Revisor's ID Number R-4837. PFAS Products. I write in favor of strengthening and clarifying the regulation of pesticide-coated seeds. Currently, these products are NOT regulated like other pesticides. As demonstrated in Mead, Nebraska, piles of these seeds polluted ground water and nearby bee hives with this deadly runoff. There are NOT adequate safeguards for public health. Furthermore, if these seeds are treated with neonicotinoid pesticides, they have been shown to be a great danger to human and wildlife health. The treated seeds must be regulated as to their proper safe use, handling and especially disposal - for the benefit of our environment and human health.

The MPCA must ensure that the "unavoidable use" rulemaking process protects Minnesota waters and the health of Minnesota citizens. MPCA must resist the pressure of special interests to find loopholes in the statute or escape transparency.
MPCA rules must protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products

that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses.
MPCA rules must make sure that any determination of “currently unavoidable use” must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions don’t become permanent loopholes.
MPCA rules must prioritize public health and transparency, so that information on use of PFAS in products is readily available and usable for members of the public. If manufacturers want to protect their trade secret formulas for products, they should use safer alternatives to PFAS.
MPCA should work with the Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at existing and legacy mining sites.

Re: Revisor ID: R-4837
MPCA must prioritize public health over financial concerns. Therefore, a total ban of PFAs must be enforced. No exceptions. The "miracle" properties of PFAs have proven to be too good to be true. Any continued use of them prioritizes cost over health. Mining must find non-toxic, non-groundwater-polluting substitutes.

Discussion: 39667 Minnesota Pollution Control Agency Request for Comments on
PFAS in Products Currently Unavoidable Use.
Revisor’s ID Number R-4837
I implore you to prioritize public health above ALL.
Nothing short of a total ban of PFAs must be put in place and more important - enforced.
No exceptions.
It is just that simple.
Mining must find non-toxic, non-groundwater-polluting substitutes or go without using anything.
My Health is at stake as is the health of fellow Minnesotan's.
REMEMBER: THESE CHEMICALS DO NOT GO WAY.
Think of the stacking effect increased exposure comes form adding more
PFA's (Forever Chemicals) into our environment.
It is a threat to ALL LIFE, ALL LIVING THINGS.
STOP IT NOW!

As individuals we have the right to know what human-made materials enter our bodies when we eat, drink, and breath; therefore with respect to PFAS, MPCA rules must assure that information on the use of PFAS in products is readily available and easily usable by the public - no exceptions, not even for "trade secret formulas". I was most discouraged to learn that PFAS are in my rice krispie bars!! Had I known that earlier, I would not have bought them and hopefully others wouldn't as well, letting the market have some impact on the use of PFAS. Industries have access to knowledge that should enable them to use safe alternatives to PFAS. Products that allegedly can't be made without PFAS don't pass the test for use and should not be made.

The same principle applies to mining. Proposed mining facilities that would release PFAS should not be granted permits and existing and legacy mining sites should be evaluated for the presence of PFAS and means made available to mitigate the effects of PFAS already released or those with the potential to be released into the environment. The use of public monies to mitigate effects should be the last resort; polluters and their insurers should foot the bills.

Alternatives to mining exist or could exist with imagination and effort eg. mining landfills - there are lots of valuable materials in landfills. The MPCA must prevent further degradation of the environment and get rid of the idea of sacrifice zones. It's not acceptable to simply make degradation more inconvenient, or marginally more costly, or simply slower.

As a resident of New Brighton, Ramsey County, I am submitting the following points:

1. MPCA must ensure that the “unavoidable use” rule-making process protects Minnesota waters and the health of Minnesota citizens. MPCA must resist the pressure of special interests to find loopholes in the statute or escape transparency;

2. MPCA rules must protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses;

3. MPCA rules must make sure that any determination of “currently unavoidable use” must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions do not become permanent loopholes;

4. MPCA rules must prioritize public health and transparency, so that information on use of PFAS in products is readily available and usable for members of the public. If manufacturers want to protect their trade secret formulas for products, they should use safer alternatives to PFAS;

5. MPCA should work with the Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at existing and legacy mining sites.

Very respectfully,

Betsy Blume · Citizen · (Postal Code: unknown) · Feb 19, 2024 6:08 pm
2 Votes

I believe based on the MPCA rules that must protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses be noted in consideration of permitting of any industry that contributes to PFAS release into water resources.
Further, the MPCA rules must make sure that any determination of “currently unavoidable use” must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions don’t become permanent loopholes.
MPCA rules must prioritize public health and transparency, so that information on use of PFAS in products is readily available and usable for members of the public. If manufacturers want to protect their trade secret formulas for products, they should use safer alternatives to PFAS.
Finally, MPCA should work with the Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at existing and legacy mining sites.
Thank you for considering these comments on a very important public health concern.

Why is this crucial?
Mining is a potential source of PFAS release both to surface water and to groundwater. Exploratory drilling for minerals, use of tunnel boring machines, use of surfactants to

enhance metal recovery in the ore floatation process, ore leaching, acid mist suppression, and use of wetting agents are just some of the ways in which the mining industry can introduce PFAS to surface water and groundwater. Products containing PFAS may also be used in mines for fire suppression and firefighting activities.
Ore flotation processes—like the processing method proposed by PolyMet for the NorthMet mine—may use aqueous foams containing PFAS to lower surface tension and separate the metals from soil and rock. PFAS in the flotation process can be released to the environment through tailings seepage to surface and groundwater and in direct wastewater discharge to surface water.
Tunnel boring machines, like the one proposed by Talon Metals for the Tamarack mine may directly introduce PFAS to groundwater through use of lubricants, protection pastes, greases, foaming agents for rock tunnel boring, grouting additives, or fire resistant fluids containing PFAS.
Although there have been few efforts to monitor mines as potential sources of PFAS to, BHP’s Mount Whaleback Iron Ore Mine in Western Australia was recently identified as the source of PFAS impacts to groundwater with the potential to threaten a nearby drinking water supply.
Thank you for acting on these concerns.

PFAS chemicals are toxic chemicals and pose real threats to human health and to ecosystems. Minnesota rules must include all industrial uses of PFAS including all the various uses in mining. Rules associated with PFAS chemicals must include the following:

MPCA must ensure that the "unavoidable use" rulemaking process protects Minnesota waters and the health of Minnesota citizens. MPCA must resist the pressure of special interests to find loopholes in the statute or escape transparency.
MPCA rules must protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses.
MPCA rules must make sure that any determination of "currently unavoidable use" must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions don't become permanent loopholes.
MPCA rules must prioritize public health and transparency, so that information on use of PFAS in products is readily available and usable for members of the public. If manufacturers want to protect their trade secret formulas for products, they should use safer alternatives to PFAS.
MPCA should work with the Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at existing and legacy mining sites.

I’m just going to be real here. The MPCA needs to stop giving polluters loopholes to pollute. I'm not sure why this is even a question, there shouldn't have been any past (allowable) PFAS's or any other pollutant in our air, land, water, or food. Furthermore, in 2024 we have alternatives that could be used in place of these deadly chemicals. The MPCA should be working on making laws to eliminate polluting industries and requesting alternatives to be used. Industrialized HEMP can do everything polluting industries do now and more, it's time to move away from polluters and do the real work.

The “unavoidable use” rulemaking process must protect Minnesota waters and the health of Minnesota citizens. Actually I question the very concept of unavoidable use. Dangerous chemicals should be banned outrigtht, no loopholes. MPCA must resist the pressure of special interests to find loopholes in the statute or escape transparency.
MPCA rules must protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses.

I would like you to make sure that the "unavoidable use" rule making process protects Minnesotans and the waters in the state. Big companies will try to find loopholes or avoid tranparency in such a subjective phrase. We are not big companies. We are people, Minnesotans. MPCA, do what you can to limit the power that these companies have to bend the rules, and please protect our waters!

The Country looks to Minnesota for clean pristine water. We know now that it is teetering on the brink of being a finite resource. Security is having clean lakes, waterways and drinking supplies.
Our state is vulnerable to contamination due to an ever irresponsible mining industry and the representative withing our government who think nothing but for short term financial gain. Minnesota will be a poor state indeed if not for clean water and its recreational businesses.

Emily Thompson · Citizen · (Postal Code: unknown) · Feb 21, 2024 5:07 pm
0 Votes

I would recommend that "Unavoidable use" needs to be proven by the manufacturer, and that outcomes of not using PFAS should be demonstrated to be somehow worse than potential health effects of using them. Decreased yields or shareholder profits do not make the use of dangerous chemicals "unavoidable." Alternatives should also be regulated--they should not be closely related chemicals with different side chains that can be expected to have similar health effects. This will require careful definition of PFAS in the ban. There should perhaps be an independent group of chemists reviewing use of PFAS and alternatives, who have veto power over companies claiming unavoidable use. Companies using PFAS should be required to label their products and justify their continued use every few years, to prevent products from being grandfathered in after a viable alternative has been produced. They should not be able to protect themselves from transparency by claiming protection of trade secrets.

Pete McDonnell · Citizen · (Postal Code: unknown) · Feb 21, 2024 8:05 pm

Dear MPCA,

There should be a standard of "essential for health, safety, or the functioning of society" to maintain the current standard of living, and that standard should be whether it contributes to people's lives and livelihoods. For example, manufacturing facilities related to social infrastructure (e.g., drinking water, water recycling, wastewater treatment), food, pharmaceuticals, and semiconductors that are essential to daily life meet the criteria of being "essential for health, safety, or the functioning of society".

MPCA must prioritize public health over financial concerns. Therefore, a total ban of PFAs must be enforced. No exceptions. There is no "unavoidable" use: mining companies must find or make alternatives. Any use of substances containing PFAs endangers ground water and public health. Mining must find non-toxic, non-groundwater-polluting substitutes.

I am the secretary general of Battery Association of Japan (BAJ).
On behalf of the Japanese battery industry, I would like to give a comment about PFAS in battery products currently unavoidable use. Please refer to the attached file.

Response:

Steve Timmer · Citizen · (Postal Code: unknown) · Feb 27, 2024 6:27 pm
Perhaps then, Mr. Secretary General, you can apply for an exemption from a rule. And submit scientific evidence why. Your submission is NOT a reason not to have a rule. Not

to mention that you have eight years to figure out how to make batteries without PFAS.

Last year, the Minnesota Legislature passed a statute (Minn. Stat. § 116.943) that would prohibit PFAS in many types of products unless their use in those products was "currently unavoidable." This was an important positive step to keep PFAS out of surface water and groundwater. Yeah! However, the MPCA is developing rules that will determine how the PFAS statute will be interpreted. The details will determine if Minnesota waters and human health are protected.

PFAS "forever chemicals" have a wide range of serious health consequences including cancers, liver damage, increased cholesterol and obesity, reduced immune response to fight infection, dangerous high blood pressure in pregnancy, reduced infant birth weight, and developmental delays in children.
PFAS "forever chemicals" are very toxic. PFAS exposure results in cancers, liver damage, reduced immune response to fight infection, increased cholesterol and obesity, dangerous high blood pressure in pregnancy, reduced infant birth weight, and developmental delays in children.

PFAS are not only found in cookware and cosmetics. Mining can release PFAS directly into surface waters and groundwater as a result of uses including drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression.

I hope speaking from my heart, my truth and offering these comments that I can encourage the reviewers and committee members to ignore pressure from special interests and listen to folks who don't have funds invested, but instead are invested with their hearts towards loved ones and our beautiful planet Earth. These are ways we can be good relatives and community members and honor our home and mother Earth. Thank you for letting me speak from my heart to yours in the hopes that I will awaken you from your slumber of the fossil fuel industry.

Letter of Support

I am the Product Compliance Manager of Smith Sport Optics who manufactures products used in the state of Minnesota, and I stand firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, I express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.
In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Minnesota. This proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders. By engaging experts from various industries, Claigan Environmental has adopted a

collaborative approach to address this complex issue.
Smith Sport Optics actively participated in the consultation process and supports Claigan Environmental's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

Best regards,
Joseph Salas

To: Minnesota Pollution Control Agency
From: Steven J. Timmer
Re: PFAS rulemaking
Date: February 27, 2024

Ladies and Gentlemen:

I am a retired Minnesota lawyer with forty-some years of private civil practice experience, including administrative law. I write today to urge rigorous protection of the citizens and the environment of the state from PFAS pollution. I write now specifically about rulemaking under the “currently unavoidable” provisions in Minn. Stat. § 116.943, subd. 5 (2023).

Any rule proposed and adopted by the MPCA must distinguish between things that are truly unavoidable versus merely inconvenient or marginally more expensive to manufacturer. There are also undoubtedly products where PFAS is unavoidable, but the product is of such marginal utility that it should be kept out of the stream of commerce and the bloodstreams of citizens or the waters and landfills in the state.

Advocates in many fields of endeavor have been known to shade the merely inconvenient or the marginally more expensive into the impossible to avoid or minimize regulation. I may have done it myself once or twice.

In order for legislators, citizens, and environmental watchdogs to have confidence in any administrative scheme of permitting “currently unavoidable PFAS use,” that scheme must be transparent enough to let these concerned parties check the MPCA’s work, and to do so without having to resort to frequent data requests, which are burdensome for everybody. Applications for exemption, and supporting documentation, ought to be published with a comment period for the public before any is granted. Since the rule won’t come into effect until 2032, there is plenty of time for industry to anticipate a period between application and possible grant of an exemption request.

All “currently unavoidable uses” must be time limited; the statute says “currently,” not “forever.” This is necessary, not only for the protection of citizens and the environment in the near term, but it will also incentivize industry to find PFAS-free solutions for their products. It would also prevent innovative competitors who find PFAS-free solutions being put at a competitive disadvantage.

It is not unfair to periodically test whether “currently unavoidable” has become “avoidable.”

I believe that it is also desirable to consider “distribution” under Subdivision 5 to include the activity of a party that purchases prohibited PFAS products out of state for use in-state, as for example, a mining company or its contractor that uses PFAS products in exploration or mining activities, or the flotation and precipitation of metals from ore.

Thank you,
Steven J. Timmer
5348 Oaklawn Avenue

Thank you for the opportunity to comment on the vital importance of ensuring that the “unavoidable use” rulemaking process for PFAs truly protects Minnesota waters and the health of all Minnesotans and others who live downstream. It is essential for MPCA to resist the pressure of special interests to find loopholes in the statute or escape transparency. Key to this protection are several essential actions and ongoing monitoring by MPCA, including

*Protecting Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses.

*Making sure that any determination of “currently unavoidable use” must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions don’t become permanent loopholes.

*Prioritizing public health and transparency, so that information on the use of PFAS in products is readily available and usable for members of the public.

*Working with the Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at existing and legacy mining sites.

All measures to discover, monitor, reduce, and eliminate PFAs will help increase the health and wellbeing of Minnesota and all who live here—and beyond. Thank you for your work focused on these priorities.

Dear MPCA
Thank you for the opportunity to submit comments on the planned new rules governing determinations of currently unavoidable uses (CUU) of PFAS. I am submitting the attached document jointly prepared by members of BioPhorum, a global biopharmaceutical manufacturing industry collaboration comprising all major manufacturers and their key suppliers (over 150+ companies, representing > 98% of all biopharmaceuticals manufactured worldwide).

Our industry sector shares a responsibility to work with all relevant stakeholders to manage the transition away from materials of concern while maintaining our ability to ensure the safety and wellbeing of patients and the communities in which we operate. Any efforts to restrict usage and production of materials of concern by our industry must be pragmatically considered; the risk of drug shortages and therefore failure to supply medicines to patients must be evaluated against the risk the materials pose to the environment and to that very same population. We welcome the opportunity to participate in this process and respectfully ask you to review the attached response and contact me if you wish to further discuss the contents.
Thank you

Attached is a combined submission of fifty-three (53) PFAS Currently Unavoidable Use (CUU) proposals. Each is an individual proposal, but listed in the attached excel file sequentially for your convenience.

These submissions were put together by Claigan Environmental in combination with over 50 companies across virtually all market spaces (consumer, professional, laboratory, life sciences, medical, safety, industrial, machinery, and IT). The data is backed up with 2022 to 2024 laboratory data from testing 1,000s of products for PFAS and PFAS salts.

Most of the included PFAS uses are very widespread and used in virtually every industry. These proposals can be broken out by industry, but that would expand the list to nearly 400 individual proposals which are really based on 53 uses.

Document 1 - PFAS Currently Unavoidable Uses Proposals Guidance Document - Feb 2024.pdf
Summary and guidance document on the currently unavoidable uses proposals being submitted. This document is a must read for anyone looking to regulate PFAS. It includes summaries and explanations based on the most recent data.

Guidance document
a). Explanation of the submission project and members
b). Definitions
c). Key findings / notes from the project (examples - over 500M products sold in the US each year contain PFAS, the forestry, life sciences, and fishing industries will be closed in the State of Minnesota if PFAS are banned, etc.)
d). Explanations of the few situations where fluoropolymers products products PFAS found in drinking water and humans. The data here is the most modern information available. There is nothing comparable to date.
e). A detailed review of an example US State (Kentucky) and the sources of PFAS in their drinking water in 2023. This is a map to determining sources of PFAS in drinking water for the State of Minnesota.
f) An detailed explanation of the criteria used to compare alternatives.

Document 2 - PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx
A very detailed listing of each Currently Unavoidable Use, industries impacted, example products, essential use of product and of PFAS, comparison of alternatives, and potential for presence of PFOA / LC-PFCA.

This document is explained in detail in the Guidance Document (Document #1)

PFAS CUU Proposal document
a). List of each CUU with summary for each criteria
b). Secondary tabs for each use type with a detailed comparison of alternative materials

There is no comparable comprehensive listing, explanation, and justification of PFAS uses. These documents should be required reading for any PFAS regulator.

The Halon Alternatives Research Corporation, Inc. (HARC) appreciates the opportunity to provide information to the Minnesota Pollution Control Agency (MPCA) in response to its request for comments on planned new rules on currently unavoidable uses of PFAS. HARC is a non-profit trade association formed to promote the development and approval of halon alternatives that serves as an information clearinghouse and focal point for cooperation between government and industry on issues of importance to special hazard fire protection. HARC members encompass all levels of the fire protection industry including agent manufacturers, equipment manufacturers, distributors/installers, recyclers, and end-users.

The HCAs used for fire protection that meet the definition of PFAS in the Minnesota law are FK-5-1-12, HFC-227ea, HFC-125, HFC-236fa, 2-BTP and HCFC Blend B. While there are non-PFAS alternatives for HCAs that have been available for several decades and are widely used, we write to inform MPCA that there are important uses of HCAs in facility, aviation and military applications for which non-PFAS alternatives do not exist and are not currently in development. As such we expect there to be continuing uses of HCAs for fire suppression well beyond January 1, 2032.

Thank you for the opportunity to comment on the vital importance of ensuring that the “unavoidable use” rulemaking process for PFAs truly protects Minnesota waters and the health of all Minnesotans and others who live downstream. It is essential for MPCA to resist the pr understanding and identifying a baseline for the term “reasonable” is critical for any future consideration of a viable PFAS alternative. ig companies will try to find loopholes or avoid transparency in such a subjective phrase. Big money and corporations think only with immediate bottom line, not the long term incentives for protecting our most valuable resource: our water. We the people, Minnesotans, want you to do what you can to limit the power that these companies have to bend the rules, and please protect our waters.

Emphasize that MPCA must ensure that the “unavoidable use” rulemaking process protects Minnesota waters and the health of Minnesota citizens. MPCA must resist the pressure of special interests to find loopholes in the statute or escape transparency.
MPCA rules must protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses.
MPCA rules must make sure that any determination of “currently unavoidable use” must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions don’t become permanent loopholes.
MPCA rules must prioritize public health and transparency, so that information on use of PFAS in products is readily available and usable for members of the public. If manufacturers want to protect their trade secret formulas for products, they should use safer alternatives to PFAS.
MPCA should work with the Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at existing and legacy mining sites.

I heard in my 1st semester back towards my bachelor degree that Earth is experiencing a mass-extinction. That was six years ago and I near my Master in Tribal Resources Environmental Sustainability Stewardship. (MTRES). Sadly, we have not improved our paradigm and it is in large part due to our own activities. Anthropocene era has been debated for decades whether we now qualify. We do. It is our activities that create our environment. It has become barren and toxic for Invertebrates and vertebrates and birds and mammals. Our "goals" of keeping our global carbon expiration and temperature low are still increasing.
"Unavoidable use" ???
please.
To stop this problem it will take doing the opposite of business as usual. We need Sustainability NOW. None of our current actions are unavoidable. We must simply stop doing them. Find a different way to accomplish our needs.
What did our ancestors do? That question sticks to me. I am of Anishinaabe-Ojibwe heritage and am a member of the Minnesota Chippewa Tribe (MCT).
Respectfully, I beg. Please do not allow business interests, whose sole existence is to profit for their small base. Please put the health and welfare of the Earth before any ill gain who continues to destroy Nature and the Natural process of life. Those bugs do more for us than we realize. The birds and fish, the mammals also contribute to healthy Ecosystems. Bioregions. Earth.
We are ALL connected.
As our pfas now is connected too. We are all exposed to this lethal agent who was released without regard for our health. There are technological advances and it may be possible to remove this toxin but it is still very expensive .. and who will pay?
Who will pay?
We all pay.
Water. Fresh Water. The basic essential to us.
Stop polluting and saying it's necessary. There are beautiful ways people existed and did maintain a paradise here once. We have been duped into submission to unnatural resources and maintaining a completely unsustainable lifestyle. We need to just stop.
Stop.
It's avoidable. And unnecessary. And wholly unsustainable.
And what do the local Native population think of it.
Consultation must be thorough. It has not been.

We can do better.
Stop pfas. Talon mine has unsustainable history forever. Don't let them turn this bioregion into an unlivable area and future Superfund site. There is no unavoidable, stop doing it.

Mining can release PFAS directly into surface waters and groundwater as a result of uses including drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression.
PFAS contamination is ubiquitous. It is a suspected carcinogen and causes multiple health effects and is "persistent" in the environment. PFOS is commonly called the forever poison. Do not license (permit) more of this forever poison into our air, water, and soils of Minnesota.

Anne Morrison · Citizen · (Postal Code: unknown) · Feb 29, 2024 8:49 pm

I have submitted one email on the topic of MPCA rulemaking but wish to add some additional thoughts.

The MPCA is in the process of developing rules regarding the regulation of PFAS, which has been classified as a “forever” chemical.

PFAS are “forever chemicals” which will impact the health of Minnesota residents into perpetuity— for as long as people continue to reside in this state. They are known to cause cancer and liver damage; to suppress here deadly immune responses; to cause dangerously high blood pressures during pregnancy, endangering mothers and their unborn children; and to cause developmental delays in children. The Environmental Protection Agency has issued advisory warnings that even tiny amounts of some of PFAS chemicals found in drinking water may pose risks. Scientists are now finding PFAS in our soil, air, and drinking water. As a result, these deadly chemicals are now four in our food, wildlife, and even our own bloodstreams.

Although PFAS are frequently ingested through contaminated surface and groundwater, the research regarding the impacts of PFAS on animal life, and therefore, on the net effects of releasing PFAS into the environment is inadequate for understanding the broad environmental effects of PFAS. Little is known about the way the PFAS affect microorganisms, or about the ever-expanding effects of PFAS as they are ingested by microorganisms and re-ingested up the entire food chain —including, ultimately, by humans.

As a result, it is currently impossible to know how releasing carcinogens and toxins which can never be withdrawn from the environment affects environmental processes as a whole. However, it would be reasonable to presume that animal, like humans, experience significant effects, and that the release of PFAS into the environment has a broader and more significant effect on our environment than we can currently comprehend l

It is also significant that the waters of northern Minnesota drain into the Hudson Bay and Mississippi watersheds: toxic chemicals released into Minnesota waters will affect the environment across vast areas of the North American continent.

The MPCA faces regularly issues involving the release of chemicals, and often deadly chemicals, into the environment. In view of the facts that the effects of PFAS on humans or the environment are yet to be fully studied, that PFAS are currently known to cause serious health and reproductive issues, that PFAS travel up the food chain to eventually contaminate the entire environment, and that the release of PFAS into Minnesota water stands to affect vast portions of North America, it would be beyond unconscionable for MPCA or its employees to promulgate rules which prioritize short-term corporate profit over the vast and irreversible health and environmental effects of releasing additional PFAS into the environment.

