our state. Feedlots are a major source of nitrate pollution in our waters, and by adding stronger rules for the handling of manure, MPCA can help ensure that all Minnesotans' water at the tap is safe to drink.

I care about this because...

I live 1 mile east of the proposed Daley expansion given preliminary approval by MPCA and the DNR. My private well far exceeds the safe level for nitrates.

Transferring manure to a non-producer requiring him to come under the same rules of recording, it will make it very difficult to find a place for my storage.

If you tell them they have to do this, they will turn it down. Farmers in my area do not put much interest in manure, do not recognize it for much value

Corn on corn - The nitrogen allowance is very inadequate

Office of Administrative Hearings

Mr. Moore:

I'm John Weiss, I live in Rochester, I fish trout in SE streams and I'm worried about feedlots. Therefore, I'm encouraging you to be as strict as possible with rewriting rules for Chapter 7020.

I am a member of Trout Unlimited and endorse the changes they would like to see. They are more the experts in this.

I'm writing more as an angler and someone who loves the blufflands and our waters.

I'm not opposed to feedlots, though there are questions about just how big they should be. That is not the purpose of these rules. But how well they work with the land and our water are part of the rules. Good farmers are some of the best friends trout and trout streams have. If they control runoff, keep nitrates out of the water - both ground water and surface water - they are helping everyone.

There is no reason farmers shouldn't be required to have good plans for the manure. Yes, it's probably more work for them but they are part of society, we all need to control what we do that affects water. I live in the city and try to keep down use of salt in winter to not pollute the Zumbro River, we don't dump grass clippings into the sewer so they go into the river. This is only a smaller thing compared with the effect a large feedlot can have but we are all responsible for our water. I've learned over nearly 50 years in the Southeast that it all comes down to water - what we do on the land ends up in the water.

So please, update the rules, make them as strict as possible so farmers can still farm but our waters are kept clean.

Finally, it's the right thing to do.

John Weiss

Dear Mr. Moore,

I attended the Minnesota Pollution Control Agency meeting in Paynesville MN in June where they informed us that any size animal unit will be considered a feedlot if there is soil without grass cover. That could be as low as a few poultry, 1 to 5 sheep, goats, pigs or calves (etc.) as this would lead to annual costly registration.

The next speaker spoke on nitrates and said a nitrate is a nitrate. They can't tell the difference whether it came from rain fall, snow melt, decaying vegetation, exhaust fumes, manure, urban runoff, commercial fertilizer or where it exactly came from.

In my opinion, this appears to be a way of getting rid of small producers through a paper work jungle or computer nightmare. As a small animal farmer, along with my two sons, we can't afford to lose valuable nutrients from manure due to the high costs of commercial fertilizer. In fact, we planted 52 foot buffers on lakeshore and stream or ditch where needed (requirements were 0 to 50 feet) so we could harvest the buffers for hay and still protect water quality.

This appears to me that this is being pushed to eliminate animal agriculture. If need be, break the southeast corner of Minnesota off but please don't include the whole state. I believe the current feedlot rules are very good and keep them as currently being used and enforced.

Sincerely yours,

Vernon J Pooch

Dear Mr. Moore:

I am a member of Trout Unlimited and an avid fly fisherman. Trout require cold, clean water and a healthy aquatic insect population. I am writing to ask the MPCA to strengthen the Animal Feedlot Rule, Minnesota Rule Chapter 7020 to prevent large volumes of manure which contain high levels of nitrogen, ammonia and other chemicals from washing into trout streams and groundwater.

I recommend amending the existing Feedlot Rules to improve land application of manure practices as follows:

1. Require NPDE/SDS permits for feedlots with 600 or more animal units.

2. Prohibit manure application on frozen or saturated ground, or when rainfall is likely.

3 Require greater setback distances for manure applications from water resources in the karst region and other vulnerable groundwater areas, including prohibiting manure applications within:

- 300 feet upslope or 100 feet downslope of a sinkhole or other direct conduit to groundwater
    - 300 feet upslope of a public waterway or tributary of a public waterway
    - 250 feet from a private well
    - 1,000 feet from a community well

4. Prohibit livestock of a feedlot or facility capable of holding 100 or more animal units from entering a designated trout stream or tributary and prohibit livestock of a feedlot or facility capable of holding 300 or more animal units from entering any water of the State.

MDA's current approach to Feedlots is failing to protect Minnesota's trout streams from fish kills and groundwater from harmful levels of contamination and I urge you to take action.

Thank you for considering my letter.

Minnesota Pollution Control Agency

Re: Planned Amendments to Rules Governing Animal Feedlots, Minnesota Rules, chapter 7020, Revisor's ID Number R-04928

I am writing on behalf of Minnesota Trout Unlimited ("MNTU") and its thousands of members around the state to comment on changes to Minnesota's Animal Feedlot Rule. Minnesota Trout Unlimited is a grassroots conservation organization working to protect, restore and sustain coldwater fisheries and their watersheds across Minnesota. Our several thousand members living and working in communities across Minnesota understand that activities on the land determine the quality of the water in streams and lakes, and the health of trout and aquatic organisms that live in these waters. We are very concerned about the impacts that animal feedlot operations, including manure applications, can have on trout streams.

MNTU urges the Minnesota Pollution Control Agency to amend the Animal Feedlot Rule to include the following:

1. Require NPDE/SDS permits for animal feedlots with more than 600 animal units. *7020.0405, Subp. 1 B (1)*
2. Require all feedlots with 300 or more animal units to prepare a manure management plan and maintain land application records, and submit these to the MPCA and county feedlot pollution control officer (in counties with a delegated county animal feedlot program pursuant to 7020.1500 to 7020.1800). These requirements should apply to **all** feedlots of this size, regardless of whether they use a commercial applicator or not. (see Minn. R. 7020.2225, subp. 4)
3. Require all owners and operators of animal feedlots with 300 or more animals to use the online nutrient management tool, including for development of manure management plans.

4. When manure is transferred by a feedlot owner/operator for application to the land by someone else, require that the transferee also follow the requirements in the manure management plan. (see Minn. R. 7020.2225, subp. 5 D)
5. Prohibit manure application on frozen or saturated ground, or when rainfall is likely. (see Minn. R. 7020.2225, subp. 6; add to Minn. R. 7020.2225, subp. 4)
6. Require greater setback distances for manure applications from water resources in the karst region and other vulnerable groundwater areas, including prohibiting manure applications within:
    - 300 feet upslope or 100 feet downslope of a sinkhole or other direct conduit to groundwater
    - 300 feet upslope of a public waterway or tributary of a public waterway
    - 250 feet from a private well
    - 1,000 feet from a community well

    (see 7020.2225, subp.6 and 8)

7. 7020.2015 should be amended to require that:
    "Animals of any animal feedlot of any size must not be allowed to enter any public water, nor any spring which flows into a Class 2A water (per MPCA rule), designated trout stream (per DNR rule), or tributary of a Class 2A water or designated trout stream. The feedlot operation must be fenced to prohibit livestock entry into these water resources."
    Note that pasture operations are not subject to 7070.2015.
8. Revise the definition in special waters in 7020.033, subpart 23 by adding a provision C: "C. Class 2A waters, designated trout streams, tributaries of Class 2A waters and designated trout streams, and springs and groundwater seeps that flow into these waterways."
9. Require soil nitrate tests prior to all manure applications in Cass, Carlton, Morrison, Martin, Winona, Hubbard, Rock, Clearwater and Stearns counties, since they are hot spots for nitrogen overload. (7020.2225 Subp.2)
10. Require annual reports to be submitted by delegated counties to the MPCA, that the MPCA review and audits these, and explicitly authorize the MPCA to revoke or rescind the delegated authority where a county regularly fails to perform its duties or does so poorly.
11. Expand mandatory groundwater and surface water monitoring at all permitted feedlot operations and associated manure storage and application sites.

12. Prohibit feedlot expansion and construction in sensitive groundwater areas and near trout streams without stringent environmental review. Consider the density and the maximum number animals units allowed in a particular watershed, with consideration to the vulnerable groundwater areas of the state including the Karst region. Use a spatial analysis to examine cumulative impacts by HUC 12 watershed.
13. Require the owner of an animal feedlot who transfers manure to another person or entity to regularly report to MPCA and the county who the manure transferees are, and the amounts and locations of manure applications by the transferee(s).
14. Require transferees to regularly report to MPCA and county when and where manure applications are made, and the amounts applied.
15. Permit applications: Add these provisions to 7020.0505, Subp. 4:
    a. require the identification of all Class 2A waters (per MPCA rule), designated trout streams (per DNR rule), tributaries of Class 2A waters and designated trout streams, and springs and groundwater seeps that flow into these waters on land where manure will or may be applied and locations where any land within 100' of these water resources where slope exceeds 6%.
    b. identify any land proposed for manure applications where manure is already being applied from another source, and identify the source and amount
    c. identify the number and locations of all sinkholes on the property where manure will be applied
16. Increase funding for manure storage and management grants to animal feedlot operations with less than 600 animal units.
17. The cumulative impact of animal feedlot operations and manure applications must be considered at the HUC 12 watershed scale to protect water quality of public waters of this size. A moratorium on permitting new feedlot operations should be instituted in HUC 12 watersheds that are already saturated with feedlot operations.
18. All animal feedlots located within a 3-mile radius that are owned by the same owner or group of owners should be treated as a single operation for purposes of determining whether the combined operations exceed various permitting or environmental review thresholds.
19. Address phosphorus requirements of plants and testing of soil and manure before application.
20. Increase funding to the MPCA to add staff necessary to manage and enforce permits for all animal feedlots with more than 600 animal units.

Thank you for this opportunity to comment on changes needed to the Animal Feedlot Rule.

Respectfully,

/s/John P. Lenczewski

Subject: MPCA Feedlot Rules

Dear Mr. Moore

My name is Chad Johnson, I am a third generation farmer from southern Minnesota. I have been a Minnesota livestock producer for my entire career. I would just like to give a few points from my perspective as the MPCA decides rule changes for feedlots.

1. I would ask that the MPCA please consider realistic yield goals from certain parts of the state when determining the amount of realistic fertilizer it takes and time of application to reach those goals so livestock producers can compete with the commercial fertilizer markets.
2. Please consider the financial aspects of rule changes to new and existing feedlots as dramatic changes and demands could lead to hardships and even farm closures.
3. Please take a look at surrounding states that use different regulations and yield goals for different areas of their state. (application rates and setbacks)
4. Technology and science are helping the Mn livestock farmer become more efficient thru variable rate applications, new tools to apply when it's the most efficient, nitrogen stabilizers to help keep fertility available for the plant longer, etc.

Thank You for listening to my concerns. Nobody cares more for the natural resources of the state than the Mn farmer. I am just asking for a practical and efficient process to work for everyone.

Chad Johnson

MPCA Feedlot rules update

I lived rurally for 40 years and am aware that our groundwater in the Drfitless is seriously contaminated with nitrates and agricultural chemicals, and has been for decades. Despite numerous programs and countless dollars spent, our water is not improving.

Confined animal operations have grown in number and size, resulting in more liquid manure stored, transferred and applied, primarily in nearby fields because of cost of transport. Ag practices have changed as well, with few animals on the land and less alfalfa and small grains being grown. The primary crops are corn and soybeans, both demanding inputs. Over application of manure and commercial fertilizer has become a huge problem. More ag land has been tiled creating severe point-source pollution to our streams and ground water.

One step in improving the crisis of contaminated water would be to reduce the permit threshold of 1,000 AUs to 600. More confined operations would then need an NPDES or SDS permit. They would need to have a manure management plan, adequate storage and follow certain BMPs.

Feedlots of over 300 AUs should be required to prepare a manure management plan, maintain application records and submit them to the MPCA and county feedlot officer.

Permits and manure management plans aren't of much use however without monitoring and reporting. Permitted feedlots should be required to monitor discharges to groundwater and drain tiles below crop fields along with monitoring surface water runoff.

It should be prohibited to spread manure on frozen ground, and application rates in vulnerable areas should be lower.

Applying manure and commercial fertilizers too close to sinkholes and waterways has impacted groundwater and caused fish kills. There should be required setback distances, and they should be marked/posted so there will be no mistakes.

Everyone deserves clean, safe drinking water, and the state agencies tasked with protecting this precious resource have failed to do so.

RE: comments on feedlot rules update

DATE: July 17, 2025

On June 24, 2025, I attended the MPCA information meeting on this topic in Albert Lea. THANK-YOU FOR TAKING THIS ON! We need to update these rules to protect the ground and surface water for all of us in SE Minnesota.

I have become aware of this need by the news about the EPA actions in our region based on high nitrate levels in our water. I have also been informed about the need for action by reading "Dodge County Inc" by Sonja Trom Eayrs. Years ago, when I was a new member of the League of Women Voters, I lamented to an older member that we seemed to be studying clean water issues again and again. She advised me that government never fully solves a problem, so we have to address it over and over. There are always changes, so government and citizens need to react. That is what you are doing now.

In 1988-9, Olmsted County created its first water plan. I, as chair of the Rochester Planning and Zoning Commission was appointed to the group that wrote it. We were very aware of the need to protect our ground water in this karst geology by the then recent work of Calvin Alexander from the U of MN. His work was horrifyingly startling....dye added to disappearing streams in a Fillmore County feedlot, emerging in less than a day in a beautiful artesian spring, which wasn't clean, 1000 year old water from the center of the earth after all. At the time, my view on how to protect the public water supply, from a planning commission perspective, was to regulate the number and placement of septic systems. From what I am now learning about concentrated feedlots, septic systems are a drop in the bucket.

Some members of this group writing the 1989 county water plan, tried to dissuade us by claiming that regulation would undermine the economy (at least of farmers). Our response was to say consider the huge health care economy of "Destination Medical Center", if we do not regulate and ground water becomes poisonous to those with fragile health... Imagine the impact of 1 headline: "Mayo Patients succumb to water born illness"

Please consider these upgrades to the current feedlot rules:

1) ground water monitoring for NPDES and SDS permit holding feedlots
2) lowering animal unit size
3) changes to how a collection of feedlots under same ownership are permitted
4) institute a manure mapping tool available to the public
5) oversight of those who spread manure, especially if not on land owned by permitted feedlots
6) there needs to be found a way thru air quality monitors to control odor so that other people can live, work, and thrive near feedlots...zoning is not enough
7) BUMP UP ENFORCEMENT to occasional spot checks as well as quick response to complaints.

Thanks for the work you are doing for all of us,

Amy Caucutt, 716 28th St NW, Rochester, MN 55901, (c)507-993-9897, amycaucutt@gmail.com

Good Morning William More,

I have also included the financial summary for Farm Business Management Education Programs for 2024 calender year.

It includes 222 dairy farms from Southeast Mn. As shown, there is not a lot of profit to reinvest in dairy, equipment and possible larger structures for manure storage.

Thank you for considering.

Duane Wild

JUL 21 2025
Office of Administrative Hearings

Hello MPCA,

Thank you for hosting regional meetings throughout Minnesota.

I would like you to consider these points that I think are important.

1. Fish kills

   I have fished the same streams for almost 60 years and continue to fish. Every fish kill I have seen was a 3.5-5 inch downpour in a very short period of time. That is not something that is predictable and we can't regulate it. When I was younger, all trout streams were grazed and cattle stood in the streams during hot weather and pooped. There were no fish kills that I knew of or were publicized.

   Today, we have more trout in the streams than ever before. Only 1-2% of fish kills are related to agriculture. Most are temperature elevation of water and stream bank debris. Streambank restoration may help. Let's not penalize agriculture for their minimal role in this problem.
2. Nitrates-Farmers are solely being blamed for nitrates but old septic systems and wells with eroded casings need to be checked as their leaks contaminate water as well. We should also be monitoring municipal sludge spreading practices to consider how they add to the nitrate and heavy metal contamination picture. In Lewiston we have had our municipal sewage pond develop a leak and disappear overnight.
3. Wintertime spread, storage pits, pad sites

   Most young livestock are housed in manure packs in Southeast MN. As the packs thaw, they release ammonia in the sheds. The sheds need to be cleaned monthly starting at the end of January or the animals will have pneumonia problems.

   We need to work with animal agriculture, like Europe does, to provide engineering plans, pads, or new buildings with financial help. If we don't, farms with under 1000 animal units will disappear due to the increased cost of operation. Dairy farms under 1000 animal units cannot afford this. Our profit margin is small. The cull price of calves have saved the day for the last 2 ½ years but that won't last forever and the milk price has not increased. Federal and state rules have already driven out most of the 50-250 cow sites in Minnesota.

   The loss of one dairy cow means the loss of one acre of hay and pasture land. Those acres will be planted to corn and soybeans. We are moving in the wrong direction. We need more alfalfa and pasture for improved water quality.

   Manure pads and liquid storage areas will cost 2-4 million dollars per dairy to meet the proposed changes. I asked at the regional meeting if funding from the state would be provided and was told, "Not at this time". Our family farm priced a manure

storage pit in 2007 for 555 cows with 7 months storage. This would be 2 units containing 4, 712,591 gallons of liquid manure. The cost was over $800,000. With your proposals, we will need over 12 months storage for wet Spring conditions like we had in 2024 in our area. 3-5 million dollars will be needed for liquid and pen pack.

Exit will be the only option. There is no funding available. I have visited our NRCS and SWCD several times to confirm this.

The rural Minnesota economy will suffer the loss and food security will be at increased risk in the U.S. In 2017, each dairy returned $7000 to the local economy through machinery dealers, plumbers, electricians, veterinarians, nutritionists, agronomists, hardware stores, grocery stores, etc. The loss of dairy farms affects not only food availability but also the economic health of our communities.

4. No winter spread of manure also has serious implications.
    - The cost of facilities for the manure will mean dairy and cattle farmers will need to sell their herds. The loss of hay and pasture ground to corn and soybeans results in lower water quality.
    - A wet spring would mean increased compaction due to repeated trips across the field to spread manure. Increased compaction reduces soil health.
    - The need for more time spreading in the spring means a shorter window for planting and/or the use of shorter day crops, which would mean lower crop yield.

I have seen no study putting a smaller amount, like 3-4,000 gallons per acre, on chiseled fields in winter on fields with less than a 6% slope. In a winter like 2024-2025 (very little snow) all water melts into the chiseling and there is little runoff. With a spring like 2024 (excess rain, wet and saturated soil) there can be a great deal of runoff due to the unpredictable large rainfall.

A broad brush approach does not work. Weather forecasts are only about 50% correct and rainfall is the biggest predictor of runoff.

5. Distance between family farms

    There should be no change. Farmers consider the distance between fields and an increased land base increases the opportunity for less manure per acre and less road travel with tankers and spreaders.

    Each farm should have its own animal – unit base.

    An exit from livestock production is very likely, going from 750 animal units to well over 1000 animal units will have different requirements. We were told not to worry if family members worked together.
6. Animal unit values need to stay the same as they are valued today.

Discharge per animal per day should be the standard, which was set-up by previous laws regarding animal unit total.

Our rural communities are already having difficulty meeting the challenge of school, fire, police, EMS, county taxes, and township taxes.

A loss of animal production will hurt rural communities. Loss of dairy/beef production will decrease alfalfa and pasture ground acres which will affect water quality. There is no perfect style of farming. There are positives and negatives for everyone. We should encourage education of farming practices that will benefit water quality and provide an opportunity to change when it is affordable-Examples: cover crops, no till planting, manure management, fertilizer application, etc. Public cooperation helps us improve water quality. We can see changes in the last 10 years with adoption of several of these practices.

It will take time to see changes in water quality considering the time it takes for water to move through the soil. All changes will not work every year. Flexibility has to be built into the plan due to changes of rain and snowfall.

As a dairy farmer with the price of milk at $17 per hundred weight and the increased cost of production, there is not much left over for larger pits and stacking slabs. Changing requirements will only leave 1000 animal unit facilities and rural communities will pay the price.

Thank you for considering these comments.

Duane Wirt

Mr. Moore,

his is a critical time to rewrite animal feedlot rules and stop toxic nitrate pollution in Minnesota's waters. I am concerned about the serious problems of runoff, seepage, and spills caused by animal feedlot manure.

Manure runoff in Minnesota waters results in fish kills. Swimming is unsafe due to E.coli bacteria from animal wastes. Excessive nitrates from manure result in blue-green algae blooms in shallow lakes and rivers, producing toxins harmful to wildlife and humans. Manure seeping into well water used to prepare infant formula causes methemoglobinemia (blue baby) nitrate poisoning. In recent decades, nitrate contamination of drinking water likely contributed to 24 Minnesota infant deaths.

Right now, Minnesota animal feedlot rules do not protect water, fish, wildlife or human health. I urge the MPCA to address these dangerous impacts by developing strong rules. I ask that you make the following changes to the Animal Feedlot Rules:

1. MPCA rules should require pollution permits (NPDES/SDS permits) for "Medium-sized" feedlots with 300-999 animal units–which contribute 43% of Minnesota's total manure.

2. MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits.

3. MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. It has not been shown that "stricter" requirements in existing rules prevent pollution.

4. MPCA rules should state that MPCA will enforce "no discharge" requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.

5. MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.

6. MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure

and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm.

7. Thank you for the opportunity to comment. Please protect the health of Minnesota's waters, fish, wildlife, and people from toxic nitrate pollution. We are counting on you.

Sincerely,
Mr. Larry Bogolub

Comment on Planned Amendments to Animal Feedlot Rule, Minn. Rs. Ch. 7020

I am writing to ask the MPCA to do more to protect our lakes, rivers, streams, and groundwater by revising the Animal Feedlot Rule to address the crisis of nitrate pollution in our state. Feedlots are a major source of nitrate pollution in our waters, and by adding stronger rules for the handling of manure, MPCA can help ensure that all Minnesotans' water at the tap is safe to drink.

I care about this because...

Water is vitally important to all life and our existence! Protect our water!

Share Your Story and Thoughts About MN's Animal Feedlot Rules Here:

Please Print clearly

There Are 2 MAIN issues I would cite. 1. Odor/Air pollution - there is the odor in & around the confinement building itself & that associated with failing to carefully knife in manure when spread. This is exacerbated by allowing multiple such facilities near one established homesites in a rural township. Cumulative effects need to be considered. 2. Water pollution - both surface water & well water are at issue. Manure if not properly knifed in or over applied runs into streams, killing fish & bugs. Nitrates pollute well water, especially in MN's Karst area. Also water demand for multiple CAFO's in an area overstresses water supply.

MPCA Feedlot Commentary Due July 22

The MPCA has begun the process of reviewing and potentially changing Minnesota's existing feedlot rules (MN Rules Ch. 7020, ID Number R-4928). This is the first time since 2000 that these rules have come up for review.

This comment period is open until July 22 and closes at 4:30pm. Writing a personalized comment to the MPCA before then is the best way to make your voice heard, and have an impact on the future of Minnesota's feedlot rules. Comments are being taken both online and by mail. Fill out this card and mail or you can comment online at bit.ly/feedlotcomments or at QR code below.

You can also fill out the form online here!

Dear William Moore:

Please ask the MPCA to do more to protect our lakes, rivers, streams & groundwater by revising the Animal Feedlot Rule regarding nitrate pollution. We need stronger rules to insure that MN H_2O at the tap is SAFE to drink!

Sincerely,
Patsy Gavin

Hello;
I was directly impacted by one of these Fish kills. We own land on Rush Creek just off of HW. 29 in Winona County. As I am sure you are aware, Fishing in Minnesota brings in an estimated 2.4 Billion dollars a year to state coffers. Aside from that, the animals in that stream are a wonderful biological indicator for water health. I have had several years to mull over the incident and after reading the law have some suggestions that may help to alleviate these situations from continuing to occur. They are as follows;
1) wouldn't it be easier and faster to use one set of rules for all the agencies? Unhear of you say, not so I worked on a county level to help design a water quality study that involved MPCA, MDH, Soil and water and county public health. All parties were able to use the data, all got along and it did a lot of good for the state and county.
2) I did not see anything in the law about inches of overburden, if I remember correctly that should be included when determining manure rates.
3)under the description of the protection method please describe the differences of floodplain, special protection area. It would clarify the requirements.
4)I am wondering why vegetative buffers are 100 feet for lakes, but 50 feet for streams. It seems that they may be backwards, why not have them the same. Especially in the steep valleys of the driftless area.
5) I would expect that most dairies feed a slightly different diet, there is probably a slightly different microbial profile. If that is the case then testing each herds manure a couple times a year may help the point source problem. A fingerprint so to speak.
6) I know how hard regulation is, however if you are considerate, true and educate them. You can mostly get the contractor in my case,
farmers in your,going in the same direction. You will have to do some big fines at first, but once they know you and understand you are a straight shooter, I have confidence they will come around.
Thank you for the opportunity to comment

As a small organic farmer and a member of the Concerned Citizens of Olmsted CountyI have the following comments.

1. Do not permit any manure storage pits or holding tanks that would be separate from the source where the manure is produced
2. Do not permit manure storage that is near a quarry that is or may be actively dynamiting to get to more gravel or rock access

A. If these are permitted the result of such action could be a major loss of manure into our streams, lakes, and aquifers.The containment loss could ruin our recreational swimming, drinkable water supply, and kill fish in our streams.

B. Locating a manure storage away from the source manure means that private citizens that do not gain any profit from the farming operation have to see their property values reduced, their quality of life in their home jeopardized,bacteria contamination in the air they breath and the obnoxious smell to deal with.

3. Drag lines that are used to transfer manure must be emptied after each transfer to fields so they do not burst under pressure and contaminate the soil and groundwater, Some of these drag lines are 5 miles long and they have no secondary containment and hold tons of manure.Drag lines must be inspected prior to any use.
4. Owner of manure will be designated as the responsible party and not defer the responsibility to the applicator. As any other industry the farm industry should be held accountable for the pollution from cradle to grave.
5. Polluter pays for loss of property value, loss of drinkable water,all fish kill restoration any harm they have done to adjacent or non adjacent property owners impacted such as trees killed, loss of revenue for parks that have to shut down because of pollution to their recreational facilities and proven health effects to the citizens that have their health has been negatively impacted.
6. Citizens with complaints of fields that look like lakes after manure has been applied should not just be dismissed when they call the hotline. They should be listened too and action taken by the MPCA
7. All manure storage should have monitoring wells,covers to contain bacteria from getting into the air and at the very least annual inspections. Field tile outlets should have water tests to measure nitrates and other contaminates leaving the field.. An allowable limit should be agreed upon and if surpassed the perpetrator should be heavily fined.

Respectfully submitted by Jan Blevins

Olmsted County Concerned Citizens

The Minnesota State Cattlemen's Association (MSCA) is a membership-based organization representing cattle farmers and individuals who are part of the cattle community in Minnesota. We represent nearly 1,000 members in the state of Minnesota.

Our members are aware of the importance of caring for the land and water, as these resources are crucial to the success of their farm or ranch. The MSCA does not feel that new and increased rules and regulations for feedlots in Minnesota will improve land and water quality, rather they will put family farms out of business. In Minnesota, there are over 18,000 beef farmers, and 97 percent of these farms are family owned and managed, according to the Minnesota Department of Agriculture.

These family farms go above and beyond to protect natural resources and with the help of technology, farmers continue to find new ways to increase production while decreasing inputs and giving back to the land. Often, farmers and ranchers do everything in their power to pass on their land to the next generation, that is what this industry is all about.

Manure is not waste to beef producers, it is valuable. Producers do not want to overspread or overuse manure. Instead, they use best management practices (BMPs) to apply during the correct conditions and apply the correct amounts. This practice is best for the farmer and for the soil. Farmers and ranchers ensure they are protecting lakes, rivers and streams through the state buffer law which is reported to have 99 percent of Minnesota farmland compliance. Farmers have also shown their dedication towards protecting water through enrolling over 1.1 million acres in the Minnesota Department of Agriculture's voluntary Ag Water Quality Certification program.

Many farmers have also taken part in cost-share programs to increase practices such as cover crops and feed efficiency and purchase or upgrade soil health equipment. Beef producers take the correct steps to ensure proper manure management, storage and application methods are being followed as well.

The MSCA supports increased education for feedlot owners and operators. We feel there are currently ample rules in place governing feedlots in Minnesota, there just needs to be increased education on these rules and BMPs.

The MSCA does not support lowering the 1,000 AU threshold for NPDES/SDS permits. We instead strongly urge the MPCA to structure the rule review process to protect and improve water quality while keeping livestock farms of all sizes viable and prosperous. Requiring NPDES/SDS permits for operations under the 1,000 AU threshold will likely make it increasingly difficult for farms to stay in business due to the lengthy and expensive NPDES/SDS permitting process. Many of these farms are operated by one or two family members that do not have the means to hire contracted services to accurately submit and maintain permitting status.

The MSCA is concerned with additional restrictions on manure application rates. The University of Minnesota Extension provides guidelines for manure application rates in Minnesota, emphasizing the importance of balancing nitrogen and phosphorus needs for optimal crop growth and minimizing environmental impact. These application rates are backed by science and should be followed. We are also concerned with restricting farmers from spreading manure in certain areas of the state. Again, manure is a valuable nutrient, not waste, and many farms do not have enough storage for this to be an option. Manure storage is expensive, and many farmers do not have the resources to increase manure storage.

The MSCA does not support enhanced manure management planning and record keeping requirements for transferred manure from feedlots. This devalues manure and will lead to an increase in commercial fertilizer usage.

The MSCA supports 7020 rules being practical for every size feedlot in the state and for the rules to serve as the baseline for all feedlots in the state. We feel that flexibility is key with any changes made

to the rules. Farmers need options for BMPs so they can choose which best fits their operation. Not every BMP will work well for each farmer, but it is important they are given options.

Sincerely,

Kaitlyn Root

My father grew up on a farm, I grew up on a farm.

Farming was once done in environmentally sustainable ways, both in how crops were rotated to let the soil recover, and in protecting runoff by using buffer zones and tree cover along fence lines. That ethic is essentially gone with the advent of so-called factory farms. Our waters are taking the hit in multiple ways.

Feedlots are one of those ways.