For all of the above reasons, I urge the MPCA to ensure that rules promulgated regarding these issues prioritize the protection of Minnesota's water resources and human and environmental health over mining activities which release PFAS, into the environment. Such rules must include:

—The requirement that any manufacturer must prove the existence of a “currently unavoidable use”;

—that any exception which would allow the release of PFAS (there should be none!) have an end date to protect Minnesotans, and our environment, from the release of PFAS on an indefinite basis;

—provisions which mandate the disclosure of information regarding the creation and release of PFAS, so that such critical health information is made available to the public.

Thank you again for considering these additional thoughts and concerns.

Thank you for the opportunity to comment on this important discussion.

MPCA must ensure that the "Unavoidable Use" rule-making process protects Minnesota waters and the health of all the humans and wildlife using Minnesota waters. MPCA must resist the pressure of special interests to find loopholes in the statute or to escape transparency.

MPCA rules must protect Minnesota surface water and groundwater from all ways in which mining process have the potential to release PFAS by using products containing PFAS in any mining processes or process steps.

MPCA rules must ensure that any determination of "Currently Unavoidable Use" must be proved by the manufacturer and must be sunset by an agreed-upon date so that temporary exceptions do not become permanent loopholes.

MPCA rules must prioritize public health and transparency, such that information on use of PFAS in products is readily available and usable by members of the public. If manufacturers choose to protect their trade secret or proprietary formulas for their product, they must certify that their product Does Not Contain PFAS.

MPCA should work in cooperation with Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS; and the MPCA must investigate whether PFAS are present at existing and legacy mining facilities and sites.

Subd. 5 (c) explicitly states that “the commissioner may not determine that the use of PFAS in a product is a currently unavoidable use if the product is listed in paragraph (a)”. One of the product groups listed in Subd. 5 (a) is “cookware” and from the perspective of a company producing electrical household appliances like e.g. coffee machines, this term needs some clarification. Subd. 1 (h) defines “cookware” as “durable houseware items used to prepare, dispense, or store food, foodstuffs, or beverages”. As an electrical coffee machine can in principle be described as a durable houseware item used to prepare and dispense a beverage (coffee), it seems to fall under the definition of cookware. However, all items listed as examples in Subd. 1 (h) – pots, pans, skillets, grills, baking sheets, baking molds, trays, bowls, and cooking utensils – are very simple objects and not at all comparable to electrical household appliances. An electrical coffee machine consists of hundreds, sometimes even thousands, of different components and a lot of the tubes and seals in such a machine are made of fluoropolymers, which fall under the definition of PFAS according to Subd. 1 (p), and it will be absolutely impossible to redesign all appliances that are currently in production or in development until January 1, 2025. Because of this, I have my doubts that such electrical appliances are actually targets of the restriction of PFAS in cookware. In any case, I would be happy about some definitive clarification.

On behalf of SEMI, the industry association serving the global semiconductor design and manufacturing supply chain, we write to offer comments on the regulations on per- and polyfluoroalkyl substances (PFAS) being developed by the Minnesota Pollution Control Agency (MPCA), as authorized in Minn. St. § 116.943 (Section 116.943). These comments discuss the MPCA's planned rulemaking governing currently unavoidable use (CUU) determinations for products containing intentionally added PFAS (the CUU Rule).

SEMI is committed to balancing the need for environmental protection and the sustainability of semiconductor manufacturing operations, which is a complex challenge. As such, SEMI is grateful for the opportunity to engage on the MPCA's planned CUU Rule and is available to meet at your convenience to further elaborate on the issues discussed in these comments. If you have any questions or would like to discuss our positions, please do not hesitate to contact us.

Keep PFAS from Mining out of Surface and Ground Water!

PFAS “forever chemicals” are toxic. PFAS exposure results in cancers, liver damage, reduced immune response to fight infection, increased cholesterol and obesity, dangerous high blood pressure in pregnancy, reduced infant birth weight, and developmental delays in children.

PFAS are not only found in cookware and cosmetics. Mining can release PFAS directly into surface waters and groundwater as a result of uses including drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression.

Christian Nelson · Citizen · (Postal Code: unknown) · Mar 01, 2024 11:06 am

PFAS is considered a "forever" chemical with demonstrated harm to humans and wildlife. No temporary project should ever release this chemical into our environment.

*The MPCA must ensure that the “unavoidable use” rulemaking process protects Minnesota waters and the health of Minnesota citizens. MPCA must resist the pressure of special interests to find loopholes in the statute or escape transparency.

*MPCA rules must protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses.

*MPCA rules must make sure that any determination of “currently unavoidable use” must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions don’t become permanent loopholes.

*MPCA rules must prioritize public health and transparency, so that information on use of PFAS in products is readily available and usable for members of the public. If manufacturers want to protect their trade secret formulas for products, they should use safer alternatives to PFAS.

*MPCA should work with the Minnesota Department of Health and the Minnesota

Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at existing and legacy mining sites.

Re Revisor's ID Number R-4837, the "PFAS in Products Currently Unavoidable Use Rule"
I am a retired professor of physics and astronomy and the natural sciences at Carleton. While my background does not give me extra knowledge of the harms and benefits of PFAS and its regulation, it does mean that I deeply understand the scientific method. In addition, I have read articles for lay readers about PFAS for years. I write to make the following points:

PFAS does not easily break down into harmless chemicals over time. This fact is why it is called called a "forever chemical," and what marks it as a long-term pollutant, requiring strict and transparent rulemaking by MPCA, and avoiding carve-outs that would permit manufacturers, users, and other stakeholders to maneuver around the regulations. Furthermore the rule must regulate the environmental harms of PFAS production in any aspect of its being mined.

The final "unavoidable use" PFAS rules must offer a high level of protection for state waters, either under or on the surface, and prioritize Minnesotans' health. In addition, manufacuturers must not be allowed to cite "trade secrets" as a reason to avoid providing information necessary for regulation, since the dangers of this chemical are great.

MPCA must collaborate with other State agencies such as MN Department of Health and the MN DNR to ensure that no new mines emit PFAS into our waters, and to study whether PFAS chemicals are sitting in already-closed or existing mines.

The term "currently unavoidable use" should not lead to "forever use" without regular regulatory assessment. Therefore any currently unavoidable use permit must automatically die after a reasonable length of time, absent new assessments.

Thank you for listening to my comments.

Eric Morrison · Citizen · (Postal Code: unknown) · Mar 01, 2024 11:17 am

Perfluorinated substances must be taken extremely seriously, and the subject of "unavoidable use" categories for these chemicals must be very thoughtfully, publicly and transparently considered.

My comments are based on working with perfluorinated liquids at 3M (relevant to PFASs) and from being a member of Ecolab's ECOPAC political action committee (relevant to seeking special treatment).

My first assignment at 3M showed me how profound is the power of suggestion, particularly as it relates to chemical safety. I invented a one part epoxy coating for eyeglasses to be used in one hour lens crafting, and the epoxy was to be cured by steaming it over a boiling perfluorinated compound (US Patent 5,314,980 Epoxy coating compositions with metal-containing stabilizers). To even think of selling a device like that, one would need to be convinced that perfluorinated compounds are actually inert and safe, a common belief because of the stability of carbon – fluorine bonds. The stability of the fluorine carbon bond means that perfluorinated compounds will last forever – but they are not inert – other bonds change and the product perfluorinated compounds can be very dangerous. The well known example is decomposition of poly tetrafluoroethylene (Teflon) to give perfluoroisobutylene (which is a potential chemical warfare agent 10 times more toxic than phosgene). While chemical changes in PFAS may not be as dramatic as Teflon decomposing to perfluoroisobutylene, they must be understood and the risks must be managed. Someone high up at 3M wisely chose to end the one hour lens crafting scheme, and now we know very well that perfluorinated compounds are not inert, but I am still moved by the power of suggestion and the passion with which we believed otherwise when we were working with these compounds in the lab.

My experience at Ecolab leads me to view “unavoidable uses” with suspicion. What “unavoidable uses” means is the compound in question is really effective, but there are alternatives but they either cost much more or they don’t work as well. An example is phosphorous compounds (which cause eutrophication of lakes and rivers) for cleaning and lubrication. But even in cases where environmentally damaging compounds give much better results than other materials (such as fire fighting foams), there still needs to be a public, transparent treatment of risk vs benefit. Giving companies a get out of jail free card in terms of unavoidable uses is unnecessary and strictly oppositional to the public good.

MPCA must ensure that the "Unavoidable Use" rule-making process is transparent, public, and seriously weighs risks and benefits. Especially concerning are mining operations which have tremendous potential to release PFASs in large amounts in ways that are very opaque.

Thank you for the opportunity to comment and for your consideration.

The American Watch Association ("AWA") submits the following comments. The AWA is a trade association representing many of the major watch brands and companies in the United States. Watches use an extremely small amount of PFAS in a way where there is virtually no risk of consumer exposure. As such, the AWA believes watches pose an exceedingly remote risk of PFAS exposure to consumers. When watches are constructed, a solution called an epilame is added to certain movement parts inside of the watch to prevent oil from spreading and to ensure the lubricant remains in place and performs as intended. Effective epilame solutions contain a small amount of PFAS, and no technically or economically feasible PFAS-free alternatives currently exist. The eplilame is applied in small drops, of a thickness between 3 to 5 nanometers. Once applied, the epilame dries and is not volatile. The quantities of lubricants involved are extremely small. Between 1.5 mg and 6 mg of fluorinated lubricant is used per watch, each containing about 30% PFAS. As noted, there is no currently available substitute; the AWA anticipates that it would take 8-10 years to develop a possible substitute. The movements that are treated with the PFAS containing epilame solutions are assembled in other countries. They are then sealed in a watch case, which also takes place in other countries. Accordingly, when a watch enters this country, the PFAS containing eplilames are sealed away and therefore inaccessible to consumers. Indeed, consumers are discouraged from opening the watch case as the movement could easily be damaged. Furthermore, it is quite difficult to open a watch case without a specialized tool, manual dexterity, and technical skill. Therefore, there is virtually no risk of PFAS exposure to a consumer from the epilame coating a watch movement. The risk of PFAS exposure from watches in the waste stream is also remote. Watches are unlikely to enter the solid waste stream as they are generally high value items and designed to last for years. For example, analogue watches have a very long life and are often passed down across generations. Given the fact that relatively few watches containing PFAS are disposed of, and in light of the exceedingly small amount of epilame at issue, which is generally inaccessible to consumers, there is very little risk that the minimal PFAS in the epilame would be released and contaminate the environment.
We therefore respectfully request that such uses of PFAS containing eplilame solutions qualify as a currently unavoidable use.

Sincerely,

David B. Perlman
Executive Director
American Watch Association

All water well drilling holes, and all mineral exploration drilling boreholes, utilize drilling fluids for lubrication. The Pollution Control Agency should insist that the manufacturers of these lubricants prove that there are no PFAS in their products. Currently, no one is testing these products to confirm they are PFAS free.

It is not good enough to rely on the National Sanitary Foundation's (NSF) recommendations, because even the NSF does not test their "drinking water treatment chemicals" for PFAS. The NSF list includes all of the biggest suppliers to the oil & gas exploration industry. These are the same chemicals used for drilling water wells and mineral exploration boreholes. None have been tested to confirm they are PFAS free. NSF 60 certified does not mean they are PFAS free!

The NSF list is here: https://info.nsf.org/Certified/PwsChemicals/Listings.asp?CompanyName=&TradeName=&ChemicalName=&ProductFunction=&PlantState=&PlantCountry=&PlantRegion=

It is also not good enough to rely on Safety-Data-Sheets that make no mention of PFAS content. All SDS's are written by the manufacturers and they never disclose 100% of the chemical content of their products. No manufacturer will disclose that their product contains PFAS on their SDS.

Please include in the rule making the requirement that all drilling fluids and drilling lubricants be tested to confirm they do not contain PFAS. If this requirement is not included, the PFAS contamination cycle will continue to start when water wells and mineral exploration boreholes are drilled.

In the attached comment letter Plumbing Manufacturers International (PMI) is requesting that all plumbing products utilized in residential and commercial construction, as well as those used in public infrastructure be designated as “currently unavoidable use”. In addition PMI recommends that MPCA use similar criterion as Maine DEP for PFAS (https://www.maine.gov/dep/spills/topics/pfas/PFAS-products/cuu.html) and requests that MPCA establish an ongoing process for granting CUU designations in the future so that manufacturers and industries that do not receive an initial CUU designation can apply in the future as more information on PFAS and its viable alternatives becomes available between now and 2032 when the state’s PFAS products ban goes into effect.

All the best,

Kyle Thompson

I have serious concerns that the ingredients list in drilling fluids may not be completely accurate. Both Pennsylvania and Colorado have found PFAS in drilling fluids and have taken action to stop their use. I urge a rule that requires PFAS testing on all drilling fluids prior to their approval for use. Water is too precious to take chances with.

Concerns over PFAS (perfluoro- and polyfluoro-alkyl substances) began when it was discovered that some fluorinated compounds were environmentally persistent, bioaccumulative and potentially toxic. In the more than two decades since then, the definition of fluorinated substance designated for concern has dramatically increased to now include any compound that contains a CF2 or CF3 group in its chemical structure. However, a comprehensive scientific assessment of volatile, hydrophobic fluorinated fluids demonstrates that these materials should not be grouped with the compounds of concern despite their inclusion in some PFAS definitions. While it is prudent for regulatory agencies to restrict some compounds designated as PFAS due to the hazards they present, not all materials that fall under the broad PFAS definition pose an unacceptable risk to human health or the environment. Considering all compounds which contain a CF2 or CF3 moiety as displaying the same inherent hazards is analogous to grouping all hydrocarbons as the same. Even small differences in chemical structure can have a profound effect on on properties. Consider the effect of one CH2 unit on the difference in toxicity of ethanol (CH3CH2OH) compared to methanol (CH3OH). One would never imply that these compounds exhibit the same hazards or present the same risks. Similarly, many in the scientific community have recognized the need to differentiate between the wide range of compounds now being encompassed in broad PFAS definitions (T. Wallington, et al., "The case for a more precise definition of regulated PFAS," Environmental Science: Process & Impacts, vol. 23, pp. 1834-1838, 2021. R. Andersen, et al., "Grouping of PFAS for human health risk assessment: Findings from an independent panel of experts," Regulatory Toxicology and Pharmacology, vol. 134, p. 105226, 2022.).
Nonafluoro-2-trifluoromethyl-3-pentanone is a fluoroketone used in a number of industrial applications and primarily in fire protection as a clean fire extinguishing agent. It performs a critical role in providing fire protection in applications where it is unsuitable to use water, an inert gas or dry chemical. The fluoroketone has chemical and toxicological properties which are vastly different from the PFAS compounds of concern. Despite containing fluorine, the fluoroketone is not a “forever chemical” since it degrades in the environment on a reasonable time scale, does not bioaccumulate and have been demonstrated through testing to be low in toxicity. The fluoroketone is not

found to be a contaminant in water or soil due to its very high volatility combined with extremely low water solubility which results in partitioning to the atmosphere. The fluoroketone then undergoes degradation in the atmosphere through natural processes (photolysis) resulting in an atmospheric lifetime of 1-2 weeks.
The largest degradant in terms of molecular weight resulting from atmospheric decomposition is trifluoroacetic acid (TFA). Several risk assessments have concluded that TFA does not pose an unacceptable risk to human health or the environment even at the projected environmental concentrations that could be generated from refrigerants and other large volume industrial compounds (J. Boutonnet, et al., "Environmental Risk Assessment of Trifluoroacetic Acid," Human and Ecological Risk Assessment: An International Journal, vol. 5, no. 1, pp. 59-124, 1999. K. Solomon, et al., "Sources, fates, toxicity, and risks of trifluoroacetic acid and its salts: Relevance to substances regulated under the Montreal and Kyoto Protocols," Journal of Toxicology and Environmental Health, Part B, vol. 19, no. 7, pp. 289-304, 2016. United Nations Environment Programme (UNEP), 2022 Assessment Report of the Environmental Effects Assessment Panel, Nairobi, Kenya, 2023. US EPA has designated TFA as a “well studied non-PFAS” and attempts to exclude compounds with TFA as the degradant from their PFAS definition (U.S. Environmental Protection Agency, National PFAS Testing Strategy: Identification of Candidate Per- and Polyfluoroalkyl Substances (PFAS) for Testing, 2021.).
The fluoroketone is recognized to have very low bioaccumulation potential. The high volatility (vapor pressure of 40 kPa at 25°C) combined with very low solubility in water (1 ppmw) results in a high Henry’s Law constant of 1.3x107 Pa.m3/mol, demonstrating extensive partitioning to the atmosphere. The physical properties also result in a low log KOW of 2.79 which is well below the threshold for concern with bioaccumulation.
The fluoroketone is low in toxicity based on a comprehensive set of tests. The fluid is low in acute and repeat-dose inhalation toxicity. It was also demonstrated as not mutagenic nor genotoxic based upon both in vitro and in vivo test protocols. Studies also established that the fluoroketone is not classified as hazardous for reproduction or development.
Data corroborating these properties and results can be found in the ECHA REACH database under E.C. Number 436-710-6.

Ladies and gentlemen,
On behalf of Valmet, Inc. and Valmet Flow Control Inc., we appreciate the opportunity to submit the attached comments on considerations for developing proposed rules for determining when products should be exempt from the January 1, 2032, ban on distribution and sale of products containing intentionally added PFAS.
Enclosed are Valmet’s comments on the particular issues raised by the Agency in its Request for Comments document, together with detailed information on a number of Valmet’s products that contain PFAS (fluoropolymers and fluoroelastomers) for which Currently Unavoidable Use
(CUU) determinations would be warranted. Minnesota Statutes 116.943, subdivision 5(c).

The
comments include additional background on the Company’s products, the important role played
by fluoropolymers and fluoroelastomers in the listed CUU products, the particular challenges
and costs of attempting substitutions in complex equipment, and the societal impacts of the bans going into effect without appropriate CUU exemptions. Valmet’s comments also urge the Agency to interpret the scope of the products rule to be limited to consumer products and to exclude industrial products. Its comments demonstrate the impracticability and high cost of applying these rules to industrial products and the limited benefit.

Attached are the comments of the Extruded Polystyrene Foam Association - XPSA. We urge the MPCA to take the overly broad definitions of the statute into account when designing Minnesota's regulatory architecture around PFAS. We suggest that CUUs should be expeditiously granted for products (like XPS foam insulation) which rarely come into contact with human beings in situ, are made with chemicals of little toxicological concern, and cannot easily be replaced by alternative products available in the market today.

PFAS causes cancer. I've had cancer. It's miserable - Much more miserable than being a car part maker who is has to do a bit of re-tooling in order to make parts without pfas in them. Please make a rule that is stringent in requiring darn good reasons for industry to get dispensations that allow them to use pfas. Above all, please do not allow mining companies to use pfas in drilling fluids, as they drill right through the water table - perhaps the most direct way to get pfas into our water supply and into us. We lived for a long time with out pfas-laden products. If it avoiding their use make corporations less profitable, so be it. How many people should have to die for corporate profits?

Juliann Rule · Citizen · (Postal Code: unknown) · Mar 01, 2024 3:53 pm

I am commenting because I believe it is imperative that PFAS from mining be kept out of Minnesota surface and ground water.

PFAS, the forever chemicals, have a wide range of serious health consequences including cancers, liver damage, increased cholesterol and obesity, reduced immune response to fight infection, dangerous high blood pressure in pregnancy, reduced infant birth weight, and developmental delays in children.

MPCA must ensure that the “unavoidable use” rulemaking process protects Minnesota waters and the health of Minnesota citizens. MPCA must resist the pressure of special interests to find loopholes in the statute or escape transparency.

MPCA rules must protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses.

MPCA rules must make sure that any determination of “currently unavoidable use” must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions don’t become permanent loopholes.

MPCA rules must prioritize public health and transparency so that information on use of PFAS in products is readily available and usable for members of the public. If manufacturers want to protect their trade secret formulas for products, they should use safer alternatives to PFAS.

MPCA should work with the Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at existing and legacy mining sites.

I would like to comment on the
"Unavoidable Use" rule. This decision process must be transparent, and seriously consider the risks. The mining operations have the potential to release PFASs in large amounts.
I comment on this as a homeowner and parent that lives in a community with PFAS contaminated water. We are constantly told our levels are ‘safe’, but no level is safe. It is not really acceptable that it is even under discussion that these chemicals could be used. They need to be banned.

Sophia Patane at March 01, 2024 at 4:43pm CST

Comment received prior to eComments manual closure at 4:31 pm on March 1, 2024.

If the Minnesota Pollution Control Agency is, in fact, committed to “ensuring that every Minnesotan has healthy air, sustainable lands, clean water, and a better climate,” then the MPCA must ensure that the rulemaking process around “PFAS in Products Currently Unavoidable Use Rule” protects Minnesota waters and the health of Minnesota citizens.

MPCA must resist the pressure of special interests to find loopholes in the statute or escape transparency. For decades after the development of PFAS in the 1940s, special industry interests hid the connection between exposure to PFOA, PFOS, and other PFAS to a huge—and heartbreaking—series of health impacts including reduced immune response, developmental delays in children, increased cholesterol and obesity, and cancer.

MPCA rules must also protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses.

MPCA rules must make sure that any determination of “currently unavoidable use” must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions don’t become permanent loopholes.

MPCA rules must prioritize public health and transparency, so that information on use of PFAS in products is readily available and usable for members of the public. If manufacturers want to protect their trade secret formulas for products, they should use safer alternatives to PFAS.

MPCA should also work with the Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at existing and legacy mining sites.

My community in the east metro of the Twin Cities has been directly impacted by PFAS contamination in our water supply. The threat to our health from PFAS is real and ever-present. I ask that MPCA take this historic opportunity to create strong, enforceable rules that protect Minnesotans and the waters, wetlands, groundwater resources, and lands that we rely upon for life itself from toxic PFAS chemicals.

Melanie Loyzim, Commissioner
Maine Department of Environmental Protection
17 State House Station
Augusta, Maine 04333-0017
PFASProducts@maine.gov

Re: Request to Maine for a Currently Unavoidable Use Exemption for Complex Consumer and Durable Goods, their Components and Replacement Parts

Dear Commissioner Loyzim:

The Coalition of Manufacturers of Complex Products (Coalition) appreciates the opportunity to submit to the Maine Department of Environmental Protection (MDEP) this request for a currently unavoidable use (CUU) exemption pursuant to 38 M.R.S. §1614 for "complex consumer and durable goods, their components and replacement parts."

Coalition members manufacture equipment and products by assembling tens to hundreds or thousands of parts, components, and raw materials to provide, in many cases, critical services to society. These include commercial and consumer products such as appliances, vehicles, vessels, motors, heating, ventilation, air conditioning, refrigeration, and water heating equipment (HVACR-WH), electronics, and their replacement parts. Coalition members serve and support nearly every major sector in the nation, providing critical products and services for government agencies, the military, law enforcement, first responders, and public safety, food and agriculture (including commercial fishing and sea farming), energy, transportation and logistics (including for commuting and for island residents), public works and infrastructure support services, critical manufacturing, the defense industrial base, conservation, and life-saving climate control and ventilation in homes, hospitals, schools, and eldercare facilities, for food preservation and processing and for critical health and life sciences. Services dependent on refrigeration include everything from the prevention of dangerous food spoilage to life-giving medicines, vaccines, proteomics, therapeutics, blood plasma, and other temperature-dependent elements in the life sciences and pharmaceutical sectors. Collectively these products and services constitute a vital part of the economy, at all levels, including for public safety.

As explained below, in response to the criteria specified by MDEP for requesting a CUU exemption, Coalition members produce complex consumer and durable goods with internal components that may contain substances in the class of substances defined broadly as per- and polyfluoroalkyl substances (PFAS) at 38 M.R.S. §1614(1)(F). The use of PFAS in these applications warrants an exemption from both Maine's reporting program and 2030 ban. There is an exceptionally low or no likelihood of exposure to PFAS from using these products, and the process of identifying where PFAS are present, researching feasible alternatives, and implementing changes throughout these large and complex supply chains will take many years beyond January 1, 2030.

1. **Description of Individual Product Category.**

Maine's law is entitled "SALE OF CONSUMER PRODUCTS AFFECTING THE ENVIRONMENT". As written, the requirements of this law apply the more general concept of a "product," defined in 38 M.R.S. § 1614(1)(G) as:

> "an item manufactured, assembled, packaged or otherwise prepared for sale to consumers, including its product components, sold or distributed for personal, residential, commercial or industrial use, including for use in making other products."[1]

The inclusion in the definition above of items that are sold and distributed *for commercial and industrial use* extends well beyond items that are sold to individuals and households.[2]

Given its scope, the Coalition is extremely grateful that Maine's law offers a rational approach to product identification, and specifically allows manufacturers to supply information for categories of products, rather than for each individual product or product type.[3] According to 38 M.R.S. §1614(5)(C), the Department may "identify products by category or use that may not be sold" (emphasis added) and "prioritize the prohibition of the sale of product categories" (emphasis added). According to 38 M.R.S. §1614(5)(D), MDEP may "specify specific products or product categories in which it has determined the use of PFAS is a currently unavoidable use" (emphasis added).[4] Maine's website specifies that a separate proposal must be submitted for each individual product category. In these comments we explain how "complex consumer and durable goods" is an individual product category.

To make the expansive scope of this law rational and targeted so that it addresses Maine's concerns, and do so in an efficient manner, the Coalition respectfully urges Maine to think broadly in establishing exempt product categories. The definition of a CUU in the law offers support for

---

1 Under subparagraph H, a "product component" is defined as an identifiable component of a product, regardless of whether the manufacturer of the product is the manufacturer of the component.

2 The expansive scope is echoed in the Frequently Asked Questions (FAQs) prepared by MDEP. In response to the question "What products must be reported? "DEP responds:

> "38 M.R.S. §1614 (1)(G) defines a product as "an item manufactured, assembled, packaged or otherwise prepared for sale to consumers, including its product components, sold or distributed for personal, residential, commercial or industrial use, including for use in making other products." The statute defines "product component" as "an identifiable component of a product, regardless of whether the manufacturer of the product is the manufacturer of the component."
>
> All products and product components sold in Maine for personal, residential, commercial, or industrial use are subject to this program. If a product is offered for sale in Maine for one of those purposes, the Manufacturer of the product must report the amount of PFAS in their product."

In response to the question "Are products that are sold for industrial or commercial use treated differently than those meant for personal or residential use?" MDEP responds:

> "No, under the law all products, regardless of whether they are sold for personal, residential, commercial, or industrial use are treated the same.
>
> The law also requires reporting for components of the final product and products that are sold to be incorporated into another product. (38 M.R.S. §1614(1)(G))."

3 38 M.S.C. 1614(2)(B).

4 MDEP, *PFAS in Products: Currently Unavoidable Uses* (Last visited February 29, 2024).

this approach, speaking in terms of "a use of PFAS" absence of a reference to a "product", "individual product category" or the term "industrial sector." It states:

> "a use of PFAS that the department has determined by rule under this section to be essential for health, safety or the functioning of society and for which alternatives are not reasonably available."[5]

Examples of the uses we ask to be exempt include, but are not limited to, HVACR-WH equipment, boats, marine vessels, automobiles, off-highway vehicles, farm equipment, personal assistive mobility devices, household appliances, consumer electronics, furniture, tools, industrial, commercial and consumer lighting installation equipment, sports equipment, and medical equipment. These items, when categorized as complex consumer and durable goods, qualify as a "product category" under the Maine law because the use of PFAS in all of these products is essential for the health, safety, or functioning of society.

Accordingly, the Coalition asks MDEP for a CUU determination for use in complex consumer and durable goods, their components and replacement parts. Complex consumer and durable goods are manufactured items that are sold and distributed for personal, residential, commercial, or industrial use. It is appropriate to treat them as a product category because of the high degree of complexity associated with identifying and requesting an exemption for each and every affected component.

A. Proposed Language for this Exemption

We request that the term "complex consumer and durable goods" be defined similar to the language found in the Toxic Substances Control Act (TSCA) § 6(c)(2)(D) to mean:[6]

> "electronic devices, mechanical devices, and manufactured goods composed of multiple components, with an intended useful life of 3 or more years, where the product is intended for consumer, commercial, or industrial use and is typically not consumed, destroyed, or discarded after a single use, and for which the components would be impracticable to redesign or replace."

Pursuant to 38 M.R.S. §1614(1)(B), we offer the following language to describe the exemption:

> "Complex consumer and durable goods, their components, and replacement parts, including but not limited to:
>
> a. Cooling, heating, ventilation, air conditioning and refrigeration equipment.
> b. Vehicles, including watercraft and marine vessels, automobiles, off-highway vehicles, farm equipment, personal assistive mobility devices, e-scooters, and e-bikes.
> c. Solid state and LED industrial, commercial and consumer lighting and system installations and smart home systems.
> d. Consumer electronics and communication devices.

5 38 M.R.S. §1614(1)(B).

6 15 U.S.C. § 2605(6)(c)(2)(D).

e. Medical devices."

The Coalition does not think Maine's law requires the use of brick codes or HTS codes to implement CUU exemptions. We do not support requiring their use as a condition for qualifying for a CUU exemption.

The Coalition's proposed approach is the kind of pragmatic thinking Maine needs to address such a critical issue. Instead of having to review and sign off on hundreds or more individual product exemptions, MDEP can address all of them under the sole product category of complex consumer and durable goods. This idea has been adopted by the federal government under TSCA.[7]

If MDEP chooses another approach, then the Coalition supports all requests in that regard for the products listed above as well as others. Additionally, the Coalition suggests that a product category can be a group of chemicals, such as fluoropolymers or refrigerants. For manufacturers of these chemicals, the fluoropolymers and refrigerants are their products. They are manufactured from other chemical components and packaged and sold for commercial and industrial use to manufacture other products and components, including complex consumer and durable goods. If MDEP permits an exemption for a product, product category, or use based on a request by a single manufacturer (or a group of manufacturers), the Coalition urges Maine to ensure that the exemption applies to all manufacturers of those products or uses.[8] Ultimately, the Coalition believes that the number of requests that Maine may receive to exempt various kinds of complex consumer and durable goods will highlight the need for a complex consumer and durable goods category as the most effective way to ensure that Maine will not be deprived of essential goods when the 2030 ban becomes effective.

2. Use Information In Complex consumer and durable goods That Are Essential For The Health, Safety, and Functioning of Society.

Complex consumer and durable goods are essential to the safety and functioning of critical domestic infrastructures such as defense, aerospace, communications, indoor climate control, cooling systems, transportation, communications, and construction. These products are used in security systems, lighting, life-saving medical devices, military equipment, and for transitioning to a clean energy-based economy. Coalition members serve and support nearly every major sector in the nation, providing critical products and services for government agencies, the military, law enforcement, first responders, and public safety, food and agriculture (including commercial fishing and sea farming), energy, transportation and logistics (including for commuting and for island residents), public works and infrastructure support services, critical manufacturing, the defense industrial base, conservation, and life-saving climate control and ventilation in homes, hospitals, schools, and eldercare facilities, for food preservation and processing and for critical health and life sciences. Services dependent on refrigeration include everything from the prevention of dangerous food spoilage to life-giving medicines, vaccines, proteomics, therapeutics, blood plasma, and other temperature-dependent elements in the life sciences and

---

7 For example, EPA is proposing to exempt wire harnesses and semiconductors from the PIP 3:1 product ban. Decabromodiphenyl Ether and Phenol, Isopropylated Phosphate (3:1); Revision to the Regulation of Persistent, Bioaccumulative, and Toxic Chemicals Under the Toxic Substances Control Act (TSCA),88 Fed. Reg. 82287 (Nov. 24, 2023).

8 The Coalition does not support granting CUU determinations that exclude other market participants. Such a determination would be contrary to 38 M.R.S. §1614(5)(C) and (D)which refer to products by category or use, not by manufacturer or groups of manufacturers.

pharmaceutical sectors. Collectively, these products and services constitute a vital part of the economy, at all levels, including for public safety. Put in the context of MDEP's proposed definition of "essential for health, safety or the functioning of society,"[9] a ban on complex consumer and durable goods could disrupt normal societal functions and jeopardize the health and safety of Maine citizens.

PFAS chemicals are on the minds of every lawmaker at the local, state, federal and international level. Exposure to these PFAS must be addressed with expediency and pragmaticism. Unfortunately, getting caught up in the Maine law meant to regulate PFAS are many products that we rely on every day that present low or no potential for exposure. These products could be outright banned by 2030 if Maine's current approach does not shift toward a more inclusive and pragmatic version. Right now, any manufacturer who sells a product in Maine will be required by 2025 to report to the state if the product contains one of nearly 8,000 chemicals designated as PFAS. By 2030, the PFAS needs to be out of the product, or they must stop selling them in the state.

Complex consumer and durable goods are necessary to maintain current lifestyles. We all have systems in our house that have PFAS enclosed in them. Thermal insulation, heating, wiring, and lighting systems are examples. Think about your refrigerator, microwave, car, computer, and most starkly, heat pumps. Heat pumps are designated as energy efficient to cool and heat homes, and Maine goes so far as to give rebates to its citizens for putting them in their homes. Under the current law, they will be banned by 2030 because the refrigerants in them contain PFAS. The refrigerants are in a closed system, and these are the kind of products that maintain their integrity.

Another example is commercial and recreational boats. The supply chain for these complex products is fragmented, with around 3000 boat builders in the US. All electrical components, tubing, speakers, electronics, fuel systems, vents, dispensers, nozzles, all ordered from a catalogue and there is a lot of customization. A typical boat has over 1000 components and each item has in turn several parts. There are parts (*e.g.* coolers, ignition box) assembled into the boat that are separate complex consumer or durable goods themselves.

Banning PFAS in all complex consumer and durable goods six years from now would have unprecedented national security consequences. The U.S. Department of Defense (DOD) issued a Report in August 2023 to explain these consequences. DOD classifies the use of PFAS as critical for several, common complex consumer and durable goods.[10] This report shows how complex consumer and durable goods are central to the functioning of all fundamental infrastructures that are essential to the functioning of society. Again, these include our defense capabilities, public safety, food and agriculture, energy, education, medical care, transportation, and logistics.

As the Maine Legislature stated in the preamble to Public Law 2021 c. 477, the purpose of Maine's law is "to phase out the sale of certain nonessential products containing PFAS."[11] The Coalition submits that there are no complex consumer or durable goods that are nonessential, and the failure to exempt complex consumer or durable goods as a category will inevitably result in

---

9 MDEP, *PFAS in Products: Currently Unavoidable Uses* (Last visited February 21, 2024).

10 Department of Defense, *Report on Critical Per- and Polyfluoroalkyl Substance Uses, Pursuant to Section 347 of the James M. Inhofe National Defense Authorization Act for Fiscal Year 2023 (Public Law 117-263)* (August 2023).

11 Public Law 2021, c. 477, An Act To Stop Perfluoroalkyl and Polyfluoroalkyl Substances Pollution (LD 1503, 130th Legislature).

spending more resources on CUU determinations, not to mention depriving the state of products that are essential to safety and health and functioning of society.

3. **The Specific Use of PFAS Essential for Products to Function. If this use of PFAS is required by federal or state law or regulation, provide citations.**

The Coalition supports a risk-based approach to regulation of the broad category of PFAS chemicals. Such an approach aligns with the directive in 38 M.R.S. §1614(5)(C) for MDEP to "prioritize the prohibition of the sale of product categories that, in the department's judgment, are most likely to cause contamination of the State's land or water resources if they contain intentionally added PFAS." The components containing PFAS are bound or encased within complex consumer and durable goods. Therefore, there is little to no likelihood of human exposure or release to the environment during the useful life of the product.[12] Many types of PFAS that can be found in complex consumer and durable goods have not yet been sufficiently studied to confirm whether they exhibit the persistent, bioaccumulative and toxic characteristics found in the most common PFAS that were studied. Less than 1% of known PFAS are currently monitored by targeted analysis.[13] Yet, Maine's sweeping definition that captures around 8,000 PFAS would ban them indiscriminately in spite of the significant differences in characteristics among the substances that fall into that category.

In some cases, the use of PFAS in complex consumer and durable goods can be essential due to their unique properties under extreme conditions (*e.g.*, elevated or freezing temperatures, high pressure, and exposure to aggressive chemicals) and electrical and thermal insulation. They are used as neat chemicals as regulated refrigerant gases, foam blowing agents, specialty fluids, aerosol propellants, and heat transfer fluids. In cases where substitutes can be identified, the replacement process for complex consumer and durable goods often takes many years.

A. <u>Applicable Federal Laws and Regulations</u>

38 M.R.S. §1614 subsection 4A states that "[a] product for which federal law governs the presence of PFAS in the product in a manner that preempts state authority" is out of the scope of the law. There are numerous examples of federal laws that govern complex consumer and durable goods. For instance, the list below provides examples of some of the federal laws already governing HVACR-WH products:

- EPA's Significant New Alternatives Program (SNAP) under the Clean Air Act;
- EPA's new chemicals and significant new uses program under Section 5 of TSCA;
- EPA's American Innovation and Manufacturing (AIM) Act Technology Transitions Final Rule for the Phase down of HFC's;
- Drugs, medical devices, biologics, and diagnostics and equipment authorized under the Food and Drug Act (FFDCA); and
- Devices subject to regulation under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) (i.e. air purifiers).

---

[12] The Coalition would like to continue to see Maine regulate the disposal of PFAS-containing products through the state's waste management laws, rather than through a law instituting a PFAS ban.

[13] Nicolas Humez, Prevention of PFAS pollution & Monitoring of PFAS environmental releases, OECD Webinar (Dec. 10, 2023).

4. **Whether There Are Alternatives For This Specific Use Of PFAS Which Are Reasonably Available.**

Maine's law mandates that the manufacturers report on PFAS and remove PFAS by 2030, but in most cases the manufacturers of complex consumer and durable goods are not the origin of the PFAS ingredient. For example, the components of a heat pump are made by multiple suppliers for assembly by the manufacturer of the heat pump. The component suppliers are not normally required to provide detailed information on the ingredients they use. Due to the sheer number of parts and suppliers, it is extremely difficult to find out if and where PFAS is used.

Determining the presence of PFAS in complex international supply chains, finding potential suitable alternatives, and performing rigorous testing, reformulation, and other steps involved in implementation can easily take twenty years or more. The process begins with a preliminary screen for possible alternatives, evolves to a more in-depth analysis on performance and economic feasibility of suitable candidates, and finally results in the need for adequate performance testing to ensure safety, reliability, performance, and quality control parameters are met. Moreover, due to the myriad and diverse products which qualify as complex consumer and durable goods, there is no single time limit that would be suitable for an exemption for these products. MDEP can and should avoid the need to spend more resources to re-engage with industry and undertake additional rulemakings to extend specific product exemptions.

5. **Contact Information For The Submission.**

The Coalition thanks MDEP for consideration of this request for CUU. For more information on this request, please contact:

RECEIVED
By: OAH on 2/19/2024

The Minnesota Pollution Control Agency (MPCA) is planning new rules governing determinations of currently unavoidable uses of per- and polyfluoroalkyl substances (PFAS) in products. The organic statute, located in Chapter 60 of the 2023 Minnesota Session Laws, at 116.943(5)(c) says that

> Beginning January 1, 2032, a person may not sell, offer for sale, or distribute for sale in this state any product that contains intentionally added PFAS, unless the commissioner has determined by rule that the use of PFAS in the product is a currently unavoidable use. The commissioner may specify specific products or product categories for which the commissioner has determined the use of PFAS is a currently unavoidable use. The commissioner may not determine that the use of PFAS in a product is a currently unavoidable use if the product is listed in paragraph (a).

The MPCA has requested public comments to specifically answer eight questions and to provide any other feedback.

Before I address the eight questions, I would like to make a few points regarding the detrimental effects of PFAS and putting the regulation in context with Amara's Law.

First, PFAS are "a group of thousands of human-made chemicals known to be toxic that do not break down in the environment." PFAS in Minnesota. Colloquially they are known as "forever chemicals." We have not studied the effects of these chemicals on their effects on humans and our environment, yet they "have been found in groundwater and surface waters throughout Minnesota and have seeped into some drinking water systems." *Id.*

Second, I would like to point out that Minnesota regards PFAS as hazardous substances and should seek to address the issue as soon as possible and as effectively as possible.

MPCA has requested comments on eight question, to which my responses are below:

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

For context, this question is addressing 116.943(1)(j), the section that defines "currently unavoidable use."

> "Currently unavoidable use" means a use of PFAS that the commissioner has determined by rule under this section to be essential for the health, safety, or the functioning of society and for which alternatives are not reasonably available.

Defining criteria for the terms “essential for health, safety, or the functioning of society” is not necessary because the Commissioner should have broad authority to determine this finding. Subsection (c) specifically grants the Commissioner this authority: “The commissioner may specify specific products or product categories for which the commissioner has determined the use of PFAS is a currently unavoidable use.” However, the Commissioner could issue guidance, specifically on what he/she believes is essential to the functioning of society, since this element could be construed as the vaguest and perhaps broadest part of the definition.

2) Should costs of PFAS alternatives be considered in the definition of “reasonably available”? What is a “reasonable” cost threshold?

The costs of PFAS alternatives could be considered in this definition. These are some ideas to consider:

- Adding the costs of PFAS alternatives could possibly reduce litigation costs because the term “reasonably” is very ambiguous.
- Listing actual numbers is a potentially bad idea because of the costs of inflation.
- A better way to clarify is to use percentages. Perhaps “reasonably available” might include PFAS alternatives that cost 15% or less than the fair market value of PFAS products.
- However, I think the State should consult with experts in economics to determine the proper percentage.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

Small businesses make up 95% of MN’s businesses and employ over 1.3 million workers, or 47% of the workforce. This is a large sector of the State’s economy but special consideration should not be given because the State has funding opportunities to help small businesses.

Care should be taken to prevent job loss, which the State has already done with PFAS source reduction grants. These grants provide “financial assistance to businesses and local governments for reducing or eliminating the use or release of PFAS.” Therefore, I don’t believe the rule needs to specifically address small businesses.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?

These determinations, as prescribed by 116.943(5)(c), should be valid for 10 years. This length of time allows for stability and it's not so frequent as to deplete resources by forcing reconsideration too often.

As to the question of whether significant changes in available information about alternatives trigger re-evaluation, MPCA and the Commissioner should re-evaluate currently unavoidable use determinations. The name itself seems to mandate it–if there is new information regarding the ***currency*** of an alternative, the Commissioner must re-evaluate in order to ensure that the product is ***currently*** an unavoidable use.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

The MPCA could conduct evidentiary hearings for the most fairness. The drawback of this option is the administrative costs to the State could be high. However, this would likely be considered to be an adjudication, so Due Process could possibly require a hearing. To determine what kind of hearing is necessary, the MPCA should consider the *Eldridge* factors when crafting a rule on this topic.

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

The products that are considered currently unavoidable uses should be strictly limited. However, here is a brief list of each element:

- ***Health***:
  - Medical equipment such as single-use tubes, syringes, catheters, etc
  - Items for medical research
- ***Safety***:
  - Protective apparatus for workers
- ***Functioning of Society***:
  - Some building materials

My list is short because I would not like to see this rule, and Amara's law diluted with exceptions. These exceptions need to be limited in order to ensure greater incentive for companies to eliminate truly unnecessary PFAS usage.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

As long as it is the Commissioner making such determinations and as long as the determinations are purely legislative determinations, the MPCA should make some determinations. Doing so would help clarify the statute for companies to ensure better compliance. And, when the MPCA conducts hearings on the matter for individual companies, providing this guidance early could potentially reduce these adjudications and the costs from them.

9) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

In this section, I simply wish to stress the importance of limiting the number of products that are part of a currently unavoidable use. While the costs to the companies conducting business in MInnesota are important, I believe that the costs to our health and environment strongly outweigh financial costs to companies. On this point, "essential to the functioning of society" should not be treated as a "junk-drawer" for the Commissioner to allow certain products with PFAS to poison our waters because what will truly allow for the functioning of society is eliminating PFAS to the maximum extent possible.

Thank you for your consideration,

Concerned Citizen of Minnesota

Comments submitted by Ali Ling, 2/20/2024

These comments are meant to address specific questions posed by the MPCA under "PFAS in products: Currently unavoidable use" (Revisor ID: R-4837)

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

I think "essential for health, safety, or the functioning of society" should be defined as providing more long-term benefit to society than harm. The total benefits of using it (the direct benefits minus long-term environmental and health impacts of PFAS resulting from use) to the total benefits of not using it (long-term benefits of environmental and health impact reduction minus the cost and drawbacks of not using it). Since some PFAS uses have demonstrated, effective, widely available, non-PFAS alternatives, (See this Royal Society publication as one source), I suggest developing a list of these uses and designating them as "non-essential" regardless of economic situation.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

In the long-term, costs of PFAS alternatives should be compared to the costs of a.) the remediation costs of removing those PFAS from the environment once released, b.) the potential future public health burden of those PFAS once released, or a combination of the two. A primary issue with ongoing PFAS use is long-term accumulation in the environment (due to their environmental persistence), so consideration of immediate replacement costs should be weighed against future health risks and remediation costs.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

Some exceptions could be made in the short-term to protect businesses, especially small local businesses, for specific applications while additional PFAS-free alternatives are developed. In the meantime, research into those types of alternatives should be accelerated (I'm not sure by whom). However, the list of non-essential uses described above should be held to, even for small businesses.

I think the state could benefit from a technical assistance program to help small businesses identify and implement readily available alternatives. This could be operated through the MPCA but supported by any number of other organizations.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

Safety judgement should be based on a combination of environmental persistence and demonstrated toxicity, if available. ZeroPM is doing some good work in this sector using "cheminformatics" to predict the environmental persistence of anthropogenic chemicals.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

"Currently unavoidable" use determinations should be valid for no more than five years, with re-evaluation triggered by changes in available information and products.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Stakeholders should request "currently unavoidable use determination" from the MPCA. Information in requests for currently unavoidable uses should include:

- Specific use and specific PFAS
- Mass rates of PFAS used and final fate
- Projected future remediation cost of PFAS emissions
- Projected future health costs of PFAS emissions
- Projected "future" cost of replacing the PFAS (discount-adjusted to account for different time frames, i.e. cost savings now resulting in larger future risks)

Samuel Choe Attachment 1

Manufacturer: Honda

Product Category: Motor Vehicles

Submission Date: February 20, 2024

1. Provide a brief description of the type of product including, if applicable, the Global Product Classification (GPC) brick category and code, or if GPC is not applicable than the Harmonized Tariff System (HTS) code.

   GPC brick code: 10005232

   GPC brick title: Batteries (Automotive)

2. Describe the intended use of the product and explain how it is essential for health, safety or the functioning of society.

   PVDF (Polyvinylidene fluoride), a type of PFAS, serves as a binder for electrode active materials in lithium-ion batteries, and there is no alternative material for PVDF. If PVDF cannot be utilized, the widespread of electric vehicles could be significantly hindered, potentially accelerating global warming.

   Furthermore, the battery cells are sealed, and the cells are additionally protected by an envelope when integrated into the product. PVDF is used inside these sealed cells, so there is no potential exposure to the end user that may lead to health risk.

3. Describe how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, provide citations to that requirement.

   Currently, PVDF is the sole option as a binder for electrode active materials in lithium-ion batteries, and no alternative materials have been identified. Therefore, the use of PVDF as a binder is crucial for the production of lithium-ion batteries.

4. Describe whether there are alternatives for this specific use of PFAS which are reasonably available.

   Currently, there is no suitable alternative.

5. Provide contact information for the submission.

Comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Date: February 25, 2024
To: State of Minnesota Office of Administrative Hearings, Minnesota Pollution Control Agency

In response to the request for comments on the currently unavoidable use determinations about products containing PFAS, we would like to comment as follows:

1) **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**
   There should be a standard of "essential for health, safety, or the functioning of society" to maintain the current standard of living, and that standard should be whether it contributes to people's lives and livelihoods. For example, manufacturing facilities related to social infrastructure (e.g., drinking water, water recycling, wastewater treatment), food, pharmaceuticals, and semiconductors that are essential to daily life meet the criteria of being "essential for health, safety, or the functioning of society".

2) **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**
   Raw materials such as super engineering plastics, which are equivalent to PFAS in performance, are several times more expensive than PFAS and are sometimes in short supply. For products that are essential for health, safety, or the functioning of society, the cost of PFAS alternatives should be comparable to PFAS to preserve people's lives and livelihoods. (e.g., Compared to typical PFAS, PES is 1.5 times more expensive, and PEEK is 5 to 10 times more expensive.)

3) **Should unique considerations be made for small businesses with regards to economic feasibility?**
   The same standards should be established for all businesses, regardless of company

size, that handle products that contribute to people's lives and livelihoods.