"MPCA rules should require pollution permits (NPDES/SDS permits) for “Medium-sized” feedlots with 300-999 animal units–which contribute 43% of Minnesota’s total manure.
MPCA rules should set a maximum limit on the size of any single feedlot and a maximum limit on the number of animal units in any local area or watershed. Hydrology and effects on both ecosystems and human welfare should be used to determine maximum limits. Existing rules do not prohibit feedlots even in the most sensitive karst regions where groundwater is most vulnerable.
MPCA rules should prohibit new or expanded animal feedlots in karst geology where groundwater is most vulnerable to seepage pollution. Groundwater contamination cannot be remedied, and it has not been shown that “stricter” requirements in existing rules prevent pollution. In addition, despite 15 years of technical evidence, no MPCA rule limits nitrates to protect fish and sensitive aquatic life.
MPCA rules should stop merely trusting that animal feedlots and manure applications are “no discharge” facilities. The permits should require regular monitoring and reporting of surface water and groundwater pollution levels both at the feedlot and on the fields where manure from that feedlot is spread.
MPCA rules should state that MPCA will enforce “no discharge” requirements, compliance with all pollution limits, reduction of contamination in impaired (already polluted) waters, and prevention of degradation in waters that are not polluted.
MPCA rules should strengthen minimum technology requirements for all permitted animal feedlots based on modern liner systems and leak detection. Rules should not assume that concrete or compacted soils containing manure will prevent seepage and discharge.
MPCA rules should prohibit application of manure, whether wet or dry, in the winter. Existing rules fail to consider the unpredictable snow, freeze, and melt conditions resulting from climate change that increase winter runoff.
MPCA rules should require feedlots to demonstrate that they comply with air quality rules at least 344 days a year (Minnesota statutes only exempt feedlots from compliance when removing manure and for 21 or less cumulative days per year). Exposure to noxious air emissions, like hydrogen sulfide has adverse health effects, including respiratory and neurological harm."

DEPARTMENT OF HEALTH

Protecting, Maintaining and Improving the Health of All Minnesotans

July 22, 2025

Office of Administrative Hearings
Attn William Moore, OAH
600 North Robert Street, PO Box 64620,
St. Paul, Minnesota 55164

Dear Mr. Moore,

The Minnesota Department of Health (MDH) would like to provide MPCA suggestions and comments for consideration in the revision of Minnesota Rules Chapter 7020 regulating animal feedlots.

The mission of MDH is to protect, maintain and improve the health of all Minnesotans. One key approach in carrying out this mission involves protecting and safeguarding water resources used for drinking water supply. MDH is responsible for implementing programs under the federal Safe Drinking Water Act and plays a key role in providing the state response to nitrate contamination of groundwater supplying private wells in southeast Minnesota.

MDH also recognizes that agriculture, including animal feedlot and livestock operations provide significant economic benefits for the state. While we desire such operations to be financially successful, we also need them to be environmentally sustainable. There are known risks in such operations. Our comments focus on opportunities and regulations that support opportunities to improve management of feedlots and manure that will minimize impacts on vulnerable drinking water resources and protect public health.

Our three priority resource concerns focus on and include:

1) **Management and placement of feedlot sites and application of manure in Vulnerable Drinking Water Supply Management Areas (DWSMAs).** The MDH Source Water Protection (SWP) Program assists public water suppliers in delineating and assessing the vulnerability of their DWSMAs. These water supplies are susceptible to land surface contaminant sources such as feedlots, manure and other nonpoint and point source threats. There are approximately 240 community water supply systems that are considered to have vulnerable aquifers or rely on surface water sources
2) **Vulnerable Groundwater Areas.** Due to the geologic conditions in some parts of Minnesota, groundwater is particularly vulnerable to land use activities such as in Southeastern Minnesota. In addition to public water supplies, MDH has been a partner in addressing nitrate contamination concerns in SE Minnesota. As a result, MDH would request similar consideration be given for manure and feedlot management in these areas to reduce manure and feedlot impact on private wells and groundwater resources in vulnerable areas. The MPCA Feedlot General Permit Vulnerable

Groundwater Areas - Overview website is a State wide tool that should be used to protect vulnerable groundwater areas as part of the implementation of MPCA Feedlot Rules 7020 and manure management efforts in the State. MDH supports the use and application of the tool as part of MN Rules Chapter 7020.

3) **Community public water supply systems that rely on surface water as their source of drinking water.** Similar to Vulnerable DWSMAs, delineated-State approved Surface Water (SW) DWSMAs are developed and approved by MDH for public water systems using surface water. Similar restrictions in the construction and restrictions on manure application should be considered in these areas given the immediate impact that can result from feedlot management and manure application. There are 23 community public water suppliers in the State. MDH can provide the latest source water assessment information for each surface water public water supply system.

Vulnerable DWSMAs and *Vulnerable Groundwater Areas* of the State should be defined and identified in the revised 7020 Feedlot Rule. In relation to the priority resource concerns identified above, considerations and changes to the rule should include:

a. **Include the same requirements found in the State Feedlot NPDES permit for all feedlots for the fall application of manure in a vulnerable DWSMA.** MDA is responsible for implementing the Groundwater Protection Rule for commercial nitrogen fertilizer. Conversely, MPCA Feedlot rules should prioritize and require more compliance monitoring and enforcement for the application, proper crediting and agronomic rate for manure application in Vulnerable DWSMAs working with delegated feedlot counties.
b. **Include the same requirements found in the 2025 Feedlot NPDES permit for the fall application of manure in MN Rules 7020 for feedlots greater than 300 animal units located or applying manure in a vulnerable groundwater area.** Greater awareness and broader recognition by feedlot operators of all sizes is needed to reduce nitrogen impacts from both commercial and organic forms of nitrogen. Recognition locally of vulnerable groundwater areas and enhanced manure management techniques such as the use of cover crops and other practices is needed to reduce N loss to groundwater.
c. **Provide training, new technology and the resources necessary to support delegated feedlot counties monitor and verify compliance with new feedlot rule requirements**. Target and prioritize monitoring and compliance in Highly Vulnerable DWSMAs and Vulnerable Groundwater Areas based on public health concerns from potential virus and nitrate contamination risks to drinking water resources. Provide tools or a web application that allow for better tracking, review and sharing of manure application data within High Vulnerable DWSMAs and Vulnerable Groundwater Areas of the State.
d. **Clarify and refine language in MN Rules 7020 that a new feedlot shall be a minimum of 1,000 feet from a public water supply well located in a Vulnerable DWSMA.** Work with MDH to clarify and improve some of the nomenclature used in MN Rules 7020 to ensure consistent use of terms and definitions are used between State agency programs.
e. **Require the new or expanding feedlots between 300 – 1000 animal units located within a Vulnerable DWSMA, vulnerable groundwater area or Surface Water DWSMA**

be required to have 9 months of manure storage capacity. In order to properly manage manure adequate storage is essential to being able to apply manure at the right time and rate.

f. **Restrict the construction of a new feedlot or manure application within the emergency response area of a Surface Water DWSMA.** MDH would like to explore with MPCA options for restrictions in the delineated SW – DWSMAs. Of particular concern is construction and manure application within the Emergency Response Area (ERA) that is closest to the intake (8 hour time of travel) and the spill management area (24 hour time of travel area).

g. **Clarify the language and use of an interim permit to correct a feedlot permit deficiency or pollution problem in a Vulnerable DWSMA.** It is not clear how and when an interim feedlot permit would be used to correct a deficiency in the existing rule in a DWSMA. Consider rule language or clarify in the rule how a manure management plan or feedlot permit would be modified or changed to address a pollution problem that impacts waters of the State, vulnerable groundwater areas or priority public drinking water sources that have been identified.

h. **Require all feedlots larger than 10 animal units be identified and registered in a vulnerable DWSMA.** Small feedlots improperly operated or managed can have impacts on public drinking water supplies.

i. **Require training and licensing of commercial manure applicators.** Ensure that training includes specific responsibilities and liabilities in terms of manure application requirements identified in Feedlot Rules Chapter 7020.

j. **Provide clear definition of manure ownership in Chapter 7020 including transfer of manure and timing of other entities responsibilities for application and management.** Apply similar language and restrictions in Chapter 7020 for manure ownership and transfer for feedlots between 300 and 1000 animal units.

k. **Include similar cover crop / perennial requirements, application timing in the fall and manure application restrictions defined for Vulnerable DWSMAs, SW – DWSMAs and vulnerable groundwater areas for feedlots between 300 and a 1000 animal units similar to the language included in the revised NPDES General Permit for feedlots over 1,000 animal units.** This provides some level of equity, fairness and consistency in the implementation of best practices that allow for the protection of groundwater, surface water drinking water resources.

l. **Work with MDA, MDH and MGS in the consistent use and maintenance of a vulnerable groundwater areas of the state website**. Presently, MDA and MPCA maintain two separate websites that depict vulnerable groundwater areas related to commercial fertilizer and manure. Explore the option to have one website that would make it easier for agricultural producers and government entities to use. See website Fall Nitrogen Fertilizer Application Restrictions (2024) (arcgis.com)

m. **Work with MDA to have a common website where growers can go to find nitrogen restrictions from both commercial and livestock fertilizer sources to protect vulnerable groundwater areas from nitrogen loss to groundwater.**

MDH would like to work closely with the MPCA to ensure protection of public drinking water sources and private wells through ongoing discussions regarding feedlot permitting of large and small facilities, manure management best practices, compliance monitoring and enforcement of permitted feedlots.

MDH wishes to encourage thoughtful consideration of drinking water resources and public health protection as part of updating the Feedlot NPDES General Permit. Thank you again for the opportunity to provide comments. Feel free to contact me at (651) 201-3724 or Chris.Elvrum1@state.mn.us if you have any questions regarding this letter.

Sincerely,

Christopher Elvrum, Manager

The Minnesota Well Owners Organization
Comments on Planned Amendments to Rules Governing Animal Feedlots, Minnesota Rules, chapter 7020, Revisor's ID Number R-04928

The Minnesota Pollution Control Agency (MPCA) requested comments on amendments to Minnesota Rules Chapter 7020 (Animal Feedlots), referred to as the Animal Feedlots Rule. The rulemaking is intended to address changes in livestock and poultry operations and business practices, account for new agency data services, modernize outdated rule language, amend existing Animal Feedlot Rules to improve land application of manure practices to address nitrates, bacteria, and fish kills, and establish additional technical standards to protect water quality and avoid fish kills.

Minnesota Well Owners Organization (MNWOO) is a nonprofit corporation created to provide education, technical and legal services, and advocacy to those who own and who rely on private wells for their drinking water, and to preserve, protect, and restore the quality and quantity of Minnesota's water resources and to ensure the safety of those who use them.

MNWOO submits the following comments.

General Comments

How do the Animal Feedlot Rules address climate change and what are effects of feedlots on the increase or decrease of carbon in the atmosphere and on the land? How can these effects be mitigated?

Given the reasons given above for the planned amendments to the Animal Feedlot Rules and concerns for human and animal safety, damage to the geography, land, soil, water, MNWOO questions the necessity for feedlots. MNWOO poses the possibility of banning feedlots altogether.

Strengthening the Animal Feedlot Rules is critical to transition from a reactive approach that addresses pollution after it occurs to a proactive one to prevent pollution by recognizing and protecting Minnesota's Nature, Air, Water, Land, its cultivated soil, its people, and the animals in the feedlot.

In general, the MPCA should undertake and formulate detailed health risk assessments and drinking water safety plans to address the tangible and ongoing threats from widespread nitrate contamination of drinking water resulting from feedlots. The health risk assessments and the drinking water safety plans should focus specifically on each township, each Drinking Water Supply Management Area, and each watershed. Public health risks need to be considered by accounting for manure and commercial fertilizers and damage to the environment and for all facets connected to feedlot operations.

MPCA should incorporate the Safe Drinking Water Act's, 42 U.S.C. §300f et seq., principles of coordination with other Minnesota regulatory agencies, communication, well testing, alternative water supplies, risk assessments, and long-range source water protection. These principles should be cited and woven into the fabric of the Animal Feedlot Rules. Thus MNWOO urges MPCA to actively reach out and coordinate with other state agencies including but not limited to the Minnesota Department of Natural Resources (MDNR), Minnesota Department of Health (MPH); Board of Water and Soil Resources (BWSR), the Minnesota Department of Agriculture (MDA), the Minnesota Department of Transportation (MDOT), the Minnesota Attorney General, pertinent Federal agencies, affected Indian Nations when promulgating the Animal Feedlot Rules and other rules.

MNWOO recommends that citizen complaints, MPCA investigations and responses be publicly available. For example, citizens with complaints about fields that look like lakes after an application or applicators applying in the middle of the night while it is raining should be followed up and not ignored by MPCA.

Summary of General Comments
•Address Climate Change
•Consider Banning Feedlots
•Be Proactive, not reactive
•Protect Surface and Ground Waters
•Coordinate and cooperate with federal, Indian, and other state agencies
•Be more responsive to citizens

.

Polluter Pays

The "Polluter Pays" principle is a widely accepted environmental and financial tenet. If a private business, regardless of sector, causes harm to public resources or private property, such as odor, other nuisance, land values, the polluter should bear the cost of remediation and compensation. The financial burden of environmental damage and community impacts from feedlots should not be borne by the public and affected individuals but should be pushed back to the polluting entity. This prevents the externalization of costs onto taxpayers and affected communities.

Animal feedlots and Confined/Containment Animal Feeding Operations (CAFOs) are point sources of pollution, and are private businesses. They should play by the same rules as every other business if they pollute waters of the state. Studies have consistently shown that feedlots can negatively impact nearby property values because of, at the very least, odors and aesthetic concerns. Additionally, the heavy truck traffic associated with large feedlot operations can cause significant damage to rural roads, imposing substantial repair costs on local governments and taxpayers. Polluters, i.e., the feedlot owners and sponsors, should thus be accountable and compensate for loss of property value, unsafe drinking water, fish kill restoration, harm to adjacent property owner such as dead trees, parks that lose revenue because the recreational waters were polluted, replacement of wells or added systems to make water drinkable. The feedlot owners and their sponsors, moreover, should resolve and mitigate the reason for any pollution. Holding operators accountable for these documented impacts ensures that the full societal costs and consequences of their operations are recognized and addressed.

Placing the financial liability for pollution and community impacts on the feedlots and their sponsors, moreover, creates a strong economic incentive for feedlot operators to invest in the best available technologies, implement stringent management practices, and choose locations that minimize harm.

Summary of Polluter Pays
•Make the feedlot owner and its sponsor/contractor pay for any and all damage and pollution

Definitions

Given that there the Animal Feedlot Rules are intended manage the feedlots, MNWOO asks for clarity of definitions. What is a feedlot? Does the definition include all animals that are confined - beef cattle, dairy cattle, swine, poultry, fish, sheep, goats? What animals? What does "confined" mean - how much space does an animal not have? How many animals?

MNWOO recommends that the Animal Feedlot Rules discontinue the use of the phrase "animal units." The use of the word "units" robotizes living creatures that have awareness, suffer, have feelings for families, have empathy. Count the living animals, not "units" for consumption and profit. The people of Minnesota ask that the Animal Feedlot Rules consider the health and well-being of the animals; not just the profit for the feedlot owners and their corporation sponsors/contractors for confining and slaughtering *animal units*.

Summary of Definitions
•Number of animals
•Species of animals
•Space requirements for animals
•Animals are not UNITS

Feedlot Permit Applications

A paramount goal of the Animal Feedlot Rules should require applicants for a feedlot permit to inform themselves and the public of potential environmental and health and safety risks from feedlot operations and manure storage and use.

Require the feedlot permit applicant to disclose the number and location of other feedlots owned or leased by or under contract to the applicant. Currently, an owner of multiple feedlots, even feedlots right next to each other, can evade regulations by applying each feedlot as a "separate" operation, though the total pollution is the same as a large feedlot.

Require the feedlot applicant to disclose if it is under contract with a larger supplier to produce, feed, provide animals and the terms of the contract, such as whether specific sources of animals, specific food and nutrients, specific veterinary services, specific slaughter houses, etc.

The principles of coordination with other Minnesota regulatory agencies, communication, well testing, alternative water supplies, risk assessments, and long-range source water protection should be cited and woven into the fabric of the permit application and its manure management plan. The permit applicant should be required to coordinate with federal, Indian, and state agencies regarding the potential effects on wildlife, nature preserves, fish, ground and surface water, air quality including odor, noise, local water planning, use of agricultural and biological chemicals, etc.

MNWOO earnestly recommends that the MPCA adopt a policy that declares confined animal feeding operations be declared “a polluting enterprise” that must demonstrate new and improved controls before qualifying for permits. This would in effect, place the industry representatives (permit applicants) on their proof that they have addressed risks and have means to manage the risks and solve the heretofore unsolved problems associated with this enterprise. To provide this "proof" the plans and specifications for new or expanding animal feeding operations should be required to be prepared by qualified and experienced licensed engineers and hydrologists familiar with confined/concentrated animal feeding operations and other feedlots. The licensed professionals responsible for the siting and design of these operations should be required to affirm that the manure management plans and safety water plans and specifications they submit will "prevent, control or abate" pollution that may be shown to be or have been originating from the operation. This is not an unusual hardship on even the smallest feedlot operation considering that individual homeowners in rural areas of Minnesota are required to have licensed professionals design and install on-site sewage treatment and disposal systems that are reviewed by qualified professional in permitting units of government.

The permit application should also discuss the contributions of the proposed feedlot to climate change and mitigation thereof.

Prior to or as part of a permit application under the Animal Feedlot Rules, an applicant should be required to submit, as an integral part of the permit application, an assessment of the site's existing conditions and surroundings as well as the available data on trends in the area’s water quality, air quality, and ecological and biological integrity. For feedlots, the risk factors are well known and can be mapped, tabulated, and summarized using fundamental tools like the USDA Web Soil Survey Suitability and Limitations maps, the County Geologic Atlas and Hydrologic Atlas plates, the MPCA Watershed Assessments (Stressor Analysis, WRAPS and GRAPS), local One Watershed One Plan (1W1P) plans, the Ag Department Runoff Forecast Advisory, MDNR Explore Watershed Health website, and the University of Minnesota Natural Resource Atlas website. and other peer-reviewed risk assessment maps. (*See* Appendix I for list of pertinent maps.)

The permit application must delineate the risks by location and activity, and prepare a risk management plan for each feedlot and each manure spreading field. If the potential risks are not avoided, the applicant should describe a response plan, a receptor survey, and a mitigation plan.

MNWOO advocates that MPCA require a standard set of risk assessment tools, maps, and strategies already adopted across the State. A standard set of risk assessment maps would eliminate many errors and omissions from the applicants and the Regulating Government Units (RGUs). As part of the standardized permit application, the prospective feedlot operator should delineate the risks of feedlot operation and include how such risks will be managed and how the operator will engage the community, government decision-makers, and permitting agencies of the tools to control significant environmental effects, as well as the project location, purpose, design, construction, and operations. By requiring complete transparency about known and probable risks, applicants are better prepared to manage the risks, the public is better informed, and permits and regulations can be applied to protect the health, safety, and welfare of all Minnesotans.

MNWOO can offer a template for assessment and management of these risks, such as nutrient runoff, leaks and spills, infiltration of pollution in groundwater and drinking water, odor and noise from feedlots, ecological and biological harm such as fish kills and deforestation, destruction of native environments, community and land use impacts.

Each feedlot permit application should develop a water safety plan based on groundwater testing and source water protection. The feedlot permit should assess feedlot and potable water well risks on abutting property. The water safety plans should define the risk, the appropriate risk managers, and the plans to ensure drinking water quality. The water safety plan of the permit application should identify local private wells, water systems, and drinking water quality.

The permit applicant should also acknowledge the 1W1P applicable to the watershed in which the feedlot will be located. These plans are often exhaustive but rarely followed, even as they promise that local efforts to implement protection, enhancement, and restoration strategies can be successful.

Summary of Feedlot Permits
•Identify multiple feedlots of same applicant
•Identify sponsor/contractor for whom feedlot owner is providing animals
•Feedlot owner coordinate with other federal, Indian, and state agencies
•Assessment of existing conditions
•Standardize feedlot application to address climate change and mitigation
•Standardize feedlot application to include risk management plan
•Standardize feedlot application to include water safety plans

Water Appropriation Permits

Minnesota's aquifers are a shared public resource. Large-scale feedlot operations, especially those with many animals can have substantial water demands for drinking, waste flushing, and cooling. Excessive groundwater pumping can lead to aquifer drawdown, impacting other well users nearby, increasing pollution infiltration rates, and potentially altering groundwater flow paths, e.g., in the karst region of southeastern Minnesota and the central sands.

Limiting annual water appropriations for large feedlot operations, such as limiting the size of a well and the volume of water to be pumped, ensures the sustainable use of groundwater for the larger impacted region, prevents excessive drawdown that depletes aquifers and impacts domestic wells, municipal water supplies, and connected ponds, wetlands, creeks, streams, rivers. Limiting groundwater appropriation ensures that large industrial agricultural operations contribute to the responsible management of water resources, just as other large water users are regulated. It encourages water conservation practices within feedlot operations.

Because of local surface water impairments and the existing trends in groundwater quality in shared underground drinking water sources, the feedlot permit application should review and cite existing and proposed water appropriation permits, or the lack of permits, and annual water use reports. For existing, re-permitted, and new applicants, disclosure of water appropriation permits, permit compliance records and links to pump tests should be required.

Water quality assessments of wells and aquifers in the area that are likely to be impacted should be documented from data available from the MDA Township Testing Plans or the MDH new well testing, or the local/regional testing programs. The appropriate maps and their applicability to the feedlot operation should be discussed in the permit and annually after a feedlot permit has been granted . To show whether or not surface or groundwater pollution is or has been originating from an animal feeding operation the feedlot should be required to submit pre-construction (for new or expanding operations) monitoring data from representative locations in the water table or aquifer both upstream downstream of the feedlot, as well as annual reporting requirements on groundwater quantity and quality.

Many smaller farms are not required to obtain water appropriation permits. Any farm with over 200 animals should have a water appropriations permit unless pumping data shows less water use.

All manure storage and field tile of existing or proposed feedlot operations should be monitored by monitoring wells and testing field tile outlets for nitrates and other agricultural contamination, such as phosphorus, pesticides, fungicides, biologics, etc. Plans for the groundwater water quality monitoring regime should be submitted to the MPCA for prior approval before the monitoring system is put into operation. The plan should include the professional hydrologist's opinion on whether the existing pre-construction water quality condition will be adequately characterized by the sampling locations, frequency and duration of sampling and the parameters to be monitored. Parameters to be monitored should reflect not only the nutrient and microorganisms that could be discharged from the facility but all other "pollutants" used at the facility relating to the feeding and raising animals.

If pre-construction monitoring demonstrates that an existing animal feeding operation owned and or operated by the applicant has already contributed to surface or ground water pollution, the prospective permittee must submit a remedial action plan to be approved by the MPCA. This remediation plan should be successfully implemented before new or expanded animal feeding operation can be permitted. Here, successfully implemented would mean the pollution levels are reduced to comply with applicable surface or groundwater standards.

Summary of Water Appropriation Permits

•Groundwater is public
•Assess existing water quality and quantity
•Require disclosure of water appropriation and compliance thereof
•Limit water appropriation if Nature and others impacted
•Require/establish monitoring wells and pump reports

Manure Storage

Applicants should submit the maps and address how the feedlot and manure storage will avoid, control, and mitigate the risks.

MNWOO advocates to restrict Liquid Manure Storage Areas (LMSAs) to smaller 250,000 gallon cells, within geologically or environmentally sensitive regions. This directly addresses the risk of catastrophic failure of LMSAs in highly vulnerable karst, central sands, and near recreational areas, rivers, lakes, and other locations where a rapid loss of stored manure can have devastating, immediate, and widespread environmental and health consequences both above and below ground.

While sinkholes or liner failures cannot be entirely prevented, limiting the volume of individual cells within a manure containment area dramatically reduces the magnitude of pollution released in a single event. A 250,000-gallon spill, while still serious, is significantly more manageable and less environmentally damaging than a multi-million-gallon release. Smaller spills are more amenable to rapid containment and remediation efforts, reducing the spread of contaminants into the broader environment and aquifers.

Geologically and environmentally sensitive regions, like the vulnerable groundwater area, drinking water supply management areas, near recreational and natural preservation areas, may pose higher risks wherein the consequences of a large-scale failure are most severe due to direct aquifer connectivity. This limitation of the size of manure storage ponds prioritizes the protection of vital drinking water sources. In Minnesota the line between groundwater and surface water is not always distinct, as in karst geology, and such failures of manure storage ponds have had and can devastate trout streams which are of huge importance to the local economy and environment.

Manure should be stored near the manure source. While the manure source owners are gaining financially so that they and the animals need not endure the smell and pollution of a feedlot, property owners near the manure storage are the ones who endure the consequences of manure storage, e.g., lower property values, reduction of quality of life on their property they own, polluted wells and unsafe drinking water, pollution of creeks and streams they may swim in or use for recreation, fish that are unsafe to eat. For example, a manure storage is being proposed near a quarry that dynamites often; this should not be permitted because if there is a loss the overflow from rain or if the storage pond is compromised, the manure would flow into Chesterwood Park where kids swim and adults recreate. This is not acceptable. Plan ahead for possible risks to health.

All manure storage should have secondary containment and covers to prevent leakage and bacteria to the air.

Summary of Manure Storage
•Risk assessment and mitigation
•Smaller capacity
•Restrict in vulnerable geologies and geographies
•Store manure by its source
•Secondary containments

Manure transfers

Under the existing Animal Feedlot Rules, transferred manure is exempt from tracking. So the application location, rate, and date of transferred manure are unknown. When manure is transferred by a feedlot owner/operator for application to the land by someone else, MNWOO advocates that the transferee adhere to the requirements in the manure management plan. Tracking requirements of transferred manure should be established and enforced.

Drag lines that are used to transfer manure to fields must be emptied after use. They have no secondary containment if they burst from the pumping pressure. Some of these drag lines are 5 miles long you can imagine the amount of manure they hold. Drag lines should be inspected by independent agency. Drag lines should be inspected.

Summary of Manure Transfers
•Regulate
•Include in manure management plan
•Inspect drag lines

Manure application to land

Manure applications are one of only a few agronomic practices the farmers can use to improve their soil quality and build organic matter. Nutrients and microbes contained within manure can feed a nation if they remain on or and within the soil on a farmer's field; those same nutrients is misapplied or over applied can move to nearby streams or rivers and poison all the aquatic life therein and thereby eutrophy whole river systems and estuaries, and contaminate the groundwater used for drinking of nearby residents for generations. The necessity of strictly regulating manure storage, handling, and applications practices has been brought about by the many failures of farmers to keep manure on their fields.

Best Management Practices are voluntary, as is certification in the Minnesota Agricultural Water Quality Certification Program (MAWQCP). Documentation of the Best Management Practices (BMPs) for runoff and infiltration should be mandatory. Practices associated with BMPs and MAWQCP should be mandatory and monitored to ensure compliance. Field audits under Minn. Stat. §103H.151, subd. 4 should be mandatory for all feedlots and agricultural operations.

Farmers apply nitrogen from various sources (synthetic fertilizers and manure). If only one of these sources is accounted for, the total nitrogen load applied can still significantly exceed crop needs, leading to leaching. To truly manage nitrogen effectively and prevent excess, multiple forms of nitrogen entering the soil system must be accurately quantified. All Nitrogen sources must be considered in nutrient management plans (not solely manure, nor just synthetic fertilizers). By comprehensively accounting for nitrogen sources, nutrient management plans can ensure that the total available nitrogen aligns more precisely with crop requirements, minimizing any surplus that is highly prone to leaching, particularly in karst areas. This ensures that the environmental impact of nitrogen is considered holistically, promoting a more responsible and sustainable approach to nutrient use that directly benefits groundwater quality. Drinking water supplies will be better protected as well.

Set stricter limits on manure application to farm fields in townships wherever the nitrate concentrations in ground and surface waters are above background levels, and especially in vulnerable groundwater protection areas, drinking water supply management areas, recreation areas, near protected wildlife and nature preserves.

Require all feedlots, regardless of whether having a NDPES/SDS permit, to prepare a manure management plan and maintain land application records, and submit these to the MPCA and county feedlot pollution control officer. By rule, MPCA should require all livestock and poultry operations to submit site-specific designs that take into account the unique natural or humanly-altered features of a proposed feedlot and accompanying manure application location. MNWOO and the Isaak Walton notes that animal feeding operations at or below 100 animals in high risk locations have been found to be major sources of pollution.

All permitted feedlots should be required to monitor not only manure application rates but both surface and subsurface discharges of specific pollutants associated with animal manure and other polluting chemicals and biologics associated with feedlot operations. Monitoring for nitrates alone is not enough and parameters such as bacteria and biological oxygen demand (BOD) for surface discharges for example, should also be required. Rates of manure application should be dictated by the site-specific character of the lands used for manure disposal from each permitted facility. Determining the need for additional restrictions on manure application are again, site specific and should be proposed for each unique facility by licensed engineers and hydrologists who are experts at manure management for water quality protection purposes.

Establish stricter manure land application requirements and lower manure application rates. These requirements include requiring conservation practices like cover crops or diversified crop rotations if a farmer applies manure in the fall, and no liquid manure application to frozen or snow-covered ground. Manure application rates must not be allowed to exceed the agronomic rate, especially in Vulnerable Groundwater Areas.

Land application of manure in areas that already have high levels of nitrates or other pollutants associated with feedlots in either surface or groundwater should not only be more restrictive, manure application should be prohibited in areas until remedial actions are successful at reducing these levels to a predetermined point. The term "high levels" are parameter specific and needs better definition. Nitrates above the background level of 3 milligrams per liter (mg/l)

should trigger groundwater monitoring and private well testing thus accounting for the lag time between a pollutant's discharge and its detection in receiving waters by monitoring.

Agronomic rates for manure applications should be customized for particular soil and geological types, highlighting sensitivity to nutrient-loss. The current understanding of "agronomic rate" often focuses solely on maximizing crop yield, which has demonstrably led to excess nutrient application and subsequent nitrate leaching into groundwater. This issue is critically amplified in karst regions where there is little natural filtration.

Different soil types (e.g., sandy vs. clayey) and underlying geological formations (e.g., fractured limestone vs. thick till) have vastly different capacities to retain or leach nutrients. A "one-size-fits-all" agronomic rate fails to account for this variability. Customizing application rates based on nutrient-loss sensitivity means applying only the amount of nutrients the crop can realistically utilize, given the soil and geological context. This minimizes the "excess" nitrogen available for leaching, directly reducing the load on vulnerable aquifers. Both manure and fertilizer applications need to be customized. While initially perceived as a burden, more precise nutrient management can reduce input costs over time by preventing the waste of expensive fertilizers that are simply lost to the environment. It shifts from "insurance" application to "precision" application.