4) **What criteria should be used to determine the safety of potential PFAS alternatives?**
Raw materials that contain as starting materials substances of concern for human health or environmental hazards under TSCA, California's Proposition 65, or EU-REACH's SVHC must not be substituted. In addition, general-purpose polymers, which have the potential to decompose and generate microplastics after prolonged exposure to pressure or chemicals, should not be used in water, food, and pharmaceuticals that enter the human body, nor in the semiconductor field, where even the smallest particulate contamination is unacceptable. In the case of products related to drinking water facilities, the product should be considered safe if it can be issued a certificate of safety, such as that it adheres to the proposed National Primary Drinking Water Regulation (NPDWR) which was announced by EPA on March 14, 2023, and Minnesota's drinking water standards. [NPDWR URL: https://www.epa.gov/sdwa/and-polyfluoroalkyl-substances-pfas]

5) **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**
It should remain in effect until alternatives are found that are equal to or better than the current product, both technically and economically. We expect the MPCA to continue its investigation of suitable raw materials for substitution and to compile a list of alternatives. The validity period can be considered again when the survey and list of alternative substances is completed. We agree with the idea that a reassessment should be made when there is a significant change in the available information on alternatives.

6) **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**
There should be an opportunity for public comment on whether to decide on products for unavoidable uses of PFAS.
In support of the request, we believe the following information should be submitted.
・Information on the intended use of the product and whether it is essential for health,

safety, or social function

・Intended use of PFAS in products

・Anticipated impact on people and society if PFAS is no longer available

・Information on alternatives (Multifaceted information on performance, safety, economy, etc.)

・Certification to standards or regulations, if those standards or regulations have been established for the application

7) **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

Hollow fiber filtration membrane modules mainly used in the following fields:

1. Drinking water, wastewater treatment, and water recycling

In the field of drinking water production, hollow fiber filtration membrane modules have the following characteristics and are used in water purification facilities in Minnesota and the United States.

- Stable water quality can be maintained over a long period of time: the size of impurities that can be removed is clearly defined.
- No need to dispose of coagulant or sludge: no need for specialized technology such as coagulant control and easy maintenance.
- Space saving of water purification facilities.

The change to water purification methods other than hollow fiber filtration membrane modules will result in deterioration of water quality, an increase in industrial waste, and an increase in the area required for facilities, which will affect people's lives and livelihoods by making it impossible to produce water at the same level as at present.

2. Food production

Membrane modules are used, for example, to remove lees from wine and have the following features:

- No industrial waste is generated: Conventional filtration using diatomaceous earth requires the disposal of a large amount of industrial waste, including filtration aids.

- Automation and simplification of the separation process
- CO2 emission reduction: In the case of diatomaceous earth filtration, the calcination of diatomaceous earth before use emits a large amount of CO2. Membrane modules do not require calcination.
- Stable quality: Membrane modules perform filtration without heat, so the flavor of the product is not compromised.

The change in manufacturing methods to methods other than hollow fiber filtration membrane modules is expected to increase industrial waste, increase CO2 emissions, and degrade food quality.

3. Pharmaceutical manufacturing

The membrane module is suitable for long-term continuous culture of high-density cells. The membrane module is suitable for long-term continuous culture of high-density cells. Compared to the conventional batch method (centrifugation), continuous culture produces higher antibody production per day and enables the production of pharmaceuticals with higher production efficiency. Continuous operation lowers the risk of contamination and can contribute to improved safety of drug quality, increased drug production, and cost containment. Others have been used for many years in the process of producing water for injection, which consumes less energy than distillation and reduces CO_2 emissions. (In a case study of 1.8 m3/hr of water for injection, data shows that the membrane method can reduce running costs by 40%.)

4. Semiconductor manufacturing

Membrane modules are used to produce ultrapure water for cleaning wafer. The semiconductor cleaning process is an important process that accounts for 30% of semiconductor manufacturing, and requires a very high level of cleanliness for semiconductors because even the smallest particle contamination can affect semiconductor performance. Currently, there is no process that can produce ultrapure water at the same level as organic membranes. If the quality of ultrapure water deteriorates, problems will arise, such as the inability to manufacture semiconductors in sufficient quantities and the difficulty of manufacturing electronic devices due to the rising price of semiconductors. There is ample potential for significant interruption of the daily functions on which society relies.

8) Should MPCA make some initial currently unavoidable use determinations as part

of this rulemaking using the proposed criteria?

As indicated in Item 7, regulating all PFAS would have significant social and environmental impacts. Considering the social and environmental impact, instead of regulating all PFAS, regulation should begin with PFAS that have already been identified as hazardous.

9) **Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.**

We request that the process be determined by considering the following.

- It is necessary to examine the impact on people's lives and livelihoods.
- The hazards of individual PFAS should be considered. Regulations should be implemented for substances with known hazards to human health or the environment or with known thresholds of toxicity.

We thank you for this opportunity to contribute to the rule making for currently unavoidable uses of per- and polyfluoroalkyl substances (PFAS) in products. If you have any questions, please let us know.

Sincerely,

Tomoyoshi Segawa, Manager
Microza & Water Processing Quality Assurance Department

Executive Summary

Watson-Marlow Fluid Technology Solutions (WMFTS) fully supports the restriction of specific, hazardous PFAS that pose a danger due to bioavailability, bioaccumulative and toxic properties. However, fluoropolymers (a group of polymers within the class of PFAS) meet the Organisation for Economic Co-operation and Development (OECD) criteria for polymers of low concern and are essential for various applications across multiple industries. WMFTS uses fluoropolymer materials in many products because of the very strong C-F bond as they are critical to achieve the chemical, heat and mechanical resistance required for the applications and industries that they are intended to support.

This report outlines the products and applications where WMFTS uses PFAS within its products for specific properties or performance characteristics, and the availability and feasibility of alternative materials.

For the majority of these applications, there are currently no alternative materials. To the extent there are apparent alternatives, they are not sufficiently evaluated or approved for these applications, creating concerns on performance and safety, that can impact medical procedures and drug products, aerospace, transport and food industries, amongst others. For these reasons, the products listed in this report and their associated applications should be considered Currently Unavoidable Uses (CUU).

WMFTS thanks the Minnesota Pollution Control Agency (MPCA) for the opportunity to share information on where and why fluoropolymers are used in our products and their specific applications, and where there are currently no suitable, available alternative materials that can meet the required performance characteristics. We look forward to the future opportunity mentioned in the MPCA Request For Comments communication to provide more detailed information on each of the products and applications mentioned in this report.

Sectors and applications

Information is provided for the following industry sectors and applications within this report and submission as shown in Table 1:

Sector	Application
Transport – Aerospace	PTFE lined flexible high-pressure hoses to convey critical Hydraulic fluids and Jet 1-A fuel whilst in-flight
Transport – Transport Vehicles	Use of PFASs in applications affecting the proper functioning related to the safety of transport vehicles, and affecting the safety of operators, passengers or goods
Chemical Manufacturing Industry	Transfer of chemicals for the general industrial and fine chemicals industries
Pharmaceutical Manufacturing	PTFE lined flexible hose assemblies used to transfer solvents, active pharmaceutical ingredients (API) and cleaning media
Biopharmaceutical Industry	Pump, tubing and connection components for assemblies used for the transfer of fluids for upstream processing, downstream processing, fill/finish and dosing applications
Cosmetics Industry	Fill finish applications for dosing fragrances and cosmetic products such as creams and lotions
Water and Wastewater	Use of pumps, tubing and connection components for water treatment applications including dosing of emulsion polyacrylamides, disinfection, flocculation and pH
Medical Devices	Tubes and catheters
	Support components for medical devices and laboratory testing
Lubricants	Lubricants containing PFASs required for use in harsh conditions and/or for safe functioning or safety of equipment
Petroleum and Mining	Used in pipelines, valves, gaskets, O-rings, seals, cable and wiring insulation, as well as in major equipment components, storage and transportation of products.
Food & Beverage	Pump, tubing, hoses and connection components for assemblies used for the transfer of fluids for Food & Beverage manufacturing

Table 1: Sectors and applications included in this report

A summary of the key industry processes and the impact and availability of alternative materials is shown below. Further detail is provided for each sector and application in dedicated sections of this report.

Aerospace Industry

PTFE-lined high pressure flexible hose assemblies are used to convey critical hydraulic fluids and Jet 1-A fuel whilst in-flight. PTFE is required due to the required wide temperature range of -55°C to +232°C, chemical resistance against key fluids and the flexibility and fatigue resistance. Alternative materials to PTFE for use in aerospace duty hose assemblies are not yet available. The impact of restriction will be the inability for aircraft, both commercial and military, to be able to fly.

Transport Vehicles

PTFE lined hose assemblies are used for fluid transfer applications within the proper functioning of transport vehicles including brake lines, turbo oil feed, hydraulic suspension systems, oil suction and scavenging systems. The operating temperature range of PTFE (-73°C to 260°C) is a key property required for these applications as well as chemical resistance with specific fluids such as brake fluids and hydraulic fluids. The flexibility and high fatigue resistance are also essential requirements. Alternative materials are available, but have significant limitations compared to PTFE including higher risk of failure which reduces the safety of the vehicle.

Chemical Manufacturing Industry

PTFE-lined flexible hose assemblies are used to transfer fluids and chemicals during chemicals manufacturing. PTFE is needed for the wide operating temperature of -73°C to 260°C as well as resistance against a wide range of chemicals. Hydrophobicity, flexibility, fatigue resistance and melt strength are also key properties required for use within chemical manufacturing. A number of alternative materials are considered in section 6, however there are no suitable materials that meet all of the required properties that PTFE offers. The impact of restriction will be a significant disruption to chemical manufacturing, where certain processes may no longer be possible. This will have significant impact of various industries that the chemical manufacturing industry serves.

Pharmaceutical Manufacturing

PTFE-lined flexible hose assemblies are used to transfer solvents, active pharmaceutical ingredients (API) and cleaning media. Corrosion resistance and chemical compatibility are key to the use of the hose assemblies within the industry to maintain purity and reduce the risk of contamination to the pharmaceutical drug products. A wide operating temperature range of -73°C to +260°C, hydrophobicity, flexibility, fatigue resistance and melt strength are also key properties. Suitable alternative materials have limited applications and where any changes that are possible by replacing parts with non-fluoropolymer alternatives, this would require development, qualification, validation, registration and approval. This could see a reduction in sector's growth and the slowing of the development and manufacture of life-saving drug products as companies will need to allocate significant resource to refocus on substituting, revalidating and recertifying processes, equipment, designs and controls.

Biopharmaceutical Industry

Pump, tubing and connection components for assemblies used for the transfer of fluids for upstream processing, downstream processing, fill/finish and dosing applications. Pump components include seals, gaskets, diaphragms and other pump components, where assembly components include tubing, connectors, elements, cartridges and filters. High mechanical strength, flexibility and chemical compatibility are key properties required for these applications. The impact of restriction could potentially lead to unavailability of critical medicines, health and safety hazards associated with the manufacturing processes, as well as significantly increasing manufacturing costs. Any changes by replacing parts with non-fluoropolymer alternatives would require development, qualification, validation, registration and approval. This could see a reduction in sector's growth as companies will need to allocate significant resource to refocus on substituting, revalidating and recertifying processes, equipment, designs and controls. These revalidation and registration activities associated with changing to alternative materials would be a huge regulatory undertaking for the whole biopharmaceutical industry and would divert focus and resources away from developing new therapies for life-threatening diseases for which there is currently no cure.

Cosmetics Industry

Fluoropolymers are used in surfactants, semi-automatic fill finish machines for development and small-scale production, transfer of products such as creams and lotions and packaging. The chemical resistance and inertness property of fluoropolymers means they can be used with various chemicals such as oils, hydrocarbons and solvents that are used prominently in cosmetics manufacturing, but are known to problematic due to their nature. Fluoropolymer cased pumps and tubing can be used in the transferring of various products e.g., creams, lotions, etc. at various product temperatures from - 10°C up to 100°C and allow for sterilisation up to 140°C. A considerable number of companies within the cosmetics industry would be affected by the restriction of fluoropolymer products as there are currently no significant alternatives available for critical applications in this sector.

Water and Wastewater

Error! Reference source not found.. The chemical resistance, hydrophobicity and non-stick characteristics make fluoropolymers an excellent repellent to many chemicals found in wastewater such as oils, fats, hydrocarbons, solvents and acids. Fluoropolymer membranes are the current standard in this sector as most membranes used in key composting solution for the treatment of organic waste (green waste, food waste, source separated organics, biosolids etc.) contain ePTFE. Most of these treatment facilities will have to replace a lot of integral equipment and components containing fluoropolymers, which could become very costly and could lead to some facilities shutting down. It may be possible to use alternative materials for certain specific applications within this industry, but there are no known alternatives that can be used exclusively for all required processes.

Medical Devices

Fluoropolymers are used in medical device tubing as well as in pump components, lubricants and tubing used for laboratory scale manufacturing and routine laboratory testing. Medical device tubing is used for a range of purposes such as port-catheters, angiographic catheters, epidural catheters, feeding tubes, infusion tubes and dialysis tubes. These medical device tubing applications often contain fluoropolymers such as ePTFE. Fluoropolymers provide products that are strong yet mouldable, flexible and yet porous, and most importantly are very biocompatible. These characteristics are very important for medical devices such as catheters and tubes that transfer fluids containing human cells or are inserted into the human body. There are limitations with available alternative materials in terms of their biocompatibility and the resistance to mechanical and physical stress leading to concerns over safety and likelihood of failure after a relatively short time. Cased pumps are used in laboratory scale manufacturing and routine laboratory testing as they are designed for dynamic conditions. Fluoropolymers are required for various components such as seals, pipes, plugs, fittings, liners, membranes for their ability to withstand various pressures and are highly chemically resistant. There are no alternative materials that can match the mechanical and chemical resistance properties of these fluoropolymer components. The impact of this restriction would result in critical medical devices being unavailable or significantly impacting the safety of these devices.

Lubricants

Fluoropolymer lubricants are used in lubricant oils and hydraulic fluids to reduce surface tension to allow effective working of pumps and assemblies. The chemical compatibility of these lubricants is a key characteristic in reducing the risk of violent reactions should they mix with aggressive media. Their low coefficient of friction is also important to reduce wear and tear and facilitate performance and prevent the generation of excessive heat when operating at high speed and pressures. Alternative lubricants exist, but they do not possess the same equivalent chemical compatibility creating a risk of reactions within the pumps resulting in a building of pressure, ignition and potentially violent explosions within the pumpheads. Fluoropolymer-based lubricants are used for various applications across numerous industries. The total number of affected companies and markets is unknown.

Petroleum and Mining

Fluoropolymers and fluoropolymer components are used in pumps and piping used for petroleum manufacture and mining applications. They can be found in pipelines, valves, gaskets, O-rings, seals, cable and wiring insulation, as well as in major components used in equipment, storage and transportation of products. The key functional properties that make fluoropolymers like PVDF and PTFE important in this sector are their durability, mechanical strength, corrosion resistance and rapid gas decompression resistance under the extreme environments found in mining e.g. high temperature, high pressure, presence of steam and harsh chemicals. There are currently no suitable alternatives available for critical applications in this sector. The impact of restriction would see a significant negative impact on the safety within this industry, as well as a considerable increase in cost for the development and transition to viable alternative materials. This cost is likely to be passed on to consumers, who have already seen substantial rises in their prices recently may result in energy prices becoming unfeasible for many people.

Food & Beverage

Fluoropolymers and fluoropolymer components are used in pumps and tubing for food and beverage manufacture. Fluoropolymers offer the high purity and sterile requirements that the food and beverage industry requires. Fluoropolymer materials are used to line valves, piping, tubing, filters, seals, gaskets and other standard fluid contact components as they are inert and therefore avoid chemical reactions and leaching into the food that it comes in contact with, thereby reducing the risk of contamination. Alternative materials could be used for certain, specific applications, but are not suitable for all conditions. As these alternatives don't meet all the requirements provided by fluoropolymers, this would mean multiple variations of materials would be needed for specific uses and for different regulatory requirements. This increases the risk of using the wrong material for the wrong application. The impact of restriction could potentially lead to significant increases in manufacturing costs. Ensuring proper systems is a critical feature in the food and beverage industry, failure in these systems could result in contamination of food and beverages or the release of hazardous materials, which could pose a risk to workers, consumers and the environment.

RECEIVED
By: OAH on 2/24/2024

1. MPCA must ensure that the "unavoidable use" rulemaking process protects Minnesota waters and the health of Minnesota citizens. MPCA must resist the pressure of special interests to find loopholes in the statute or escape transparency.
2. MPCA rules must protect Minnesota surface waters and groundwater from the many ways in which mining processes have the potential to release PFAS by using products that contain PFAS for drilling, tunnel boring, flotation processing, fugitive dust control, and fire suppression among other uses.
3. MPCA rules must make sure that any determination of "currently unavoidable use" must be proved by the manufacturer and must sunset after a specific time so that temporary exceptions don't become permanent loopholes.
4. MPCA rules must prioritize public health and transparency, so that information on use of PFAS in products is readily available and usable for members of the public. If manufacturers want to protect their trade secret formulas for products, they should use safer alternatives to PFAS.
5. MPCA should work with the Minnesota Department of Health and the Minnesota Department of Natural Resources to prevent new mining facilities that release PFAS and to investigate whether PFAS are present at
6. Exploratory drilling for minerals, use of tunnel boring machines, use of surfactants to enhance metal recovery in the ore floatation process, ore leaching, acid mist suppression, and use of wetting agents are just some of the ways in which the mining industry can introduce PFAS to surface water and groundwater. Products containing PFAS may also be used in mines for fire suppression and firefighting activities.
7. Ore flotation processes—like the processing method proposed by PolyMet for the NorthMet mine—may use aqueous foams containing PFAS to lower surface tension and separate the metals from soil and rock. PFAS in the flotation process can be released to the environment through tailings seepage to surface and groundwater and in direct wastewater discharge to surface water.
8. Tunnel boring machines, like the one proposed by Talon Metals for the Tamarack mine may directly introduce PFAS to groundwater through use of lubricants, protection pastes, greases, foaming agents for rock tunnel boring, grouting additives, or fire resistant fluids containing PFAS.
9. Although there have been few efforts to monitor mines as potential sources of PFAS to, BHP's Mount Whaleback Iron Ore Mine in Western Australia was recently identified as the source of PFAS impacts to groundwater with the potential to threaten a nearby drinking water supply.

RE: Request for Comments-PFAS in Products Currently Unavoidable Use Rule OAH Docket No. 71-9003-39667

Thermo Fisher Scientific (Thermo Fisher) appreciates the opportunity to submit comments in response to the Minnesota Pollution Control Agency's (MPCA) request for comments on PFAS in Products Currently Unavoidable Use Rule.

Thermo Fisher is the world leader in serving science. Our mission is to enable our customers to make the world healthier, cleaner, and safer, whether our customers are accelerating life sciences research, solving complex analytical challenges, increasing productivity in their laboratories, improving patient health through diagnostics or the development and manufacture of life-changing therapies, we are here to support them.

Thermo Fisher appreciates the opportunity to provide the following comments and applauds MPCA's commitment to robust public engagement. We offer brief comments below in response.

MPCA Question (1): ***Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?***

Despite the apparent risks from the full lifecycle of continued uses of PFAS, its use at this time, is largely irreplaceable across products and applications within the Life Sciences, Bioproduction, and Laboratory sectors. The unique chemical properties conveyed by PFAS are essential in plastics used in every academic and clinical laboratory and in the manufacture of devices, diagnostic, and tools for research and development. The equipment used in these and other critical sectors such as mining, chip manufacturing, and in environmental monitoring and testing also uniformly and unavoidably rely on PFAS starting with basic components such as semiconductors and capacitors, displays, wiring/cabling insulations, and batteries as well as tubing and connectors where aggressive chemicals are used. In fact, every type of analytical equipment used in detecting PFAS have a critical reliance on components which themselves contain PFAS. While not every form of electrical or electronic equipment (EEE) are reliant upon PFAS, specific exclusions for PFAS used in components EEE are certainly necessary to maintain market access to critical monitoring, control and measurement equipment as well as medical devices and diagnostics instruments.

Given the complexities of a global supply chain with varying regulations impacting PFAS and other substances of concern and the unique and near existential reliance on the physical-chemical properties conveyed by PFAS substances, it is realistic to believe full elimination of PFAS throughout the global supply chain for all products will take more time that current legislation foresees. Therefore, a means to ensure the good functioning of society while invention, development, and market introduction of new chemicals advances is necessary.

Thermo Fisher Scientific
168 Third Avenue
Waltham, MA 02451
thermofisher.com

In order to provide industry with clarity and certainty over new product development and market access, a means and criteria to enable a self-declaration of essentially is needed. This is already addressed in a limited manner in SubDivision 8 of the Rule, providing for exemptions for drugs, devices, and medical applications as well as for fire-fighting foams and food packaging. We believe this list should be expanded according to essentiality for the health, safety or the functioning of society and offer 3 aligned proposals according to product use and industry sector:

Health

i. Inclusion in any product which enables the manufacture of any drugs, medical devices, and diagnostic products (human and veterinary).
ii. Inclusion in any product sold to support or enable research on human health or the environment.

Safety

iii. Inclusion in any primary packaging used to ensure safety from spills/leakage of aggressive or otherwise hazardous chemicals or has functional use in primary packaging of drugs, devices, or diagnostic products.
iv. Inclusion in any product for analysis, testing, monitoring, or measurement relating to human health and environmental pollution.

Functioning of Society

v. Inclusion in products used for academic, governmental, or industrial research.
vi. Any product which depends on PFAS for safe operation per established standards and building codes.

Secondarily, because the lifespan of industrial/professional monitoring, control and measurement equipment is intentionally designed for long-lasting and reliable performance with lifespans of up to 40 years, it is vital that Amara's law be amended to enable placing spare parts onto the market in keeping with commonplace objectives of a circular economy.

Where the regulation may require a case-by-case determination for Currently Unavoidable Use (CUU), the MPCA must establish criteria for:

a) A methodology for analysis of alternatives including hazard assessment in conjunction with risk management measures for control of exposure and environmental releases – accommodating standards for best available science and adaptation as new information becomes available; and
b) A socio-economic methodology to determine proportionate and economic feasibility for implementing alternatives which factors the broad value of use as well as cost to the citizens of Minnesota where the product is removed from the market. We also recommend that these determinations be time-bounded allowing for renewal to account for scientific and technical progress.

MPCA Question (2): ***Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?***

Thermo Fisher Scientific
168 Third Avenue
Waltham, MA 02451
thermofisher.com

A "reasonable" cost threshold is not easily defined as a single value or as a cost/benefit ratio – rather it is an inexact science relating to perceived value of continued use and risk of potential harm. Moreover, we recognize the fully realized cost of any risk reduction measures relating to PFAS use must be established to determine if those measures are proportionate.

Ooserhius et al have estimated the cost of substitution, emission control, and remediation associated with 8 persistent, bioaccumulative and toxic substances. Their data showed a high variation in the reported data ranging from approximately €50/kg to an extreme of €1.2M/kg and with PFOA and PFOS remaining the highest at €1.5K/kg and €7.7K/kg, respectively, when ranked to median estimates.[1] However, this report did not factor-in the broader socio-economic impact where an alternative is not feasible, leading to the product becoming unavailable on the market.

The market cost of implementing an alternative PFAS will include not only the development of the novel chemistry, but also the cost associated with converting that novel chemistry into an intermediate product along with validating and recertifying the alternative into an end-use product. Under a realistic scenario of no universal PFAS alternative, the socio-economic model turns to societal costs of a non-use scenario. This would include costs related to plant closures or down-sizing as well as the broader impact to the Minnesota economy if the products would become unavailable.

We ask the MPCA to require consideration of a comprehensive socio-economic analysis of the costs directly associated to implementing an alternative to PFAS as well as, alternatively, the cost associated with a non-use scenario where implementing an alternative is not possible or immediately practicable.

MPCA Question (3): ***Should unique considerations be made for small businesses with regards to economic feasibility?***

No Response.

MPCA Question (4): ***What criteria should be used to determine the safety of potential PFAS alternatives?***

Any component recognized as:

- Category 1A or 1B Carcinogen, Mutagen or Reproductive Toxicants
- Substances that are Persistent, Bioaccumulative and Toxic,

[1] Oosterhuis F, Brouwer R, Janssen M, Verhoeven J, Luttikhuizen C. Towards a proportionality assessment of risk reduction measures aimed at restricting the use of persistent and bioaccumulative substances. Integr Environ Assess Manag. 2017 Nov;13(6):1100-1112. doi: 10.1002/ieam.1949. Epub 2017 Jun 24. PMID: 28548694.