Summary of Manure application to land
•Regulate more vigorously
•Conduct Field Audits
•Consider all nitrogen sources
•Restrict when nitrate and other chemicals levels are above background levels
•Require NDPES/SDS permit
•Require manure management plan and compliance thereof
•Maintain application records - when, where, how much, who

Locations and Setbacks

MNWOO notes that setbacks from any and all surface waters should also be determined on a case-by-case basis because a setback that may function well in one location may be inadequate for others depending on slopes, ground cover, soil types and other site-specific characteristics. MNWOO, nonetheless, advocates for greater setback distances for manure applications and manure storage ponds from water resources in the karst region and other vulnerable groundwater protection areas, including prohibiting manure applications within: 300 feet up slope or 100 feet downslope of a sinkhole or other direct conduit to groundwater; 300 feet up slope of a public waterway or tributary of a public waterway; 250 feet from a private well, 1,000 feet from a community well.

Summary of Locations and Setbacks
•Determine using specific and local conditions
•Increase setbacks

Livestock access to waters

Prohibit livestock of a feedlot or facility capable of holding 100 or more animals from entering a designated trout stream or tributary of a designated trout stream and prohibit livestock of a feedlot or facility capable of holding 300 or more animals from entering any water of the State.

Summary of Livestock Access to Waters
•DON'T

Air Quality

Monitor air quality, to ensure standards are met, using instruments provided by the MPCA to which MPCA and public has access to data obtained therefrom.

Feedlots are significant sources of air pollutants (ammonia, hydrogen sulfide, particulate matter, volatile organic compounds) that impact public health and contribute to environmental degradation. Feedlot emissions can negatively affect the respiratory health and general well-being of nearby residents. State-funded and state-managed monitoring ensures transparency and accountability with independent, unbiased data to assess compliance with air quality standards and protect public health. State-managed monitoring also provides regulatory enforcement and objective data to inform the public about air quality impacts from feedlot operations.

Summary of Air Quality
•Monitor Air Quality with MPCA-provided instrumentation
•Odor, Noise, Chemicals
•Make data public

How many animals

MNWOO supports requiring permits for the construction, expansion, and operation of feedlots with far less than 600 animals. MNWOO is aware that animal feeding operations at or below 100 animals in high risk locations have been found to be major sources of pollution. MNWOO supports that all feedlots have publicly available manure management plans, as outlined below. All feedlots should require not only manure application records but water quality monitoring records as well. There is no evidence that feedlots below a certain number of animals should be exempted as a class on the basis of their low pollution risk; small operators should apply for site-specific exemptions (variances) instead of being offered blanket exemptions based on the number of animals.

Require NDPES/SDS permits for feedlots with 600 or more animals. Lower the size for a feedlot operation to be required to apply for a water pollution permit. Limit the number of animals within a geographical area, within drinking water supply management areas, within state-defined and recognized sensitive regions, such as vulnerable groundwater area, and areas where the nitrate levels in ground and surface water exceed the background level.

Even with stringent management practices, a very high density of animals in a highly vulnerable karst landscape generates an immense volume of manure and associated nutrients, increasing the cumulative risk of groundwater and surface water contamination.

This measure directly addresses the source of potential pollution. By capping the density of animals such as in defined sensitive karst regions, the overall nutrient load (nitrogen and phosphorus) being generated and potentially applied to land in these vulnerable areas is reduced.

Every landscape has a finite carrying capacity for nutrient assimilation, especially in karst where natural filtration is limited. This rule acknowledges that some areas are simply too sensitive to safely accommodate very large concentrations of animal agriculture without incurring unacceptable health and environmental risk.

This proactive measure would help prevent the exacerbation of existing groundwater quality issues and protect currently unaffected areas from future degradation due to an unsustainable density of nutrient sources.

Summary of How Many Animals
•Decrease the number of allowed animals in a feedlot
•Consider land for nutrient assimilation
•Consider surrounding communities
•Consider possible ground and surface water contamination
•Consider the welfare of the animals

Vulnerable Groundwater Protection Areas

The existing Animal Feedlot Rules falls short in adequately protecting groundwater in vulnerable groundwater protection areas, like the karst region in southeastern Minnesota and the central sands in central Minnesota.

In the eight karst counties of SE MN, the US Environmental Protect Agency (EPA) Ordered the State of Minnesota to immediately address the imminent health risk of nitrate contamination in drinking water. The order demands that the Safe Drinking Water Act principles be applied to private well owners and community water supplies who share underground drinking water sources in these eight counties. Permit applications for new and expansion of feedlots in these counties should acknowledge the EPA Orders in the permit application and discuss how the feedlot will protect drinking water.

The unique hydro geology of karst facilitates rapid and direct pathways for surface contaminants to reach underlying aquifers. Karst landscapes, especially in the Drifters Area of southeastern Minnesota, are characterized by soluble carbonate bedrock (limestone and dolomite) that has been extensively dissolved by slightly acidic water over geological timescales. This dissolution primarily occurs along existing joints (fractures) and bedding planes within the rock. Networks of bedrock fractures that extend upwards to within a few feet of the ground surface are often beneath a thin soil cover. During dry periods, these joints allow plants to access moisture deeper within the bedrock, leading to patterns of denser, greener vegetation known as "karst lineations" or "crop lines." These lineations are not just curiosities; they are direct evidence of highly permeable pathways that bypass the filtering capacity of surface soils. Water, sediment, and pollutants can rapidly infiltrate through these subtle yet widespread features, directly into the underlying fractured carbonate aquifers.

The existing Animal Feedlot Rules with their fixed setback distances (e.g., 300 feet from a sinkhole) and quantitative triggers (e.g., 4 or more sinkholes within 1,000 feet), are insufficient

to protect groundwater quality because they do not fully account for this pervasive, interconnected nature of karst. A contaminant traveling through a discreet joint or conduit can traverse hundreds of feet in a short period, rendering arbitrary linear distances ineffective. The real vulnerability lies in the hydrogeological connectivity which often extends far beyond visible features or simple numerical thresholds.

The current rule's reliance on arbitrary distances and sinkhole counts is inadequate for truly protecting complex karst systems. Karst vulnerability is highly site-specific. A comprehensive Karst Vulnerability Assessment using multiple, state-of-the-art techniques (e.g., advanced remote sensing, geophysical surveys, detailed drilling, dye tracing) to qualitatively and quantitatively map the actual pathways of water flow to the aquifer. This moves beyond assumptions to data-driven decision-making. By identifying specific "high-vulnerability zones" based on robust scientific data, resources can be more effectively targeted for protection, ensuring that the most sensitive areas receive the highest level of scrutiny and protective measures. This avoids over-regulating low-risk areas while under-protecting critical ones. A karst vulnerability assessment allows for proactive land-use planning and siting decisions, preventing new pollution sources from being placed in extremely sensitive areas where remediation is difficult or impossible once contamination occurs. Existing feedlots of at least 100 animals in vulnerable groundwater protection areas should be sent information about karst vulnerabilities discovered in the Karst Vulnerability Assessment.

Thus, MNWOO supports the establishment of a Karst Vulnerability Assessment for new or expanding feedlots that will ensure karst sensitive regions are qualitatively and quantitatively reviewed.

While MNWOO advocates for a Karst Vulnerability Assessment, MNWOO also notes that all geography, land, water, and Nature is vulnerable to continued human consumption.

Summary of Vulnerable Groundwater Protection Areas
•Be Aware of Unique Geohydrology
•Establish Karst Vulnerability Assessment
•Establish Vulnerability Assessment throughout the State

MNWOO thanks the MPCA and the State of Minnesota for the opportunity to share its concerns and comments regarding protection of Minnesota's groundwater and safety of drinking water for human and animals from private water wells.

Respectfully Submitted,

Minnesota Well Owners Organization Board of Directors
Prepared by Karuna Ojanen, MN Board

APPENDIX I

Regional or County Scale Maps:

The list of maps should be expanded to include a small number of published risk assessment maps from the USDA Web Soil Survey, the Minnesota Geological Survey, the Department of Natural Resources, the Pollution Control Agency, the Department of Agriculture, the Department of Health and Board of Water and Soil Resources. All the proposed maps are in addition to the other required maps, and all maps should have a scale, north arrow, and legend and must accurately identify and delineate the feedlot, the manure storage site, and all the fields used for manure application.

I. HUC-10 Watershed maps from MDNR and US EPA for all watersheds with feedlots and manure applications.
II. One-Watershed, One-Plan watershed maps, and link to website.
III. Groundwater Province Map from MDNR.
IV. MDNR Groundwater Pollution Sensitivity Maps: (https://www.dnr.state.mn.us/waters/groundwater_section/mapping/mn-hydro-atlas.html)
    A. Pollution sensitivity of bedrock surface (HG-01)
    B. Pollution sensitivity of near-surface materials (HG-02)
    C. Water table elevation and depth to water table (HG-03) from MDNR
V. Regional Hydrological Assessments, where applicable: (https://www.dnr.state.mn.us/waters/groundwater_section/mapping/regional-hydro-assess.html).
    A. Surficial Geology
    B. Water table hydrology
    C. Geologic sensitivity to the uppermost aquifer
VI. Map of Groundwater Advisory Areas, DWSMAs, Wellhead advisory areas, and the EPA Safe Drinking Water area.
VII. Karst features maps where applicable.
VIII. MN Dept of Agriculture Township Well Testing:
    A. Initial and Final Test Results
    B. Pesticide Analysis

Township Scale Maps

I. Township Plat Map and Legend showing public land survey sections, roads, and parcel ownership with location of occupied building sites.
II. Minnesota Well Index/County Well Index map with a Legend and Scale.
III. County Geologic Atlas Maps, each with a legend, scale, and north arrow:
    A. Part A: Geologic Atlas:
        1. Bedrock geology
        2. Surficial geology
            I. Quaternary Stratigraphy and Sand Distribution Model where applicable
            ii. Karst Features, where applicable
        3. Bedrock Topography and Depth of Bedrock

4. Nearest geological cross-sections that identify the approximate distance and direction from the center of the cross-section

B. Part B Hydrologic Atlas map or citations from the Hydrology Report:

1. Each Part B atlas is different and usually has three or four maps and cross-sections. Regional factors apply, and appropriate mas should be required based on the area.

I. Bedrock hydrology

ii. Multiple aquifer pollution sensitivity

iii. Sinkholes, springs, seeps, and spring-sheds (dye trace studies)

iv. Water chemistry

v. Hydrogeologic cross-sections

IV. Land Cover (NASS).

VI. County Land Use Plan and Zoning maps.

Site and abutting properties maps

I. LiDAR topography in greyscale

A. Stream power index

II. USDA Web Soil Survey Maps with 1.5-mile radii
https://websoilsurvey.nrcs.usda.gov/app/WebSoilSurvey.aspx

A. Soil Map

B. Suitability and Limitations for Use

1. Waste Management Manure and Food Waste

2. Waste Management Sensitive Lands for Nutrient Management

C. Water Management

1. Subsurface Water Management Outflow/Effluent Quality

2. Other valuable maps include data on soil qualities, parent materials, water features, depth to water table, flood frequency, and pending.

Minnesota Pollution Control Agency

c/o Addison Otto

520 Lafayette Road North
Saint Paul, Minnesota 55155

Dear Ms. Otto and Commissioner Kessler,

The Land Stewardship Project's Animal Agriculture Policy Steering Committee, on behalf of all of the Land Stewardship Project's members, submits these comments on what we see needs amended in Minnesota's feedlot rules.

The Land Stewardship Project is a grassroots, member-driven, nonprofit organization that works with farmers and rural communities across Minnesota and has organized with thousands of small and mid-sized farmers, rural residents, and others to build a more just and sustainable farm and food system. We work with our members every day to build an agricultural system in which small and mid-sized farms and farming families can thrive, our air and water is clean, our soil is healthy, rural communities can prosper, and our climate is resilient. Currently, our membership includes approximately 1,500 small and mid-sized farming households and an additional 3,000 households in rural, suburban, and urban areas.

For 43 years, our members have worked together to advance our shared vision for agriculture and rural communities in the Upper Midwest. We have done that by advancing policies that promote and support farmers, farming practices, and food systems that can sustain everyone involved, from the farmer that grows the food to the person that eats it. We also do this through direct programming that allows farmers to learn from each other about how to implement crop and livestock production practices that build soil health and reduce input costs, and by facilitating a nationally-recognized beginning farmer training program. This work has put over 1,000 new farmers on the land, won tens of millions of dollars in public funding for farmers who are building soil health, helped create regional food systems, created tax incentive programs that make it easier for beginning farmers to gain access to land, and put in place moratoriums on farm foreclosures during times of financial stress in agriculture.

We also move this vision forward by working with our members to push back against the agricultural practices and policies that undermine our shared vision. Small and mid-sized farms, and by extension, rural communities, cannot thrive, or even survive, in an environment where the agricultural sector

becomes increasingly consolidated. This consolidation includes the proliferation of large-scale feedlots that threaten our air, water, soil, climate, wildlife, farm economy, local rural economies, human health, and more. This work is has been centered around preventing the expansion of the "get big or get out" model of agriculture by stopping over 40 large-scale feedlots from being built or expanding, and protecting our shared air, water, land, climate, and communities from the harmful effects of factory farms.

The Land Stewardship Project has a deep familiarity with building an agricultural system that is good for our planet and our communities in a way that works for farmers and rural communities. That is why we and our members advocate for a more robust permitting process for the largest livestock operations in Minnesota and are committed to making the Minnesota Pollution Control Agency's proposed changes the best that they can be.

Unfortunately, over the past few decades public policy and corporate interests have driven the agriculture industry toward fewer, larger farms, mainly in the pursuit of maximization of profit, and the consolidation of profits into fewer and fewer hands. This has come at the expense of other farmers, rural economies, and public health, as well as our land, water, and climate. In animal agriculture, this has resulted in increasingly larger feedlots that concentrate millions of gallons of liquid manure in lagoons, or thousands of tons of solid manure collected into one spot. This causes the nutrients in the manure to become more potent and concentrated, while also increasing the risk of manure running off a field and into a waterway.[9]

This shift has had significant consequences. Crop and livestock production accounts for roughly 70% of the state's nitrate pollution, putting the health of our families at risk.[10] Currently, nearly 80,000 people[11] in southeastern Minnesota alone have unsafe drinking water due to nitrate contamination. But it's important to note that this issue is not limited to the karst region. Tens of thousands of Minnesotans live in communities or have personal wells with elevated nitrate levels, and these people live both inside and outside the new designation of Vulnerable Groundwater Areas[12], which to our understanding corresponds with the map created by the Minnesota Department of Agriculture to comply with the Groundwater Protection Rule.[13] This designation would exclude parts of northwestern Minnesota and points in southern and western Minnesota that have had wells test high for nitrates but were excluded from the groundwater protection rule map.

This is an expensive issue to remedy and Minnesotans with contaminated water face undue financial burdens. The families and residents that are affected by this contamination face the hard financial choice of installing a reverse osmosis system or a point-of-use ion exchange filter. They may even have to pay tens of thousands of dollars to drill a new and deeper well. Some are forced to rely on bottled water or to even move out of the community entirely. If none of those options are financially viable for them, oftentimes folks end up with large medical bills from nitrate-caused health conditions.[14] These are costs these citizens are forced to take responsibility for, even though they are not the source of the contamination in the first place.

And in addition to keeping groundwater free from contamination, we need to also focus on protecting our shared surface waters in Minnesota. Minnesota's lakes and rivers are something our state is incredibly proud of. Millions of people each year rely on Minnesota having clean surface waters that they can swim, fish, paddle, and float in, as well as irrigate their plants or crops with. Not only are clean surface waters something that people individually appreciate, but tourism around water recreation is also a large economic driver for many in Minnesota.[15] These permits need to be designed to protect these surface waters from the kind of feedlot runoff or contamination that can contribute to fish kills and large algae blooms.[16] This contamination can come from single events like manure spills or discharges due to extreme weather events, which are projected to continue to increase in frequency over the coming years. It can also happen by simply operating one of these facilities under the stipulations of a permit. Allowing "routine" manure runoff to happen under an active permit is not acceptable and must change.

The status quo simply isn't and hasn't been working. Even though these rules have been in place for decades, our communities are still seeing an increase in the harmful effects of mismanaged and over-applied manure. And, as we've said, while there are some good steps in your initial proposal, they are not adequate to address the issues our members and rural communities are facing. All Minnesotans, regardless of their zip code, deserve safe drinking water. Gaining access to clean water should not be a luxury good. These permits must protect our common resources so that every Minnesotan can have equal access to them.

We request that you amend the current feedlot rules to address some of the longstanding environmental and economic injustices that have been taking place under the current feedlot rules and that are having direct negative impacts on our members, as well as on the communities that we represent. We have detailed a few improvements below that we believe must be implemented, and look forward to continuing the conversation about what Minnesota's feedlot rules look like in the future.

Improvement 1: Everyone deserves to have their surface and groundwaters protected, not just individuals in vulnerable groundwater areas.

While protecting water sources in Minnesota's vulnerable groundwater areas is particularly important, all Minnesotans, regardless of where they live, deserve to have access to clean water. These permits should be proactive in keeping Minnesotans protected from surface and groundwater contamination. The MPCA should not be creating rules that will only protect people once they have proven that they are at risk and have a well that is unusable. The additional requirements to the October, November, and winter manure application restrictions and practices that NPDES and SDS permit holding facilities are now required to adhere to must be extended to all feedlots that are required to complete or comply with a manure management plan (currently all operations over 300 animal units or operations receiving manure from a manure management plan covered site). This is a commonsense measure that is easy for farmers to comply with once some pre-planning is done through the manure management plan creation

process, and when adequate storage space is maintained to act as a buffer for any unexpected issues such as large rains or long winters.

The role of the MPCA is to protect all Minnesotans, regardless of where their property is or what the vulnerability status is of their well. The most impactful way for the MPCA to do that is to be a proactive partner and prevent contamination from happening in the first place.

Improvement 2: Record-keeping requirements must be strengthened.

While it is good that record-keeping of manure applications — including documentation related to water sampling results and applications that are done by manure buyers or custom applicators — will be required of NPDES and SDS permit holders to help make sure that permits are being followed by everyone, the requirements around this recordkeeping need to be much more robust to meet the needs of Minnesotans.

The information that the agency gathers from these records should be made available to the public. Communities dealing with the risks of feedlot contamination deserve to know that permits are being followed and deserve to have the ability to check that information for themselves. What lands are part of the manure management plans of permit holders, the results of water sample tests, and other information gathered in these records should be mapped, and this information should be made publicly available. This will allow community members to know what is going on around them and help them identify risks. In this way, they can help the agency ensure that permit requirements are being met.

We believe that increasing communication between permit holders and feedlot officers will be beneficial to everyone involved. Nobody — farmers, agency staff, or community members — likes surprise inspections or surprise contamination events. If permit holders are sharing information with feedlot officers regularly, it helps the permit holder if they have more clarity around what is being asked of them. It also helps the agency ensure permits are being followed, and helps community members become more confident that they are being protected. Making this requirement a role that the agency holds also means that this change would not affect the day-to-day role of the permit holder to comply with their permits and manure management plan, making this a reasonable requirement of the permitting structure.

Improvement 3: On their own, the proposed water sampling requirements are inadequate and more must be done to proactively protect our shared waters.

While the new requirements of NPDES and SDS permit holders and those who receive manure from a permitted facility to do water sampling/testing after a discharge event is a good start, all NPDES and SDS permitted facilities must be required to do more proactive water sampling and testing to not only ensure long-term compliance with the permit, but also to help ensure accountability, and to ensure that feedlots are being permitted, constructed, maintained, and operated in a way that is not negatively effecting the surrounding area. Regular water sampling

and testing near the permit holding site and where manure from the permitted site is being spread is vital so that the agency and the public can know that long-term damage and contamination is not occurring. This testing should take place at locations of potential surface water contamination like drain tile outlets, streams, drainage ditches, or field low points where stormwater typically runs off. Groundwater access sites like wells should also be tested regularly. These locations should be listed on the manure management plan as well, so that whatever entity analyzes water samples taken after a discharge event has a baseline to compare to, and so repeated tests can be accurately compared.

This requirement is particularly important for any new construction of manure basins and new lands used for spreading or when a permitted facility plans to expand. Undergoing water sampling and testing before construction begins or manure is spread to establish a baseline nutrient load at that location is the only way that the agency can ensure the public that these permits meet our goals of reducing contamination. If this kind of testing is done, the agency will be able to speak more effectively to the public about what is and is not causing contamination issues in their communities. This kind of information is critical, and because Minnesota is a state that values local control, local people who are being impacted by any contamination have the authority to make decisions about what is and is not allowed in their community through their local planning and zoning process. Being able to compare water quality tests at specific sites and sharing that information with the public through the more open sharing of manure management plans will give communities, through the local zoning process, the ability to more accurately address the issues they are experiencing on their own. While we know that the NPDES and SDS permits are designed to only allow discharges during extreme weather events, these kinds of events are becoming more frequent.[1] It is important that we prepare for this reality and are proactive in protecting our communities. We understand that this would be an additional requirement of the permitting, feedlot building, and manure management plan creation process, but once the initial tests are done, there would be no additional requirements that are not already part of the new version of Minnesota's NPDES and SDS permits.

Improvement 4: The work done to improve Minnesota's NPDES and SDS permits should be expanded upon.

We were encouraged by the steps the agency took to modernize Minnesota's feedlot permitting structure and want to see that work built upon. We believe that while those permits do leave room for improvement, they include quite a few good, commonsense rules for the largest feedlots in Minnesota to follow and are a good step towards a place where Minnesota's feedlot rules are working well for everyone.

Unfortunately, our members who live, farm, and are connected to the communities where large feedlots are being built have shared with us that time-and-time again they see operations trying to skirt around the additional requirements by crafting building or expansion proposals that put their operation's animal unit count at just below the threshold where operators are required to

[1] https://www.pca.state.mn.us/air-water-land-climate/climate-change-impacts

apply for these permits. We do not feel that this is within the spirit of what Minnesota's feedlot rules seek to accomplish and allows for a small subset of operators to avoid the requirements that Minnesotans have asked them to comply with. Because of this, we believe that the threshold that a feedlot should be required to obtain both an NPDES and SDS permit to build and operate should be lowered to 600 animal units.

Improvement 5: Adjusting how feedlots under the same ownership structure are addressed when in close proximity to one another.

In addition to seeing many proposals brought forward in their communities that are proposed just below the NPDES and SDS permit threshold, our members have noted that many proposals are being brought forward by already existing feedlot owners and are located near an already existing site, but are listed under a different site name. This adds confusion as to who is the actual owner of the site, and that is often left unaddressed in the local permitting process. The local permitting process is the key manner in which community members are informed about what is happening with feedlots in their community.

Because of this, we believe the agency must change the way that facilities under the same ownership structure are permitted to account for proximity to one another. Our suggestion would be to create a calculation tool that utilizes a facility's proposed animal unit size to calculate a radial distance for how far away it must be from another barn under the same ownership structure. Anyone who is applying to build or expand a feedlot who has another site connected to them under the same ownership structure must then do this calculation for each operation that is under that ownership structure before siting their new facility or expanding their operation. If the radius around the new operation intersects with another facility, a new site must be found. Our suggestion would be to make the distance per animal unit in this calculation five feet and three inches for every animal unit.

Improvement 6: Minnesota's new feedlot rules must address the elephant in the room for livestock producers: consolidation.

In Minnesota and across the country, increasing attention is being drawn to the animal agriculture industry and the anti-competitive practices that are being used to benefit a small minority of parties along the food supply chain. From lower milk check amounts and issues related to accessing processing at a fair price, to higher prices at the grocery store, everyone — farmers, the communities they are a part of, and eaters — is being affected by this.

For example, during the summer of 2023, dairy farmers in the Upper Midwest Federal Milk Marketing Order Region received the lowest milk check prices in the nation. At the same time, consumers in the Upper Midwest were paying extremely high prices for their milk. More recently, we have heard stories of farmers having a new generation ready to take over the operation only to be told by their local processor that they are not taking any more producer contracts. This is occurring while the processor is turning around and accepting multiple

shipments of milk from large operations every day. All of these issues are symptoms of the problem of consolidation in the dairy and livestock industries, and it is pushing producers off the land, stifling communities and local economies, and degrading the land and water that we all rely on.

Over the past five years, we have been building a farmer-led campaign to address the problem of consolidation, and time-and-time again we have heard from producers that there needs to be a halt to the expansion of huge feedlots in Minnesota. Mega-sized operations use their massive economies of scale to influence every part of the livestock economy. Having to compete with operations like that is the main reason farmers are seeing their friends, neighbors, and relatives leave the land.

Operations of this scale are also one of the major risk factors when it comes to protecting land and water resources in rural parts of the state. A spill from a feedlot with 200 cows is an issue that is addressable; a failure of manure infrastructure on a 10,000 animal-unit facility is a disaster that puts the wastewater equivalent of a whole town's annual output spilling out onto the land. Your agency, as the main permitting authority for large feedlots in Minnesota, has a duty to help producers and communities deal with this issue and must institute a moratorium on permitting large operations until our state finds a way to give all farmers a fair shake.

In summary, we are encouraged by the steps the Minnesota Pollution Control Agency has taken to strengthen Minnesota's NPDES and SDS permits to help keep us, our communities, and our shared water and land safe, but we respectfully insist that more must be done. We believe that, just like your initial proposed changes, the improvements we have detailed here to Minnesota's feedlot rules are good, commonsense requirements that will help these rules have the effect that all Minnesotans need them to have, while still not being onerous for feedlot operators. We hope you incorporate these improvements into your review of Minnesota's current rules and are happy to discuss the best way these changes can be implemented as your process progresses.

Sincerely,

Matthew Sheets,

Policy Organizer with the Land Stewardship Project

On behalf of the Land Stewardship Project's Animal Agriculture Policy Steering Committee

MINNESOTA DIVISION OF THE IZAAK WALTON LEAGUE OF AMERICA

COMMENTS ON MPCA FEEDLOT RULE-MAKING

by

THE IZZAK WALTON LEAGUE OF AMERICA'S MINNSOTA DIVISION
John Siekmeier, President
6601 Auto Club Road, Bloomington, MN 55438

July 22, 2025

The comments that follow are submitted by the Izaak Walton League of America (IWLA) Minnesota Division and pertain to the Minnesota Pollution Control Agency's planned amendments to rules governing animal feedlots, Minnesota Rules, chapter 7020, Revisor's ID Number R-4928 - OAH Docket No. 25-9003-40661.

Statement of Qualifications and Standing

The Izaak Walton League of America is the nation's oldest and most successful conservation organization. Founded in 1922 the "Ikes" have for over 100 years stood for the protection and restoration of the nation's fish, wildlife and natural areas and is especially focused on matters affecting water quality.

Wherever these comments refer to "the League" this reference should be understood to be the collective opinions of members of the Izaak Walton League here in Minnesota that include a wide variety of experts in the natural sciences, water quality, hydrology, agriculture, public health and regulatory governance. The League is especially well positioned to make these comments on feedlot rules because many of our members are retired agency professionals from the Departments of Agriculture, Natural Resources, Pollution Control Agency, Health, Transportation, Board of Soil and Water Resources, Soil and Water Conservation Districts, U.S. Army Corps of Engineers, U.S. Geological Survey, U.S. Fish and Wildlife Service, the U.S. Environmental Protection Agency and more. Many League members are or were academics researching or teaching in colleges and universities in these disciplines. Other members have doctorate degrees and have been practicing family or specialty medicine for years, while still others are active citizens in natural resource protection in the League and other advocacy groups and have dedicated extraordinary amounts of time studying these matters and developing organizational policies to address conservation, pollution and environmental degradation.

Scope and Perspective for Comments

In the agency's request for public comments the MPCA has stated that the agency's three main areas of focus for these rule amendments include:

1. Updates to address changes in livestock and poultry operations and business practices, new agency data services, and outdated language.
    - Permit and registration applicability;
    - Animal unit factors;
    - Clarity of definitions and requirements;
    - Legislative alignment; and,
    - Utilization of agency data services.
2. Land application of manure practices to address nitrates, bacteria, and fish kills.
    - Transferred manure requirements;
    - Nitrogen Best Management Practices (BMPs);
    - Setbacks;
    - Manure Management Plan (MMP) applicability;
    - Visual monitoring; and,
    - Compliance monitoring.
3. Technical standards to protect water quality and avoid fish kills.
    - Manure storage capacity;
    - Feed storage design and operation;
    - Existing Liquid Manure Storage Area (LMSA) integrity;
    - Ground water monitoring; and,
    - Livestock access to waters.

The agency then asks: "Should any of the following bullets be considered? If so, at what size (in AUs - animal units)?"

- Operating permits (NPDES or SDS) for feedlots less than 1000 AUs.
- Submittal of manure management plans and land application records for feedlots without operating permits.
- Monitoring of feedlots and land application sites for subsurface discharges of manure or nitrate to groundwater.
- Additional restrictions on manure application rates.
- Soil nitrate tests prior to land application of manure.
- Increased setback distance for land application of manure near sensitive features.
- Restricting land application of manure in areas with high levels of nitrate in waters or in areas with existing high densities of feedlot operations.

MPCA's Three Area of Focus

The League generally agrees that the MPCA's three areas of focus listed above are appropriate. But, of particular concern to our members is the first one in this list: the significance of "*changes in livestock and poultry operations and business practices".*

There has been dramatic shift in animal and crop agriculture toward larger industrialized models over the past few decades that are thought to be primarily the result of government subsidy and world trade policy. As profit margins narrow and farm land prices rise the response has been to increase production rates to maintain viability. As

costs of inputs increase, the income from production has not been keeping pace. To hedge financial risks, producers (both crop and animal producers) have taken advantage of hidden subsidies that externalizes a major cost of production at the expense of a public asset: *degraded water quality and quantity.* By maximizing fertilization of crops with commercial fertilizer and manure to boost production (as recommended by established "agronomic rates") producers are encouraged to gamble on having a bumper crop every year. And there is an understandable tendency to augment the production benefits using less of the of higher cost commercial fertilizer, with more of the lower cost manure. But this gamble depends on having ideal weather conditions every year, which seldom happens. The result is that total nutrient inputs on an annual average, almost always exceed uptake and removal by harvested crops. The excess application of both forms of fertilizer accumulates each year that a "bumper" crop is not realized. Soil testing will not detect either form of nutrients that has leached below the root zone. As the build-up of excess fertilizer either washes off or leaches down below the root zone, this fertilizer is "released" as pollutants to groundwaters, surface waters, or both.

Current best management practices, even deployed to their maximum capability, which they seldom are, have not proven sufficient to recover, treat or retain these excess applications or the discharges to surface and groundwater. Uncontrolled discharges, "releases" of pollutants by these means, should be prohibited by the new rules because they are intentional, measurable and preventable.

As the MPCA works to develop rules for feedlot operations that reduce or eliminate this avoidable source of water pollution, the agricultural community's hidden profit subsidy *(degraded water quality and quantity*) that depends on continued release of pollutants will be significantly threatened. Powerful political forces will push back claiming that regulatory over-reach by the MPCA is threating the economic viability of farming in Minnesota.

Special attention must be given to this predictable political argument well in advance of the agency's proposed new rules that will make this unwarranted subsidy clear to the public, to the agricultural community and to our elected officials. Failure to anticipate and successfully dispel this argument in advance would imperil the success of the new rules.

The League believes that the MPCA must work with social scientists and other experts to carefully craft an educational campaign that exposes this unwarranted subsidy and builds support for ending it. The current industrial models for both crop and livestock production are seriously flawed in this regard and there are viable alternatives. The League stands ready to work with the MPCA, other state agencies and our partner non-profits to develop and roll out this educational campaign.

Later in these comments we will propose a structure and cite the authority for assembling an expert advisory panel to assist the agency and cooperating entities in

developing and implementing this plan based on existing statutory mandate and an Iowa example.

MPCA's Bullet-Points

The next section of our comments is directed toward the several bullet-points the MPCA offered for considerations. These summary responses on those points will be followed by more detailed discussion of them in a later section.

Overall, it is the League's position that the amended feedlot rules must not only be effective at reducing feedlot pollution, but should eliminate it to the degree necessary to support all classified uses of the state's surface and groundwaters. This has been and remains the goal of the Federal Clean Water Act, and actually provides the name of the federal NPDES permits many feedlots and all other discharges require. NPDES is short for the National Pollutant Discharge *Elimination* System.

The business and operating models for industrial-scale livestock and poultry production is vastly different from the conventional, family-farm model, and its waste handling and disposal methods are largely experimental. The industrial model has outside entities called integrators that own the animals. The "farmer" landowner owns the buildings, manure storage and handling equipment, and only some of land needed for manure disposal. Liquid manure rather than dry storage became the norm due to technical advances in manure handling equipment, but this required retention or addition of water to the manure. This business arrangement tends to bifurcate the responsibilities and liabilities of manure ownership, complicates storage and disposal options, and tends to shield the animal owner from any responsibilities.

Conventional family farms had the farmer owning both the animals and the all the related capitol infrastructure and all the land needed for manure. Dry handling storage of manure, depending on site conditions, has less tendency for run-off or seepage pollution because the manure inherently had more bulk (i.e. added bedding such as straw) and less added water.

Our research reveals that the industry's adoption of a wide variety of recommended best management practices have failed markedly at protecting surface and groundwaters nation-wide, and thus cannot continue to be the basis for either the voluntary norms or the regulatory requirements for permitting. Our recommendations for rule changes are premised on this fact. Unproven methods for manure storage and handling should be deemed "experimental" by rule. And these experimental waste management methods should only be allowed on a trial-and-error basis with close monitoring, and have prompt, pre-determined correction, remediation and compensation measures built in (for harms to public or private water supplies).

The comments below and the findings and recommendations in the League's Prairie Woods Chapter's AFO/CAFO report (attached) on feedlots to Becker County[1] are each

[1] See attached report entitled: ADDRESSING AFO & CAFO IMPACTS IN BECKER COUNTY'S COMPREHENSIVE LAND USE PLAN, ZOINING MAPS & ORDINANCES – August 1, 2024.

offered as useful information in regard to the MPCA's rule revisions. That report details gaps or deficiencies in federal and state rules governing feedlots that the League recommended Becker County address in their revised comprehensive land use plan. We also refer the agency to a recent Iowa report entitled *"Currents of Change*" [2] and offer that report into the record by reference. The Iowa report is offered here because it fortifies the findings of the League's AFO/CAFO report. The MPCA is encouraged to review the findings of each of these reports and address the identified deficiencies.

Our experience in Becker County is instructive. The League and specifically the members of the League's Prairie Woods Chapter in Detroit Lakes have examined the pollution potential of industrial-scale animal feeding operations and manure disposal in depth and on a national scale. This was done in preparation for a large swine operation that was proposed for a western Becker County township that requires a conditional use permit and an SDS or NPDES permit from the MPCA (application to MPCA yet filed). When the League challenged the adequacy of the county's zoning ordinances as being inadequate to control pollution from the facility, the county opted to update its Comprehensive Land Use Plan and review its ordinances. At the conclusion of that year-long process, county officials concluded that they were relying on the MPCA's rules to protect water quality. The county viewed their role and ordinances as intended to prevent land use conflicts, not protecting water quality. This, they concluded, was entirely the purview of the MPCA.

Our chapter members prepared the referenced report to demonstrate the inadequacy of Minnesota's and other states feedlot rules nation-wide. The report references the MCEA, et. al., petition to EPA that led to the current proposal for rule-revisions. Becker County officials were not convinced that they were obliged to fill this gap and have proceeded to issue the county permit.

This, and the *Currents of Change* report from Iowa, are offered to point out that local units of government are relying on the state governments (MPCA) to not only provide needed regulation of the design and operation of feedlots to prevent pollution, but to also to help them apply appropriate land use controls to avoid locating large feedlots in sensitive or already degraded areas of the state.

Summary Responses to the MPCA's Bullet Point Consideration Questions:

The League supports that construction and operating permits be required for feedlots far less than 1000 animal units in size. We suggest that all permitted feedlots should have both manure management plans, and require not only manure application records be kept, but water quality monitoring records as well. Because there is no evidence that feedlots below a certain number of animal units should be exempted as a class on the

[2] Currents of Change – An Analysis of the Racoon and Des Moines Rivers in Central Iowa - Final Scientific Assessment of Source Water Research Report available on-line at: https://www.polkcountyiowa.gov/media/lixlchbz/ciswra-currents-of-change_final-scientific-assessment-of-source-water-research-report_jun272025.pdf

basis of their low pollution risk, we recommend that small operators should apply for site-specific exemptions (variances) instead of being offered blanket exemptions based on their being below a certain number of animal units. Such exemptions could be applied for with assistance and documentation provided by county Soil and Water Conservation Districts or County Feed Lot officers. Criteria for exemptions would necessarily have to be spelled out in the new MPCA feedlot rules.

For example, traditional family-farm-scale feedlots often use dry handling and stacking methods for storing manure before field spreading. As mentioned above, dry stacked manure has far less potential for runoff or seepage than liquid manure handling and storage systems. If suitable vegetated setbacks are observed, slopes are moderate to level and runoff deflection and detention berms are constructed these operations could be considered exempt by rule.

We suggest that all permitted feedlots (that are not exempted) be required to record not only manure application rates, but additional commercial fertilizer rates as well. Permits should require active sampling and analysis of both surface and subsurface discharges for specific pollutants associated with animal manure storage and disposal and for other polluting chemicals associated with large feedlot operations. Monitoring for nitrates alone is not enough and parameters such as bacteria[3], biological oxygen demand (BOD), phosphorus and any other chemicals or pharmaceuticals being administered at the site for example, should also be required. Rates of manure application should be dictated by the site-specific character of the lands used for manure disposal from each permitted facility. Removal of nutrients such as nitrogen and phosphorus, through crops and residue harvested from fields receiving manure should be documented and compared to combined commercial and manure fertilization rates to assure excesses are not accumulating or being discharged. Determining the need for additional restrictions on manure application are again, site specific and should be proposed for each unique facility by licensed engineers and hydrologists who are experts at manure management for water quality protection purposes.

Setbacks from any and all surface waters should also be determined on a case-by-case basis, because a setback that may function well in one location may be inadequate for others, depending on slopes, ground cover, soil types and other site-specific characteristics.

Land application of manure in areas that already have high levels of nitrates or other pollutants associated with feedlots in either surface or groundwaters, should not only be more restrictive, but manure production, storage and land application should be prohibited in these areas until remedial actions are successful at reducing these

[3] U.S. Department of Agriculture studies in Wisconsin have shown that bacteria from feedlot seepage into ground water can travel several miles from the source underground so bacteria should be a monitored parameter for both surface and groundwaters. See section entitled GREEN BAY WISCONSIN – ON LAKE MICHIGAN on pages 22-23 of Leagues AFO/CAFO Report to Becker County attached.

excessive levels to a predetermined point. The term "high levels" are parameter specific and needs better definition. But, to be preventative, nitrates should have a trigger level well below the drinking water standard of 10 mg/l. This margin accounts for the lag time between a pollutant's discharge and its detection in receiving waters by monitoring.

The fact that the MPCA has not yet promulgated surface water nitrate standards for all waters other than those used for drinking water, is now being drawn into the public spot light. While adopting new nitrate water quality standards is not up for consideration in the current rule-making for feedlots, the League strongly encourages the agency to move forward with that long-delayed, much overdue process.

Detailed Discussion of Summary Above and Other Comments

The League respectfully suggests that any attempts to specify technical standards that are protective or remedial practices for most animal feeding operations by rule, are unlikely to accomplish the agency's statutory mission to: *"enforce reasonable orders, permits, variances, standards, rules, schedules of compliance, and stipulation agreements, under such conditions as it may prescribe, in order to prevent, control or abate water pollution."*[4] Minnesota's landscape, topography, soils, ground cover and the state's surface and groundwater vulnerabilities are far too varied in aspects relating to pollutant movement, retention and processing to allow a single "one-size-fits-all" approach. It is the League's strongly held opinion that most if not all permitted livestock or poultry operations should be required (by rule) to submit site-specific designs that take into account the unique natural or humanly altered features of a proposed feedlot and accompanying manure application locations. This is because animal feeding operations at or below 100 animal units in higher risk locations have been found to be major sources of pollution.

A Proposed "prove it first" Policy

The findings of the Prairie Woods Chapter's AFO/CAFO Report and the Iowa *Currents of Change* report referenced above, demonstrated that the intensification (concentration) of animals in what has become the industrial model for producing meat, has created a high risk for water pollution. The report also finds that in many other states that have experience with this scale of feedlot operations, citizens, environmental NGOs and regulatory entities alike have concluded that the array of pollution prevention methods (best management practices or BMPs) currently being deployed (whether mandatory or voluntary) have been inadequate to satisfactorily prevent feedlot pollution from entering public waters.

Based on this finding, the League recommends that the MPCA adopt a policy that declares this intensified method of livestock farming an experimental, high-risk polluting enterprise that must demonstrate new and improved controls before qualifying for permits. This would in effect, place the industry representatives (permit applicants) on

[4] Minnesota Pollution Control Agency enabling legislation at: Mn Statutes Chapter 115.03 POWERS AND DUTIES Subd 1(5).

notice that they must prove they have solved the heretofore unsolved problems associated with this industrial-scale enterprise.

To provide this "proof" the plans and specifications for new or expanding animal feeding operations should be required to be prepared by licensed engineers and hydrologists qualified and experienced in this specialized field. Existing permits should have renewal (expiration) dates after which time they would be required to meet these new rules. The licensed professionals responsible for the siting and design of these experimental operations should be required to affirm that the plans and specifications they submit will, in their professional opinion "prevent, control or abate" pollution.

This should not be viewed as an unusual hardship on even the smallest feedlot operation, considering that individual homeowners in rural areas of Minnesota are required to have licensed professionals design and install on-site sewage treatment and disposal systems that are reviewed by qualified professional in permitting units of government.

Furthermore, this is equitable, because municipalities and other industries in Minnesota, by rule, must hire qualified and licensed engineers to prepare plans and specification for wastewater treatment facilities before they can be permitted for construction and operation. Permittees from these facilities must submit monthly discharge monitoring reports that demonstrate compliance with effluent standards specifically designed to protect the public uses of the receiving waters. By "signing off" on these plans and specification, the designing engineers and hydrologists effectively warrant, by peril of their professional certification, that the facility, when built and operational can and will meet the prescribed water quality standards.

Permits for feedlots should be required to have both a construction and operation permits to detail the specifications by which this unique kind of pollution will be controlled and problems remedied.

Establishing a Point of Discharge as Compliance Boundary

The League recommends that the agency adopt a "point of discharge" policy as a compliance boundary that identifies the soil layer below land applied manure that represents the uncontrolled release of agricultural pollutants. This point would be below the root zone of current or planned crops that could capture or recover nutrients and biologicals applied to the land. Detection of "released" pollutants should be provided by monitoring devices such as lysimeters installed prior to a facilities operation and at locations representative of the areas, included in a facility's manure management plans.

To show whether or not surface or groundwater pollution is or has been originating from an animal feeding operation the permittee should be required to submit pre-construction (for new or expanding operations) monitoring data from representative locations in the water table or aquifer both upstream and downstream of the existing or proposed operation. Where the groundwater flow paths are uncertain due to karst or other geologic character the monitoring plan should demonstrate schemes for collecting data

that does documents the rates, routes and reservoirs of feedlot pollutants escaping (discharging) from a facility and its associated manure application fields. If the groundwater regime proves too complicated to monitor, these facts should constitute grounds for permit denial. Lack of information or the inability to collect it should not be used to justify avoidable risks.

Plans for the groundwater water quality monitoring regime should be submitted to the MPCA for prior approval before the monitoring system is put into operation. The plan should include the professional hydrologist's opinion on whether the existing pre-construction water quality condition will be adequately characterized by the sampling locations, frequency and duration of sampling and the parameters to be monitored. Parameters to be monitored should reflect not only the nutrient and microorganisms that could be discharged from the facility, but all other "pollutants" used at the facility relating to the feeding and raising animals.

In areas having heavy clay soils that a design engineer has determined to be an adequate barrier to downward movement of "released" pollutants, any and all drainage systems serving these fields, including surface ditches, natural waterways or underground tile, should have sampling locations and methods identified to detect "releases" of feedlot related pollutants.

If pre-construction monitoring demonstrates that an existing animal feeding operation owned and or operated by the applicant has already contributed to surface or ground water pollution, the prospective permittee must submit a remedial action plan to be approved by the MPCA. This remediation plan should be successfully implemented before new or expanded animal feeding operation can be permitted. Here, successfully implemented would mean the pollution levels are reduced to comply with applicable surface or groundwater standards.

Available tools for early detection of existing degradation include the MPCA's Watershed Restoration and Protection Plans, coupled with the One-Watershed-One-Plan documents prepared by each county or watershed boards if they exist. These plans are intended to gather and survey existing data on surface and groundwater and identify contributors (stressors) on these water bodies. The plans often include remedial measure needed to address impaired waters. If animal feeding operations are identified as one of the stressors causing impairments, new or expanding feedlot permit applications should be reviewed in light of these findings. As existing permits come up for renewal, the new monitoring and discharge control requirements in the new rules should then apply to these existing lots with a compliance schedule.

Joint Permits for Industrial Model Feedlots

The industrial model for large feedlots often includes a three-layer pyramid of agreements between the land-owner (farmer) and the animal owners (called integrators) and the contracted industrial meat processors. The new feedlot rules must include ways to obligate each of these entities to the responsibility for compliance with permit limitations on discharges, and for financial assurance necessary for remediation upon

discovery of a release. The integrators and the meat processors have been attempting to place the farmer/landowner in the position of responsibility for manure disposal in an effort to protect themselves from this liability. The farmer is not likely to have the financial wherewithal to withstand the costs of remediation should the manure threaten or contaminate surface or groundwater. Faced with this problem, the landowner/farmer may declare bankruptcy leaving the state (taxpayers) to bear the costs of the pollution and remediations.

The need for joint permitting of the parent companies and the intermediate integrators, along with the farmer/land owner must be addressed in the new rules.

Interstate Transport of Manure

Large feedlot operators are generating such large quantities of manure that they may need to seek lands in neighboring state for disposal options. The new rules should anticipate the issues raised by these circumstances. A Minnesota feedlot operator disposing of manure in a neighboring state should be required to comply with rules for long-distance transportation of manure through Minnesota. It is unlikely that the MPCA would have control of that manure once it crosses state lines. However, there may be opportunity for interstate cooperative agreements that provide a seamless protection for water quality. On the other hand, an importer of manure from another state should be required to prepare manure management plans that include the same level of monitoring and release response required of a Minnesota operator. Interstate agreements may also be needed to alert the MPCA to planned importation of manure. The same level of joint permitting for land and animal owners as discussed above would seem appropriate for these circumstances as well.

Importation of manure raises another issue that may be outside the MPCA's authority but nevertheless requires regulatory attention. The interstate transport of manure carries the potential for spread of livestock and poultry disease. If other state departments have the authority to regulate the interstate transport of animal disease, the MPCA should work toward some interagency agreement to address these issues. The MPCA could perform this courtesy for neighboring states receiving manure exported from Minnesota.

Groundwater Supply Impacts

Private well owners in agricultural areas have little or no protection for their water supplies and seldom have their wells tested. When they do test, they may only get results for nitrates and coliform bacteria and they may be unaware of fluctuations in supply aquifer levels influenced by high-capacity wells such as those needed to supply large feedlots.

These are data gaps that the proponents of industrial scale agriculture must help fill. Published studies[5] from N.E. Iowa have shown that

[5] Juxtaposition of intensive agriculture, vulnerable aquifers, and mixed chemical/microbial exposures in private-well tapwater in northeast Iowa available on-line at: https://pubmed.ncbi.nlm.nih.gov/36657670/

"… contaminant exposure in unregulated private-well point-of-use tapwater (TW) is a recognized public-health data gap and an obstacle to both risk-management and homeowner decision making.

The current results address a critical lack of directly comparable data on broad contaminant exposures in TW in agriculturally-developed settings and document commonplace simultaneous exposures to inorganic, organic, and microbial contaminants of human-health concern.

Heterotrophic bacteria detections were near ubiquitous (94 % of the samples), with detection of total coliform bacteria in 28 % of the samples and growth on at least one putative-pathogen selective media across all TW samples. Health-based hazard index screening levels were exceeded frequently in private-well TW and attributed primarily to inorganics (nitrate, uranium). Results support incorporation of residential treatment systems to protect against contaminant exposure and the need for increased monitoring of rural private-well homes."

The Prairie Woods Chapter's AFO/CAFO report also cited studies in Wisconsin where manure pit related bacteria traveled over three miles to neighboring private wells.
To assess potential impacts of a proposed feeding operation on both the quality and quantities of available groundwater supplies, the permittee should be required to submit appropriate assessments of these water supplies that identify other area users (both public and private) potentially impacted and what measure will be taken to ensure supplies will be adequate in quantity and quality to serve all existing and planned future uses of these waters. Once again, these assessments should be prepared by licensed professional engineers and/or hydrologists.

Permits for sites that have downstream private wells within five miles should be required to pay for well water analysis of these wells prior to beginning operation, to establish background levels of indicator pollutants. If indicators of agricultural pollution are found, more exhaustive sampling and analysis should be required to determine if other agriculturally related biologicals or chemicals, including pharmaceuticals, are present. Likewise, pumping tests on new water supplies for large feedlots should be required, with water level impacts on existing private wells within five miles being reported. If no existing wells are located within five miles, special monitoring wells should be installed temporarily to determine the zone of depression caused by the new well and neighboring property owners should be formally notified if the aquifer they may rely on in the future may be impacted.

If these requirements should exceed the MPCA's authority or expertise, the League strongly suggests that either a memorandum of understanding or other agreement be developed between the MPCA, the Departments of Natural Resources, Health and Agriculture, to assure this impact is adequately addressed. For example, some form of written commitment between agencies to prepare a joint discretionary environmental assessment worksheet (EAW) or an environmental impact statement (EIS) may provide the level of scrutiny and public comment this problem requires.

Reasonableness of Requiring Compliance With Discharge Standards

The current MPCA policies and rules and the similar laws and policies in other states nation-wide have allowed feedlots to discharge both directly and indirectly into both surface and groundwaters causing serious pollution and impairment of these waters in many parts of the state, and only required that feedlots employ "best management practices" to "minimize" the discharges.

The League's position advocating the agency strengthen its policies and rules is supported by provisions of the Minnesota Environmental Policy Act (MEPA) which, in Chapter 116.04 subdivision 6 states:

> ***"Prohibitions**. No state action significantly affecting the quality of the environment shall be allowed, nor shall any permit for natural resources management and development be granted, where such action or permit has caused or is likely to cause pollution, impairment, or destruction of the air, water, land or other natural resources located within the state, so long as there is a feasible and prudent alternative consistent with the reasonable requirements of the public health, safety, and welfare and the state's paramount concern for the protection of its air, water, land and other natural resources from pollution, impairment, or destruction. Economic considerations alone shall not justify such conduct."*

This is a powerful mandate and a provision in state statute that would appear to compel the MPCA to prohibit (by denying permits) feedlot operations that pollute, impair or destroy the state's waters. Should the agency decide otherwise, it is the Leagues pointed request that the agency provide its explanation for allowing such pollution or impairment in their statement of need and reasonableness for any proposed rule that continues to allow this pollution.

Economic considerations

As discussed above, the League recognizes that the economics of livestock and poultry farming may have influenced landowners to increase that scale of their operations in order to increase or even maintain their profit margins as market prices for their livestock varied. However, manure storage and management practices that routinely allow pollution also increase profit margins, but do so at the expense of our precious water resources, a public trust to be managed for the public good. We maintain that feasible and prudent alternatives to the industrial-scale CAFO model do exist, thus this MEPA policy requires the agency to apply far more stringent standards for those feedlots. It is not our intention in these comments to list or outline these alternatives but instead recommend the MPCA, in conjunction with other state agencies and universities fully explore the available alternatives and make them known to the farming community.

In the section of the League's AFO/CAFO report to Becker County entitled *Economic Impact of CAFOs on Rural Communities (*on page 13) we present the economic arguments based on the work of Dr. John Ikerd, who holds a PhD in Agricultural Economics from University of Missouri-Columbia, that this form of industrialized meat

production is by many indicators, detrimental to the economies of communities where large feedlots of this type exist.

The League is sympathetic to the plight of farmers who may lack the technical or engineering resources to choose a less polluting alternative to the industrial CAFO model. Another section of MEPA requires agencies to do some of this work. *Minnesota Statutes* 116D.04 subdivision 2 (1&2) to establish advisory councils and forums to consult with experts on such matters:

> *"Subd. 2. Duties. All departments and agencies of the state government shall:*
> *(1) on a continuous basis, seek to strengthen relationships between state, regional, local and federal-state environmental planning, development and management programs;*
> *(2) utilize a systematic, interdisciplinary approach that will insure the integrated use of the natural and social sciences and the environmental arts in planning and in decision making which may have an impact on the environment; as an aid in accomplishing this purpose there shall be established advisory councils or other forums for consultation with persons in appropriate fields of specialization so as to ensure that the latest and most authoritative findings will be considered in administrative and regulatory decision making as quickly and as amply as possible;"*

The League strongly recommends that the MPCA act on this legislative mandate to create a feedlot advisory council to provide independent and objective input not only on these rules but to develop information and the means for its distribution to farmers who need to explore alternatives to the prevailing industrial CAFO model. The past practice of the MPCA, the EQB and other agencies to appoint "stakeholder" panels that includes those with obvious conflicts of interest should be avoided. The statute citation above emphasizes that advisory councils be populated *"with persons in appropriate fields of specialization so as to ensure that the latest and most authoritative findings will be considered in administrative and regulatory decision making as quickly and as amply as possible;"*

We offer instead the example of the panel of science advisors involved in preparing Iowa *Currents of Change* report. The report lists the names, qualifications and an indication of the independence of those panel members that contributed to the report.

<u>Currents of Change Panel of Science Advisors as Listed in the Report</u>

Currents of Change's depth, breadth, and comprehensive interpretation are due to approximately 4,000 hours of analysis and assessment by CISWRA's science advisors—all respected researchers and experts across multiple disciplines. The County is grateful for the passion and commitment devoted to CISWRA on the part of the science advisors.

Request for On-going Public Participation

Finally, the League respectfully requests that the current comment period not be the only opportunity for the public to have input into the new amendments to the feedlot rules before the draft rules are published. We request that the MPCA hold regular update forums around the state to provide transparency into the direction the agency is going and to what extent any of the public's comments (including those of the League) are being taken into account by the agency.

The League thanks the MPCA for providing this opportunity to submit comments on the agency's plan to revise the state's feedlot rules. We look forward to working closely with the MPCA throughout this rule-making process and beyond.

ADDRESSING AFO & CAFO IMPACTS IN BECKER COUNTY'S COMPREHENSIVE LAND USE PLAN, ZOINING MAPS & ORDINANCES

An Izaak Walton League of America

Prairie Woods Chapter Special Report

to

The Becker County Board, the County Zoning Administrator, the County Planning Commission, the Comprehensive Planning Consultants and the Public on Confined Animal Feeding Operations (CAFOs)

August 1, 2024

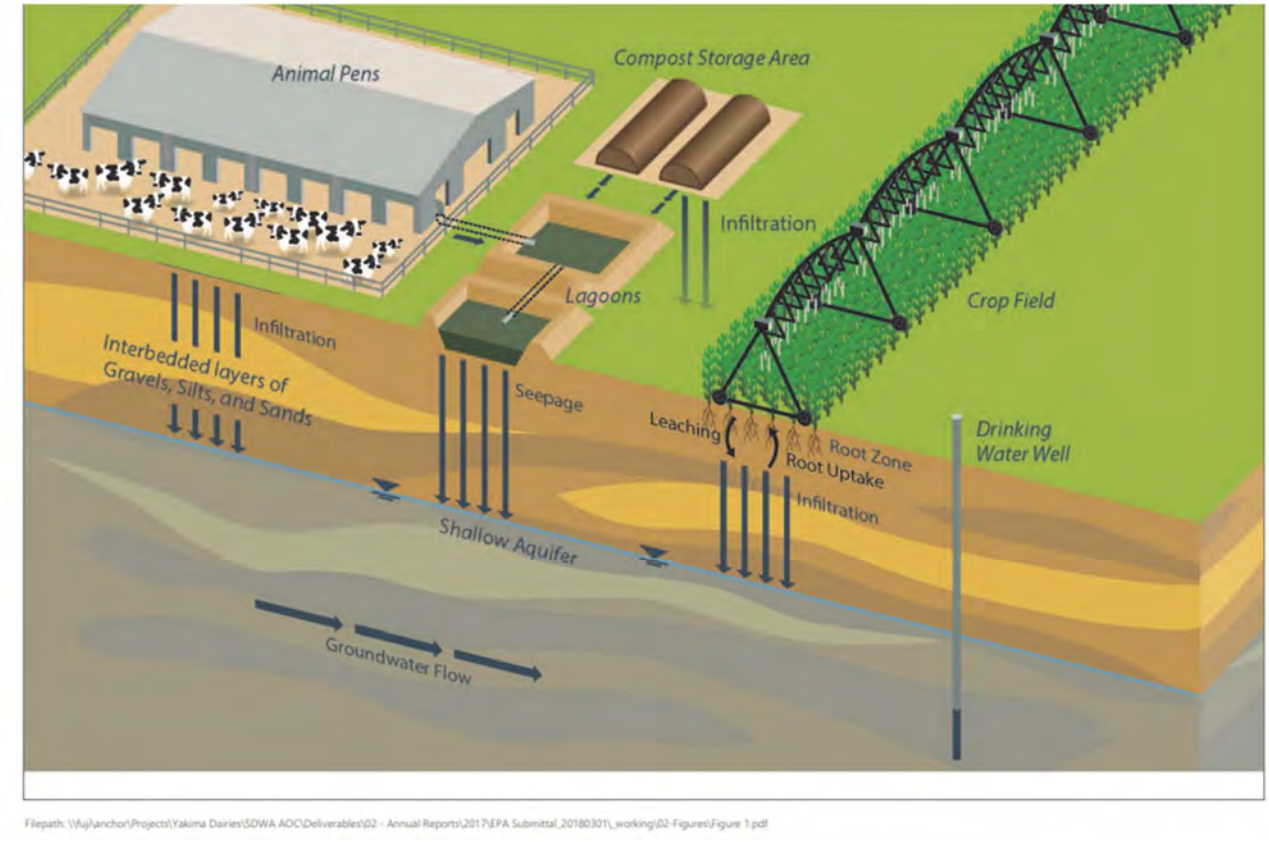

Photo Credit: Anchor QEA – Anchor Project – Yakima Dairy – 2017 Report to the Environmental Protection Agency

EXECUTIVE SUMMARY

The Becker County Board's decision to use a comprehensive plan update to address CAFO and Wake Boat issues has afforded the public and non-profit organizations unique opportunities to participate and even contribute their unique resources to the effort. With County Board Chair approval, members the local Izaak Walton League's Prairie Woods Chapter offered to perform research to fill technical information gaps that neither the staff or the planning consultant could fill. Thus, written reports were prepared on CAFOs and Wake Boats.

This report explains that the trend of more CAFOs migrating north into Becker County is real. The report dispels industry claims that they handle manure responsibly, by surveying other states and region's experiences. It describes how the evolving food industry model engenders industrial-sized feeding operations to maximize their profits, but to the detriment of smaller family farms and water quality. The report discloses that all manure storage facilities leak and can significantly affect sensitive groundwater, like that found in some regions of Becker County. State and Federal rules and permits are found to be too lax because the rules allow manure to be applied excessively enough to pollute both surface and ground waters. Manure leaks and spills are directly linked to fish kills. The spills resulted from heavy rainfall causing overflow from manure pits or were associated with manure transport tank wagon or pipeline accidents or failures.