- Substances which are very Persistent and very Bioaccumulative,
- Substances which are Persistent, Mobile and Toxic
- Substances which are very Persistent and very Mobile
- Substances recognized as Endocrine Disruptors for human health or the environment

should be regarded as an undesirable alternative unless there are mechanisms to manage the risk of used of those substances than what is afforded with PFAS (e.g., adequate hazardous waste incineration capacity).

MPCA Question (5): ***How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?***

To avoid costly and unpredictable interruptions to the market, a reasonable period must be afforded to each CUU determination. Furthermore, a reasonable transition time must be provided to allow for a petitioning for renewal or for market withdraw following denial of an applied for CUU determination.

We recommend, particularly for professional/industrial use products which have longer design cycles than more traditional higher volume consumer products, that an initial CUU determination period of at least 12 years be granted with provisions to allow renewal applications within two years of the date of termination of the determination period. Where a renewal is not granted, there must be a further transition period of two years from renewal denial allowing for market withdraw. A shorter CUU determination period of seven years would be appropriate after the first determination. This is particularly required given the broad scope of products potentially impacted by the market restriction and limitations in technical resources to redesign broad portfolios without compromising ongoing portfolio innovation.

The ability of industry to adopt to 'significant changes' in alternatives is highly dependent on factors the MCPA are unable to assess (such as a business' ability to make critical capital investments to re-tool or to re-obtain regulatory approvals). Therefore, it is critical that the determination period be honored in full and consideration of the reasonableness of the alternatives be factored in any renewal petition.

MPCA Question (6): ***How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?***

In addition to our proposal for expanding the exemption for industry sectors in SubDivision 8, we envision a process by which a party may submit an application for a CUU determination to MPCA for consideration. The application to MPCA would be constructed according to the provisions outlined in the eventual rule and submitted via a secure portal established by the

MPCA. A further provision regarding confidential business information regarding content of the application would be necessary. It would be advisable that this process be publicly transparent. Where a sectorial use exemption is not provided under subdivision 8, the CUU application should contain information on an analysis of alternatives, human and environmental exposure scenarios, as well as broader socio-economic data regarding implementation of any possible alternative and the corollary non-use implications.

MPCA Question (7): ***In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.***

Professional and industrial use products containing PFAS within the Life Sciences, Bioproduction, and professional/industrial monitoring, control and measurement equipment sectors as well as professional and industrial use stationary refrigeration equipment are low-volume/high-mix as compared to portfolios intended for consumer markets (e.g. domestic appliances) are high-volume/low-mix. As a result, the actual number of impacted products would be high – though containing a very small fraction of the PFAS currently emitted into the environment.
Non-inclusive list of impacted products:

- Electrical and electronic equipment used in laboratories and industrial facilities
- Environmental monitoring and test equipment
- Filtration devices used in manufacturing and bioproduction
- Laboratory apparatus (e.g., Fluorinated plastics)
- Laboratory consumables (e.g., pipete tips, fluorinated containers, semi-rigid tubing, etc.)
- Packaging of high purity chemicals, reagents and standards used in manufacture of drugs and devices as well as for sensitive laboratory applications.

MPCA Question (8): ***Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?***

We believe MPCA should make an affirmative initial CUU determination for the sectorial uses described as points i-vi in response to Q1.

MPCA Question (9): ***Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.***

A) Please clarify definition of “Intentionally Added” as it relates to PFAS inclusion in component parts of a complex article where the end-product manufacturer did not specify inclusion of PFAS; however, an upstream supplier did intentionally may have intentionally added the PFAS unknown to the downstream user of the component?

   <u>Example Scenario:</u> *Party A (based in Minn) owns the functional specifications of a wire-harness assembly which is used as a component part of a complex article (e.g., a Mass-*

Thermo Fisher Scientific
168 Third Avenue
Waltham, MA 02451
thermofisher.com

Spectrometer). Party A purchases this component from Party B (based in the US) who is a distributor for a supplier (Party C). Party C (based in Asia) creates and owns the performance specifications for the insulating plastic used in co-extrusion of the wire (e.g., a specific frictional coefficient; however, they do not stipulate the performance must be enabled by PFAS Party D (based in the EU) provides the plastic resin which meets the frictional coefficient specification through formulating the PFAS into the resin. Would Party A have the obligation to file for CUU as 'intentionally adding' the PFAS into their complex article?

B) How does MCPA envision communicating decisions on CUU Determination and renewals (if any)?

C) What standard will MCPA make in determining if alternatives are or are not reasonably available <u>and</u> qualified for end applications?

D) How does MCPA foresee enabling the circular economy by facilitating equipment repair with PFAS containing spare parts when the equipment has been placed on the market before any restriction set forth by this rulemaking?

Conclusion

Again, Thermo Fisher appreciates the chance to provide these comments in response to this proposed rulemaking. We welcome the opportunity to further engage with the MPCA to answer questions and serve as a resource.

Kind Regards,

Jeff Schatz
Director, Product Legislation Compliance

BAJ BATTERY ASSOCIATION OF JAPAN

2024/02/27

Battery Association of Japan

Kikai Shinkokaikan Building, 3-5-8, Shiba-koen,
Minato-ku, Tokyo 105-0011, Japan
contact: Kunihiko Inamura (email: inamura@baj.or.jp)

Battery Association of Japan's Observation about the PFAS restriction

Battery Association of Japan (BAJ) represents Japanese primary and rechargeable battery manufacturers. We are aware that sales of any product containing intentionally added PFAS will be prohibited in Minnesota from 2032 if it has not been determined by rule that the use of PFAS in that product is a "currently unavoidable use". However, not a few PFAS materials are used in both primary and rechargeable batteries, playing vital roles. Here we would like to explain the reason briefly why PFAS use in batteries should be a "currently unavoidable use".

What we can point out are typical PFAS materials used in batteries, their roles and potential threats caused by their ban as follows:

1. Examples of PFAS used in batteries (no guarantee that all PFAS in batteries are covered)

abbreviation	PFAS substance	CAS RN
PVDF	polyvinylidene fluoride	24937-79-9
PTFE	Polytetrafluoroethylene	9002-84-0
PFA	Perfluoroalkoxyalkane	26655-00-5
ETFE	tetrafluoroethylene-ethylene copolymer	25038-71-5
LiTFSI	lithium bis (trifluoromethanesulfonyl) imide	90076-65-6
LiTFS	lithium trifluoromethanesulfonate	33454-82-9
TEE-FP copolymers	poly(propylene-co-tetrafluoroethylene)	27029-05-6
FEP	tetrafluoroethylene hexafluoropropylene copolymer	25067-11-2

2. PFAS materials above are used as:

   a) binder of active material and electric collector to support electrode structure in lithium batteries (primary and rechargeable), nickel metal-hydride batteries, nickel cadmium batteries and alkaline button batteries.
   b) composing element of electrolyte in lithium batteries (primary and rechargeable)
   c) material for sealing parts in lithium rechargeable batteries
   d) catalyst for nickel metal-hydride batteries
   e) water-repellent membrane in zinc air batteries for hearing aid

   PFAS materials are essential for performance and safety in above batteries. After years of research battery manufacturers have finally reached the present material balance. At the moment there are no alternatives of PFAS with equivalent characteristics and costs.

3. If PFAS use in batteries is banned:

   Battery manufacturers will not be able to supply the market with lithium, nickel cadmium, nickel metal-hydride, zinc air and alkaline button batteries. Hearing aid users cannot go without zinc air batteries, and above all, the modern life without lithium-ion batteries is unimaginable. If production of lithium-ion batteries were stopped, it would have significant consequence, inevitably leading to great delay in electric vehicle promotion.

4. Conclusion

   As mentioned above, PFAS materials are widely used and irreplaceable for batteries.
   We will propose that the use of PFAS in battery is a "currently unavoidable use."

Letter of Support

ResMed Pty Ltd stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.

In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Maine and Minnesota. This proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders. By engaging experts from various industries, Claigan Environmental has adopted a collaborative approach to address this complex issue.

ResMed Pty Ltd actively participated in the consultation process and supports Claigan Environmental's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

CLEAN WATER ACTION
PEOPLE • ACTION • JUSTICE

March 1, 2024

Thank you for the opportunity to comment on the **"**Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837**".**

Clean Water Action has worked in Minnesota since 1982, focusing on finding solutions to health, consumer, environmental, and community problems; developing strong, community-based environmental leadership; and working for policies that improve lives and protect water. Our focus includes supporting environmental justice; protecting and restoring the Great Lakes for Minnesota; and ensuring safer chemicals for use in our homes and daily lives, as well as source and toxics reduction in plastics and other forms of waste. All our work culminates in the overarching goal of protecting the water we drink for generations to come.

The use of PFAS in consumer products, from firefighting foam to clothing to cosmetics, has caused extensive contamination of drinking water, wildlife, food, and people. We must turn off the tap of new PFAS entering into the waste stream by having strict rules around what is considered essential for the health, safety, and functioning of society while approaching both decision making and the ongoing quest for safer alternatives with a hazard-based approach. A strong rule is urgent and necessary to protect public health, drinking water, and the environment.

1. **Continuous quest for safer alternatives –** MCPA should adopt a clear framework for determining "safer" alternatives.

    - The state of Washington has been implementing a framework for making "safer alternative" regulatory decisions for five years and can serve as a model for Minnesota to build upon. Key elements of this framework include: 1) using a hazard approach with criteria based on EPA's Safer Choice and Design for Environment (DfE) programs, and the GreenScreen® for Safer Chemicals Hazard Assessment Guidance (GreenScreen®); 2) using a class-based approach; and, 3) including safer alternatives as alternative products or processes.

        - **Hazard- Based Approach:** When implementing the PFAS ban, it is important to have a hazard approach with an established set of criteria.

          The GreenScreen hazard criteria and its assessment tool are reliable. ChemForward is another tool based on similar hazard criteria that can be used to assess chemical alternatives.

          Both GreenScreen and ChemForward are used by both governments and companies. ChemForward partners include Nike, Sephora, Apple, Google, Levi's, H&M, HP, Credo, Method, Cradle to Cradle, Steelcase, HBN, Environmental Defense Fund, Target, and ZDHC. Many industry associations such Green Chemistry Council, Phosphorus, Inorganic, and Nitrogen Flame Retardants Association, and Textile Sector: Zero Discharge of Hazardous

Chemicals, already use the GreenScreen for Safer Chemicals system to find safer alternatives to hazardous chemicals, including PFAS. There are also GreenScreen certification standards for firefighting foam, textile chemicals, furniture and fabrics, cleaners and degreasers in manufacturing, food service ware, medical supplies and devices, and reusable food packaging, service ware, and cookware.

Researchers and chemical formulators alike rely on GreenScreen, which uses an open and transparent standard for assessing chemicals. The goal of GreenScreen is to avoid the use of chemicals that have negative impacts whenever possible and, when it isn't possible, to commit to continuous improvement and reduce harm as much as possible.

- **Class-Based Approach:** For too long, chemicals have been regulated one at a time, forcing regulators to play whack-a-mole when one toxic chemical is substituted for another. Further, it is unreasonable to wait for the federal government to act on chemical policy reform when the threat of PFAS exposure is impacting Minnesota in such a negative way. The intent of Amara's Law is to take a meaningful class-based approach and regulate all PFAS since all PFAS that have been studied persist in the environment, cause harm to biological systems, and endanger public health.

- **Safer Solutions:** It is vital that the agency define safer alternatives to include alternative processes, materials, and removing the chemical all together. With PFAS in particular, removing the chemical altogether or using a different material or process to achieve the function of the product is important to evaluate.

  In the process of continually searching for safer substitutions for PFAS, Minnesota works with other states, uses a process such as GreenScreen to prevent regrettable substitutions, and is holding industry accountable for consistent evaluation of ensuring they are using the safest chemicals possible in place of toxic PFAS.

2. **Process for determining "currently unavoidable"** –
It is clear from the definition of "currently unavoidable" that the MCPA must determine by rule whether a use of PFAS in a product is currently unavoidable. It should not be left to the industry to determine this and regulate itself.

Amara's Law uses "*currently unavoidable*" as the standard, and is defined as, "a use of PFAS that the commissioner has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available." There is a difference between "currently unavoidable" and "essential" – "currently unavoidable" use, in and of itself, does not necessarily mean that the use is *essential* to the health, safety, or functioning of society - it simply means the use is temporarily unavoidable in a particular product. Therefore, a "currently unavoidable" determination should only be a temporary exemption granted by rules that requires both a demonstration that there are no reasonable available alternatives AND the use of PFAS in the product is essential to the health, safety, or functioning of society.

The use of PFAS must be essential to the functioning of the product in a way that supports the functioning of society. Evaluation of the need for PFAS must include questioning whether the presence of PFAS is essential to the function of the product and whether the product still functions as it was intended without the presence of PFAS. For example, the function of a couch is to sit. Adding PFAS to resist stains does not change the function of the couch, therefore PFAS is not an essential function of the couch. Removing PFAS still allows the couch to serve its function, which is sitting. Stain resistance for the couch is an added benefit, not a core function of its existence and society isn't harmed if stain resistance is a benefit that is eliminated in order to protect the public from PFAS.

The rules must only provide time-limited exemptions that have a clear schedule for re-evaluation for the products where PFAS use is "currently unavoidable," because safer alternatives are being developed rapidly for many product sectors as states and countries set bans on PFAS in products. Ongoing evaluation of PFAS use in products exempted as "currently unavoidable" is vital to the success of the program and the quality of our water and human health. We recommend that exemptions be granted for no more than 5 years and that the agency establishes a process for re-evaluation of exemptions similar to the process established to review initial exemption claims.

We recommend the following process be used to evaluate claims of "currently unavoidable" use:

- Upon petition from the manufacturer of a product, the department shall review and determine, by rule or regulation, whether the use of PFAS in the product is a currently unavoidable use.

- The manufacturer in its petition must provide all of the following:

    - Identification of the alternatives that have been evaluated and considered as replacements for PFAS. Alternatives can mean either a chemical replacement or a change in process or material. If the only alternative being considered is a chemical alternative, petitioners must provide evidence of a chemical alternative's hazard profile demonstrating that the alternative is not safer. Hazard assessment tools including Green Screen, Chem Forward or other similar tools can be utilized to demonstrate hazard profiles of alternatives; and,

    - evidence from an independent source that demonstrates the absence of safer alternatives. Independent source in this context means a source of information that has no perceived or actual financial conflict of interest; and,

    - evidence that the function of the PFAS is necessary for the product to work for its stated purpose; and,

    - evidence that the use of PFAS in the product is critical for health, safety, or the functioning of society; and,

    - any additional information requested by the department to assist in making the determination.

- In making an unavoidable use determination, the department should:

- Adopt the state of Washington definition of “safer” when considering whether there are no reasonably available alternatives and require non-chemical alternatives and process changes to be evaluated; and,
- consider other credible sources of information. Credible sources of information should include, but not be limited to a report or publication that has been scientifically peer reviewed; published in a report of the United States National Academies; or published in a report by an international, federal, or state agency or body that identifies safer alternatives or implements laws governing chemicals. Information considered should include availability of safer alternatives for the product category or the function of PFAS in that product.
- Consider bans on the sale and use of PFAS in the product or product category in another state or states within the United States or in other countries; and,
- make the determination in relation to a category of PFAS use or a type of product rather than for each individual use or product.

Finally, for the program to function effectively, the department must uphold existing laws with respect to confidential business information (CBI) claims from manufacturers seeking exemptions, particularly when it comes to disclosing the use of alternative chemistries. The agency must have full knowledge of the chemistries used in products to evaluate if an alternative to PFAS is actually safer. And, to carry out rulemaking to exempt certain product categories, the agency must be able to provide the rationale to the public so that they can have the information to comment. Additionally, it should be the policy of the state that the presence of PFAS in a product, or any other chemical known to cause harm, not be granted CBI protection. The public health interest of knowing the ingredients of a product outweighs any business’ need to keep information about the use of harmful ingredients secret.

3. **Healthy, Safety and Functioning of Society** - While opponents of this law claim that Minnesotans will lose access to products in key sectors, it is important to remember a key provision of the law includes exemptions for products for which there are no safer alternatives and for products that are necessary for the health, safety and functioning of society. It is important that the department establish guidelines for what would constitute a product that is essential for the health, safety and functioning of society.

   Fortunately, the statute has some guidance for the department to follow. Amara’s Law has clear exemptions for “a product for which federal law governs the presence of PFAS in the product in a manner that preempts state authority; (2) a product regulated under section 325F.072 or 325F.075; or (3) the sale or resale of a used product. (b) Subdivisions 4 and 5 do not apply to a prosthetic or orthotic device or to any product that is a medical device or drug or that is otherwise used in a medical setting or in medical applications regulated by the United States Food and Drug Administration.”

   Products necessary for health and safety will likely be easier for the MPCA to identify; however, it is critical that the agency develop a rubric to determine if a product is necessary for society to function. For example, products required to meet Federal Aviation Administration or corresponding foreign aviation regulatory authority, including the European Union Aviation Safety Agency and the Transport Canada Civil Aviation or

National Aeronautics and Space Administration may receive time limited exemptions by rule.

Ultimately, no matter what decision-making framework is used, it is critical for the MPCA to only offer time-limited exemptions as a way to spur the search and use of safer alternatives. Additionally, it is important to include complex products (those with several component parts) in the regulation. First, since the law doesn't exempt these products, the legislature clearly intended for these to be included. Second, while many manufacturers claim that PFAS may only be found in the internal components of a product and therefore exposure is limited, we argue that no matter where PFAS is in a product, it endangers health and the environment.

Even though the average person might not encounter the internal component containing PFAS in complex appliances or vehicles, repair technicians do. Many of these technicians are not informed about the presence of PFAS in a complex product like appliances and therefore do not know about appropriate measures to protect themselves and the customers they are serving. Moreover, products at the end of their life cycle likely end up in landfills and in Minnesota, 98 out of our 101 landfills are leaching into the groundwater. Putting products on a timeline to be reevaluated for safer alternatives will keep Minnesota moving forward in terms of the end of toxic PFAS exposure for our community.

Thanks to an MPCA study, we know that the cost of removing PFAS from wastewater could cost Minnesota taxpayers up to $20 billion over the next 20 years. We also know that even one life lost due to an illness linked to toxic chemical exposure is too high of a cost to pay. Strong rules defining what essential use is will put Minnesota on a path towards meaningful cleanup and lives saved.

Minnesota is a national and global leader. Nearly 30 states have adopted policies to protect the public from PFAS but none are as comprehensive as Minnesota's policy. By supporting rules in Minnesota that will spur the use of safer alternatives, create a clear process for exemptions and offer time-limited exemptions, Minnesota will be taking the lead and setting an example for what can, and must, be done to eliminate the threat from PFAS.

Sincerely,

AStarck

PFAS Public Comment

1.HTS Codes

Please refer to the table on the right.

Products		HTS Codes
Tire Valve	Valve Core	8481.90.1000
	Swivel Valve	8481.80-13.00
	Valve Extension	8481.80-13.00
Relief Valve		8481.40.000
Check Valve		8481.30.100
Hot Gas Switching Valve		8481.80-13.00
Electric Expansion Valve		8481.80-13.00
TPMS (Tire Pressure Monitoring System)		9026.20.4000

2. The intended uses of the products.

PFAS are widely used in cars and motorcycles, etc.
These products are indispensable to society in transportation and outdoor activities.

3. How the specific uses of PFAS in the products are essential to the function of the products.

・As an example, regarding the valve core, we must also consider the possibility that the valve core may come into contact with gasoline.
PTFE, which has excellent fuel oil resistance, heat resistance, and wear resistance, is indispensable for valve cores.
This is evident from the fact that PTFE is used in almost all valve cores, including those manufactured by other companies.

・Other products are also essential for reasons such as improved flame-resistance, heat-resistance, and sliding properties.

4. Whether there are alternatives for this specific uses of PFAS which are reasonably available.

・There is no substitute material for PFAS, and there is no prospect of a substitute.
In fact, we have considered using rubber for some products in the past, but it was not possible to replace it due to poor setting properties.

・These are essential parts for maintaining airtightness inside automobile parts such as tires, and if they are replaced with sealants of inferior performance, the safety and reliability of the vehicle will not be ensured over the long term.
In addition, the economic burden increases due to the increased frequency of parts replacement.

・Furthermore, since these products are used not only in automobiles but also in motorcycles, construction machinery, agricultural machinery, industrial vehicles, etc., the negative impact is expected to be even greater.

・In all of these industries, PFAS are used in harsh environments to ensure safety, just as in automobiles, so switching to them is impossible unless there is an alternative material with comparable performance.

Request for Proposal Seeking Current Unavoidable Uses (CUU)

Use of Polytetrafluoroethylene (PTFE) Powder and Concentrates Used in Thermoplastic Materials of Construction for Telecommunication Equipment to Meet Flammability Standards.

CONTENT

1. INTRODUCTION TO COMMSCOPE AND THE RELEVANT EQUIPMENT

CommScope is a manufacturer of communications technology. We design, manufacture, install and support hardware infrastructure and software intelligence that enable our digital society to interact and thrive. Working with customers, CommScope advances broadband, enterprise and wireless networks to power progress and create lasting connections.

This document is CommScope's request for Currently Unavoidable Uses (CUU) of polytetrafluoroethylene (PTFE, Teflon) CAS # 9002-84-0 as powder, which is categorized in the Harmonized Tariff Schedule (HTS) with the code 3904.61.0000; or as pellets, categorized as 3904.61.0010; or in any other form, categorized as 3904.61.0090.

PTFE, as solid powder, is a commonly used by plastic manufacturers as anti-dripping agent and flame retardant because it forms fibrils in the polymeric matrix,[1,2] furnishing thermoplastic materials with increased extensional viscosity, improving the fire safety of polymers used in construction for any indoor or outdoor telecommunication equipment. When the telecommunication equipment is attached to a domicile, it is required by law to comply with flammability standards to ensure safety and adequate functionality throughout their lifespan.

PTFE powder fibrillates, compounded into thermoplastic resins, help molten plastic bead up and extinguish, rather than dripping and spreading a flame. The standards related to fire hazard testing of electrotechnical products require no drip. Standard UL 94, the Test for Flammability of Plastic Materials for Parts in Devices and Appliances, determines the material's tendency to either extinguish or spread the flame once the specimen has been ignited. Additionally, Standard UL 723, the Safety Test for Surface Burning Characteristics of Building Materials, determines the material's propensity to burn rapidly and spread flames.

2. SEPECIFIC USE OF PTFE IN THE ARTICLE

PTFE, as a thermoplastic material, is necessary to retard dripping (usually at less than 0.5 wt.% loading). CommScope, as a downstream user of thermoplastic materials, determines the required properties of plastic pellets that are used in manufacturing of telecommunication equipment, used in the construction of telecommunication infrastructures. However, CommScope is dependent on the expertise of suppliers and polymer manufacturers for the formulation of thermoplastic materials.

PTFE can form a fibril structure due to high shear forces during compounding. This fibril structure together with the strength of the carbon=fluorine bond, creates a very stable structure and helps molten plastic bead up and extinguish rather than dripping and spreading a flame.

Polytetrafluoroethylene (PTFE), as an additive with anti-dripping properties, plays a safety-critical role and its use is essential to achieve compliance with strict UL 94 and the National Electrical Code (NEC/NFPA 70).

3. INTENDED USE OF THERMOPLASTIC MATERIAL OF CONSTRUCTION IN TELECOMMUNICATION EQUIPMENT

Plastic construction materials for any indoor or outdoor telecommunication equipment, attached to a residential dwelling, are required by law (electrical code) to comply with UL94 V0 at the design thickness. Relevant equipment includes fiber optic (FO) splice and connector housings (closures, boxes, cabinets) and associated components for fiber management, FO connectors and adapters, fiber optic cable and cable attachments, enterprise (ethernet/twisted pair copper) cables, jacks, and plugs. The quantity of PTFE powder annually used by CommScope, as anti-dripping agent, we have estimated to be in the range of 10 to 20 metric tons globally.

Use case - Tunnel application for mission-critical communication:
Due to safety requirements in tunnels longer than five hundred meters, materials need to be used during their construction that guarantees mission-critical communication amongst the emergency response forces, such as fire-brigade, police, first response and medical personnel. Communication is usually done with an active Distributed Antenna System (supplied by CommScope) where RF signals from Base Stations outside of the tunnel are received at a Head End, converted into optical signals, and distributed intelligently over fiber to Remote Units which are installed inside the tunnels. These are then reconverting the optical signals into RF, amplifying the RF signals, and serving these radiating cables. Certain flammable requirements for the DAS and the radiating cables are set and can only be met when a FR resin (containing PTFE) is used for the outer insulating layer (jacket) of the cable.