The economic impact section of the report finds evidence that disputes nearly all industry claims that communities will benefit economically from industrialization of livestock farming. CAFOs are shown to ultimately be harmful to local economies because they displace family-scale family farms, reduce the number of farm worker needed, reduce hourly pay and can actually depopulate counties where CAFOs become dominant. Decreasing property values in counties with higher numbers of CAFOs is documented while lower CAFO counties experience increased property values. And many counties have been forced to raise taxes to offset increased costs of repairs to rural roads and bridges.

Credible monitoring of existing area wells and surface waters in any area designated for CAFO introduction or expansion, both before and after the first facilities are approved, is strongly recommended to establish baseline data. Therefore, private wells in areas zoned for more

intensive animal agriculture (CAFOs) in Becker County should have base-line testing done well in advance to protect well-owners, followed by regular sampling. Other states, and counties in the S.E. corner of Minnesota having experiences with CAFO's, are reviewed through published articles and each reveal significant unresolved levels of surface and groundwater pollution attributable to large and industrial scale feedlots. State and federal rules are reviewed and found inadequate to prevent or mitigate water pollution from CAFOs.

Minnesota is under Federal (EPA) orders to improve regulations for these areas, and new rules affecting eastern Becker County have already been judged as inadequate. Clean water supplies in quantities essential to Becker county's present and future economy, and for drinking purposes, are found to be inadequately regulated or apportioned by the state's water appropriation permitting program. Proposals for water quality and quantity (well-levels) monitoring for private well-owners could be recommended in the comprehensive plan. With state and federal regulations of CAFOs found inadequate to protect the health and welfare of Becker County citizens, zoning ordinances and permit conditions are considered quite important to fill these gaps. CAFO disease control methods are linked to the growing ineffectiveness of antibiotics in humans.

Testimonials are cited as evidence that small farmers can actually get financially trapped and even punished, by the CAFO industry when they find contract demands are draining their available capitol. A host of educational resources are included in the report that the League, other civic groups, county staff and the media can use to better inform the decision-makers and the public about these issues. Some of the resources listed in the full report are shown here below.[1]

Comprehensive Land Use Planning for CAFOs

Most land use decisions are inherently local. In Minnesota local governments create their own "comprehensive plan" for growth and development. The plan, in conjunction with zoning maps and ordinances establishes the way development occurs in that area. The primary purposes of the plan, zoning maps and the ordinances that implement it, is to "promote and protect the health, safety and general welfare" of the public, to "preserve and enhance the quality of surface waters" and to "provide for the wise use of water and related land resources of the County"[2]

Decisions about local planning and zoning, local utilities and other infrastructure are all made pursuant to the plan and maps. State law requires certain minimum elements in the plans, but leaves it to local units of government to develop and implement them through ordinances. The plans, maps and ordinances are ordinarily reviewed, updated and approved every 10 years.

The Becker County Public Engagement Survey used to gauge citizen priorities for the current planning effort found that 70% of Becker County citizens thought more should be done to protect the water quality of lakes and streams. When the nearly 500 respondents were asked to note their top priorities in terms of issues facing the county, 83% considered housing one of the three highest concerns. Further over 70% consider jobs and economic development a key priority and slightly more than 50% see the environment as an issue to be prioritized. Additionally,

[2] Quotes from statement of purpose section 101 in Becker County Zoning Ordinance

citizens raised two new issues to be addressed by the plan, animal feeding operations (AFOs) and confined animal feeding operations (CAFOs).

A county's land-use decisions about these livestock and poultry operations can have significant effects on the county's water quality, natural resources and human health, and economy, but impacts vary widely depending on sizes and locations of the operations. Factors such as soil types, depth to groundwater, topography and proximity to surface waters, proximity to neighbors, and compatibility of activities are important to consider along with the cumulative impacts of all other land uses on valued natural, cultural and aesthetic resources. Highly sensitive water bodies may need special protections and waters already impaired may need remedial measures in a land use plan. The impact of a single livestock or poultry project may seem small, but when we look at the bigger picture, the challenges to the environment and human health from both the small and industrial scale agriculture projects added together can be dramatic.

The livestock industry has experienced increasingly adverse conditions attributable to over-crowding; too many large facilities in close proximity, increasing animal disease risks, depletion of available clean water supplies, saturation of available crop lands with manure, and growing community animosity stemming from nuisance odor, traffic and insect (fly) populations.

Because industrial scale livestock agriculture is a recent arrival in Becker County the current comprehensive plan update is particularly well timed to perform its purpose serving to protect the county's water quality, natural resources and human health, as well as its economy.

The information provided here will serve to inform the County Board, the Planning Commission, County Planning and Zoning staff, and the public, on the consequences of allowing industrial scale animal feeding operations to first become established and then to possibly expand in Becker County. Potential impacts and risks to the public health and welfare of its current and future residents are identified. Factors that may potentially degrade the value of the county's natural resources and potential threats to the vitality of the County's rural economy are described in detail.

Filling the AFO/CAFO Information Gap

Conventional wisdom expressed in recent deliberations about these divisions of government responsibility for livestock facilities, led Becker County officials to defer to state and federal laws, permits and standards, to protect surface and ground water, as well as look after the general welfare and economic well-being of the county's citizens. The reliance on other entities to fill this role was examined for this report and was determined, at least in part, to be misplaced. And it was determined that neither the county zoning staff nor planning commission members had the assignment and neither had the time or resources to fully research the laws or the literature on large confined feeding operations. Zoning staff stated that no one had alerted them to issues relating to these operations and invited the public's assist in gathering more information.

Furthermore, the county planning a zoning staff found they did not have the necessary capacity or resources to research the impacts of, or find solutions to, either the industrial scale feedlot or the wake boat issues. And, the needed research was determined to be beyond the scope of work the consultants could be authorized to do for the money available.

When alerted to the need, the local IWLA chapter members met with county officials offering the League's wealth of expertise and volunteer time to research the controversial issues and generate fact-based reports and recommendations for inclusion in the draft comprehensive plan before the final plan was published.

The Izaak Walton League of America (IWLA) is well positioned to perform this public service. The League is a nation-wide, grassroots conservation organization that just celebrated its 100-year anniversary in 2022. Chapter membership includes conservation, natural resource, medical, pollution control, scientific research professionals, and other volunteers, many who are current, retired or former natural resource agency, university or consulting firm employees. Others are skilled, self-taught citizen scientists.

The local ILWA Prairie Woods Chapter, established in the 1940's has a long-standing collaborative relationship with area communities in a variety of conservation matters. Most recently, chapter members worked cooperatively with the Becker County Board the "Save the Trees Coalition" and other citizens to prevent unnecessary tree removals in the Smoky Hills

State Forest along the Lake Country Scenic Byway. The successes realized from these and other collaborations helped build the County Board's, the staff's and the public's trust in the IWLA member's scientific credibility and civic-mindedness.

The Izaak Walton League's Prairie Woods Chapter located in Detroit Lakes, the Becker County seat, has offered to help fill information gaps for both the livestock feedlot issue and for wake boats as well. This report will address the livestock feedlot issues while a separate companion report will similarly address wake boats.

CAFOs Are Migrating North Into the Lakes Region– Why?

New industrial scale feeding operations have been migrating north from Iowa and southern Minnesota, into northwestern Minnesota, in order to reduce animal disease risks, and have access to more clean water. In Iowa, an analysis by the Environmental Work Group produced a report that stated in part:

> *"The number of large concentrated animal feeding operations, or large CAFOs, in Iowa increased nearly fivefold in the past two decades, a new study from Environmental Working Group (EWG) reveals, with almost all of the growth from big hog-feeding operations.*
>
> *EWG found that in 1990, Iowa had 789 large CAFOs – those housing 1,000 or more animal units – swelling to 3,963 in 2019. The findings are supported by the federal Census of Agriculture, which reported that Iowa, the top hog-producing state, housed more than 22.7 million hogs in 2017, an increase of 8.5 million since 1992.*
>
> *Swine and other livestock raised in Iowa's large CAFOs now produce 68 billion pounds of manure a year – conservatively, 68 times the total amount of fecal waste produced each year by the state's 3.15 million residents.*
>
> *Large hog CAFOs house a minimum of 2,500 pigs each, and the largest hog CAFO in Iowa houses 24,000 animals. In total, more than 60 percent of the animal waste produced*

by the largest CAFOs in Iowa comes from hogs. The mountains of animal waste produced by these facilities pose a serious and growing threat to human health, the environment and water resources in the state.

EWG used satellite and aerial imagery to pinpoint where and when the new large CAFOs appeared in Iowa. The interactive map (found at the link in footnote 2) below shows their locations, the type of facility, the animals housed there and the growth in facilities over the past two decades.[3]

Industry Claims That They Handle Manure Responsibly Examined

Industrial farming representatives often claim farmers don't contribute to water nitrate or phosphorus pollution by over-applying fertilizers or manure because these materials cost too much, and to do so would be wasteful. However, Jeff Mitchell, Laboratory Supervisor for the Des Moines Iowa Water Works has found ever increasing concentrations of nitrates in the Des Moines and Racoon Rivers, primary sources of the city's drinking water over the past 50 years. In an August, 2023 webinar entitled "*Nitrate in Drinking Water – Public and Private*" to the Izaak Walton League, Michell presented nitrate concentration trends for the Raccoon River from 1972-2023, shown in the graph below that was included in the presentation. By multiplying river concentrations, by river flow volumes, Michell calculated the total amount of nitrogen flowing past the city in 2018. If applied as anhydrous ammonia, it would have cost $10 million and could have fertilized 400,000 acres, over 20% of the watershed. Since 1974, he calculated that 1.8 billion pounds of nitrogen had flowed past the city in the river. Using similar calculations Mitchell demonstrated that in 2015, 116,000,000 pounds of nitrogen was lost to the river at a cost of $35,000,000, and as fertilizer it would have adequately treated (fertilized) 800,000 acres (40% of the watershed).[4]

[3] EWG Study and Mapping Show Large CAFOs in Iowa Up Fivefold Since 1990 – See interactive map at: https://www.ewg.org/interactive-maps/2020-iowa-cafos/

[4] Jeff Mitchell – 2023 Izaak Walton League Clean Water Webinar Series *"Nitrate in Drinking Water: Public and Private"* at: https://www.youtube.com/watch?v=OpSnuGti2k0

These data and calculations clearly show that farmers do over-apply both commercial and manure fertilizers at a great economic loss to the farmers themselves, and at great expense to municipal water suppliers such as Des Moines to remove that fertilizer. Nitrate removal has cost the city over $317,000 in 2016 and over $750,000 in 2015.

	2013	2014	2015	2016	2017	2018	2019	2020	2021	2022
Number of Days in Operation	76	28	177	65	24	3	9	-	-	20
Number of Vessels Operated	313	96	726	265	72	9	58	-	-	70
Marginal Cost Per Vessel	$1,015	$1,015	$1,038	$1,159	$1,045	$1,090	$1,199	$1,199	$1,199	$1,199
Marginal Cost to Operate Facility	$317,695	$97,440	$753,588	$307,135	$75,240	$9,810	$69,542	$0	$0	$83,930

Public water supplies must meet drinking water standards (10 ppm), are routinely tested, and as shown above, treatment can be effective when the nitrate contamination is found to exceed safe levels, but it is expensive.

On the other hand, private well owners in rural areas lack testing or are tested only at the owner's expense, no standards are being enforced, and well-owners are "on their own" when contamination comes from their neighbor's activities. More information on private well contamination and aquifer draw-down issues can be found in the sections that follow.

All Manure Pits and Lagoons Leak

In Wisconsin and other states, including Minnesota, manure pits and lagoons are designed and allowed to leak, under provisions of regulatory permits, with a leak rate limit of less than 500 gallons/acre/day. This means that a three-acre lagoon is allowed to leak 1,500 gallons per day

and could total over one half-million gallons per year into the groundwater below. This has the potential to cause major problems for rural well owners.

A USDA study in Wisconsin examined this problem and found that not only nitrates were reaching private drinking water wells, but that fecal coliform bacteria from the manure pits were traveling over three miles from the source. (more on Wisconsin's experience issue later in this report)

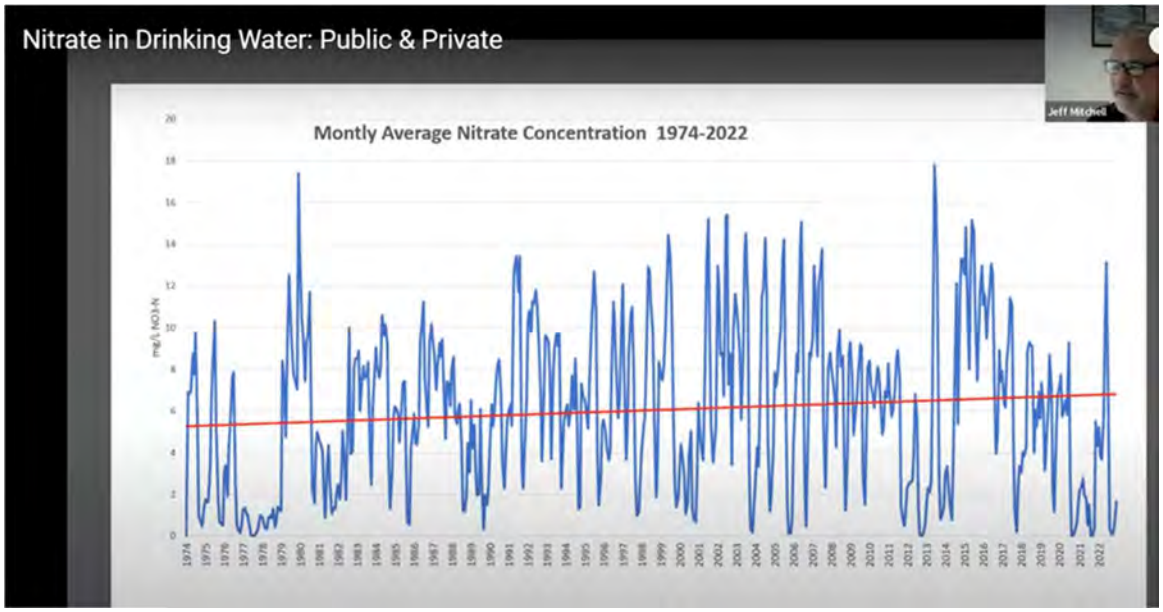
The Minnesota Pollution Control Agency's construction standards for manure pits and lagoons are "theoretical" rather than practical. This means that if construction standards are followed, the pits should theoretically not leak more than the amount allowed, but the owner/builder need not demonstrate that they are not leaking in excess of the standard. Pits and lagoons are allowed to leak slightly less than 500 gal/acre/day leakage, but the standard is generally understood to be 500 gal/acre/day.

> *"Minn. R 7020 requires that non-concrete liners for LMSAs be designed to achieve a theoretical seepage rate of no more than 1/56 of an inch per day. The required seepage standard is routinely considered to be approximately 500 gal/acre/day; however, this is slightly more than the actual 485 gal/acre/day allowed by the rule. Long-term protective and maintenance measures are required to meet this limit throughout the life of the structure."*[5]

This maximum leak-rate standard applies to manure storage facilities no matter what kind of liner is provided, including concrete, clay, Geotech (bentonite) or petroleum (plastic) liners.

It is important to note that while the MPCA rule requires this leak rate be maintained throughout the life of the pit or lagoon, and maintenance aimed at preventing greater leaking is required, there are no requirements for monitoring and actually demonstrating that the structures are not leaking more than this rate at the time of construction or after years of use and system deterioration.

[5] **Liquid Manure Storage Areas MPCA guidelines for design, construction, and operation of all types of liquid manure storage areas** – p 30 of 60, found at: https://www.pca.state.mn.us/sites/default/files/wq-f8-04.pdf



As part of the same Izaak Walton League webinar, Jesse Campbell, the Private Well Coordinator for the Midwest Assistance Program, shared information the Iowa Environmental Council had gathered about the presence of nitrate in groundwater and the challenges faced by private well users in avoiding nitrate contamination. In a 2019 Water and Land News report, Campbell revealed that "more than 6,600 private wells (12% of those tested) had nitrate averages at or above the EPA's legal limit (10 ppm) for drinking water systems and more that 12,330 wells (22%) had nitrate levels at or above 5 ppm. Natural background nitrate levels in Iowa groundwaters are generally less than 1 ppm.

Becker County, like most other rural counties, does not have private well protection strategies in place via policy or ordinances, other than well setbacks from on-site sewer systems. And private well-owners seldom, if ever, have their wells tested to see if drinking water standards are being met. If a neighbor's feed lot or CAFO should contaminate a private well, the well-owner has little recourse and will have the choices of either continuing to drink the contaminated water, purchase bottled water or drill a deeper well. In-home reverse osmosis treatment systems are effective at removing nitrates as well and may be more affordable than a new well. However, reverse osmosis technology is not designed to remove bacteria and viruses. If bacteria enter these systems, it can continually grow in pre-filters and deteriorate the osmotic membrane over time. Thus, most reverse osmosis system manufacturers specify that the system "must be used with biologically safe water".

Economic Impact of CAFOs on Rural Communities

Dr. John Ikerd[6], who holds a PhD in Agricultural Economics, now retired from University of Missouri-Columbia, in a Freshwater Futures May 15, 2024 webinar presentation entitled *"Economic Fallacies of CAFOs*[7]*,* presented the following conclusions from multiple peer reviewed studies[8]:

- 2008 Review: Reams of research dating to the 1940's shows local economies suffer economically and socially from industrial agriculture;
- 2001 Study: Many CAFO counties are forced to raise taxes to offset increased costs of repairs to rural roads and bridges;
- 2008 Study: Lower income, greater income inequality, more poverty, less active "Main Street", fewer stores, and less retail trade are found in CAFO counties;
- 2015 Study: Property values up to 7 miles from CAFO were lowered from 3.1% to 26%; while property values next to CAFOs were down 88%;
- 2022 Study: Personal incomes dropped 8% from 1982 to 2017 in Iowa counties with most CAFOs. Other rural counties with fewer CAFOs rose 41%.

Dr. Ikerd, in his own paper entitled: *Economic Realities of CAFOs*[9] draws the same conclusions and more. He includes an extensive list of reference publications that support his findings in his paper. Below are some excerpts from that paper on rural community impacts:

> *"Defenders claim that regardless of the need for CAFOs to meet the needs of consumers, CAFOs are necessary for the economic survival of many farming communities. They point specifically to community economic benefits from local investments in CAFOs,*

[6] Dr. John Ikerd - University of Missouri-Columbia, in a Freshwater Futures May 15, 2024 webinar presentation entitled *"Economic Fallacies of CAFOs*

[7] **Freshwater Futures' Great Lakes HABs & CAFO Manure Conference Series,** May 9, 2023. YouTube Recordings from the Conference can be found at: https://www.youtube.com/playlist?list=PL_JsLZuTdlRu96Q1tarJmgjsWOHEdoIYv

[8] The many studies referenced by Dr. Ikerd will be made available to all who want to read them upon request.

[9] *Economic Realities of CAFOs- Dr. John Ikerd, May, 2020 at:* https://ikerdj.mufaculty.umsystem.edu/presentation-papers/factory-farms-cafos/economic-realities-of-cafos

local sales of animals and animal products, and local employment in CAFOs and related local industries. However, decades of socioeconomic research and actual experience in CAFO communities reveal something very different. Whatever CAFOs contribute to local tax bases is more than offset by increased costs of maintaining rural roads and bridges that were not built to accommodate the heavy truck traffic associated with CAFOs. Also, local CAFOs operators typically source construction materials and labor from outside their local communities. Feeder animals, feed, and other supplies are shipped in from elsewhere. Even animal health care is typically provided by corporate veterinarians. Few of the economic benefits from CAFOs remain in local communities.

The most frequent claim for community benefits is probably that CAFOs will increase local employment, which is sorely needed in many farming communities. However, the economic reality is that CAFOs employ far fewer people per dollar invested or unit of production than do the independent family farms they inevitably displace. The first research I personally did on this subject was an evaluation of CAFOs as a rural economic development strategy. I evaluated the employment implications of PSF's planned operation in north Missouri. My conclusion was that if PSF came into Missouri, their CAFOs would displace up to three independent Missouri hog farmers for every job they created.[26] CAFOs came to Missouri, and Missouri lost more than 90% of its independent hog producers. I doubt that the number of workers employed in CAFOs in Missouri exceeds more than one-third of the independent hog farmers they displaced.

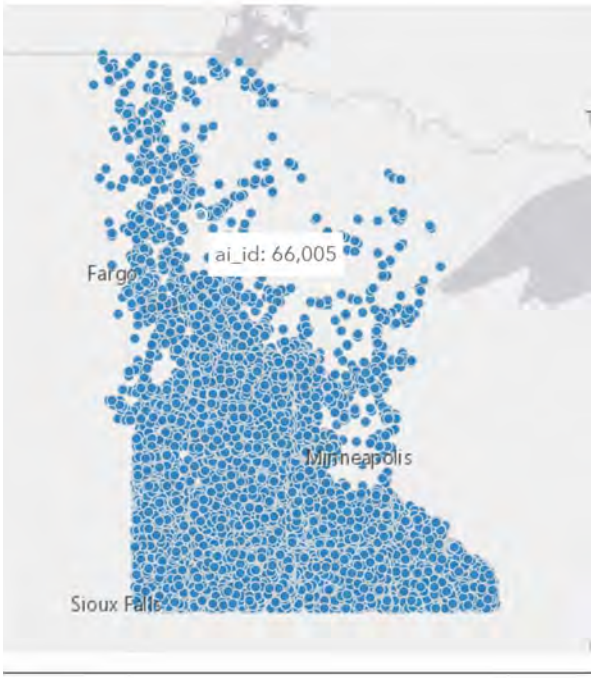
In the case of CAFOs, once livestock and poultry production became specialized, previously diversified family farms became specialized producers of either livestock or crops. Livestock and poultry were major sources of farm income that had made many diversified family farms economically viable. So, farmers who specialized in grain production were forced to farm more acres of land than before to maintain adequate family incomes. Larger crop and livestock operations meant fewer economic opportunities for farmers. With the industrialization of agriculture, the percentage of the U.S. labor force employed in agriculture dropped from 4.4% in 1970[27] to less than 1.5% in recent years.[28] Even in the communities where they locate, CAFOs do not actually

create jobs. They simply relocate and concentrate fewer lower-paying jobs in CAFO communities than had previously existed on family farms elsewhere.

In addition, this loss of farm families cannot be offset by people moving into rural communities from elsewhere. No one really wants to move to a CAFO community. A 2015 study reviewed thousands of assessed property values for residences located up to 7 miles distant from CAFOs. The review concluded: "Overall, the new studies confirm the [negative] valuation impacts reported in earlier studies, as they range from 3.1% to 26% losses depending on multiple factors, and that properties immediately abutting an AO [CAFO] can be diminished as much as 88%." [29] It takes people, not just production, to support rural communities. It takes people not only to buy farm supplies and equipment but also to shop on Main Street for cars, clothes, shoes, and haircuts. It takes people to send their kids to local schools, to attend local churches, and to serve on volunteer fire departments and local town councils. When independent family farmers are displaced by CAFOs, it's not just a matter of losing employment; it's a matter of losing the essence of what it takes to be a viable rural community."

The map below depicts the northerly progression of large confined animal feeding operations AFOs into Minnesota now stretching to the far northwestern corner of the state. [10]

[10] Source: MPCA on-line, data may not be current: https://hub.arcgis.com/datasets/mpca::feedlots-2/explore?layer=3&location=45.932764%2C-92.791165%2C6.00



These realities highlight the importance and necessity of using local land use plans and ordinances for proper siting, inspection and monitoring of large livestock facilities, so the public can have greater confidence local economies will thrive and that pollutants are not and will not enter surface or groundwaters without detection. Becker County has set an important protective precedent by requiring water sampling for large feedlots needing conditional use permits. But the design for the water sampling regime requested lacked science-based specificity and thus did not include sufficient sophistication to assure the monitoring would accomplish the intended purpose of detecting pollution and in turn, protecting surface and groundwater.

Industrialized Food System Engenders CAFOs.

Eric Schlosser in his recent book, *Barons – Money, Power, and the Corruption of America's Food Industry* states:

> *"Over the last 250 years, almost every sector of the American economy has become dominated by a handful of corporations. The forces that drove that trend have also come together to transform the most important sector of the American economy: the food system. The way in which the United States produces and distributes is food has a profound effect on worker rights, animal welfare, air quality, water quality, the landscape, rural communities, public health, international trade, and the global climate.*

Livestock and poultry DNA are now owned, manipulated and sold to American farmers by a handful of corporations. Four companies control 66 percent of the hog genetics; three companies control 95 percent of the broiler chicken genetics; two companies control 99 percent of turkey genetics.[11]

Iowa Select Farms employes more than 7,400 people, including contractors, and brings about five million pigs to market annually. Since Iowa Select was founded in 1992, the states pig population has increased more than 50 percent while the number of hog farms has declined by over 80%. Pigs now outnumber human residents by a ratio of more than seven to one, and they produce a volume of manure equivalent to the waste of nearly eighty-four million people, more than the populations of California, Texas and Illinois combined.[12] *One expert estimated that each confinement facility produces "the same amount of waste as a city of 90,000 to 150,000 people," spread over 640 acres with no sewage system."*[13]

State and federal laws do regulate some environmental impacts of livestock operations, but other than prohibiting siting in flood plains and wetlands, these regulations do little else to control the location of this particular agricultural land use. Recent findings by the Environmental Protection Agency show that Minnesota's regulations are inadequate to protect surface and groundwaters from nitrate pollution (more details on these findings are found later in this report).

Therefore, local governments have an important role to play in the proper siting of industrial scale livestock facilities in Minnesota. And, this local government role takes on new importance now that the State and federal government's protective network has not only been found to be incomplete, but has been shown to be ineffective as well. This means that local governments must exercise their authority and responsibility for deciding if and where large livestock facilities are located in their county, in order to close this loophole in the state and federal regulatory structure.

How the Clean Water Act and U.S. Farm Bill Remedies Fail to Protect Water

Under the Federal Clean Water Act, *direct* discharges of manure to surface waters from livestock holding pits and lagoons is prohibited for large Confined Animal Feeding Operations (CAFOs are over 1000 animal units). However, the controls for on-land spreading of manure from both larger CAFOs or smaller AFOs (animal feeding operations under 1000 animal units) for disposal or as fertilizer are strictly voluntary. Furthermore, penalties for discharging manure, even when it kills fish, are small, and therefore have not served as an effective deterrent; spills, leaks and ruptures continue to occur in every state that has these facilities.

Manure management plans, whether for CAFOs or AFOs, generally adopt what is known as best management practices (BMPs) for manure spreading, based on so-called "agronomic rates" of application. Such agronomic rates are designed to maximize the crop growth that is nurtured by manure application. Because these rates are designed to maximize crop production alone, it becomes clear that they are not designed for surface or groundwater quality protection. These BMPs have time and time again, been demonstrated to be ineffective, not only in Minnesota, but in a number of states and watersheds around the country.

Once surface and groundwaters are degraded by concentrated livestock feeding operations (or other source, for that matter) little can be done to reverse these impacts. Given the Becker County's location in the heart of the lake country's tourism region, degraded surface water quality has potential significant adverse economic consequences. Therefore, Becker County officials can benefit greatly from the experience of other states and regions, by insisting on more effective pollution prevention measures for feedlots in the comprehensive planning process. Chapter members are aware of other proven measures and are prepared to do further research to identify more effective pollution prevention strategies if county officials indicated their interest.

The chapter has researched other regions of Minnesota and several other states, to gather the experience of others with industrial scale agriculture, beginning with the Chesapeake Bay.

Chesapeake Bay

Over forty years ago, Chesapeake Bay watchers and state officials noticed significant water quality and aquatic life deterioration. Chesapeake Bay's watershed drains part of six states so an umbrella foundation was formed to fund and coordinate point and non-point pollution remedies. In 2004, studies investigating severely degraded water in the bay revealed the primary causes were increased nitrogen and phosphorus from several sources, but mainly from agriculture, and especially from intensive livestock agriculture. A 2004 Report by the Chesapeake Bay Foundation stated:

> *"The Chesapeake Bay is choking on nutrient pollution from a myriad of sources – from urban runoff, industry, automobiles, and human sewage, but the largest source is agriculture and, increasingly, from the manure produced by livestock, which now outnumber the watershed's human population by 11 to 1. Most of that manure is spread on the surface of nearby cropland, and studies show that within two years as much as half of its nutrient pollution washes out of the soil and into rivers and streams or seeps into groundwater. Both of these pathways lead to pollution in local waterways and, ultimately, in the Bay.*
>
> *"Of the nitrogen and phosphorus that reach the Bay, agriculture is the largest source and animal manure is the largest agricultural component. Chemical fertilizers and airborne pollutants such as ammonia gas—a common manure by-product – make up the rest of the agricultural sources. This makes animal manure not only the largest source of nitrogen and phosphorus deposited on the land, but also the second largest source that reaches the Bay, behind sewage, which is deposited directly into the water. Animal manure is a major source of the Bay's pollution and must be addressed swiftly and comprehensively.[14]"*

After the 40 years of intensive, watershed wide efforts to restore water quality from this severe degradation caused by non-point pollution, the Chesapeake Bay is barely holding its own,

[14] **Manure's Impact on Rivers, Streams and the Chesapeake Bay- Keeping Manure Out of the Water, A Report by the Chesapeake Bay Foundation** July 28, 2004 at: https://www.cbf.org/document-library/cbf-reports/0723manurereport_noembargo_7567.pdf

because crop and farm animal sources of nutrients have proven difficult if not impossible to cure. A 2024 Chesapeake Bay Foundation report[15] (that is well worth reading) states:

> *"Controlling agricultural runoff, the largest source of nutrients, has turned out to be more complex. Significant regionwide reductions have proven difficult. Data suggest, though, that efforts over the last 15 years have held the line, despite increases in crop production and growing numbers of chickens and other farm animals."*
>
> *Now, as the Bay Program celebrates its 40th anniversary, its partners are contemplating what comes after 2025, the deadline for meeting most of the 31 outcomes set in its 2014 agreement. Of those, 15 are on track, 10 are off-course and the status of four others is unclear. Nutrient goals will be missed by a large margin."*

Maumee River in Ohio and Western Lake Erie in Michigan

Lake Erie water quality improved greatly in the 1980s-90s when point sources of nutrient pollution were mostly remedied by the Clean Water Act. However, recent expansion of intensive crop and animal agriculture (factory farms) have reversed these gains, and frequent toxic algae blooms have once-again become the norm. A recent joint report by the Environmental Working Group and the Environmental Law and Policy Center states:

> *"The Maumee River, overloaded with fertilizer and manure, is the single largest source of the phosphorus that triggers blooms of toxic algae in Lake Erie. Over half of the manure in the Maumee River watershed comes from an exploding number of unregulated factory farms, a new EWG and Environmental Law & Policy Center investigation reveals.*
>
> *Outbreaks of toxic algae, fueled by pollution from manure and fertilizer from farm fields, are increasing in frequency and severity across the U.S. In 2014, a toxic bloom in Lake*

[15] **After 40 years, Chesapeake Bay Program Yields Mixed Results** – Bay Journal at: https://www.bayjournal.com/news/pollution/after-40-years-chesapeake-bay-program-yields-mixed-results/article_4af88180-92b0-11ee-9d06-ab0f3bb0d72f.html

Erie imperiled the drinking water of 500,000 residents in Toledo, Ohio. The Lake Erie outbreak, now an annual event, is getting much worse.[16]

Tim Boring, a sixth-generation farmer and Director of Michigan's Department of Agriculture and Rural Development, has bad news about Michigan's efforts to curb the farm pollution that fuels Lake Erie's toxic green algae. He finds that farm programs designed to protect water quality aren't working and that "factory-sized megafarms" are detrimental to the traditional farm economy.[17]

Lake Erie's phosphorus pollution problems have grown worse amid decades of consolidation in farm country. Diverse family farms have been steadily gobbled up by massive operations that primarily grow either cattle feed such as corn, or cows — and not on the same piece of land. The corn grown on one megafarm is shipped to a separate factory-sized livestock operation, which produces huge amounts of manure yet lacks the cropland on which cow poop becomes a valuable fertilizer.

The corn farm, in contrast, has plenty of acreage but no cows to fertilize it. So the farmer resorts to chemical fertilizers.

"It's not the problem that we have too much manure, it's that we have manure in all the wrong places," Boring said. Boring sees the state playing a bigger role in protecting small farms, which tend to grow more diverse crops while also raising livestock, and helping them succeed without expanding their acreage.

In doing so, he said, Michigan can bolster rural communities that rely on farming and food processing jobs.

Freshwater Futures based in Petroskey, Michigan recently hosted a day-long conference on CAFO manure impacts on surface and groundwater, and especially their contributions to harmful algae blooms (HABs) on Western Lake Erie. The conference was recorded and featured technical experts in all fields of concern, an attorney, a local politician, a pollution control engineer, and others. The recording of individual speakers and their PowerPoint slides can be

GREEN BAY WISCONSIN – ON LAKE MICHIGAN

The Green Bay Press Gazette[19] carried this headline after covering the *Midwest Manure Summit* in Green Bay in 2019:

> *"Scientists are one step closer to understanding how dangerous contaminants from fecal matter are entering private wells in Kewaunee County. New research by U.S. Department of Agriculture microbiologist Mark Borchardt shows nitrate and coliform in the water mostly comes from agriculture — and not human waste.*

[18] See links to YouTube video recordings at the end of this report. This webinar, while useful to disclose the wide variety of environment, human health and economic problems with CAFOs may not be suitable for comp plan content. It may be better suited for a series of public education events for the Becker County Board, Planning Commission members and the public. Citizens, once well informed on CAFOs by these means can build fact-based support for the County's leaders taking appropriate actions.

[19] Green Bay Press Gazette, March 2019 by Sarah Whites-Koditschek and Coburn Dukehart -Wisconsin Public Radio and Wisconsin Center for Investigative Journalism found on line at;
https://www.greenbaypressgazette.com/story/news/investigations/2019/03/04/tainted-kewaunee-county-drinking-water-wells-tied-manure-pits/3054018002/

"Where we see the strong relationships, the strong linkages, those are with agricultural factors. So that would suggest that agriculture is primarily responsible for those two contaminants," he said in an interview.

Borchardt presented his updated findings on the risk factors associated with contamination in wells at the Midwest Manure Summit in Green Bay on Wednesday. In 2017, his research found over 60 percent of wells sampled in Kewaunee County were contaminated with fecal microbes, which can come from both septic systems or animal waste.

The new study aims to understand the precise sources of contamination and how certain factors can reduce or increase the risk of tainted drinking water. Borchardt used models to predict how those factors — like the distance of a well from a manure lagoon or agricultural field, weather and the quality of well construction — can impact contamination levels.

Borchardt's study found that the No. 1 risk factor for contamination was the proximity of a well to a manure storage pit. Borchardt said the closest well in the study was 150 feet from a manure pit, but even wells three miles away still have some risk of being contaminated with coliform."

Identifying and notifying owners of private (and public) wells within a 3-to-4-mile radius of any proposed industrial-scale feedlot may be an important public health function for consideration in Becker County's planning process for these facilities. And zoning maps that are updated to depict where large or industrial scale feedlots can be allowed by standard permit or conditional use permits could be used as a guide for a county-sponsored and targeted private-well monitoring program.

EPA Intervenes to Protect Southeast Minnesota's Ground and Surface Water – Orders Permit and Guideline Improvements

In April, 2023, citizens petitioned the U.S. Environmental Protection Agency, saying nitrate in the groundwater in southeast Minnesota's karst region — largely from fertilizer and manure applied to crop land — poses an imminent danger to human health. They asked the Federal Environmental Protection Agency (EPA) to use its emergency authority under the Safe Drinking Water Act to intervene. [20]

In response to the citizen's petition, in an August 2023 letter to four Minnesota State agencies, the EPA stated that the MPCA's permit and manure management requirements for CAFOs were inadequate and needed to be "more protective" of sensitive groundwater resources. The federal agency says state agencies need to take additional steps to protect drinking water in southeast Minnesota from nitrate contamination.

> *"While this letter is largely focused on addressing immediate health concerns regarding nitrate contamination in drinking water in the Karst Region, Minnesota must also develop and implement a long-term solution to achieve reductions in nitrate concentrations in drinking water supplies. Developing a complete understanding of potential sources of nitrate contamination is an important immediate step for the state. A risk analysis of current and future nitrate contamination of the impacted groundwater will be critical for determining long-term solutions, and such analysis should incorporate the latest science and technologies. Minnesota has tools to effect reductions in nitrate concentrations through the National Pollutant Discharge Elimination System (NPDES) and State Disposal System permit programs, including development and implementation of more protective NPDES/SDS CAFO permits. In addition, Minnesota should consider adopting monitoring requirements in NPDES/SDS permits related to (1) subsurface discharges from manure, litter, and process wastewater storage, as well as (2) discharges from land application, similar to those proposed by EPA as modifications to* the EPA-issued CAFO general permit for Idaho: https://www.epa.gov/npdes-*permits/npdes-general-permitconcentrated-animal-feeding-operations-cafos-idaho.*

[20] EPA says 'further actions' needed to protect human health from nitrate in southeast Minnesota by Kristi Marohn - November 8, 2023 at: https://www.mprnews.org/story/2023/11/08/epa-says-further-actions-needed-to-protect-human-health-from-nitrate-in-southeast-minn

> *We also encourage Minnesota to consider modifications to the state's Technical Standards for Nutrient Management with regard to land application of manure, litter or process wastewater, and any Minnesota guidelines for land application of commercial fertilizer, specific to Karst areas.*[21]

In response to the citizen petition and an order from the EPA, MPCA has drafted revised permit conditions and manure management rules for large CAFOs, but the draft rules are drawing strong criticism from experts for falling far short of what the EPA ordered and what is needed to protect the state's waters, and private well-owners. This is especially true in sensitive ground water and high value surface waters (trout streams) in S.E. Minnesota, and the central sand plains area, which includes eastern Becker County.

The Straight River is known as a premier trout stream although trout populations and species have declined and shifted to more tolerant species (i.e. Brown trout rather than Brook Trout.) Soils in the area known as the Ponsford Prairie consist primarily of glacial outwash sands and gravel, where the shallow ground water is not protected by less porous clay or silty soil layers nearer the surface. Many private wells in this rural area were developed to use these shallow waters because these wells are lower in cost than deeper water aquifer wells, and this water historically was fairly high quality in spite of its vulnerability to pollution from various land uses like those described above.

Minnesota Outdoor News published an article in July, 2024[22] that quoted a groundwater hydrologist who is focused on private well owner interests:

> *Jeff Broberg is a founder of the Minnesota Wells Owners Organization and former president of the Minnesota Trout Association. Broberg, who lives in southeastern Minnesota, said the new proposed rules on the two feedlot permits are welcomed but long overdue and don't go far enough.*
>
> *"I'm pleased that the MPCA is finally starting this effort," said Broberg, adding that*

[21] US Environmental Protection Agency August 2023 Letter to Minnesota Agencies found at: https://www.epa.gov/system/files/documents/2023-11/ao-rmod-reponse-letter_20230510-508.pdf

[22] **MPCA Seeks Comments on Plan to Curb Pollution in State Waters** -Outdoor News Minnesota, Vol. 57, No. 29, Page 1 By Tori J. McCormick

Minnesota's "regulatory environment for feedlots is far too friendly."

"I'm dubious that it will have any effect. But we'll see," he said.

Broberg said if the MPCA is serious about tackling nitrate contamination in state lakes, rivers, and streams, the agency needs to better regulate all state feedlots – not just the largest 1,000. That's a sentiment shared by other state groups, including the Minnesota Center for Environmental Advocacy and Land Stewardship Project.

"Feedlots are altering our environment and our public health," said Broberg, who urged water quality advocates of all stripes to comment on the proposed changes to MPCA feedlot permits. "We need to recognize that … and how our surface and groundwater are so vulnerable and being impacted."

A similar petition to EPA has recently been filed by citizen groups in the Northeast corner of Iowa, where nearly identical topography and groundwater sensitivity exist. Private wells and public water treatments systems in this and other parts of Iowa, have experienced rapidly increasing nitrate concentrations in both ground and surface waters. In an article posted in their publication[23] Food & Water Watch staff attorney Dani Replogle said:

"The state's failure to regulate industrial agriculture pollution has steadily eroded Iowans' right to clean drinking water. For decades, Northeast Iowa residents have been exposed to dangerous levels of nitrate contaminated water. As the state reckons with high cancer levels and ongoing pollution regulation rollbacks, federal action is needed to safeguard the right to clean water. EPA must exercise emergency authority to hold polluters accountable and deliver safe drinking water in Iowa."

With this information and the additional reference material below, Becker County can benefit from other's experiences and take more effective planning and zoning actions to avoid the predictable outcome of industrial-scale agriculture migrating into the county without the necessary safeguards and monitoring in place.

Becker County's sensitive surface and groundwater regions include its eastern Becker County sand plain areas, with its high value trout streams, its more highly developed central lakes area, and its western agricultural areas served by extensive patterned drain tile and drainage ditch

[23] https://www.foodandwaterwatch.org/2024/04/16/iowa-environmental-groups-petition-epa-for-emergency-action-on-iowa-drinking-water/

systems. Having sufficient, pre- and post-CAFO project construction ground and surface water monitoring in place, can be a useful tool for holding industrial agriculture accountable for its operations and providing the assurances Becker County citizens need to keep from reliving the regretful experience of others.

The MNDNR has recently completed a groundwater atlas for Becker County that could serve as a preliminary baseline for groundwater quality before industrial livestock agriculture has a greater impact. Groundwater sensitivity maps are also available from the MPCA. The MPCA also publishes an impaired (surface) waters list that is updated and submitted to the EPA and released to the public periodically. This information, along with the Watershed Restoration and Protection Plans (WRAPS) co-produced by the MPCA and local water management entities, provides much of the historical background information on water quality in Becker County. Here again, this background information can be used proactively to gauge and even predict the water quality trends attributable to increases in industrial agriculture, both in crops and livestock.

These realities highlight the importance of using local land use plans, zoning maps and ordinances for proper siting, inspection and monitoring of large livestock facilities, where the public can have greater confidence that pollutants are not and will not enter surface or groundwaters.

Importance of Water Sampling and Monitoring

The feedlot industry persistently claims that manure management plans limited to "agronomic rates" of application are sufficient to protect surface and groundwaters. The information presented in sections above demonstrate that this is not true.

One of the best strategies to test the performance of such plans is to actually monitor the water. New Mexico began requiring performance monitoring for large confined dairy operations as early as the 1990's. During the first six years of monitoring, significant increases in ammonia and nitrates were found in groundwater. A 1999 state agency report entitled: *Dairy Feedlot Contributions to Groundwater Contamination - A Preliminary Study in New Mexico* states:

"Feedlot milk production has increased dramatically in New Mexico in the past decade, along with the potential for groundwater contamination from animal wastes. State statutes require animal feedlots to maintain groundwater-monitoring wells and report water quality analyses quarterly to the New Mexico Water Quality Control Commission. This preliminary study analyzed six years of groundwater quality data from seven dairy feedlots and found elevated levels of nitrate, ammonia, chloride, total Kjeldahl nitrogen, and total dissolved solids. Samples were obtained from groundwater-monitoring wells located around dairy wastewater lagoons that were lined with clay, concrete, or synthetic membranes. Mean nitrate concentrations were significantly higher in groundwater samples taken in the vicinity of lagoons with clay liners. Lagoons with synthetic liners produced the lowest mean groundwater concentrations of ammonia and nitrate. Mean concentrations for all contaminants tended to increase as the size of dairy herds increased. Nitrate was the only groundwater contaminant measured that showed a consistently increasing trend from 1992 to 1997. [24]

In 2015, the state adopted the Dairy Rule, which requires dairies to monitor groundwater impacts and to line waste lagoons. The rule came following a 2009 study by NMED's Groundwater Protection Division that found 60 percent of the state's dairies were polluting groundwater. [25]

The Public Engagement Survey used to gauge citizen priorities for the current land use planning effort found that 70% of Becker County citizens thought more should be done to protect the water quality of lakes and streams.

Becker County has already set an important protective precedent by requiring a modicum of water sampling for large feedlots needing conditional use permits. But the water sampling required in a recent Conditional Use Permit lacks sufficient sophistication to ensure the

[24] **Dairy Feedlot Contributions to Groundwater Contamination - A Preliminary Study in New Mexico** – Sept, 1999. At:
https://go.gale.com/ps/i.do?id=GALE%7CA55884900&sid=googleScholar&v=2.1&it=r&linkaccess=abs&issn=00220892&p=HRCA&sw=w&userGroupName=anon%7Ee4bab884&aty=open-web-entry

[25] **New report looks at dairy operations in NM** -March 29, 2022
https://nmpoliticalreport.com/news/new-report-looks-at-dairy-operations-in-nm/

monitoring would provide useful information. Becker County could take a page from the New Mexico playbook and begin to require "performance monitoring" from new or expanding AFOs and CAFOs.

The comprehensive plan could present guidelines or suggest qualified consultants for designing appropriate ground or surface water monitoring regimes. Monitoring has been shown to clearly gauge the effectiveness of manure lagoon or pit containment and manure management plans that are supposed to protect both the surface and ground waters of the county. As has been found in New Mexico and Wisconsin, state and federal rules have, thus far, not proven effective enough. So, water quality monitoring, may be the county's best defense to protect the public's health.

MANURE PIT OVERFLOWS BECOME MORE FREQUENT WITH CHANGING WEATHER PATTERNS

Manure spills and pit overflow incidents present serious pollution risks to receiving waters and to human health. Risks that are increasing as the number of CAFOs increase and severe storms with high rainfall amounts increase in frequency under changing climate conditions. In June of this year seventeen CAFO owners were obliged to report overflows after heavy rains occurred in southern Minnesota. The state's largest feedlots, which include dairies and pig and turkey operations that have roughly 1 million pounds of total livestock or more, are required to report any manure overflows to the state. There are about 1,000 feedlots of that size in the state. State regulators ask smaller farms to report overflows as well, but they are not required to."

The Minneapolis Tribune account[26] of these overflows is quoted here below:

> *"Relentless rains this month have caused 17 manure pits at 15 large farms in southwestern Minnesota to overflow, releasing livestock waste into the environment.*

[26] **Seventeen manure pits reportedly overflow at large feedlots in southern Minnesota**
Heavy rain has spilled an unknown amount of livestock waste into the environment. By Greg Stanley
Star Tribune JUNE 26, 2024. At: https://www.startribune.com/manure-pits-reportedly-overflow-at-16-large-feedlots-in-southern-minnesota/600376074

The overflows, all at open pit lagoons, happened in Rock, Nobles and Jackson counties, said Andrea Cournoyer, a spokeswoman for the Minnesota Pollution Control Agency (MPCA). The agency is working to monitor and mitigate any potential damage from the spills, she said.

High concentrations of manure can be dangerous to human health and can cause fish kills and threaten water quality even after floodwaters recede. But the manure in the basins overflowing from the extreme rainfall is heavily diluted, said Randy Hukriede, feedlot program manager for the MPCA. None of the basins that overflowed contained pure manure.

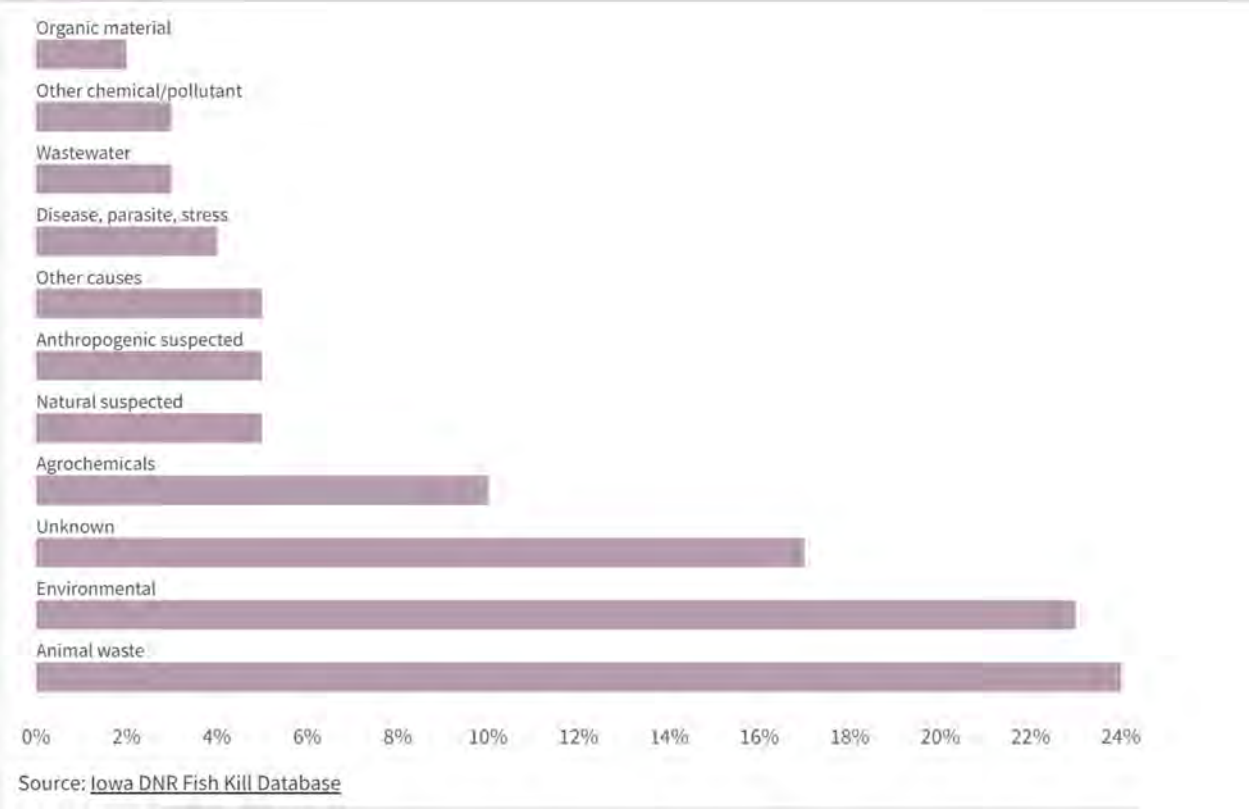
Manure pit overflows in Southeast Minnesota and Iowa have been linked to numerous fish kills. An Investigate Midwest report[27] in 2023 stated:

"Over the past four decades, 35% of fish kills are related to the state's primary industry — agriculture, according to an Investigate Midwest analysis of state data from 1981 to 2022."

What causes the fish kills in Iowa waterbodies?

Over four decades, animal wastes and fertilizers have been responsible for 34% of fish kill events.

[27] **Animal waste and agrochemicals are leading cause of fish kills in Iowa waterways**
Agriculture is the lifeblood of Iowa, but it also contributes to mass die-offs of fish in the state's waterways.
https://investigatemidwest.org/2023/06/01/animal-waste-and-agrochemicals-are-leading-cause-of-fish-kills-in-iowa-waterways/



Becker County has experienced similar increases in frequency and severity of storms dropping 3-6 or more inches of rain in a single event so it is predictable that manure pit overflows and potential fish kills will occur in our area. It is reasonable to predict that these risks will continue to increase if the number of CAFOs is allowed to grow given our changing climate in Becker or any other state or county.

CAFOs DEMAND LARGE QUANTITIES OF GROUND WATER

Industrial scale animal agriculture concentrates livestock in small areas and must extract all the water these animals need from just one or two wells. Large groundwater extraction from aquifers that are either small or are slow to recharge can cause supply problems for neighbors who rely on the same aquifer.

Some compare the water demands of CAFOs to that of small cities. One cow (one animal unit) consumes as much water as four adult humans. Therefore, a 10,000 cow CAFO requires as

much water as a city of 40,000 people. Becker County's population was 35,183 (2020 census), so just one industrial size CAFO would demand more water than all the people in the county.

State rules for protecting aquifers from over-extraction are fragmented and have been shown to be ineffective at protecting individual well-owners whose wells go dry or suffer reduced yield. One of the earliest systematic reviews of the CAFO impacts was found in a 2019 paper entitled: *WATER USE IN CONFINED ANIMAL FEEDING OPERATIONS (CAFOS) IN MINNESOTA: WHO'S KEEPING TRACK?* by Dara Meredith Fedrow. In his graduate thesis, prepared for Minnesota's Land Stewardship Project, Fedrow analyzed how effective Minnesota's water appropriation permit system was in overseeing water usage by large CAFOs. This research, conducted to inform the work of Land Stewardship Project (LSP), which is an advocacy nonprofit based in Minnesota, was published to inform state government agencies, water researchers, and local citizens. The entire paper can be read at the link in the footnote[28] below. Fedrow cites research by others that warned that:

> *"Groundwater is unequally distributed throughout Minnesota which can pose issues as agricultural groundwater use increases. Groundwater pumping is unsustainable in some parts of Minnesota and could deprive ecosystems and humans of water needed to survive."*

One of the recommendations Fedrow offers that is useful for the Becker comprehensive planning effort, is inserted here below.

> *"New areas of CAFO development should be watched closely to ensure CAFOs are obtaining the proper permits and for their impacts to the surrounding communities and watersheds. Hog CAFOs are reporting increasingly more water use in the south eastern part of Minnesota. This is particularly apparent in Mower and Steele Counties, corresponding to the Cannon River, Cedar River, and Upper Iowa River. Dairy CAFOs*

[28] *WATER USE IN CONFINED ANIMAL FEEDING OPERATIONS (CAFOS) IN MINNESOTA: WHO'S KEEPING TRACK?* by Dara Meredith Fedrow accessed on line at https://scholarworks.umt.edu/cgi/viewcontent.cgi?article=12430&context=etd

appear to be opening in Norman and Kandiyohi counties. Norman county corresponds to a large percent increase in use of the Wild Rice River."

Fedrow's paper is recommended reading for those who seek to know more about CAFOs' demand for water, and the regulatory and societal problems foreseen for the ever-increasing demands on Minnesota's limited "clean" water supplies by industrial animal agriculture.

Becker County could use is Comprehensive Plan to alert well-owners to potential groundwater drawdown in the vicinity of proposed CAFO sitings and assist rural home-owners in monitoring their wells for signs of draw-down that may be caused by the facility. Well water levels could be added to a nitrate and fecal coliform county-wide well-monitoring program similar to the Midwest Assistance Program in Iowa. This program obtained grant funds to initiate and maintain the Iowa private well monitoring. The IWLA Chapter is willing to assist Becker County in designing a similar program and seeking the necessary grant funds to implement and maintain it.

Meanwhile, Becker County should request that MDNR monitor stream flows to establish the background and trend levels necessary to detect changes in critical low steam flows attributable to large groundwater appropriation by CAFOs. Low stream flows can impact Becker County's recreation and tourism economies including river-tubing, kayaking, canoeing, wildlife watching and stream fishing.

Ordinary Small Farmers Can Get Financially Trapped and Even Punished by the Industry

Conventional scale (small) farmers are not at fault or in any way to be blamed for being attracted to the offers from the industry representatives. With persistently narrow profit margins it makes a lot of sense to scale up and grow overall profits even though margins remain slim. But once "in the contract system" farmers all too often discover they are on a financial treadmill that is extremely difficult to escape. Some who try unsuccessfully to escape have suffered retribution from the industry. Some farmers who once were "contract farmers" are speaking out to alert

others of the risks and their efforts to transition back out. Modern Farmer's on-line magazine published one farmer's story.

> *When Paula and Dale Boles took over Dale's father's farmland in North Carolina, they thought that poultry farming would be a good way to work the land until they were ready to pass it on to their children. They obtained a contract with Case Farms, eventually switching over to Tyson, and built two poultry barns to company specifications, going $300,000 in debt to do so. It seemed like a good situation, though—as long as they could make their annual mortgage payment of $40,000, they'd be able to pay it off within 10 years.*
>
> *But soon, other expenses started getting tacked on. Tyson required a new computer system to control the temperature in the barns. This was another $70,000. Their propane bill averaged around $25,000 per year. Not making the updates wasn't really an option—no matter how much time and money you invested to be a farmer for the company, they could cut your contract at any time.*
>
> *And the income wasn't quite what they expected. Companies like Tyson pay their farmers in what's called a tournament system. There's a base pay, but whoever raises the best flock and has the best "feed conversion"—the biggest birds for the least feed— makes the most money, and payment decreases the further you go down the ladder. This essentially pits all the regional farmers against each other.*
>
> *"While contract farming, or "factory farming," has been exposed in the media for being exploitative of animals, the farmers who sign contracts with companies like Tyson, Perdue or other big players in animal agriculture also find themselves backed into a financial corner. But, over the last several years, there has been a wave of efforts to find ways to support farmers transitioning out of factory farming.*
>
> *"The way that the current structure of factory farming is designed is that the steps that carry with it the most risk and the most debt and the most liability are transitioned to the farmers," he says. "And so what you have is you have farmers building these extremely expensive facilities at the very specific direction [and] design of the company that they're working for. But they don't own the animals.*[29]

Antibiotic Resistance Linked to Feedlots

Becker County may not have the authority to address or curb the contribution of large animal feeding operations to antibiotic resistance, but the Comprehensive Plan could provide or suggest

[29]**They Once Worked in Factory Farming. Not Anymore.** Modern Farmer, May 07, 2024 at: https://modernfarmer.com/2024/05/they-once-worked-in-factory-farming-not-anymore/

tools to educate the public about the problem. This in turn could influence policy-makers at the appropriate level of authority to take remedial steps.

> *A **report** in 2020 by the Natural Resources Defense Council (NRDC), reveals that US cattle producers use more than 40% of all medically important antibiotics—those that are also used in human medicine—sold for use in US livestock, and use them three to six times more intensively than many of their European counterparts.*
>
> *NRDC says this overuse of antibiotics is a strategy used by the beef industry to offset heightened disease risks in feedlots, where cattle are routinely fed antibiotics to prevent disease whether or not they are ill, a practice that the World Health Organization discourages and that the European Union will no longer allow starting in 2022.*
>
> *The reports also argues that there is little transparency or accountability in the beef industry regarding its use of medically important antibiotics, and little urgency to rectify the problem.*
>
> *"Many infectious disease and antibiotic resistance experts believe such use is improper and helps contribute to reservoirs of drug-resistant bacteria on farms that can spread easily to humans through consumption of meat, exposure to soil or water contaminated with manure containing antibiotic-resistant pathogens, or contact with animals. They also worry that it reduces the effectiveness of antibiotics that are needed to fight infections in people."*[30]

This concludes our report. There are several other issues relating to large feedlot pollution problems that time did not allow Chapter researchers to investigate fully enough for inclusion here. While we make general references to the health impacts of nitrates that exceed regulatory standards, there is growing evidence that the standards are not seen as being fully protective of human health and linking nitrates to certain cancer risks.

[30] https://www.cidrap.umn.edu/antimicrobial-stewardship/report-slams-beef-industry-overuse-antibiotics

Also, there could be a chapter in the plan that informs citizens about the risks to public health when storms cause overflows of these storage facilities. A derecho or other storm or series of storms like those that occurred in S.E. Minnesota recently, could have similar impacts here in Becker County.

This concludes this report.

The IWLA Chapter, at the invitation of the planning consultants is preparing a narrative based on this and the Wake Boat Report for inclusion in or attachment to the draft Becker County Comprehensive Land Use Plan. Additional sources of information compiled by the League are shown below.

SOURCES OF OTHER USEFUL INFORMATION AND PUBLIC EDCUCATION TOOLS ON CAFOs.

The IWLA Chapter members compiled other authoritative reference materials, including video interviews with groundwater experts, lawyers, and citizens from Minnesota and neighboring states, that provide testimonials on their knowledge and experience with AFOs and CAFOs. Some of the content includes discussion of local economic impacts and describes how other local units of government are working to adopt plans and ordinances to address industrial scale feedlots. Interactive MPCA maps of feedlot locations in Minnesota are also provided.

7020 Rule comment

I have grown up on a family farm in southeast Minnesota. My wife and I now farm with our son and his wife and their 3 daughters. It is very important to our family that we have clean water. We raise hogs in Fillmore County and also raise corn, soybeans and hay. MPCA has implemented rules that all livestock producers must follow. There are some rules and setbacks that are exclusive to the karst region of Minnesota. These current rules make sense for everyone and are easy to understand and follow.

Family farms work hard to be good stewards of land, following many Best Management Practices, and follow many rules set forth in MPCA guidelines.