A recent review, published by the Society of Environmental Toxicology and Chemistry (SETAC) in 2023,[3] states that emissions to the environment of PTFE are negligible during the use phase of final products. PTFE is bound within the polymer. PTFE does not release any chemical substances of toxicological or environmental concern. In addition, PTFE is one of the most thermally stable plastic material and there are no appreciable decompositions at ambient temperatures.

When articles containing PTFE, as anti-dripping additives, reach the end of their lifecycle, various waste pre-treatment methods are commonly practiced by the industry, such as recycling, re-use, landfilling and incineration.

For example, during **incineration,** PTFE thermally degrades completely without formation of non-polymeric PFAS at combustion temperatures higher than 850 °C and then residues are removed when the flue gases are cleaned. This fluoropolymer is mineralized by breaking all C-F bonds and generating hydrofluoric acid, which is scrubbed to calcium fluoride. On the other hand, no fluorine-containing products of incomplete combustion are produced above background levels under commercial Waste-to-Energy (WtE) incineration operating conditions.

The RIVM report[4] affirmed that PTFE is the most stable fluorine-containing polymer. When users of PTFE opt for **recycling/reusing** and **landfilling** an article or a complex object, PTFE remains as a fluoropolymer, which is not water soluble or mobile., These articles or complex objects do not decompose into non-polymeric PFAS presenting a risk to the environment by the non-polymeric PFAS. There is considerable data demonstrating that PTFE do not release substances of toxicological or environmental concerns at ambient temperatures in any climate. In contrast to non-polymeric PFAS, PTFE being a polymeric material is chemically, thermally, and biologically stable and therefore is not expected to transform to dispersive nonpolymeric PFAS if it was disposed of in **landfill**.

4. ANALYSIS OF ALTERNATIVE POLYMERS

A low concentration of PTFE solid powder is formulated with other polymers to produce different grades of thermoplastic material, which is supplied to CommScope as pellets, ready for injection molding. CommScope, is a downstream user of PTFE and relies on the expertise of suppliers and manufacturers of these materials.

Some of our suppliers have conducted a thorough analysis of the latest available flame-retardant and anti-dripping technology for polycarbonate, via a patent and literature review, as well as their own in-house technical expertise based on decades of experience with plastics.

There are no known alternative polymers to PTFE used as an anti-dripping agent and flame retardant in thermoplastic materials of construction for indoor or outdoor telecommunication equipment with equivalent flammability, electrical, impact, weathering, and other properties and application performance. It is known that additives used as anti-dripping agents and flame retardants are costly and present processing challenges such as non-homogeneous dispersion due to poor mixing.[5,6]

There are no other technologies that provide adequate flame-retardant properties without significantly degrading impact resistance or other mechanical properties.

Request for Proposal Seeking Current Unavoidable Uses (CUU)

Use of polytetrafluoroethylene (PTFE) and perfluoroalkoxy alkanes (PFA) in printed circuit boards (PCBs) for telecommunication applications.

CONTENT

1. DESCRIPTION OF PRINTED CIRCUIT BOARDS (PCBS)

CommScope is a manufacturer of communications technology. We design, manufacture, install and support hardware infrastructure and software intelligence that enable our digital society to interact and thrive. Working with customers, CommScope advances broadband, enterprise and wireless networks to power progress and create lasting connections.

This document is CommScope's request for Currently Unavoidable Uses (CUU) of polytetrafluoroethylene (PTFE) CAS # 9002-84-0 and perfluoroalkoxy alkanes (PFA) in printed circuit boards (PCBs), which are categorized in the Harmonized Tariff Schedule (HTS) with the code 8534.00.0020. CommScope's telecommunication equipment and many other apparatuses require PCBs to function. These products are categorized in the Harmonized Tariff Schedule (HTS) with the 45 codes listed in Appendix 1. Some of the most representative HTS codes are: 8504.90.6500 and 8536.30.8000.

Printed Circuit Boards (PCBs) are crucial in base station antennas, active distributed antenna systems, and small cell solutions for indoor and outdoor use. They are all critical components of wireless communication systems like cellular networks. PCBs are used in these antenna systems for various purposes, contributing to the functionality, efficiency, and performance. The PCBs used by CommScope in base station antennas have a two-layer board, 0.76 mm, or 1.53 mm thick plastic substrate with 1OZ copper trace on one side and 1OZ copper ground on the other side.

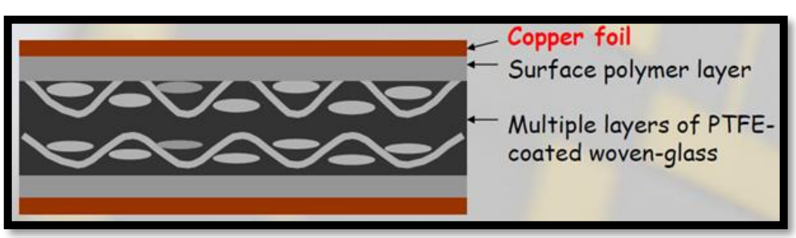

Figure 1. A printed circuit board containing multiple layers of PTFE.

2. SPECIFIC USE OF FLUOROPOLYMERS IN PCBS

Fluoropolymers are used in printed circuit boards (PCBs) for a variety of reasons due to their unique properties. Some common uses of fluoropolymers in PCBs include:

1. **Dielectric Materials:** Fluoropolymers such as polytetrafluoroethylene (PTFE) and perfluoro alkoxy (PFA) are excellent dielectric materials with high electrical insulation properties. They are used as insulating layers between conductive traces and layers in multilayer PCBs. Their low dielectric constant and low dissipation factor help maintain signal integrity and reduce signal loss at high frequencies.

2. **Thermal Stability:** Fluoropolymers have remarkable thermal stability and can withstand high temperatures without undergoing significant degradation maintaining high strength and toughness. This property is essential in PCBs, especially those used in high-power applications where components might generate a lot of heat.

3. **Chemical Resistance:** Fluoropolymers exhibit exceptional chemical resistance, making them suitable for use in harsh environments where exposure to corrosive chemicals or moisture is a concern. This is crucial in protecting PCBs from environmental factors that could lead to deterioration or failure.

4. **Radio Frequency (RF) and Microwave Applications:** The high-frequency performance of fluoropolymers, coupled with their low signal loss characteristics, makes them valuable for RF and microwave applications in PCBs. These applications include antennas, RF filters, and other components used in wireless communication systems.

5. **Impedance Control:** Fluoropolymers' consistent electrical properties make them useful in maintaining controlled impedance in transmission lines on PCBs. Impedance control is crucial for high-speed digital and RF circuits to minimize signal reflections and maintain signal integrity.

6. **Environmental Sealing:** Some fluoropolymers are used for environmental sealing and encapsulation of sensitive components on PCBs. This helps protect these components from moisture, dust, and other contaminants that could lead to performance degradation or failure.

The unique combination of electrical, thermal, chemical, and mechanical properties exhibited by fluoropolymers makes them versatile materials for various aspects of PCB design and manufacturing, especially in applications that demand high-performance characteristics.

3. INTENDED USE OF PCBS IN TELECOMMUNICATION EQUIPMENT

Base station antennas, active distributed antenna systems (DAS), and small cell solutions serve crucial roles in indoor and outdoor wireless communication networks. Some essential uses for these technologies:

Base station antennas facilitate high-speed data transmission, enabling users to connect to the network for voice, data, and messaging services. They help in increasing the capacity of a cellular network by serving as access points for many mobile devices, allowing for more simultaneous connections in each area. Base station antennas are essential for emergency services, providing reliable communication for first responders and emergency personnel during critical situations.

Active Distributed Antenna Systems (DAS) are used to improve cellular coverage and capacity in large indoor spaces like stadiums, shopping malls, airports, and office buildings, where signal penetration can be challenging. They can support multiple carriers, making them suitable for venues where different wireless providers need to provide coverage. In critical environments like hospitals, active DAS ensures reliable wireless communication for medical staff and patients, supporting emergency response and patient care. DAS systems can be scaled up or down to accommodate changes in the number of users or the layout of a venue, making them flexible for various applications.

Small Cell Solutions are deployed in densely populated urban areas to boost capacity and improve network performance where traditional microcells may be insufficient. They are used indoors to provide reliable cellular coverage in places like shopping centers, airports, hotels, and corporate offices where indoor signal penetration may be weak. Small cells play a critical role in the rollout of 5G networks, as they provide the necessary capacity and low latency required for high-speed 5G data services. In rural and underserved areas, small cell solutions can extend network coverage to provide connectivity in locations where traditional infrastructure is limited. Small cells can be deployed for private cellular networks in various industries, including manufacturing, logistics, and healthcare, to support IoT devices and mission-critical applications.

These technologies collectively contribute to ensuring reliable and high-quality wireless communication services for both indoor and outdoor environments, addressing the growing demand for mobile connectivity in a wide range of scenarios.

4. ANALYSIS OF ALTERNATIVE MATERIALS

Currently, alternative polymers that can match the unique properties, performance, and reliability of PTFE and PFA are not available in the supply chain. In our pursuit of alternatives, we rely on the expertise of our suppliers to develop innovative materials. Some of these suppliers have started investigations to find alternative polymers but they are in an early stage to confirm if a suitable alternative will be made available in the future. The process of creating a viable substitute for even a single application demands substantial investments of time and resources. Currently, there is no certainty if polymer manufacturers will identify a viable replacement.

CommScope's experts have compared two PCBs currently available on the market, PCB 1 hydrocarbon based (free of fluoropolymers) and PCB 2 made of PTFE. PCB 1 is not currently used in those pieces of equipment that require printed circuit boards of the properties of PCB2.

	PCB 1	PCB 2
	Made of hydrocarbon	Made of PTFE
Dielectric Loss Tangent @10GHz	0.004	0.0018
Dielectric Constant (Permittivity) @10Hz	3.5	2.94
Peel Strength	1.22 N/mm	2.1 N/mm

If PCB1 was used instead of PCB 2 in some equipment, we would observe a significant increase of electricity consumption and lower performance of our equipment due to the higher dissipation factor of PCB 1. The equipment reliability will be compromised by using PCB 1 due to the Peel Strength and Dielectric Constant not meeting the current expectations. Existing PCB 1, hydrocarbon-based, will need new designs, further testing, and verifications prior to be used in those applications where PCB 2 is currently used.

For manufacturers of PCBs, the main reason for choosing PTFE as based material is its lower insertion loss and stable dielectric constant. An alternative material based on hydrocarbons can be displayed similar properties, but they cannot achieve the same level of insertion loss. It has been also observed with the use of alternative materials that the peel strength of the copper trace will be degraded. In addition, manufacturers of PCBs highlight that the use of alternative materials will be increased the cost of PCBs by 40%.

The complexity of the challenge is heightened by the fact that the existing material is widely employed across diverse electronic applications. This complicates the search for a universal solution and makes it less likely that a single replacement material can effectively replace the current fluoropolymer across all applications. There is no certainty that a viable replacement can be identified at all.

APPENDIX 1. LIST OF HTS CODES FOR PRINTED CIRCUIT BOARDS AND CONTAINING PCBs

8414901080	Air or vacuum pumps, air or other gas compressors or recycling hoods
8414909180	Air or vacuum pumps, air or other gas compressors or recycling hoods
8421990180	Centrifugal dryers
8504312000	Electrical transformers
8504408500	Static converters
8504409570	Static converters
8504409580	Static converters
8504906500	Printed circuit assemblies
8504907500	Printed circuit assemblies
8504909650	Printed circuit assemblies for transformers
8504909690	Printed circuit assemblies for transformers
8517620090	Machines for the reception, conversion and transmission or regeneration of voice, images or other data, including switching and routing apparatus:
8517690000	Aerials and aerial reflectors of all kinds; parts suitable for use therewith
8517790000	Aerials and aerial reflectors of all kinds; parts suitable for use therewith
8531909001	Electric sound or visual signalling apparatus (for example, bells, sirens, indicator panels, burglar or fire alarms)
8532240020	Electrical capacitors, fixed, variable or adjustable (pre-set)Electrical capacitors, fixed, variable or adjustable (pre-set)
8534000020	Printed circuits
8534000040	Printed circuits
8534000070	Printed circuits
8534000080	Printed circuits
8534000095	Printed circuits
8536308000	Electrical apparatus for switching or protecting electrical circuits
8536509020	Electrical apparatus for switching or protecting electrical circuits
8536509031	Electrical apparatus for switching or protecting electrical circuits
8536509040	Electrical apparatus for switching or protecting electrical circuits
8536509050	Electrical apparatus for switching or protecting electrical circuits
8536509065	Electrical apparatus for switching or protecting electrical circuits
8536694010	Electrical apparatus for switching or protecting electrical circuits
8536694040	Electrical apparatus for switching or protecting electrical circuits
8536694051	Electrical apparatus for switching or protecting electrical circuits
8536698000	Electrical apparatus for switching or protecting electrical circuits
8536904000	Electrical apparatus for switching or protecting electrical circuits
8536908585	Electrical apparatus for switching or protecting electrical circuits
8537109170	Boards, panels, consoles, desks, cabinets
8538903000	Parts suitable for use solely or principally with the apparatus of heading 8535, 8536 or 8537
8538908140	Parts suitable for use solely or principally with the apparatus of heading 8535, 8536 or 8537
8538908180	Parts suitable for use solely or principally with the apparatus of heading 8535, 8536 or 8537
8541410000	Semiconductor devices (for example, diodes, transistors, semiconductor-based transducers); photosensitive semiconductor devices
8544200000	Insulated (including enamelled or anodised) wire, cable (including coaxial cable) and other insulated electric conductors
8544429090	Insulated (including enamelled or anodised) wire, cable (including coaxial cable) and other insulated electric conductors
8544700000	Insulated (including enamelled or anodised) wire, cable (including coaxial cable) and other insulated electric conductors
8547200000	Insulating fittings for electrical machines, appliances or equipment, being fittings wholly of insulating material apart from any minor components of metal
9025198085	Hydrometers and similar floating instruments, thermometers, pyrometers, barometers, hygrometers and psychrometers,
9030902500	Parts and accessories for oscilloscopes, spectrum analysers and other instruments and apparatus for measuing or checking electrical quantities
9030908940	Parts and accessories for oscilloscopes, spectrum analysers and other instruments and apparatus for measuing or checking electrical quantities
9032906180	Parts and accessories for autormatic regulating or controlling instruments and apparatus

COMMSCOPE®

Request for Proposal Seeking Current Unavoidable Uses (CUU)

Use of PFAS in Coaxial Antenna Cables, Category Cables, and Optical Fiber Cables in High-Speed Communication Networks Enabling Rapid Data Exchange

CONTENT

1. DESCRIPTION OF COAXIAL ANTENNA CABLES, CATEGORY CABLES AND OPTICAL FIBER CABLES

CommScope is a manufacturer of communications technology. We design, manufacture, install and support hardware infrastructure and software intelligence that enable our digital society to interact and thrive. Collaborating with customers, CommScope advances broadband, enterprise and wireless networks to power progress and create lasting connections.

This document is CommScope's request for Currently Unavoidable Uses (CUU) of polytetrafluoroethylene (PTFE) and fluorinated ethylene propylene (FEP) in coaxial antenna cables, which are categorized in the Harmonized Tariff Schedule (HTS) with the code 8544.20.0000. Products in this category code are described as insulated (including enameled or anodized) wire or cable (including coaxial cable) and other insulated electric conductors, whether or not fitted with connectors. Coaxial cables are used in high-speed communication networks and are made of four essential components:

1. Central Conductor: Constructed from highly conductive metals like copper or aluminum, it is the pathway through which high-speed data signals travel at elevated frequencies.

2. Dielectric Layer: The dielectric material surrounding the central conductor plays a critical role in maintaining signal integrity in high-speed communication networks. Advanced dielectric materials with low dielectric constants are employed as insulator to ensure efficient signal transmission and minimize signal loss and distortion. Antenna cables, also known as RF (Radio Frequency) cables, utilize polytetrafluoroethylene (PTFE), fluorinated ethylene propylene (FEP) or similar fluoropolymers as dielectric material due to their properties.

3. Metallic Shield: It serves as a guard against electromagnetic interference that could compromise signal quality.

4. Outer Insulating Layer: This layer provides mechanical protection and insulation, ensuring the cable's durability and safety.

Figure 1 – coax cable

This CommScope request for Currently Unavoidable Use (CUU) also includes polyvinylidene fluoride (PVDF) and fluorinated ethylene propylene (FEP) when used in category cables, which are categorized in the Harmonized Tariff Schedule (HTS) with the code 8544.49.1000.

Products in this category are described as insulated (including enameled or anodized) wire, cable (including coaxial cable) and other insulated electrical conductors, whether or not fitted with connectors; for voltage not exceeding 80V, and of a kind used for telecommunications.

Category cables use FEP as tape separators and copper wire insulators. Vinylidene fluoride-hexafluoropropylene polymer, also known as polyvinylidene fluoride (PVDF) is also used to make the jackets as a dielectric layer around a central conductive material like copper. The cross-shaped isolator, which can be found in some category cables, also could be made with FEP for CMP rated cables, in addition to the pair insulation being made with FEP.

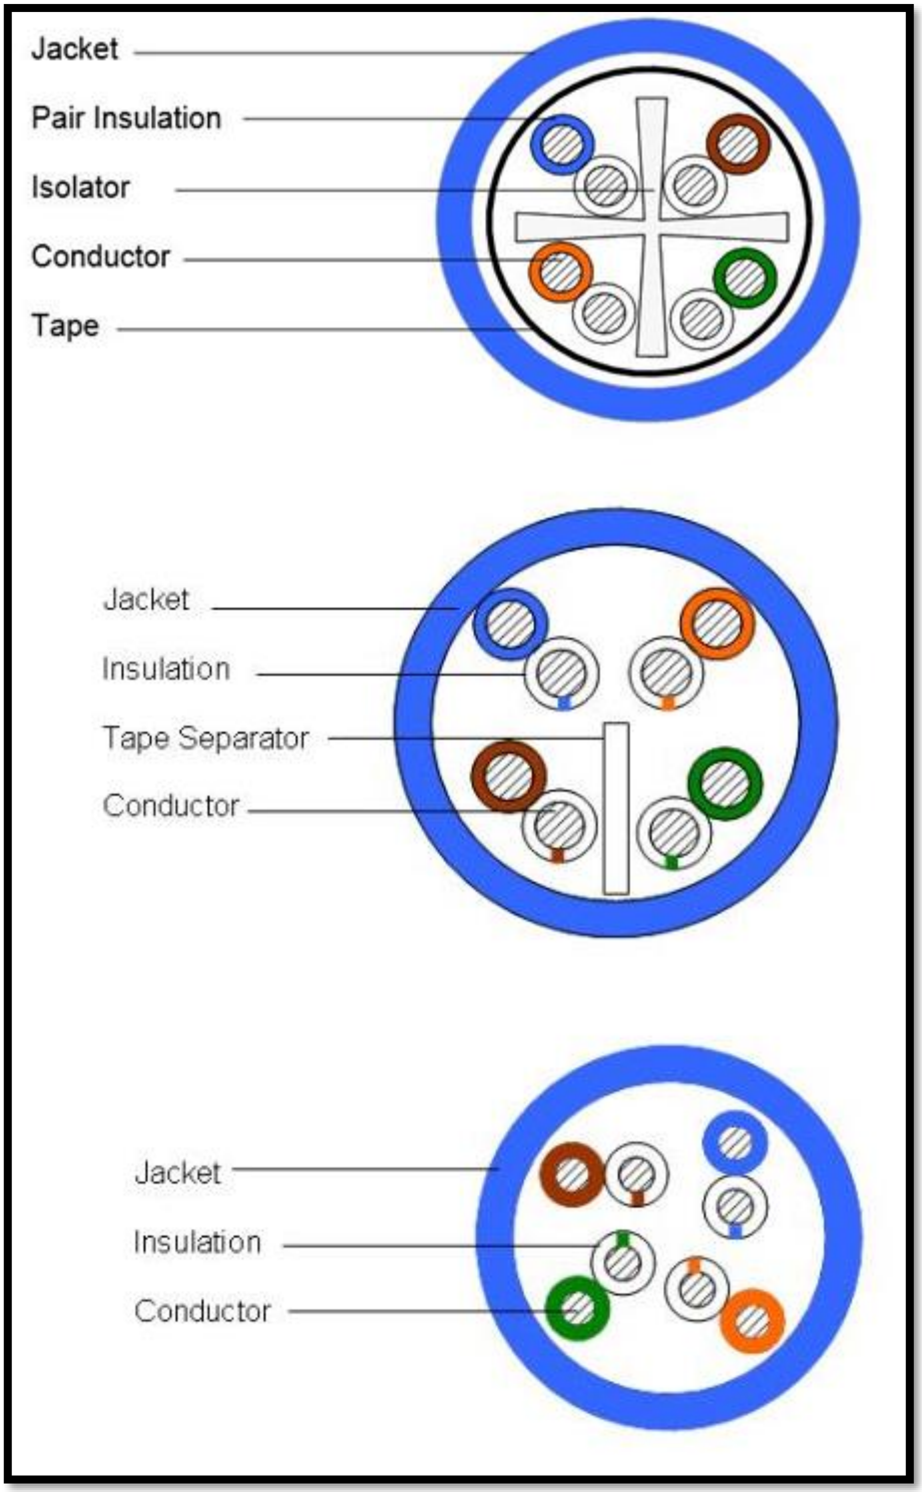

Figure 2 – Category cable

This CommScope request for Currently Unavoidable Use (CUU) also includes polyvinylidene fluoride (PVDF) and fluorinated ethylene propylene (FEP) when used in category and optical fiber cables, which are categorized in the Harmonized Tariff Schedule (HTS) with the code 8544.70.0000.

Polyvinylidene difluoride (PVDF) or the copolymer poly(vinylidene fluoride-co-chlorotrifluoroethylene) (PVDF-CTFE) are commonly used in fiber optic cables, which must be Plenum rated for outdoors use. On the other hand, Plenum-rated cables for indoor use typically use highly filled PVC (polyvinyl chloride) jackets only to pass Plenum flame test NFPA-262 Standard Method of Test for Flame Travel and Smoke of Wires and Cables for Use in Air-Handling Spaces. However, it is widely known that Plenum PVCs can crack when exposed to mechanical stresses at outdoor temperatures less than -20ºC (-4ºF). All indoor/outdoor rated cables at CommScope are tested to cable standard ICEA 696 Indoor-Outdoor Optical Fiber Cable, which requires Cold Temperature Bend at -30ºC (-22ºF) and Temperature Cycling and Cable Aging between -40ºC (-40ºF) and +70ºC (158ºF). This same cable standard requires a complete dissection of the cable after Cold Impact and Low Temperature Bend testing, and any cracks in the cable jacket and/or buffer tubes constitute a failure.

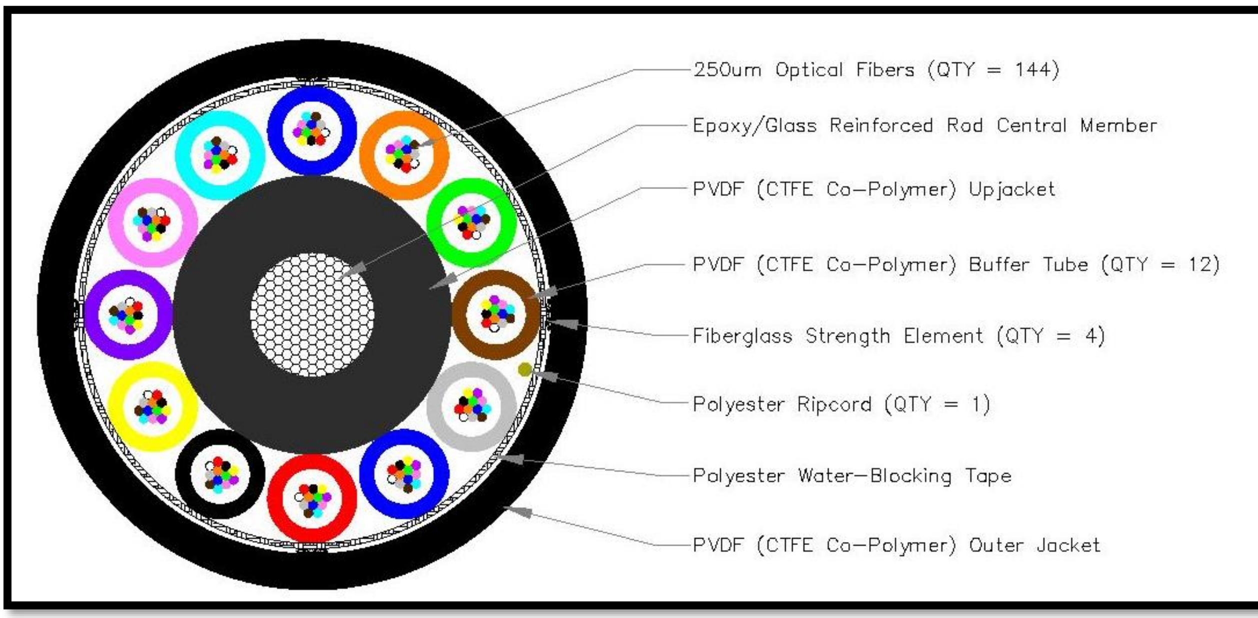

Figure 3. Optical Fiber Cable

2. INTENDED USE OF COAXIAL ANTENNA CABLES, CATEGORY CABLES AND OPTICAL FIBER CABLES

The primary intended use of coaxial antenna cables is to transmit signals with minimal distortion and interference. The design of coaxial antenna cables minimizes the impact of external electromagnetic radiation and reduces signal loss, allowing for higher data transmission rates and improved signal quality compared to other transmission media. Coaxial cables facilitate rapid and reliable data exchange over considerable distances, which is an essential function in nowadays society.