When it comes to BMP's one size does not fit every farm. It's important to have several options to fit a wide variety of farms. One example of this is that cover crops do not fit everyone. I think it's important to have the option to use a nitrogen stabilizer instead.

The 7020 rules need to serve as a baseline for all feedlots in the state and be based on sound and accepted science and soil and geographic conditions. The rules should take into consideration other requirements like including riparian buffers as part of the setback distances and the required set backs from karst features in our corner of the state.

Thank you for the opportunity to comment

Dave Mensink

Cass County Minnesota Chapter of the Izaak Walton League of America Comments on Planned Amendments to Rules Governing Animal Feedlots, Minnesota Rules, chapter 7020, Revisor's ID Number R-04928

Any changes to the current inadequate rules governing feedlots in Minnesota should consider the following. References and citations are excluded for brevity, and with the understanding that reasons for the rules changes are well established and have been for decades. Thorough investigations and rules must be in place before feedlots are permitted, before manure applications take place. This is vital to preserve the public health of all local citizens.

1.

The Cass County Minnesota Izaak Walton League Chapter has members with direct experience of soil and water contamination due to industrial agriculture operations on the vulnerable soils of the Pineland Sands. The effects of row cropping and CAFOs

are easily understood to be the largest contributors to water contamination, and the effects are very predictable before operations begin. Many tools are available for risk assessment of industrial ag in Minnesota. These should be employed before feedlots are permitted and the responsibility for remediation of any contamination of surface or groundwater should be established beforehand. Some soils of the state are simply not able to handle large feedlots, areas such as karst or sandy, outwash plains like the Pineland Sands. The most vulnerable soils need the most protection.

2. Any existing or potential feedlot will have a connected row cropping activity for feedstocks. These operations have been shown to be quite problematic for water quality without feedlots involved, therefore a feedlot should be considered as a risk multiplier for water contamination due to associated row cropping.

3. Any feedlot of 100 animal units or more should be considered a CAFO with an inherent risk of contamination of resources.

4. All feedlots should begin composting manure immediately. This would create a resource instead of a liability.

5. A bioremediation plan for any spills or contamination associated with feedlots and row cropping should be established beforehand. A bond could be issued by feedlot owners to the state to aggregate funds for such. A ¨polluter pays¨ approach is justified.

6. Water testing should be done in advance (to establish baselines) and during operations of feedlots. A detrimental effect on water quality or quantity should be grounds for rescinding permits.

7. Livestock access to water such as riverbanks should be prohibited. Manure brought directly to water bodies is unacceptable.

8.

A feedlot rehabilitation/retirement plan should be created for instances where a feedlot demonstrates a repeated deleterious effect on neighboring resources or properties. CAFOs are well known to have a negative effect on neighboring property values.

Thank you for considering these items. Should there be questions regarding these comments feel free to contact :

Cass County Minnesota Chapter of the Izaak Walton League of America

Minnesota Center for Environmental Advocacy

**Comments to Minnesota Pollution Control Agency on
Planned Amendments to Rules Governing Animal Feedlots, Minnesota Rules Chapter 7020,
Revisor's ID Number R-04928**

July 22, 2025

I. Introduction

Minnesota Center for Environmental Advocacy ("MCEA") appreciates the opportunity to submit these comments on the Minnesota Pollution Control Agency's ("MPCA") planned amendments to the rules governing animal feedlots, Minnesota Rules ch. 7020 ("Animal Feedlot Rule"). Minnesota has more than 20,000 feedlots, which produce 49 million tons of manure each year.[1] This manure, when stored in massive lagoons or spread on fields as fertilizer, runs off into surface waters, leaches into groundwater, and volatilizes into the air, ultimately polluting Minnesota's waters with dangerous bacterial coliforms and nutrients, particularly nitrate. The Animal Feedlot Rule, which governs these feedlots in order to limit discharges of pollutants, has not been comprehensively revised for 25 years. During that time, feedlot practices and our knowledge about nitrate pollution have changed significantly—but nitrate pollution in the state remains widespread, persistent, and dangerous to the health of Minnesota's residents and its rivers, lakes, and streams. Both MPCA and the U.S. Environmental Protection Agency ("EPA") have acknowledged that the state's current approach is not sufficient to address nitrate pollution in the state's surface waters and groundwater.

[1]Ethan Bahe, *Five Years After EWG's First Analysis, Manure Still Overloads Minnesota*, Environmental Working Group (May 15, 2025), https://www.ewg.org/research/five-years-after-ewgs-first-analysis-manure-still-overloads-minnesota (MCEA Ex. 23) ("EWG, Manure Overloads Minnesota").

In this context, MPCA has proposed considering changes to the Animal Feedlot Rule. To protect Minnesota's health and environment, and to comply with the strict protections for surface waters and groundwater in Minnesota law, MPCA must make significant changes to the Animal Feedlot Rule, including the following:

- Require State Disposal System Permits for feedlots with more than 600 animal units.
- Require Manure Management Plans to be submitted through the online Nutrient Management Tool for feedlots with more than 300 animal units, including feedlots from out of state that apply manure in Minnesota, and make manure application information from the online tool publicly available.
- Require monitoring of feedlot production areas and land application areas, including visual inspections for surface discharges, and underground monitoring for subsurface discharges based on the requirements of a Subsurface Discharge Monitoring Plan.
- Require additional best management practices for fall application of manure in Vulnerable Groundwater Areas, similar to practices required by the revised feedlot water pollution permits.
- Prohibit risky manure application practices statewide by (1) requiring larger setbacks from sensitive features, (2) prohibiting application of manure on frozen or snow-covered ground, and (3) prohibiting manure application when the risk of runoff from rainfall is high.
- Reduce allowed manure application rates to the rates recommended by the University of Minnesota Extension Service, with no deviations allowed or use of rates from contiguous states.
- Explicitly prohibit discharges from production areas or land application areas that may limit the use of groundwater as a potable water supply or may pollute the underground waters.
- Prohibit livestock from all feedlots from entering waters of the state, or at a minimum livestock from medium and large feedlots.
- Ensure multiple feedlots are considered a single feedlot for purposes of permit determinations when they (1) have common ownership, including ownership by entities that share some common owners, and (2) are located within three miles of each other or share a common liquid or solid manure storage area.

II. Minnesota has an ongoing nitrate pollution crisis, and a major source is manure from feedlots

Nitrogen is a nutrient that is applied to crops, in the form of animal manure or commercial fertilizer, to help them grow.[2] Once it has been applied to cropland, some of the nitrogen converts to different forms, including nitrate and ammonia, that can be used by plants.[3] When commercial fertilizer and manure are applied to croplands at too-high rates, at inopportune times, in vulnerable areas or near sensitive features, some of the nitrate may not be taken up by crops.[4] Nitrate is highly soluble in water, and it moves easily through soil, so unused nitrate is likely to leach through the soil and ultimately enter the groundwater.[5] As MPCA has stated, "[I]f it is not managed correctly, manure can result in pollution, and it can be a threat to human health."[6]

A. Nitrate is dangerous to humans, animals, and aquatic life

When too much nitrate makes its way to surface waters and groundwater, it endangers human health and aquatic life. [7] For humans, federal and state regulatory standards set the limit for nitrate in drinking water at 10 mg/L.[8] Drinking water with nitrate levels above this limit can cause methemoglobinemia, or blue-baby syndrome, which can lead to severe injury or death,

particularly for infants or pregnant people.[9] Recent research, however, has demonstrated that long-term exposure to nitrate levels well below the 10 mg/L limit is also linked to serious health risks.[10] Peer-reviewed medical research demonstrates that exposure to nitrate at or above 3 mg/L—less than one-third of the 10 mg/L limit—is linked to a variety of cancers, birth defects, and pregnancy complications. Numerous human-based epidemiological studies now show that exposure to nitrate at levels below the 10 mg/L limit and as low as 3 to 5 mg/L leads to a statistically significant increase in the risk for colorectal cancer,[11] thyroid cancer,[12] ovarian cancer,[13] and pregnancy/birth complications.[14]

In addition, the MPCA has concluded that nitrate levels of more than 5 mg/L for cold waters and 8 mg/L for other waters are unsafe for aquatic life, although it has not adopted a water quality standard based on this conclusion.[15] For ammonia, another form of nitrogen, Minnesota has set an aquatic life water quality standard of 4.1 mg/L for cold waters and 10.1 mg/L for other waters, but MPCA has recommended adopting EPA's even stricter, temperature-dependent standards for total

ammonia nitrogen.[16] Excess nitrate is toxic to fish and other aquatic life, and elevated levels of nitrate and other nutrients in surface waters cause algae blooms and eutrophication, which harm aquatic life by lowering oxygen levels in the water.[17] Exposure to nitrate and ammonia at toxic levels can lead to massive fish population die-offs, called "fish kills." In heavily agricultural areas, fish kill events have increased in intensity and frequency: the Rush Creek fish kill in July 2022, where MPCA concluded contaminated runoff killed more than 2,500 fish, was the fourth major fish kill in the Winona County area since 2015.[18]

Unfortunately, the effects of nitrate pollution do not stop in Minnesota. The 158 million pounds of nitrate that leave Minnesota annually via the Mississippi River are in part to blame for the hypoxic "dead zone" that forms every year in the Gulf of Mexico.[19] As of a 2025 draft update to the state's Nutrient Reduction Strategy, Minnesota needs to reduce total nitrogen loads from agriculture to the Mississippi River by 62 million pounds to meet its goals to improve downstream water quality.[20] One study estimates that nitrate from the Mississippi has caused $2.4 billion in annual damages to fish stocks and habitat for more than 30 years.[21]

B. Nitrate pollution in Minnesota's groundwater is widespread and longstanding, particularly in vulnerable groundwater areas

The contamination of Minnesota's surface waters and groundwater with nitrate is a pervasive problem that has been well documented for decades.[22] Contamination has remained persistent over time. In groundwater, an analysis from 2019 showed that 16% of wells in shallow aquifers tested had significant increases in nitrate, and another 63% had no improvement, between 2005 and 2017.[23] A more recent analysis by MDA of nitrate trends in 253 monitoring wells and 14 springs showed "that most sites continued to exhibit no change in nitrate concentrations from 2013-2023."[24] While some sites had downward trends, these trends "should not be interpreted to mean that concentrations are below the [10 mg/L limit]. Several sites, primarily in the state's agricultural areas, have downward trends in nitrate from 2013-2023, but the most recent concentration measured still was above 10 mg/L."[25] One monitoring well in Morrison County, for example, still showed a nitrate level of 33 mg/L despite a downward trend.[26]

Similarly, in surface waters, trends do not show significant improvement. A 2020 analysis of trends over the previous 20 years in the state's major rivers found increasing trends at half of the sites, with increases ranging from 21% to 55%.[27] Narrowing the focus to only the previous

[26] *Id*.
[27] Five Year Progress Report on NRS at 18.

decade showed that nitrate levels increased or at best showed no clear trend—none of the 38 sites studied by MPCA showed nitrate decreases in that time period.[28]

The problem of nitrate groundwater contamination is particularly acute in areas identified by MPCA as vulnerable groundwater areas—areas with karst geology, shallow depth to bedrock, or coarse textured soils, which are particularly susceptible to pollutants from the surface moving through soil to underground aquifers.[29] MPCA created a map of these regions, which will be referred to as "Vulnerable Groundwater Areas" or "VGAs."[30] This includes the Central Sands area, with its coarse-textured soil, in the middle of the state, and the southeastern karst region, which has significant areas of karst geology and shallow bedrock; these two areas "were determined to be the most vulnerable to and the most impacted by nitrate contamination."[31]

Nitrate pollution in groundwater in the karst region has been well-documented for decades. In karst geology, fractured bedrock is generally overlaid with shallow soils, allowing nitrate in soil water to move easily down into groundwater.[32] More than 30 years ago, MPCA documented high nitrate concentrations in wells in Minnesota's karst region, with nearly half of wells tested already exceeding the 10 mg/L limit.[33] In the past dozen years, numerous state studies have documented

wide-spread and persistent exceedances of the 10 mg/L limit in southeastern Minnesota's groundwater in both shallow wells and drinking wells. For example:

- From 2008–2018, the Southeast Volunteer Nitrate Monitoring Network tested approximately 300-500 private drinking water wells each year. Results ranged from a low of 7.5% (in 2012) to a high of 14.6% (in 2008) of wells testing above the 10 mg/L standard.[34]

- From 2013-2019, the Township Testing Program tested wells in vulnerable townships and found that 12.1% of the private drinking water wells tested across eight karst counties had nitrate levels above the 10 mg/L standard.[35] In two townships in Winona County, samples taken in 2017 showed more than 40% of wells in the initial testing set had more than 10 mg/L of nitrate.[36]

- In 2023, the Southeast Volunteer Nitrate Monitoring Network tested 374 private drinking water wells and found that 8% were over the 10 mg/L limit.[37]

- From 2014-2024, Minnesota Department of Agriculture ("MDA") analyzed between 37 and 43 samples of groundwater each year from ambient groundwater monitoring sites in southeastern Minnesota (PMR 9). Every year between 24% (in 2015) and 34% (in 2017 and 2018) of wells tested had nitrate levels above the 10 mg/L limit.[38]

Coarse-textured, or sandy, soils like those in the Central Sands pose a similar susceptibility to nitrate pollution[39] because sandy soils have a lower water-holding capacity and accordingly have more potential to lose nitrate from leaching than do finer textured soils.[40] One study showed that background losses of nitrogen in coarse-textured soils were around 20 to 50 pounds per acre,

as compared to 10 pounds per acre for fine-textured soils.[41] Data from state agencies show that exceedances of the 10 mg/L limit are also widespread and persistent in the Central Sands in both shallow wells and drinking water wells. For example:

- From 2011-2018. MDA's Central Sands Private Well Network tested approximately 300-500 private drinking water wells each year. Results ranged from a low of 2.2% (in 2017) to a high of 4.5% (in 2015) of wells tested above the 10 mg/L limit.[42]

- From 2013-2019, MDA's Township Testing Program tested thousands of private drinking water wells in vulnerable townships and found many violations of the 10 mg/L limit. In Morrison County, 15% of the 1,222 wells tested in the initial set were over the limit.[43] In Wadena County, 11.9% of the 269 wells in the initial set were over the limit.[44] In Hubbard County, 10.5% of the 1,106 wells in the initial set were over the limit.[45]

- From 2014-2024, a study by MDA analyzed between 74 and 86 samples of groundwater each year from ambient groundwater monitoring sites in the Central Sands region (PMR 4) and found that between 48% (in 2022) and 72% (in 2015 and 2016) had nitrate levels above the 10 mg/L limit.[46]

- In 2024, the Central Sands had the highest median concentration (14.7 mg/L); the highest 90th percentile concentration (28.0 mg/L), and the highest nitrate level (an astonishing 81.2 mg/L) of any region in the state.[47]

[47] MDA, *2024 Water Quality Monitoring* Report, at 6-3, 6-6 (June 2025), https://wrl.mnpals.net/node/4355 (MCEA Ex. 30).

Unfortunately, many of these vulnerable areas are also heavily agricultural, which makes the risks of nitrate pollution higher. More than 6,400 feedlots are located within VGAs.[48]

C. Most of Minnesota's nitrate groundwater pollution comes from croplands, including from manure applied to croplands

MPCA has acknowledged that the greatest source of Minnesota's groundwater nitrate pollution, including in the VGAs, is croplands. According to MPCA, "More than 70% of the nitrate in Minnesota waters is coming from cropland, the rest from regulated sources such as wastewater treatment plants, septic and urban runoff, forests, and the atmosphere."[49] In intensively agricultural areas of the state, nitrogen loads from cropland sources are even higher; such sources produce an estimated 89 to 95 percent of the load in the Minnesota, Missouri, and Cedar rivers, and the Lower Mississippi River basin.[50] State studies confirm this by showing intense groundwater pollution in agricultural areas. Groundwater monitoring data shows median nitrate concentrations in shallow wells in agricultural areas are four to eight times higher than the concentrations in urban areas.[51] Almost 40% of shallow wells in agricultural areas had nitrate levels above the 10 mg/L limit.[52] Water in soil beneath fields where corn is grown had far higher levels of nitrate—an average of 22.3 mg/L—than other lands uses, such as forests, lawns, or golf courses.[53]

The main cropland sources of nitrate pollution are both commercial fertilizer and manure applied as fertilizer, MPCA has acknowledged.[54] These two sources together accounted for 1.8 *billion* pounds of the nitrogen added to land in Minnesota in 2013, compared to 12 million pounds for lawn fertilizer and 9 million pounds for septic system drain fields.[55] Although manure accounts for only about 25% of the nitrogen applied to fields in the state (as compared to 75% for commercial fertilizer),[56] the use of manure is particularly problematic for nitrate pollution because producers often overapply nitrogen when they use manure as one of their nitrogen sources.

There are two key reasons why producers commonly overapply nitrogen when they use manure as fertilizer. First, manure often is treated as a waste product. Minnesota's feedlots house up to 1.6 million beef and dairy cattle, 10.8 million hogs, and 58.7 million turkeys and chickens, which produce nearly 49 million tons of manure every year—which is disposed of by spreading it, untreated, on croplands.[57] The need to dispose of manure leads some producers to apply it not in response to crop needs but instead because storage space is running out or because of the need to work around wet weather or other production processes.[58] Manure also may be overapplied at fields nearest the livestock operation to free up storage capacity without incurring the expense of transporting the manure further away.[59]

Second, producers often fail to accurately account for the amount of nitrogen in manure, and thus overapply it. The nitrogen content in manure is highly dependent on many variables,

[59] *See id.*

including type of manure, storage methods, climatic conditions, and more,[60] and the nitrogen in manure is not all immediately available for plants to use for growth.[61] The uncertainties mean producers "frequently over-apply manure" because they do not properly credit the amount of nitrogen in the manure.[62] Encouraging this practice, the University of Minnesota Extension Service ("Extension Service") recommends applying *more* nitrogen per acre when manure is used, as compared to commercial fertilizer.[63] Studies and farmer interviews show producers apply more nitrogen when manure and fertilizer are applied than when only non-manure sources are used.[64]

Across the state, Minnesota's producers are simply applying more nitrogen than crops need through a combination of commercial fertilizer and manure. In 2018, MDA stated that by a conservative estimate, Minnesota producers could reduce nitrogen application by 200 million pounds each year while still maintaining "optimum yields."[65] With respect to the southeastern karst region in particular, an analysis by environmental scientist Christopher Jones found that between the commercial fertilizer sold and the animal manure produced in the region, producers are applying 60 million pounds of nitrogen more than their crops need each year.[66] This amount of nitrogen could contaminate approximately 722 billion gallons of water to a level exceeding the

10mg/L limit and water quality standard.[67] A 2025 study by the Environmental Working Group found that in nine Minnesota counties, nitrogen in manure produced by feedlots combined with nitrogen in fertilizer purchased in the county exceeded recommendations for the Extension Service's nitrogen application rates by more than 40%.[68]

D. Unsafe manure management practices also lead to coliform impairments

Beyond the widely documented nitrate contamination trends in public and private water supplies, there are also other microbial contaminants associated with manure that impact public health—further emphasizing the need for responsible manure management. Coliforms are a standard indicator of drinking water quality associated with acute gastrointestinal illness, and the goal under the Safe Drinking Water Act for these contaminants is set at zero.[69] Yet 243 Minnesota waters are listed as impaired for fecal coliform, and another 672 are listed as impaired for E. coli (one of the main fecal coliforms).[70]

One of the main sources of bacteria in surface waters—including coliforms—is runoff from feedlots and land application sites. MPCA has stated that one of the most effective ways to reduce coliforms in water is to ensure this runoff is controlled.[71] This is supported by a 2021 study in Northeastern Wisconsin that analyzed private well contamination data across a five-county region with vulnerable fractured bedrock and concentrated dairy feedlot production, similar to the karst region of Southeastern Minnesota. Of the 6,739 wells sampled for microbial contamination, 23%

tested positive for total coliforms.[72] The primary risk factors for coliform detection were bedrock depth (which determines groundwater vulnerability) and distance to the nearest manure storage structure, with wells located within 48 meters of manure storage structures 87% more likely to have coliform detection than wells 4,000 meters away.[73] The single risk factor most associated with an increase in coliform concentration levels was the distance to the nearest field with a nutrient management plan where commercial fertilizer and animal manure were land applied.[74] Practices that reduce manure runoff, accordingly, are critical to addressing not only nitrates but also dangerous bacteria.

E. Minnesota's efforts to control nitrate pollution have not met the state's nutrient reduction goals or adequately protected drinking water supplies

Although the causes and dangers of nitrate and bacterial pollution have long been known, Minnesota state agencies have not taken effective steps to control this pollution, despite express direction from the Legislature to the state agencies to address groundwater pollution from agricultural sources.[75] For decades, Minnesota's agencies have implemented programs, policies, and even rules—including the Animal Feedlot Rule—that attempt to address nitrate pollution. Yet groundwater and surface waters across the state continue to show persistent levels of contamination and even increases in nitrate loads and concentrations. The state's Clean Water Fund alone has directed at least $148 million to the nitrate problem since 2010, according to a Star Tribune analysis, and millions more in federal and state funding have paid for efforts that include nitrate research, programs and training to encourage farmers to make voluntary changes to

[72] Mark A. Borchardt et al., *Sources and Risk Factor for Nitrate and Microbial Contamination of Private Household Wells in the Fractured Dolomite Aquifer of Northeastern Wisconsin*, Environmental Health Perspectives 129(6), at 3-4 (June 2021) (MCEA Ex. 8).

practices, and nitrate filtration systems for several cities.[76] The response from state agencies has included a combination of regulatory and voluntary conservation programs, with an emphasis on voluntary incentives. These voluntary incentives, encouraged by technical and financial assistance from governmental programs, have not achieved the necessary reductions in nitrate pollution.[77] Despite the development of the updated Nitrogen Fertilizer Management Plan, the Groundwater Protection Rule, and the Nutrient Reduction Strategy over the past decade, there have not been significant decreases in nitrate levels in surface waters or groundwater.

MPCA has acknowledged that its current regulations and voluntary best management practices are insufficient to protect groundwater from pollution.[78] MPCA's own progress report on nutrient management practices in 2020 admitted that none of the nutrient management practices adopted during the past decade were "expected to yield measurable nutrient reductions to surface waters at a large scale."[79] MPCA's website acknowledged that refinements in fertilizer rates and application timing could reduce nitrate loads by roughly 13% statewide, but "additional and more costly practices will be needed to make further reductions."[80] As the agency has stated, "statewide reductions of more than 30% are not realistic with current practices."[81] In making incremental

changes to the water pollution permits that govern the state's largest feedlots, MPCA stated, "There are serious nitrate issues in the vulnerable areas of Minnesota that will necessitate changes to current crop production practices."[82] Only with significant regulatory changes—and enforcement of those changes—will Minnesota make progress on the nitrate pollution problem.

F. EPA has instructed Minnesota to make changes to address nitrate pollution

Not only are changes to address Minnesota's nitrate pollution compelled by the facts, the EPA has instructed MPCA to address this problem. In April 2023, MCEA led a coalition of 11 national, regional, and local organizations in submitting a petition that asked the EPA to use its powers under the Safe Drinking Water Act to address the "imminent and substantial endangerment to human health" posed by groundwater nitrate contamination in Minnesota's karst region.[83]

On November 3, 2023, the EPA responded with a letter to the MPCA, MDA, and Minnesota Department of Health regarding nitrate pollution in the karst region, stating "there is an evident need for further actions to safeguard public health."[84] The EPA directed state agencies to take immediate action to safeguard public health in the region, and to "hold sources of nitrate accountable using all available tools to reduce the amount of nitrate they release to ground water."[85] Specifically, the EPA encouraged the state to consider modifications to its nutrient management standards in karst areas with regard to land application of manure.[86]

[86] *Id.*

II. MPCA has the authority and the duty to change the Animal Feedlot Rule to comply with water protection requirements in state and federal law

MPCA has the authority and the duty under Minnesota and federal law to protect the state's groundwater and surface waters from manure-related pollution, but its current Animal Feedlot Rule does not fulfill this duty, based on the widespread and persistent violations of water quality standards caused by feedlot-related pollution.

Federal and state laws contain critical and stringent protections for the state's surface waters and groundwater, and MPCA has the duty to enforce these protections.[87] Under the Clean Water Act, MPCA has the obligation to set and enforce water quality standards to protect "designated uses" in particular water bodies—such as waters used for drinking, recreation, or aquatic life.[88] These water quality standards must protect public health or welfare, enhance the quality of water, and ensure that the water is clean enough to be safe for the designed uses.[89] Under state law, this authority is confirmed and expanded, with MPCA required to protect "waters of the state," which include both surface waters and groundwater.[90] The agency's duties include adopting

[87] Minn. Stat. § 115.03, subd. 1(a)(1).
[88] *See* 33 U.S.C. § 1313; 40 C.F.R. §§ 131.3(f), .10, .11.
[89] 33 U.S.C. § 1313(c)(2)(A); 40 C.F.R. § 131.11(a)(1).
[90] Minn. Stat. § 115.01, subd. 22 ("'Waters of the state' means all streams, lakes, ponds, marshes, watercourses, waterways, wells, springs, reservoirs, aquifers, irrigation systems, drainage systems and all other bodies or accumulations of water, surface or underground, natural or artificial, public or private, which are contained within, flow through, or border upon the state or any portion thereof.").

and enforcing rules "in order to prevent, control or abate water pollution."[91] Specifically, MPCA must issue rules that:

- Prohibit the discharge of wastes[92] into the waters of the state, or to deposit wastes "where the same is likely to get into any waters of the state" in violation of Minnesota's rules and pollution standards.[93]
- Require adoption of remedial measures "to prevent, control or abate any discharge or deposit of … wastes by any person."[94]
- Require establishment of systems of recordkeeping, sampling, monitoring, and reporting by dischargers for provision of information to the agency.[95]
- Include additional limits if technology-based standards are not adequate to maintain water quality standards.[96]

Pursuant to this authority, MPCA has set policies and rules to protect both groundwater and surface waters. For groundwater, MPCA has adopted an antidegradation policy, under which it must "consider the actual or potential use of the underground waters for potable water supply as constituting the highest priority use and as such to provide maximum protection to all underground waters."[97] For surface waters, MPCA's policy "is to protect and maintain surface waters in a condition which allows for the maintenance of all existing beneficial uses."[98] In other words, surface waters should not be polluted in a way that stops a current use—such as for drinking water or sustaining aquatic life.

[91] Minn. Stat. § 115.03, subd. 1(a)(5).
[92] Although certain components of land-applied manure may be used by plants, where manure, nutrients, or other pollutants escape their intended use and are instead discharged into waters of the state those pollutants are properly characterized as "other wastes," which as defined includes "agricultural waste" and "biological materials." Minn. Stat. § 115.01, subd. 9.
[93] Minn. Stat. § 115.03, subd. 1(a)(5)(ii).
[94] Minn. Stat. § 115.03, subd. 1(a)(5)(iv).
[95] Minn. Stat. § 115.03, subd. 1(a)(5)(vii).
[96] Minn. Stat. § 115.03, subd. 1(a)(5)(viii).
[97] Minn. R. 7060.0200.
[98] Minn. R. 7050.0150, subp. 1.

To implement these policies, MPCA has adopted water quality standards to protect surface waters and groundwater. For Class 1 waters—all waters used for drinking water, including all groundwater in the state—MPCA has set a water quality limit for nitrate at 10 mg/L.[99] MPCA also prohibits any wastes from point or nonpoint sources to be discharged into or permitted to gain access to any Class 1 waters in the state "so as to cause any material undesirable increase in the . . . nutrient content, or in any other manner to impair the natural quality or value of the waters for use as a source of drinking water."[100] As an additional protection for groundwater, MPCA adopted a prohibition against discharges of waste and pollutants into the unsaturated zone (the area between the land surface and the water table) that "may actually or potentially preclude or limit the use of the underground waters as a potable water supply, nor shall any such discharge or deposit be allowed which may pollute the underground waters."[101]

For Class 2 waters—those that may support aquatic life, which includes virtually all surface waters in Minnesota—there is no numeric standard for nitrate. However, there is a "narrative" water quality standard—an enforceable, descriptive standard—that prohibits degrading the water quality "in any material manner." The narrative standards also require that

> there shall be no material increase in undesirable slime growths or aquatic plants, including algae, nor shall there be any significant increase in harmful pesticide or other residues in the waters … the normal aquatic biota and the use thereof shall not be seriously impaired or endangered, … and the propagation or migration of aquatic biota normally present shall not be prevented or hindered by the discharge of any sewage, industrial waste, or other wastes to the waters.[102]

---

[99] Minn. R. 7050.0221, subps. 2–4 (incorporating the limit from 40 C.F.R. § 141.62(b)(7)).
[100] Minn. R. 7050.0221, subp. 6.
[101] Minn. R. 7060.0600, subp. 2. This rule does not prohibit the use of chemicals and fertilizers for crops only if "such practices do not pose a significant pollution hazard." Minn. R. 7060.0600, subp. 5. As land application of manure is causing pollution of groundwater—as admitted by MPCA—this exception for fertilizer does not apply.
[102] Minn. R. 7050.0150, subp. 3.

Additionally, for Class 2 waters, ammonia is limited to 4.1 mg/L in cold waters and 10.1 mg/L for other waters.[103]

Accordingly, under state and federal law, MPCA is required to take actions to protect both surface waters and groundwater from nitrate, nutrient, and bacterial pollution in excess of these standards. As the Animal Feedlot Rule self-evidently is not ensuring that these standards are met, it is inadequate under state and federal law, and it must be revised to ensure these water quality standards are not subject to further exceedances due to pollution from manure.

III. MPCA must make changes to its Animal Feedlot Rule to comply with state and federal law and address nitrate pollution

Based on decades of research, MPCA knows of practices that significantly reduce or prevent nitrogen loss from croplands. However, these practices have not been required in the Animal Feedlot Rule, making it inadequate to protect Minnesota's surface waters and groundwater. MPCA must make extensive changes to make the rule more effective and address nitrate pollution.

A. MPCA should require water pollution permits for feedlots with more than 600 animal units

Under the current Animal Feedlot Rule, only the largest feedlot operations, called Concentrated Animal Feeding Operations, or CAFOs—those with more than 1,000 animal units[104]—require federal National Pollutant Discharge Elimination System ("NPDES") or State

[103] MPCA, *Aquatic Life Quality Standards for Ammonia: Draft Technical Support Document* 19 (July 2022), https://www.pca.state.mn.us/sites/default/files/wq-rule4-25b.pdf.

[104] An animal unit is a way of comparing different-sized animals by the amount of manure they produce. One animal unit is equal to one 1,000 lb. beef steer, .3 hogs of 55 to 300 lbs., or .005 chickens over 5 lbs. Minn. R. 7020.0300, subp. 5. To require a water pollution permit, then, a feedlot would need to have more than 1,000 beef cattle, 3,334 market hogs, or 200,000 chickens. *See* Minn. R. 7020.0300, subp. 5 (defining animal units under Minnesota Rules); Minn. R. 7020.0405, subp. 1(B) (requiring an SDS permit for feedlots with 1,000 or more animal units). MPCA, *Livestock and the Environment* 4 (Jan. 2021), https://www.pca.state.mn.us/sites/default/files/wq-f1-01.pdf (MCEA Ex. 40).

Disposal System ("SDS") permits for water pollution.[105] This means only about 4% of Minnesota's more than 23,000 feedlots require federal or state water pollution permits.[106] It is critical for these largest feedlots to have permits, because they produce about one-third of the state's manure.[107] However, the remaining feedlots produce two-thirds of the manure generated in Minnesota and have fewer restrictions on their management and application of manure because of their lack of permit coverage. MPCA should lower the SDS permit threshold to 600 animal units to ensure that more feedlots are required to follow the stricter provisions of state water pollution permits. Based on current registration data, this would cover approximately 10% of registered cattle, poultry, and swine feedlots in Minnesota and an additional 26% of manure generated by animal feedlots in the state.[108]

The benefit of this rule change to better protect groundwater from the improper application of nutrients from animal manure on cropland is clear: when combined with the current permit coverage under state and federal law, this would mean that approximately 60% of the manure generated by animal feedlots in Minnesota would be subject to the land application requirements of state and federal permits. These permit requirements were revised in January 2025 to better

[105] 40 CFR § 122.23; Minn. R. 7020.0405, subp. 1(B)(1) (requiring SDS permits for feedlots with 1,000 or more AUs).

protect VGAs of the state with additional steps to minimize the risk of nitrate loss to groundwater when manure is land-applied in the fall or on frozen, snow-covered ground. Of the registered feedlots that fall between 600 and 999 animal units that would be covered under a lower permit threshold, approximately 14% are located within VGAs as defined in the January 2025 permit feedlot revision, and approximately 35% of all feedlots in the 600-999 animal units range are within a one-mile buffer of VGAs and therefore likely land apply manure within VGAs[109] (see Figures 1 and 2).

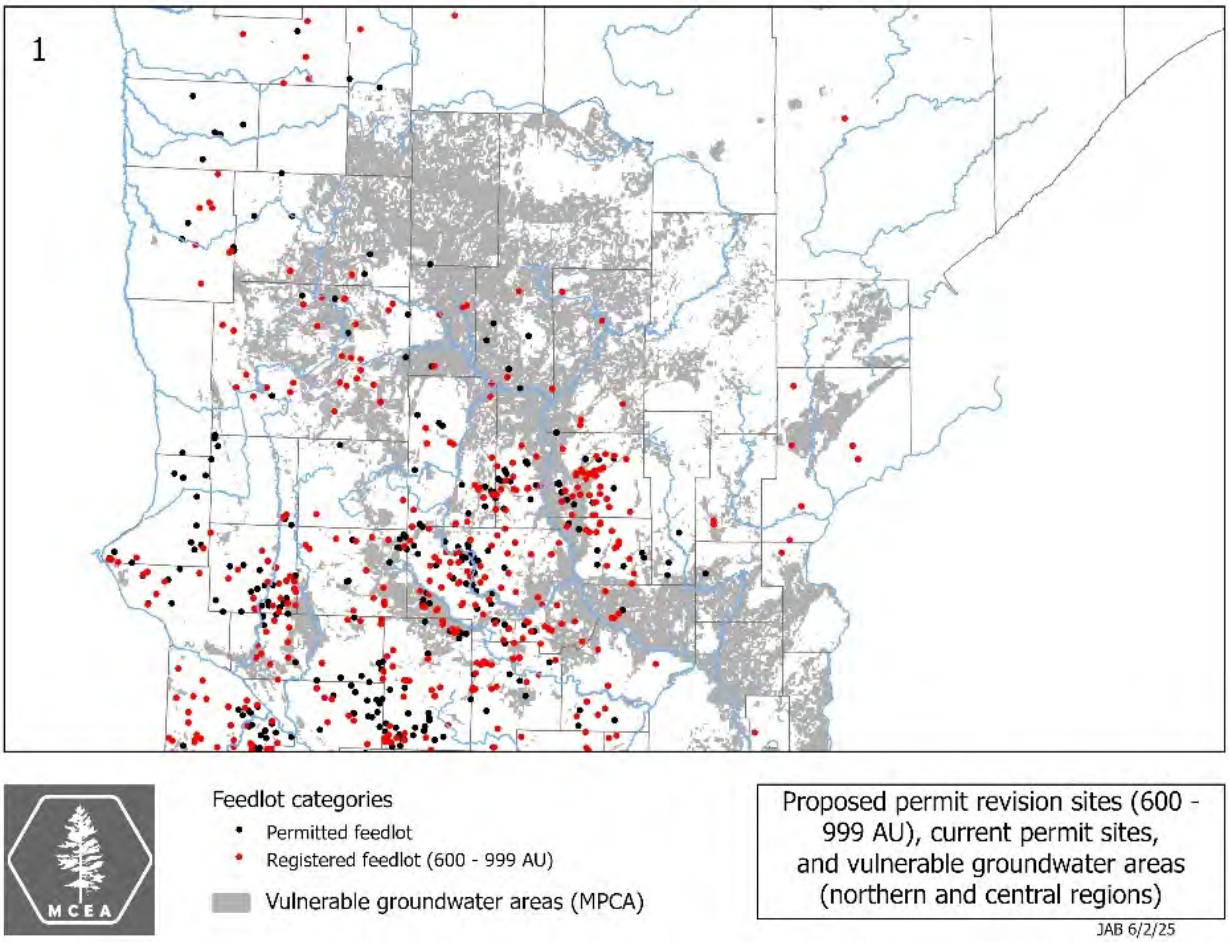

Figure 2: Proposed permit revision feedlot sites in northern and central regions vulnerable groundwater areas. Map created by Jim Berg with data from the Minnesota Geospatial Commons.

MPCA's NPDES and SDS permits impose a number of conditions that are not explicitly set forth in the Animal Feedlot Rule in order to "achieve compliance with state and federal statutes/rules" and "to protect human health and the environment."[110] For example, both permits impose additional limits on application of manure, including requiring manure to be incorporated into the soil if rainfall is predicted[111] requiring manure applied in June, July, August, or September to be added to a growing crop or cover crop[112] imposing additional restrictions on application of

[112] *Id*. at § 13.4.

manure in October and November in VGAs,[113] and restricting application of manure to frozen or snow-covered ground.[114] The permits also require some visual inspections and monitoring of discharges[115] and that manure transferees follow the feedlot's manure management plan,[116] along with other provisions to control pollution discharges. Feedlots with permits are also required to follow additional reporting requirements,[117] including submission of their manure management plans and manure application records,[118] construction reports,[119] facility maintenance reports,[120] and discharge reports.[121] These are important provisions for nitrate pollution, but the vast majority of the state's feedlots do not have to follow them.

Minnesota has many feedlots that are quite large, and that produce many tons of manure every year, but that are not subject to these rules. More than 2,300 cattle, poultry, and swine feedlots fall between 600 and 999 animal units, and these feedlots produce 25.8% of all the manure generated in the state.[122] For certain animal categories like swine, feedlots that fall between 600 and 999 animal units account for approximately 44% of the manure generated by swine feedlots statewide.[123] While currently not subject to the state SDS permit, each of these feedlots still produces a massive amount of manure. For example, a feedlot with 600 animal units of beef cows, or about 600 cows, would produce around 10,000 tons of solid manure or 2.4 million gallons of

liquid manure each year.[124] This quantity of manure should require careful handling in order to minimize water pollution. The practices required by the permits have been determined by MPCA to be useful for reducing pollution and reasonable for feedlots to follow. Accordingly, requiring certain feedlots of less than 1,000 animal units to follow these requirements would help reduce water pollution.

MPCA has the authority to reduce the permit threshold for SDS permits to 600 animal units. NPDES permits are federal permits, and federal law requires that they be issued for feedlots with more than 1,000 animal units that discharge to the waters of the United States.[125] SDS permits, however, are state permits, and MPCA has the authority within the Animal Feedlot Rule to set the threshold for these permits at a different level than 1,000 animal units.[126] Currently, a feedlot that is required to obtain an SDS permit may choose to obtain a NPDES permit instead, so if the threshold for SDS permits decreased, producers might choose to obtain a NPDES permit instead.[127] As the provisions of the SDS and NPDES permits are largely similar with respect to land application of manure, inspection requirements, reporting obligations, and other provisions, allowing producers to obtain NPDES permits instead of SDS permits would provide many of the same protections. Lowering the SDS threshold to 600 animal units would increase the number of feedlots that have to follow critical regulation that would reduce water pollution, and MPCA should revise Minnesota Rule 7020.0405, subpart 1 to make this change.

B. MPCA should require Manure Management Plans to be submitted for feedlots with more than 300 animal units through the new Online Nutrient Management Tool

Although the current Animal Feedlot Rule requires most feedlots with more than 300 animal units to create a Manure Management Plan ("MMP"),[128] only the largest feedlots—those that are required to apply for an SDS or NPDES permit (and feedlots that need interim permits because they were identified as pollution hazards)—are required to submit that plan to MPCA (or the county feedlot officer).[129] Requiring all feedlots with more than 300 animal units to create and submit MMPs annually through MPCA's new online Nutrient Management Tool would ensure that more feedlots manage and apply their manure according to appropriate plans, which would help to reduce pollution. It would also ensure that those plans are readily available for review by the MPCA or, in delegated counties, by the county feedlot officer. In addition, information from the online tool regarding manure application in fields should be made publicly available to community members for review. This rule change would provide greater oversight and accountability for the land application of manure from medium feedlots in Minnesota, which accounted for 18% of all feedlot operations in the state as of 2025 but generated the largest share of manure at 43%.[130]

[128] Under Minn. R. 7020.2225, subp. 4(A)(1), a facility must prepare a Manure Management Plan when it applies for a NPDES, SDS, or construction short-form permit construction permit for a facility capable of holding 100 or more animal units. Facilities with 300 or more animal units need to obtain a construction short-form permit under Minn. R. 7020.0405, subp. 1(D). A feedlot with 300 or more animal units that is not required to obtain a permit must prepare a manure management plan when manure is applied by someone other than a professional applier. Minn. R. 7020.2225, subp. 4(A)(2). Accordingly, under the rules, most feedlots with more than 300 animal units need to create an MMP and once it is created, to update it annually. Minn. R. 7020.2225, subp. 4(C).
[129] Minn. R. 7020.2225, subp. 4(B).
[130] EWG, Manure Overloads Minnesota (MCEA Ex. 23).

Manure, "in general, is complicated."[131] When manure is applied to fields, the risks of nitrate pollution can depend on factors such as "rate calculations, sampling, setbacks and buffers, [and] spreader calibration [application]."[132] MMPs are critical to ensuring that manure is applied at appropriate rates, times, and places, as such plans require producers to identify the amount of manure that will be spread, where and how it will be spread, the planned application rate, the other sources of nutrients that will be applied, and a description of the protective measures to minimize water pollution when applying manure in sensitive areas.[133] Without creating such a plan, it is difficult for producers to determine whether they are applying their manure appropriately to minimize the risk of water pollution.[134] Because overapplication of nitrogen is so common in Minnesota, particularly when manure is used, the use of MMPs is crucial for decreasing the risk of water pollution.

Changes to the rule will make the use of MMPs more effective. First, requiring all medium feedlots of 300 to 999 animal units (hereinafter, "medium feedlots")[135] to submit an MMP to a regulatory authority will ensure that medium-sized feedlots are required to do critical annual planning to ensure excess nitrogen is not applied to their fields. Most of these feedlots are already supposed to create a MMP,[136] so simply requiring them to use the online Nutrient Management Tool to submit it would provide little extra burden on producers.

[135] Medium feedlots are defined by the EPA as those with more than 300 animal units. EPA, *Regulatory Definitions of Large CAFOs, Medium CAFO, and Small CAFOs*, https://www3.epa.gov/npdes/pubs/sector_table.pdf (last visited July 18, 2025) (MCEA Ex. 43).
[136] *See* Minn. R. 7020.2225, subp. 4(A).

Second, requiring all feedlots to use MPCA's new Nutrient Management Tool will make MMPs more effective at minimizing water pollution. Currently, only feedlot operators that submit permits directly to the MPCA, rather than to delegated county feedlot officers, are required to use the online tool. The new tool incorporates maps with information on where manure application restrictions apply, including VGAs, sinkholes, tile inlets, wells, surface waters, ditches, and floodplains.[137] These features will help users identify sensitive features at the field scale and are an improvement from previous MMP practices, when MPCA merely provided a list of sensitive features that the feedlot operator had to then identify themselves in their fields. The new tool will also allow an analysis of acres used for land application to ensure that the same fields are not being used by more than one feedlot.[138] Operators that receive manure from a registered feedlot operator should be required to use the digital Nutrient Management Tool as well to ensure they are following the requirements of the land application rule, and if appropriate, the feedlot's permit.[139]

Third, any medium and large feedlots located outside of Minnesota that intend to spread manure inside the state should be required to create, submit, and follow an MMP that meets the requirements of the Animal Feedlot Rule (and require their transferees to follow that MMP) if they have more than 300 animal units. Manure does not become less polluting merely because it crosses state lines, and in recent years more large feedlots constructed on the borders of the state have sent—or plan to send—their manure into Minnesota for field application. For example, Riverview Dairy plans to build a 12,500-cow dairy new Abercrombie, N.D., and a 25,000-cow dairy near

---

[138] MPCA Responses to Feedlot Comments, at 93.

[139] The January 2025 revision of the Minnesota General Feedlot Permit requires people who receive transferred manure from feedlots with a NPDES or SDS permit to follow the requirements of the permit in addition to the requirements of the feedlot rule.

Hillsboro, N.D., both along the Minnesota border.[140] Both of these facilities intend to apply some of the 321 million gallons of manure they will produce[141] across the border in Minnesota—the dairy near Hillsboro intends to spread its manure on around 1,180 acres in Minnesota.[142] This may only be the vanguard of more across-the-border feedlots, as North Dakota is taking steps to encourage more livestock production.[143] Facilities should not be allowed to circumvent regulations that protect the health of Minnesotans and its waters by simply locating across state lines.

Finally, the information from the new tool regarding how manure will be applied should be made public through the Minnesota Geospatial Commons, so that community members can confirm that producers are following their MMPs and that fields are not receiving manure from multiple feedlots. Because of MPCA's and delegated counties' limited resources for enforcement and inspections, enlisting the public will help ensure MMPs are properly followed.

These proposed rule changes are particularly important in VGAs. In a May 2025 report, the Environmental Working Group found significant overlap between counties overloaded with nitrogen (defined as counties where nitrogen from manure and commercial fertilizer inputs exceed the Extension Service crop recommendations by more than 40%) and VGAs as defined by the MPCA (see Figure 3). Of the 6,480 feedlot operations that fell within VGAs in 2024, only 161 are above the 1,000-animal unit permit threshold and required to submit MMPs directly to MPCA

through the new online Nutrient Management Tool. Nearly five times that number (791 facilities) fall into the medium category.[144] Therefore, this proposed rule change would increase the number of feedlot operations within VGAs that have to submit MMPs through the MPCA's online Nutrient Management Tool from approximately 2% to just under 15%,[145] further ensuring that more feedlots are creating appropriate plans to reduce pollution.

[144] EWG, Manure Overloads Minnesota (MCEA Ex. 23).
[145] *Id.* (161 facilities represents just under 2.5% of the 6,480 feedlots in VGAs; adding the 791 medium facilities to this figure results in just under 15% of the 6,480 feedlots in VGAs).

C. MPCA should require monitoring of feedlot production areas and land application areas for surface and subsurface discharges

Although MPCA added some minimal visual inspection requirements to its new NPDES and SDS permits for feedlots, the Animal Feedlot Rule currently has few requirements for inspections or monitoring to ensure that Minnesota's feedlots are not causing water pollution. The rule has some provisions for inspections of newly constructed liquid manure storage areas, manure compost sites, and poultry barn floors,[146] but it contains no other requirements for inspections or monitoring of production areas or land application areas. To ensure compliance with the Animal Feedlot Rule and identification of facilities that are causing pollution problems, MPCA should add inspection and monitoring requirements, both for production areas and land application sites.

The Animal Feedlot Rule has several prohibitions on discharges to Minnesota's waters. It prohibits discharges of manure from any feedlots into any channels that convey fluids to groundwater or from CAFOs to surface waters of the state unless authorized by a permit.[147] The rule also prohibits land application of manure in a manner that will result in a discharge to the waters of the state during the application process or cause pollution of the waters of the state due to manure-contaminated runoff.[148] In addition, Minnesota's rules prohibit the discharge of wastes to the unsaturated zone that "may pollute the underground waters"[149] and for surface waters prohibit significant increases in harmful residues and pollutants that harm aquatic life. [150] However, there are essentially no monitoring or inspection requirements to ensure that these prohibitions are

[148] Minn. R. 7020.2225, subp. 1(A)(1)-(2).
[149] Minn. R. 7060.0600, subp. 2. This rule does not prohibit the use of chemicals and fertilizers for crops only if "such practices do not pose a significant pollution hazard." Minn. R. 7060.0600, subp. 5.
[150] Minn. R. 7050.0150, subp. 3.

met. Nor do inspections by MPCA's feedlot staff fill this hole. MPCA has only a limited staff to inspect the state's more than 20,000 feedlots—generally, the goal is for agency staff to inspect each MPCA-permitted feedlot once per decade. For counties with delegated authority over feedlots, the goal is to inspect at least 7% of the total number of registered feedlots in the county per year:[151] in counties with many feedlots this can lead to inspections even less frequently than once per decade.

Clearly, neither feedlot inspections nor monitoring are sufficient to prevent discharges from production facilities and land application areas that are causing or contributing to water pollution. While the NPDES and SDS feedlot permits in Minnesota require regular visual inspections of liquid manure storage area freeboard markers and perimeter drain tile, there are no requirements to monitor impacts to groundwater below production areas or to groundwater or drain tile below land application fields.[152] This makes it impracticable or even impossible to consistently identify facilities that meet the definition of a pollution hazard or have violated the Animal Feedlot Rule or the terms of the NPDES and SDS permits.

Multiple courts have held that feedlot permits that do not include monitoring provisions sufficient to ensure compliance with their terms do not meet the requirements of the law, as such permits are of little use.[153] For example, the Washington Court of Appeals found that "[m]onitoring is necessary because it is meant to ensure that dischargers act in compliance with permit

[151] Minn. Stat. § 116.0711 subd. 2c.

[152] *See* MPCA, *Feedlot Inspection Records: NPDES and SDS Permitted Sites* (2025), https://www.pca.state.mn.us/sites/default/files/wq-f5-21.pdf (MCEA Ex. 46).

[153] *Food & Water Watch v. Env't Prot. Agency*, 20 F.4th 506, 515 (9th Cir. 2021) ("Our case law confirms that NPDES permits must contain monitoring provisions sufficient to ensure compliance with the terms of a permit.") (internal citation omitted); *Nat. Res. Def. Council v. Env't Prot. Agency*, 808 F.3d 556, 583 (2d Cir. 2015) (quoting *Nat. Res. Def. Council, Inc. v. conditions."[154] The court explained that without such monitoring, permits "contain inherent contradictions that would render them unenforceable," because they prohibit certain discharges while simultaneously allowing conduct which would result in those same discharges.[155] The court found this concept specifically applied to groundwater monitoring. The previous permits contained a condition "that '[d]ischarges conditionally authorized by this permit must not cause or contribute to a violation of water quality standards.'"[156] The Washington Court of Appeals stressed that "[e]nsuring compliance with this condition requires analyzing the effects of a CAFO's activities on groundwater"; and that the agency's own research concluded that "groundwater monitoring . . . is the single method available to ascertain a CAFO's direct impact on groundwater quality."[157]

Similarly, the Ninth Circuit vacated an Idaho permit due to lack of monitoring requirements. The Idaho permit prohibited "discharges of pollutants from production areas" (with a single exception) and "[d]ry-weather discharges from the land-application area," but had no monitoring provisions to ensure these prohibitions were met.[158] The court concluded that "[w]ithout a requirement to monitor runoff from irrigated CAFO fields, there is no way to ensure that a CAFO is complying with the Permit's dry weather no-discharge requirement for land-application areas."[159] In reaching this conclusion, the Ninth Circuit relied on a prior ruling in which

it found explicitly that "an NPDES permit is unlawful if a permittee is not required to effectively monitor its permit compliance."[160]

To address the Ninth Circuit's decision in that case, the EPA established new permit requirements for CAFOs in Idaho.[161] For production areas, the Idaho permit now requires all permitted feedlots to prepare a Subsurface Discharge Monitoring Plan ("SDMP") "to identify and monitor any functionally equivalent subsurface discharges to Waters of the United States ["WOTUS"] from each wastewater or manure storage structure."[162] The only exceptions to this requirement are if one of the following criteria are met: either a) a "Professional Engineer, geologist, hydrogeologist or another qualified individual" documents that the storage structure does NOT have a subsurface discharge to WOTUS; or b) the permittee confirms and maintains documentation in the MMP "that each wastewater and manure storage structure is constructed of concrete or steel, or with a double-layer synthetic liner with leak detection."[163] The SDMP itself must include "site-specific information and procedures" that outline routine, periodic monitoring "adequate to identify leaks, damage, and other issues that could cause a functionally equivalent subsurface discharge, including the frequency of monitoring and the site-specific technology or protocols that will be used."[164]

[163] *Id.* § III.A.2.iii.a-b.
[164] *Id.* § IV.D.6.b.

To assess compliance with the prohibition on dry weather discharge for land application areas, the Idaho Permit imposes specific monitoring requirements, including the collection of grab samples "prior to mixing with the receiving waters" as well as upstream and downstream of the point of discharge to the receiving stream.[165] The permit also requires soil samples to be "taken from every field to which manure, litter, and process wastewater will be applied."[166] The soil samples must be analyzed by a certified laboratory for pH, soil organic matter, Nitrate-Nitrogen, Ammonium-Nitrogen, and phosphorus.[167] Finally, the results of these soil sample analyses must be included in the MMP and used to determine application rates.[168]

This concept established in both the Washington and Idaho court decisions that permits must include adequate monitoring to ensure compliance applies equally to the Animal Feedlot Rule—a rule that requires feedlots to take no steps to ensure they are complying with its prohibitions is not an effective rule. MPCA has the authority to include monitoring and inspection provisions in the rule. It has been specifically entrusted by the Legislature with the authority to require owners or operators of point sources to install and maintain monitoring equipment needed to prevent and abate pollution.[169] Accordingly, it should add provisions to the Animal Feedlot Rule to require adequate monitoring both at land application areas and production areas to ensure compliance with the Rule.

1. Land application areas

At a minimum, the Animal Feedlot Rule should be revised to add visual inspection requirements for land application areas for all medium (over 300 animal units) and large feedlots,

[165] *Id.* § IV.E.1.
[166] *Id.* § III.A.2.g.ii.
[167] *Id.* § III.A.2.g.ii-iii.
[168] *Id.* § III.A.2.g.ii.
[169] Minn. Stat. § 115.03, subd. 1(a)(5)(vii).

similar to those added to the NPDES and SDS feedlot permits. The new feedlot permits have added requirements for visual inspections of land application fields at all downgradient field edges; sensitive features including tile intakes, sinkholes, and wells; ditches; and other features that could convey manure to waters.[170] These inspections must take place at least once on each day of manure application, at the end of each day of application, and after any significant rainfall within 14 days after application unless the manure is injected or incorporated.[171] Any discharge must be responded to and reported to the State Duty Officer and the MPCA.[172] These requirements are not overly burdensome; they do not require investing in expensive equipment or even expending a significant amount of time. Instead, they are common-sense provisions that take the first necessary step toward adding monitoring provisions that will ensure compliance with Minnesota's rules protecting groundwater. Producers cannot know whether they are causing pollution if they do not—at an absolute minimum—look to see if manure is visibly running from their fields during or immediately after application, or after a significant rainfall. To comply with state and federal law, MPCA should include *at least* these monitoring provisions in the Animal Feedlot Rule.

In addition to visual inspections, MPCA should require groundwater monitoring on fields with the highest risk of nitrate loss to groundwater for feedlots with a NPDES or SDS permit. Subsurface monitoring of this kind is the only way to ensure that unauthorized discharges to groundwater, which would not be discovered by a visual inspection, are not occurring in violation of the prohibitions in the Animal Feedlot Rules and Minnesota's water quality standards. Based on conversations with MPCA feedlot staff, there are currently fewer than 20 feedlots statewide where

---

[170] *See* MPCA, *Authorization to Construct and Operation a Concentrated Animal Feeding Operation Under the National Pollutant Discharge Elimination System (NPDES) Program*, § 14.3 https://www.pca.state.mn.us/sites/default/files/wq-f3-62.pdf ("Minnesota NPDES Permit").
[171] *Id.*
[172] *Id.* §§ 14.3, 27.2, 27.3.

MPCA has installed a well network to monitor groundwater discharges. At a minimum, MPCA should undertake a risk-based assessment to determine whether further well networks are necessary, such as investigatory geo-probes to collect temporary well data at permitted feedlots located in VGAs or where contamination exceeds a certain threshold. Possible thresholds include townships with a highly vulnerable Drinking Water Supply Management Area ("DWSMA")[173] where nitrate levels have exceeded 5.4 mg/L nitrate or a township where more than 10% of private wells have tested above the 10 mg/L limit.

Such risk assessments are already used in Wisconsin. There, the state's Department of Natural Resources "may require the installation of a leakage collection of monitoring system or secondary containment."[174] The Wisconsin rule provides a series of factors to consider in determining whether to require installation of such a system:

a. Whether facilities are located on or near areas that are susceptible to groundwater contamination such as direct conduits to groundwater, sandy soils, and sites with minimal separations between bedrock and high water tables.
b. The size and depth of the facility.
c. The type of liner used.
d. Characteristics of waste being stored.
e. Other considerations based on potential impacts to waters of the state.[175]

In addition to the above, the Wisconsin Department of Natural Resources "may require the installation of groundwater monitoring wells in the vicinity of manure storage facilities, runoff control systems, permanent spray irrigation systems and other treatment systems where [it]

[173] The Minnesota Department of Health defines vulnerable DWSMAs as those where the land is "highly vulnerable to contamination from the land surface because of their geologic conditions." *Protecting Vulnerable Drinking Water Sources*, Minn. Dep't of Health (Mar. 23, 2021), https://www.health.state.mn.us/communities/environment/water/docs/cwf/vulnacres.pdf (MCEA Ex. 47). "Currently, there are approximately 400,000 acres in vulnerable groundwater DWSMAs" that "represent less than 1% of the overall land area of the state." *Id.*
[174] Wi. Admin. Code DNR § 243.15(3)(c)(2).
[175] Wi. Admin. Code DNR §§ 243.15(3)(c)(2)(a)-(e).

determines monitoring is necessary to evaluate impacts to groundwater and geologic or construction conditions warrant monitoring."[176] MPCA should adopt a similar approach to protect groundwater from pollution.

MPCA has already determined that fields in the VGAs are those most at risk of discharging nitrate and other pollutants to groundwater because of their soil and geologic conditions. State agency data and producer surveys demonstrate that producers who land apply manure in addition to commercial fertilizer are likely to exceed recommended nitrogen application rates. And MPCA has determined that the largest feedlots, those that are required to obtain NPDES or SDS feedlots, should be required to comply with additional regulations because of the dangers of overapplication that come with the vast amounts of manure they produce. Based on this combination of risk factors, the Animal Feedlot Rule should require that feedlots that need a NPDES or SDS permit should create a SDMP for any land application fields within the VGAs as part of their MMPs.

For land application areas in VGAs, a SDMP would require the use of soil probes to take annual soil samples to inform agronomic application rates, as well as soil moisture probes or lysimeters to monitor water quality within high-risk fields. These steps would allow the feedlot operator and the MPCA to determine whether manure applications are likely to "cause pollution of waters of the state due to manure-contaminated runoff."[177] Annual soil sample requirements in the SDMP could be modeled on the recently revised Idaho Permit: samples should be taken from every field to which manure, litter, and process wastewater will be applied and should then be analyzed by a certified laboratory for pH, soil organic matter, Nitrate-Nitrogen, Ammonium-

[176] Wi. Admin. Code DNR § 243.15(7).
[177] Minn. R. 7020.2225, subp. 1(A)(2).

Nitrogen, and phosphorus. The results of these analyses must be included in the MMP and used to determine application rates.

Informed by the language in the recent Washington state court decision, the SDMP for land application areas in VGAs should also include the use of soil moisture probes or lysimeters to monitor for subsurface discharges to groundwater. Soil moisture probes and lysimeters require uniform installation across a field to generate representative data,[178] so a field-wide system must be used. Generally, one sample should be taken for every 20 acres, and monitoring should occur during land application or irrigation of fields where manure has been land applied. If a discharge is discovered at a land application area and it is clear that there has not been an appropriate agronomic utilization of nutrients, the producer must have a professional engineer or hydrogeologist review the MMP.[179] Results of the assessment would then be uploaded to the new online Nutrient Management Tool and any deficiencies would have to be addressed by the feedlot to ensure no additional discharges occurred. This combination of visual and subsurface monitoring would ensure that feedlots were not discharging from land application areas in violation of Minnesota's water quality standards, the Animal Feedlot Rule, and their permits.

2. Production areas

The few inspection requirements imposed by the Animal Feedlot Rule on production areas are entirely inadequate to stop the many ways feedlots discharge from production areas. MPCA should require more monitoring of feedlot production areas—specifically, requiring that all