Coaxial antenna cables face extreme environmental conditions and customer demands for signal transmission quality. The ability to achieve low transmission loss in this environment requires unique material properties derived from the molecular structure of fluoropolymers and is impossible to achieve with any other polymer.

Current coaxial cables are essential components of high-speed communication networks, which have a wide range of applications in various sectors and industries. Examples of the most essential applications for the functioning of society are:

1. **5G networks**: While 5G networks rely heavily on wireless technologies, coaxial cables maintain their significance by providing reliable, high-speed connections for antenna feedlines, backhaul, fronthaul, small cell deployments, in-building coverage and more. Their ability to offer low-latency, high-quality connections and their compatibility with various deployment scenarios make them a crucial component in the evolving 5G landscape.
2. **Telecommunications and Internet Connectivity**: High-speed communication networks are the backbone of modern telecommunications and the internet. They enable fast and reliable data transfer, video conferencing, voice-over-IP (VoIP) services, and seamless browsing experiences.
3. **Cloud Computing and Data Centers**: Cloud computing relies on high-speed networks to provide on-demand access to computing resources and storage. These networks ensure quick data transmission between users and remote data centers, enabling efficient deployment of virtual machines, storage, and applications.
4. **Smart Cities and Internet of Things (IoT)**: High-speed communication networks play a crucial role in creating smart cities and powering IoT devices. These networks enable real-time data collection, analysis, and control of various urban systems, such as transportation, energy management, and public safety.
5. **Streaming and Online Entertainment**: Services like video streaming, online gaming, and interactive entertainment heavily depend on high-speed networks to deliver high-quality content and low-latency experiences to users. These networks ensure minimal buffering, lag, and latency issues.
6. **Telemedicine and Remote Healthcare**: High-speed communication networks are essential for telemedicine and remote healthcare applications. They facilitate real-time video consultations, remote patient monitoring, and the exchange of medical data between healthcare professionals and patients, regardless of their geographical locations.
7. **Radiating cable**: A special form of a coaxial cable is a radiating cable, which is used as an antenna in tunnel applications. Due to safety requirements in long tunnels (>500 m), these cables are critical for communication among emergency response teams, fire-brigades, police, and emergency medical teams. Communication in long tunnels is usually done with an active Distributed Antenna System (supplied by CommScope) where RF signals from Base Stations outside of the tunnel are received at a Head End, converted into optical signals, and distributed intelligently over fiber to Remote Cable Units, installed inside the tunnels.

These applications are an illustration of the critical role that high-speed communication networks play in shaping the digital landscape and driving innovation across various sectors.

As technology continues to evolve, coaxial cables remain an asset, underpinning the seamless flow of data in the era of rapid information exchange.

3. SPECIFIC USE OF PFAS IN COAXIAL ANTENNA CABLES CATEGORY CABLES AND OPTICAL FIBER CABLES

Fluoropolymer dielectric insulator properties are crucial for efficient signal transmission and overall antenna performance:

1. **Low Dielectric Constant**: Fluoropolymers have low dielectric constants, which enable the propagation of RF signals with minimal signal loss and reduced phase distortion. This characteristic is crucial for maintaining the integrity of high-frequency signals, especially in applications where signal clarity and accuracy are paramount, such as in wireless communications.

2. **Low Dielectric Loss**: Fluoropolymers also exhibit low dielectric loss, which means they absorb minimal energy from the RF signals passing through the cable. This property contributes to higher efficiency in signal transmission, reduced heat generation, and improved overall signal quality.

3. **Stable Performance Across Frequencies**: Antenna systems operate over a wide range of frequencies, and the dielectric material used should maintain consistent electrical properties across the spectrum. Fluoropolymers offer stable performance over various frequencies, which is crucial for maintaining signal quality in broadband communication systems.

4. **High Power Handling Capability**: Some antenna applications require the handling of high-power levels, such as in broadcasting or radar systems. Fluoropolymers can withstand higher power levels due to their low dielectric loss and excellent insulating properties, reducing the risk of signal degradation or insulation breakdown.

5. **Temperature Stability**: Antenna cables are frequently exposed to a wide range of temperatures, from extreme cold to high heat. Fluoropolymers exhibit excellent temperature stability, maintaining their electrical properties across the entire range of temperatures. This stability is essential to ensure consistent antenna performance under varying environmental conditions.

6. **Chemical Resistance**: Fluoropolymers have strong resistance to chemicals, moisture, and environmental contaminants. This resistance prevents degradation of the dielectric material over time, ensuring long-term reliability and consistent signal transmission.

7. **Mechanical Durability**: Antenna cables can be subject to mechanical stress during installation, bending, and movement. Fluoropolymers offer good mechanical strength and durability, reducing the risk of cable damage and maintaining signal integrity even under physical strain.

8. **Non-Stick Surface**: PTFE is known for its non-stick surface properties, which can make cable installation and handling easier and more efficient.

The dielectric layer in coaxial antenna cables, category cables and optical fiber cables are made of the fluoropolymers listed below:

PTFE	CAS No.9002-84-0	(Polytetrafluorethylen)
FEP	CAS No.25067-11-2	(Fluorionated ethylene propylene)

PVDF CAS No.24937-79-9 (Polyvinylidene difluoride)

The ability to achieve efficient signal transmission and overall antenna performance is a unique property derived from the molecular structure of fluoropolymers and is with the current state of technology impossible to achieve the same properties with any other polymers.

4. ANALYSIS OF ALTERNATIVES

The key function of fluoropolymers as the dielectric material in coaxial antenna cables is to be a good dielectric insulator that provides flexibility and low friction for the cable. Additionally, the fluoropolymers provide these cables with temperature stability and remarkable mechanical durability. These cables can today only achieve the performance prescribed by industry standards with a fluoropolymer dielectric material.

The use of fluoropolymers in category cables allow them to meet the North American Cable Fire Safety Ratings – Plenum. A space in building that handles HVAC or other supply air (air you might breathe) is called a plenum. Plenum cable is the highest rated fire-proof/smoke-proof cable available in North America.

Standards that set performance requirements for coaxial, category and optical fiber cables:

IEC 61196	Coaxial communication cables
IEC 60966	Radio frequency and coaxial cable assemblies
ICEA S-104-696	Indoor – Outdoor optical fiber cables
UL 444	Safety communication cables
ANSI/TIA-568.2-D	Copper cabling standards basis
NFPA 70	National electrical code (NEC)

CommScope is a downstream user of dielectric materials. We specify, based on the relevant standards and customer demands, the required properties but CommScope depends on our suppliers for the exact chemical composition of these materials. Currently, we have not identified viable dielectric materials, PFAS free, capable of meeting international standards and customer demands.

Investigations for substitution of PFAS-based dielectric materials have been performed, however the results have not been positive. Additional research work will be required by polymer manufacturers to identify potential alternatives and to conduct associated development, testing, as well as the implementation into markets. Based on the current investigation, we believe that it will take more than a decade to conclude if suitable alternatives to the existing dielectric materials will be available in the future.

Industrialization is a long and complex step-by-step methodology followed to implement a qualified material or process throughout the manufacturing, supply chain and maintenance operations, leading to the items' final certification. This includes renegotiation with suppliers, investment in process implementation and the final audit to qualify the new process throughout the supply chain. Any change in the process or in the components concerned can take a number of years to requalify and ensure that the level of performance achieved is as good as the previous one.

February 27, 2024

Dear Madam/Sir.

Tecan is submitting this input upon Agency's request to manufacturers to inform on currently unavoidable uses of PFAS rule, OAH Docket No. 71-9003-39667, before March 1, 2024.

Tecan Group stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.

In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Maine and Minnesota. This proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders. By engaging experts from various industries, Claigan Environmental has adopted a collaborative approach to address this complex issue.

Tecan Group actively participated in the consultation process and supports Claigan Environmental's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

The Tecan Group of companies is a global supplier of laboratory automation products that specializes in complex laboratory automation workflow solutions for clients in the medical device, biotechnology, research, and pharmaceutical industries. Our products include highly specialized sample preparation, detection and liquid handling laboratory equipment with applications in research and clinical diagnostics as well as components (i.e., pumps) for this type of equipment.

Information about our products is accessible from our website: https://www.tecan.com

Tecan US, Inc.,

State of Minnesota, Minnesota Pollution Control Agency (MPCA), Request for Comments to proposed rulemaking identifying Currently Unavoidable Uses (CUUs) pursuant to Minnesota Statute 116.943

RTX Submission in response to Request

Introduction

Thank you for providing the opportunity to respond to the State of Minnesota, Minnesota Pollution Control Agency ("MPCA"), request for comments on it's proposed rulemaking referred to as **PFAS in Products Currently Unavoidable Use ("CUU") Rule** required under the State's Amara's Law. Specifically, MPCA is inviting comments to assist it in identifying those PFAS uses that are considered to be CUUs because they are essential for the health, safety, or functioning of society and where alternatives are not reasonably available.

As more fully described below and in the attachments, RTX Corporation ("RTX"), as part of the global aerospace and defense industry, has critical dependencies upon certain PFAS in the manufacture, maintenance, repair and overhaul of products and equipment that are indeed essential for the safe, orderly, and efficient functioning of society, including, but not limited to, national security.

While RTX and its peers in the aerospace and defense ("A&D") sector are actively engaged in an analysis of PFAS dependencies and potentially available alternatives, the unique demands of our uses and that of our customers, are often such that there are no immediate drop-in replacements available for many end use applications. PFAS are chemically stable and provide necessary resistance to heat and other extreme and critically important application conditions required of products produced in the A&D sector. Accordingly, RTX asks the MPCA to accept A&D uses as a whole, and further described in these comments and attachments, as CUUs in its rulemaking process thereby excluding such uses from the 2032 ban.

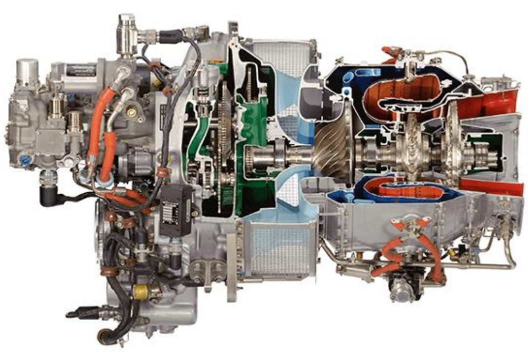
About RTX (www.rtx.com)

RTX is the world's largest A&D company. With more than 180,000 global employees, RTX pushes the limits of technology and science to redefine how we connect and protect our world. Through industry-leading businesses – Collins Aerospace, Pratt & Whitney, and Raytheon – we are advancing aviation, engineering integrated defense systems for operational success, and developing next-generation technology solutions and manufacturing to help global customers address their most critical challenges. In particular, RTX provides products, integrated systems, and services for commercial, military and government customers across the globe. Such products and services support marine, land-based, aviation and space customers.

Our Collins Aerospace business specializes in advanced structures, avionics, connected aviation solutions, interiors, mission systems, and power and control systems that serve customers across the commercial, regional, business aviation and military sectors. Pratt & Whitney designs, manufactures, and services the world's most advanced aircraft engines and auxiliary power systems for commercial, military and business aircraft. Lastly, our Raytheon business specializes in next-generation defense solutions that are smarter, faster, and better than previously thought possible, including integrated air and missile defense, advanced sensors, space-based systems, hypersonics, effectors and cyber solutions.

Our businesses have a special and longstanding distinct relationship with Minnesota and its residents and have invested in the success of the Minnesota economy. The following are a few examples of how RTX's businesses rely on certain PFAS:

Collins Aerospace's Burnsville, MN facility hosts a unique wind tunnel testing laboratory and clean fabrication space for commercial and defense aerospace products. This campus produces proprietary components for critical external aircraft systems and sensors while the wind tunnel simulates the high speeds and high altitudes at which the sensors operate. PFAS containing materials are typically present in such products to repel moisture, prevent corrosion, and handle extreme fluctuations in temperature and pressure.



PW-200

Pratt & Whitney is a global leader in propulsion systems, powering the most advanced aircraft in the world, and we are shaping the future of aviation. Our engines help connect people, grow economies and defend freedom. The PW-200 series engine is used in a variety of missions including emergency medical services, security and defense, utility, business, and other operations in Minnesota. Certain of the engine components and connections require use of fluoropolymer containing materials.

The Raytheon Company RAIVEN product, an electro-optical intelligent-sensing device and capability, which enables operators (e.g. pilots) to have faster and more precise identification, may be sold into the State of Minnesota. RAIVEN can identify objects optically and spectrally simultaneously in real-time. Similar to the two examples above, certain fluoro-based materials are present in the finished product.

RTX Response to MPCA Questions

RTX appreciates the opportunity provided by the MPCA to submit comments in response to questions being considered by the MPCA for its CUU rulemaking. We note that while we have attempted herein to provide brief answers to Agency questions, our ability to satisfy some of the more detail-oriented questions on or before March 1, 2024, is unworkable given the short notice provided.

Question 1: Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

RTX Answer: RTX appreciates that this could be very difficult to complete given broad market interests and characterizations of "essentiality". However, we point MPCA to the following language that has been considered in the State of Maine for inclusion in its rulemaking: **"Essential for Health, Safety or the Functioning of Society"** means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations. Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction.

Question 2: Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

RTX Answer: This term is also very difficult to characterize. Similar to above, the State of Maine has considered the following: **"Reasonably available"** to mean a PFAS alternative which is readily available in sufficient quantity and at a comparable cost to the PFAS it is intended to replace and performs as well as or better than PFAS in a specific application of PFAS in a product or product component. One of the most significant challenges in this regard to the A&D sector, as expressed in much detail in the attachments, is that it can take a very long time (years if not decades) to qualify, test and obtain other regulatory agency (e.g. FAA) approvals/certifications as well as that of customers, including military and defense customers. PFAS as a category of materials do not today have simple alternative options that will perform as well or better than what is currently in place. Reducing performance capability for the types of products in A&D is not an option due to the criticality of things like flight safety, airworthiness, and defense capability. Costs are always a consideration for any change that may occur, but it in and of itself should not be the main criteria for deciding what is possible. It should, however, be one of many considerations in alternatives / product design options analysis.

Question 3: Should unique considerations be made for small businesses with regards to economic feasibility?

RTX Answer: This question is best left to those of small businesses and their respective associations such as the Small Business Administration of MN.

Question 4: What criteria should be used to determine the safety of potential PFAS alternatives?

RTX Answer: There are a plethora of quality, acceptability, accessibility, performance, and physical/chemical criteria differing typically for each intended end use application. There is no "one-size fits all" in the A&D sector. Each application must be evaluated individually to be certain all criteria for that end use application are met or exceeded. There are further specific references to the types of performance attributes needed for A&D within the details of the attached documents for your further review.

Question 5: How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?

RTX Answer: The response here is similar to that of Question 4. For some end use applications, maintaining an open-ended CUU may be the only option enabling the continuation of essential uses as previously defined. Others may be suitable for re-evaluation following an extended period of time for the A&D sector. It is difficult to pinpoint what time period this should be, but we suggest that allowing 10-12 years before re-evaluation occurs is reasonable given the complexity and time it takes to implement change in our sector.

Question 6: How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

RTX Answer: If CUU determinations are adopted through rulemaking at a high-level (e.g. on a sectoral basis), the need for, and frequency of, new requests for CUUs should be kept to a minimum. If on the off chance an "intentionally added PFAS product" is not somehow already covered within the higher-level CUU groups, MPCA rulemaking should occur to allow for a submission to be considered for CUU designation. In the case of any CUU rulemaking, there should be time parameters around the length of time that it takes so that impacted parties have an idea of when the CUU determination will be made and can plan around it with customers and suppliers. RTX discourages MPCA from inserting language to allow parties to petition for a use to be "disqualified" as a CUU. Information should be submitted that sufficiently supports the broader definition provided above in answer to Question 1.

Question 7: In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and product you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

RTX Answer: The types of products and criticalities of PFAS uses for the A&D sector that warrant CUU coverage discussed above in this document but are more fully detailed in the enclosed documents.

Question 8: Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

RTX Answer: Yes.

Question 9: Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

RTX Answer: RTX appreciates the MPCA's efforts to solicit comments regarding CUU rulemaking and work with companies like RTX that have critical PFAS dependent products and uses to ensure that PFAS restrictions or bans do not unintentionally undermine critical aerospace and defense products and processes for the essentiality and importance of the health, safety, and societal interests that such products serve. We welcome the opportunity to answer any questions about these comments or PFAS as it relates to the RTX businesses. To this end, I invite you to contact Mark Herwig of my staff at (203) 224-0713 or mark.herwig@rtx.com for further discussion if it would assist the MPCA in its efforts.

Thank you for your time and consideration of these comments.

Respectfully submitted,

Annette McNeely

I. Introduction

Section 347(a) of the James M. Inhofe National Defense Authorization Act (NDAA) for Fiscal Year (FY) 2023 (Public Law 117-263) directs the Secretary of Defense, in consultation with the Defense Critical Supply Chain Task Force (i.e., the Office of the Assistant Secretary of Defense for Industrial Base Policy (OASD(IBP))) and the Chemical and Material Risk Management Program (CMRMP) of the Office of the Assistant Secretary of Defense for Energy, Installations, and Environment (OASD(EI&E)), to submit to the Committees on Armed Services of the House of Representatives and the Senate a report outlining the uses of per- and polyfluoroalkyl substances (PFAS) that are critical to the national security of the United States. This report focuses on critical uses in the sectors outlined in the February 2022 Department of Defense (DoD) report titled *Securing Defense-Critical Supply Chains* and sectors of strategic importance for domestic production and investment to build supply chain resilience.

PFAS are common chemicals used across DoD. Most weapons platforms incorporate PFAS, and PFAS are found throughout the defense industrial base in roles supporting mission critical component production and supply. PFAS uses may be direct, where a PFAS is a constituent in a consumable item or is incorporated into an article (e.g., end item), or indirect, where a PFAS is used to formulate another chemical or is part of a manufacturing process. These uses and processes are necessary to the production of key components of the defense industrial base, such as microelectronic chips and lithium-ion (Li-ion) batteries.

PFAS are chemically quite stable, and many are water and oil repellent, heat resistant, and/or stain resistant, often leading to non-stick surfaces on various materials. Examples of applications of PFAS are in plastics, o-rings, gaskets, lubricants, coolants, and fabrics. DoD is reliant on the critically important chemical and physical properties of PFAS to provide required performance for the technologies and consumable items and articles which enable military readiness and sustainment. Losing access to PFAS due to overly broad regulations or severe market contractions would greatly impact national security and DoD's ability to fulfill its mission, and impact domestic defense industrial base manufacturing and supply.

This report provides details on what is currently known about direct and indirect mission critical PFAS uses that could impact mission readiness if the substances are no longer available. It also highlights the challenges and costs related to finding and qualifying equal or improved performing alternatives to existing PFAS materials in sectors of strategic importance to DoD. It is important to note that the information contained in this report is limited to what was available at the time of its drafting. As such, the information presented represents a fraction of the mission critical PFAS uses due to a lack of knowledge of the complete chemical composition in consumables and articles (e.g., end items)[1]. In addition, there is significant uncertainty regarding

[1] A consumable is defined as "an item of supply or an individual item (except explosive ordnance and major end items of equipment) that is normally expended or used up beyond recovery in the use for which it is designed or

the presence of PFAS in products that make up a complex value chain. A more complete understanding of PFAS essential uses would require an extensive and complex evaluation of the market, a gap analysis of current requirements for manufacturer-provided product information, and illumination of the value chain of products.

II. Definitions

For purposes of this report, the terms used within section 347(a) of the NDAA for FY 2023 are defined in the following sub-sections.

II.1 Per- and Polyfluoroalkyl Substances

There is currently no consensus definition of PFAS as a chemical class.[2] Congress did not define PFAS within section 347(a) of the NDAA for FY 2023 for purposes of this report.[3] While there is no consensus definition, regulators in the European Union (EU) and the United States have proposed, but not yet adopted, different chemical-structure-based (rather than hazard- or risk-based) definitions. In anticipation of the most stringent future regulatory actions, DoD used the definition put forward by the Organisation for Economic Co-operation and Development (OECD) in its 2021 report, *Reconciling Terminology of the Universe of Per- and Polyfluoroalkyl Substances: Recommendations and Practical Guidance*,[4] for collecting data and developing this report. OECD states "The term 'PFASs' is a broad, general, non-specific term, which does not inform whether a compound is harmful or not, but only communicates that the compounds under this term share the same trait for having a fully fluorinated methyl or methylene carbon moiety." OECD cautions that this definition should not be used in deciding how to group and manage PFAS in regulatory actions; however, future PFAS legal and regulatory frameworks may disregard the OECD caution and seek to restrict the use of PFAS based on chemical structure.

---

intended. An end item is the "final combination of end products, component parts, or materials that is ready for its intended use, e.g., ship, tank, mobile machine shop, or aircraft." *DoD Supply Chain Terms and Definitions* (February 21, 2023). https://www.acq.osd.mil/log/LOG_SD/.policy_vault.html/DoD_Supply_Chain_Terms_and_Definitions.pdf.

[2] *Per- and Polyfluoroalkyl Substances (PFAS) Report: A Report by the Joint Subcommittee on Environment, Innovation, and Public Health*, Per- and Polyfluoroalkyl Substances Strategy Team of the National Science and Technology Council, March 2023.

[3] Congress previously defined PFAS in the NDAA for FY 2021 for purposes of establishing the interagency working group to coordinate federal activities related to PFAS research and development. Section 332(g)(1) defines PFAS broadly as (A) man-made chemicals of which all of the carbon atoms are fully fluorinated carbon atoms; and (B) man-made chemicals containing a mix of fully fluorinated carbon atoms, partially fluorinated carbon atoms, and nonfluorinated carbon atoms. William M. (Mac) Thornberry National Defense Authorization Act for Fiscal Year 2021, Pub. L. 116-283 (2021).

[4] "PFASs are defined as fluorinated substances that contain at least one fully fluorinated methyl or methylene carbon atom (without any H/Cl/Br/I atom attached to it), i.e., with a few noted exceptions, any chemical with at least a perfluorinated methyl group (–CF3) or a perfluorinated methylene group (–CF2–) is a PFAS." OECD, *Reconciling Terminology of the Universe of Per- and Polyfluoroalkyl Substances: Recommendations and Practical Guidance* (Series on Risk Management No. 61), July 9, 2021. https://one.oecd.org/document/ENV/CBC/MONO(2021)25/En/pdf.

The figure below provides an overview of the PFAS groups based on the OECD definition. This very broad definition encompasses more than 38,000 individual PFAS chemicals.[5] DoD uses are represented in each major category of PFAS (i.e., perfluoroalkyl acids (PFAAs) and polyfluoroalkyl acids (polyFAAs)), PFAA precursors, and other PFAS (e.g., fluoropolymers, fluoroelastomers).

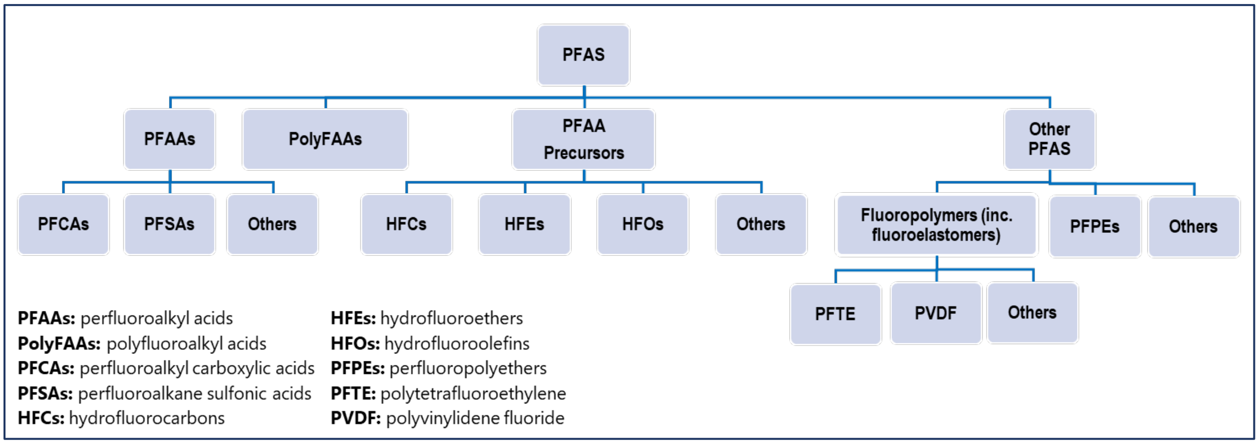

Figure: Overview of PFAS Groups (refined from OECD 2021)

II.2 Critical to the National Security

Congress did not define "critical to the national security of the United States" within section 347(a) of the NDAA for FY 2023. The term "mission-critical military end use (MCMEU)," however, is defined in regulations promulgated by the U.S. Environmental Protection Agency (EPA) under the American Innovation and Manufacturing Act of 2020 (AIM Act).[6] The AIM Act addresses the phasedown of production and consumption of hydrofluorocarbons (HFCs) (e.g., regulated substances). MCMEUs are "[t]hose uses of regulated substances by an agency of the Federal Government responsible for national defense that have a direct impact on mission capability, as determined by the U.S. Department of Defense, including, but not limited to uses necessary for development, testing, production, training, operation, and maintenance of Armed Forces vessels, aircraft, space systems, ground vehicles, amphibious vehicles, deployable/expeditionary support equipment, munitions, and command and control systems."[7]

The MCMEU definition focuses on *regulated substances*. As with HFCs, PFAS are undergoing increased regulation. But in addition to regulation, market forces can directly impact mission capability by limiting DoD's ability to source and use PFAS and PFAS-containing

---

[5] Williams, et al. 2022. Assembly and Curation of Lists of Per- and Polyfluoroalkyl Substances (PFAS) to Support Environmental Science Research. *Front. Environ. Sci*. 10:850019. doi:10.3389/fenvs.2022.850019.
[6] 42 U.S. Code 7675.
[7] See 40 Code of Federal Regulations 84.3, "Phasedown of Hydrofluorocarbons" (October 5, 2021).

products. The most recent example is 3M's decision to phase out production of PFAS and PFAS-containing products by 2025.[8]

For purposes of data collection and report development, DoD used the MCMEU definition with the recognition that both market forces and increased regulation can have a direct impact on mission capability.

II.3 Sectors Considered

Section 347(a) of the NDAA for FY 2023 directs DoD to focus this report on critical PFAS uses in the four focus areas identified in DoD's February 2022 report *Securing Defense-Critical Supply Chains.*[9] The four focus areas—kinetic capabilities, energy storage and batteries, microelectronics, and castings and forgings—have critical supply chain vulnerabilities posing the most pressing threats to national security. In addition, this report focuses on semiconductors—a sector of strategic importance for domestic production and investment to build supply chain resilience—and strategic and critical minerals. These areas are described as:

- **Kinetic capabilities**: Current missiles systems and advanced and developing missile capabilities, including hypersonic weapons technology, as well as directed energy weapons.
- **Energy storage and batteries**: High-capacity batteries, with a particular focus on lithium batteries.
- **Microelectronics and semiconductors**: State-of-the-Practice (SOTP) and legacy microelectronics, State-of-the-Art (SOTA) microelectronics, and semiconductors.
- **Castings and forgings**: Metals or composites developed into key parts and manufacturing tools through high-intensity processes.
- **Strategic and critical minerals**: Minerals to supply U.S. military, industrial, and essential civilian national emergency needs, with emphasis on those that are not produced in sufficient quantities in the United States.

III. Data Collection Methodology

Data collection efforts for this report were led by the CMRMP of the ODASD(E&ER) and the OASD(IBP) and included engagement with the DoD Components and Military Departments (MilDeps), industry, and industry associations.

III.1 CMRMP Data Call

In March 2023, the CMRMP asked the DoD Components and MilDeps to provide information about its critical uses of PFAS, to include use of neat PFAS, use of PFAS-containing products, the functionality provided by the PFAS, specific uses and applications, and availability of alternatives (if known).

III.2 Additional Industry Engagement

The CMRMP held engagement sessions with various industries and industry associations to obtain information about the PFAS and PFAS-enabled products that they (or their member industries) manufacture and how DoD uses those products. The CMRMP shared this information with the DoD Components and MilDeps to inform their data collection efforts.

III.3 OASD(IBP) Industry Sector Data Collection Process

The Kinetic Capabilities Team at Policy, Analysis, & Transition (PA&T), OASD(IBP), engaged with PA&T Industry Sector leads and their industry partners to identify PFAS uses that are critical to U.S. national security. These sectors include Kinetic Capabilities, Energy Storage and Batteries, Microelectronics and Semiconductors, Castings and Forgings, and Strategic and Critical Materials. The Sector leads identified PFAS uses in industry, operation, manufacturing, processes, components, parts, and materials. They also discussed how and where losing access to PFAS could have significant mission readiness impacts and what they could do or are doing to mitigate those impacts.

IV. Results

DoD's known critical uses of PFAS are summarized in the following sub-sections, organized by focus area, and in the Appendix. The complexities in dissecting the defense industrial base value chain and supply chain dependencies, in addition to the lack of transparency in chemical and material content data, prevented the CMRMP from gathering comprehensive data on all critical PFAS uses.

Critical PFAS uses were identified in almost every major weapon system category including but not limited to fixed wing aircraft (trainers, fighters, bombers, transports, refuelers, ground support, unmanned, and associated support equipment); rotary wing aircraft (attack, transports, heavy lifts, search-and-rescue, and associated support equipment); surface ships (combat, destroyers, aircraft carriers, cutters, landing crafts); submarines; missiles (air-to-air, ground-to-air, air-to-ground, ballistic); torpedo systems; radar systems; and battle tanks, assault vehicles, and infantry carriers.

IV.1 Kinetic Capabilities

Kinetic capabilities represent a direct use of PFAS, as PFAS are found in a variety of applications across the DoD munitions portfolio. About a dozen fluoropolymers, including fluoroelastomers, are ingredients in polymer bonded explosives, pyrotechnics, and propellant components used in munitions, decoy flares, and chaff. They serve as high temperature resistant binders and resins. These uses, which represent some of the few purely military PFAS applications, include:

- Unique binder materials specifically developed for use in the energetic portion of conventional and strategic weapons platforms.
- Fluoroelastomers, such as Viton™, used as a binder in explosive and booster charge formulations integrated into many DoD munitions.
- Fluoropolymers, such as Teflon™, used in pyrotechnics and as a material used in the manufacture of munitions for a variety of missile systems.

PFAS are used in a variety of applications during energetics processing and testing. Currently, non-PFAS alternatives do not exist for most of these applications, and the likelihood of developing alternatives for these uses is estimated to range from moderate to almost impossible. If available, alternatives require multi-year processes and cost program offices millions of dollars to requalify every missile system that used the material, even if products are similar.

IV.2 Energy Storage and Batteries

Impacts to national security from PFAS applications in energy storage and battery applications are indirect. Manufacturers use fluoropolymers (e.g., polytetrafluoroethylene (PTFE)) and polyFAAs in multiple subcomponents in modern Li-ion batteries. They serve as heat transfer materials or insulation and provide weather resistance and ultraviolet (UV) light resistant functionalities to final components. Military applications rely on Li-ion battery technologies that are largely innovated in the civilian sector. Manufacturers use PFAS in the electrolyte solutions, cathode binders, and separator coatings; and, to a lesser extent, PFAS are found in casing materials and gaskets due to their deterioration resistance properties.

PFAS materials also play an important role in battery manufacturing. Filters and other components of manufacturing equipment are essential to battery production. The battery industry's ability to make products for a broad range of commercial and military applications would be greatly impacted if PFAS were no longer available for use in these components. The significant time and money needed to identify and qualify alternatives as replacements would cause ripple effects throughout the economy as consumers and users absorb the additional cost.

Fully eliminating PFAS from energy storage in the U.S. economy would likely take more than 10 years. Energy storage is a broad issue for U.S. industrial competitiveness as well as an important part of Federal initiatives around combating climate change. DoD is not the primary consumer of batteries in the United States, but battery supply chain issues would impact the ability to produce missiles and field military vehicles that increasingly rely on batteries.

IV.3 Microelectronics and Semiconductors

The semiconductor industry produces the chips that drive modern electronic devices. The microelectronics packaging and assembly industry integrates these chips into the electronic products used every day across the defense enterprise. In the semiconductor industry, fluoropolymers, fluoroelastomers, polyFAAs, and other fluorochemicals are used in a number of applications and at every stage of semiconductor fabrication. These uses include etching materials (photoresists), etching coolants, masks in photolithography processes, packaging materials that provide heat dissipation for the chip, and cleaning gases at various stages in the microchip production process. Examples of specific PFAS in the semiconductor industry include polyvinylidene fluoride (PVDF; a fluoropolymer), ethylenechlorotrifluoroethylene (ECTFE; a fluoropolymer), FKM/FFKM (fluoroelastomers), and perfluoroalkoxy alkanes (PFAs).

One significant use of PFAS in semiconductor manufacturing is during the photolithography process, where the patterns that define the microchip circuitry are developed onto bare silicon surfaces. Manufacturers use photolithography specialty formulations containing fluorinated compounds in various steps of this process to ensure final chip quality and reduce the probability of defects. PFAS are ideal for these purposes due to their low surface tension and compatibility with other chemicals. The PFAS materials used in these processes are typically no longer present in the finished product, except in some specific applications, such as imaging chips used in cameras, displays, and some medical devices.

Similar to the energy storage industry, PFAS are essential for semiconductor manufacturing equipment and factory infrastructure. The exceptional combination of heat and chemical resistance and chemical inertness allows fluoropolymers to be used both in equipment components (e.g., tubing, gaskets, containers, filters) and lubrication (e.g., various oils and greases). These same properties are also needed to ensure the functioning of the surrounding infrastructure.

In wider microelectronics applications, PFAS remain key industrial materials in applications that integrate microchips into electronic products, such as printed circuit boards. PTFE and PFA base laminate materials are currently used in many radio frequency (RF) and microwave circuits, as they provide unique properties related to isolating RF and microwave signals. Identifying and qualifying potential replacement materials will require significant time, particularly for use in fielded systems. There currently are no available drop-in replacement materials for a PTFE designed printed board. Lack of access to PTFE laminate will necessitate the redesign and requalification of the printed board, the assembly, and potentially the system.

Several PFAS-containing vapor phase soldering and flux removal products are used in the manufacture of printed circuit boards. Vapor phase soldering is used primarily for printed board assembly when there is a high thermal mass, in combination with advanced technologies such as fine-pitch features, or when there are temperature sensitive components used. Alternative materials are not currently identified and would need to be evaluated for performance and safety. New equipment may be required to implement new vapor phase soldering liquids. PTFE cable jackets are used in printed circuit board and other electronic systems in connectors and wire. PTFE has unique properties as a wire insulator including fire, smoke, and chemical resistance to mitigate the risk of wire exposure in harsh environments. PTFE can withstand 450°C and is used widely in products that have been developed to meet MilSpec applications. Manufacturers also use fluoropolymers as electronics sealants and encapsulants to protect microelectronic components from degradation due to environmental, chemical, or UV-light exposure. Vapor degreasing solvents, used in a variety of cleaning processes during microelectronics production, contain hydrofluorocarbons (HFCs) and hydrofluoroolefins (HFOs), which, in many cases and in the broadest sense, are defined as PFAS. These materials impart fire suppression properties to the degreasing solvent, creating safer manufacturing environments for workers.

Currently, no alternatives to PFAS have been identified that can provide the functional properties required for photolithography or some applications in semiconductor manufacturing equipment. Even if alternative chemicals and technologies were discovered today, due to the extremely complex qualification process throughout the value chain, it would take another 15 years to deploy them in high-volume manufacturing. Therefore, continued access to PFAS is a prerequisite for high-volume and advanced semiconductors. Lack of continued access to PFAS could lead to an inability to produce and supply semiconductor manufacturing technology.

Replacing most PFAS uses in semiconductor fabrication would require industry-wide re-tooling and other process innovations, at a minimum. Some might be achievable within 10 years, but many would not. As stated above, there are some PFAS uses for which no alternatives are known. For these uses, it may be necessary to invent novel chemistries and processes. Replacing PFAS in semiconductor fabrication could be a 25-year effort and may not succeed in all respects if alternatives cannot be identified or qualified at the microchip level.

Consideration must also be given to the resultant impact on DoD programs. It is highly probable that manufacturers would need to change semiconductor manufacturing processes to accommodate PFAS replacements. This change has the potential to result in the costly requalification of specific components. For example, radiation hardened microelectronics applications typically mandate requalification if a manufacturer substantively alters the fabrication process, which can easily exceed $10 million; many programs lack intrinsic funding for requalification.

IV.4 Castings and Forgings and Strategic and Critical Minerals

Specialty fluorochemical gases and fluids are used for advanced metalworking, casting, and fabrication due to the temperature and wear resistance functionalities they provide. These gases and fluids are used in the production of advanced metal parts throughout U.S. industry, including military-specific parts. Requiring a move to PFAS-free alternatives in under 10 years may make construction using certain alloys impossible and require returning to previous methods of construction leading to lower performance, shorter life, and higher weight of constructed parts.

In both the casting and forging and strategic and critical minerals industries, loss of access to PFAS is an indirect threat to national security and a potential source of significant disruption to supply chains vital to the DoD mission. These industries depend on PFAS in products used during normal business operations. A product used as a liquid cold spray in castings and forgings or coolant in drilling operations for critical minerals may contain PFAS, but the product user would not know that PFAS are present until the product is discontinued. Both industries are at risk of losing critical capabilities with little warning, as there are limited requirements for companies to provide composition information for the materials used to create the products they sell to DoD or on the commercial market. The risk for these industries is particularly high, even if the probability is low, because there may be no warning for critical product obsolescence and no ability to develop and qualify alternatives in a timely fashion.

PFAS are also contained in mold release chemicals and release films typically used in composite manufacturing processes. Loss of access of PFAS would impact the commercial composites manufacturing industry and, indirectly, the DoD who is reliant on the commercial industry for applications.

Mold release chemicals are applied to mold hardware to prevent the composites from strongly adhering to the mold hardware during cure. The mold release chemicals typically contain PFAS chemicals or a PTFE polymer spray. Peel plies are used to prevent attachment of vacuum bag materials and other disposable molding materials to the composite part and to impart a textured surface to the molded component to improve adhesion in secondary bonding or painting. Peel plies are typically made of non-PFAS polymers, such as polyamides and polyesters; however, to prevent adhesion of the composite to the peel ply, PFAS modification (most commonly) or silicone modification is done to the fabric. Additionally, if high cure temperatures are required, PTFE and PVDF peel plies are typically used. Polymer release films are similar to peel plies but are generally used with composite resins that need to release gasses during cure. Many of these release films are polyethylene, polypropylene, or other polyolefins and work well for many applications; however, certain applications (typically higher temperature curing systems) require use of fluoropolymers, such as PTFE, PVDF, and others. Pre-preg release film is used to keep individual layers of pre-pregs (e.g., fabrics that are pre-impregnated with a fully curable, mixed resin system during manufacture) separated from each other within the rolls of materials that are prepared and transported for use in composites manufacturing facilities. Fluoropolymer release films are generally used to ensure the releasability of the release film during composite layup. Silicones are also useable for this application but are generally not used because of the low rigidity of silicone films.

IV.5 Additional Mission Critical PFAS Uses

Mission critical PFAS uses extend beyond the five industries discussed to this point. DoD identified a range of additional critical uses for which the potential risk of supply chain disruption would undercut not only mission readiness but the U.S. economy. These uses are discussed in more detail in the following sub-sections.

IV.5.1 Refrigeration and Air Conditioning, Cooling, and Electronics Thermal Control

Most refrigerants used in civil and military cooling and refrigeration applications can be classified as PFAS. Many next-generation refrigerant alternatives adopted by U.S. industry (and U.S. households) between now and the end of 2025 are also PFAS. Under the AIM Act and EPA technology transition regulations, the U.S. economy is in the process of switching from one set of PFAS-classified refrigerants (e.g., HFCs) to a new generation of refrigerants (e.g., HFOs), which are also, in the broadest definitions, considered to be PFAS. Known non-PFAS alternatives (e.g., hydrocarbon or ammonia alternatives) pose flammability, toxicity, or high-pressure concerns. The same PFAS that are used in quantities of several hundred million pounds per year throughout the U.S. economy for cooling applications are used in much smaller quantities (i.e., a fraction of one percent) for military cooling and military thermal control of all kinds.

IV.5.2 Fire Suppression in Naval Vessels, Aircraft and Ground Combat Vehicles

Fluorochemical specialty gases are used in “clean agent” fire suppression in naval vessels, aircraft, and ground combat vehicles. Most known clean agent, low-corrosion, low-weight, low-toxicity alternatives will likely be classified as PFAS, broadly defined.

Since the advent of regulations against halogenated agents, Naval vessels commonly utilize an HFC clean agent in compartments subject to flammable/combustible liquid fuel fires such as engine modules and hazardous material storage spaces. For new U.S Naval ship designs, the Navy continues to move to alternate fire suppression technologies (e.g., water mist) where suitable, however limited use of HFC remains for those spaces where the alternatives are not appropriate. For existing ship HFC uses, there is no “drop-in” replacement for these HFC agents.

Well over 10 million pounds of PFAS fire suppressants are installed in civil aircraft engine, cargo compartment, and lavatory fire suppression systems, and in hand-held aircraft fire extinguishers, worldwide. This includes halons (which meet PFAS definitions but are frequently excluded from draft PFAS regulations because they are separately covered by ozone depleting substance regulations) and all currently implemented aviation replacements for halons. In 2022, Working Paper 96 presented at the 41st Assembly of the International Civil Aviation Organization recommended considering PFAS use in aircraft fire suppression an essential use in prospective PFAS regulations to maintain progress in replacing halons.[10]

[10] International Civil Aviation Organization (ICAO), Working Paper 96: Aircraft Halon Replacement, A41-WP/96, 28 July 2022. https://www.icao.int/Meetings/a41/Documents/WP/wp_096_en.pdf.

IV.5.3 Aqueous Film Forming Foam

Mission critical ocean-going vessels employed by DoD and the Military Services continue to use aqueous film forming foam (AFFF) containing PFAS for combating Class B (flammable/combustible liquid) fuel spill fires. U.S. Navy ships are required to use AFFF qualified to MIL-PRF-24385. MIL-PRF-24385 qualified AFFF provides the capability to rapidly control and extinguish shipboard fires. AFFF is critical for fire emergencies on flight decks where aircraft movement, fueling, launch/recovery, and weapons loading occur, and substantial risk exists for loss of aircraft, ship, and life if a fire is not rapidly controlled and extinguished.

Past flight deck fires, such as those that occurred on the United States Ship (USS) FORRESTAL, USS ENTERPRISE, and USS NIMITZ, all demonstrate the potential for such catastrophic events to occur. The risk of devastating loss of life and warfighting capability in incidents such as these, and the more recent fire emergency which resulted in the loss of the USS BONHOMME RICHARD, necessitates the use of the most effective firefighting agents available.

Beyond the potential for the immediate loss of life and impacts to operational capability that can result from an uncontrolled fire on a warship, the defense industrial base has limitations with respect to repairing or delivering replacement national security assets, including ordnance, aircraft, and ships. It could take a decade or longer to replace large amphibious assault ships and aircraft carriers.

Currently available fluorine-free foams (F3s) have significant limitations compared to AFFF that preclude their use on DoD ocean-going vessels, including the U.S. Navy fleet. Those limitations include reduced firefighting performance; chemical and physical properties that make them unsuitable for use with existing ship firefighting foam storage and delivery systems; and cross-agent compatibility issues. There are currently no equivalent, fully performing firefighting alternatives to AFFF for shipboard use.

DoD continues to sponsor research and development for F3 technologies to address these limitations, with the goal that continued technology improvements will support efforts toward a future path for use on ships. To date, DoD has invested approximately $45.8M since 2017 toward the development and qualification of F3 technologies.

Until such time that a capable F3 alternative is found, the safety and survivability of naval ships and crew from shipboard fires depends on the continued availability of MilSpec AFFF products and their PFAS-containing constituents, which were formulated, tested, qualified, and implemented in order to save lives and military assets.

IV.5.4 Lines, Hoses, O-Rings, Seals and Gaskets, Tapes, and Cables and Connectors

Dozens of different fluoropolymers (e.g., PVDF, ECTFE, PTFE) and fluoroelastomers (e.g., FKM/FFKM) are critical to modern UV-resistant, ozone-resistant, weather-resistant, temperature-resistant, high pressure-resistant, chemical-resistant "rubberized" fuel lines. They are also key materials in hoses, tubing, hydraulic system lines, O-rings, seals and gaskets, tapes, and cables and connectors widely used in civil and military aircraft, space systems, vehicles, weapon systems, utility systems, and other applications. Alternatives are not as resistant to embrittlement and break-down and have a much shorter useful life, leading to more frequent part replacement, which is not feasible for space or satellite uses.

IV.5.5 Electronic/Dielectric Fluids

Fluorochemicals are found in electronic and dielectric fluids that are used in civil and military radars and high-power electronics and electrical system/utility system components because of their dielectric and heat transfer properties. Industry and DoD have repeatedly investigated alternatives for these applications. Known alternatives have high global warming potential (e.g., sulfur hexafluoride) or may pose health/environmental risks (e.g., the polychlorinated biphenyls banned by the U.S. Toxic Substances Control Act and the Stockholm Convention on Persistent Organic Pollutants). Examples of PFAS-containing electronic/dielectric fluids used by DoD include 3M™ Fluorinert™ Electronic Liquids FC-40, FC-72, FC-770, and FC-3283.

IV.5.6 Advanced Oils, Greases, Fluids, and Lubricants

PFAS are used in many advanced turbine engine oils, greases, fluids, and lubricants due to their wear- and heat-resistant properties. These uses are common throughout the most demanding applications in the U.S. civil transportation, industrial, and space sectors. Analogous PFAS-containing oils, lubricants, and fluids are used in military critical ground, sea, air, and space applications. Previous generations of oils, fluids, and lubricants approached, but did not equal, the performance of PFAS additives that have become more prevalent in high performance oils, greases, fluids, and lubricants over the past 20 years.

Castrol Braycote 640AC is an example of a PFAS-containing grease, designed to be oxidizer and propellant compatible for use in aerospace vehicles, spacecraft, rocket and aircraft engines, and associated ground support equipment, oxygen equipment, and transport equipment. Braycote 640AC is typically used to lubricate threaded fasteners, connectors, valves, gaskets, elastomers, and bearings. Perfluorinated greases, in general, exhibit excellent shelf lives due to their intrinsic inertness.

Two additional examples of PFAS-containing greases used by DoD (and original equipment manufacturers and the maintenance, repair, and overhaul industry) are NYCO GREASE GN25013 and NYCO GREASE GN617. PTFE is used as a thickener in both products and perfluoropolyether is used as the base stock for GN617.

IV.5.7 Precision Cleaning Fluids

Fluorochemicals are used in precision cleaning applications, including the cleaning of sensitive oxygen systems in civil and military aerospace.

IV.5.8 Degreasing/Cleaning Fluids

The MilDeps reported the use of PFAS-containing degreasing/cleaning products and contact cleaners (e.g., 3M™ Novec™ Engineering Fluids, 3M™ Novec™ Contact Cleaners, 3M™ Novec™ Contact Cleaner/Lubricant) in vapor degreasing and flux removal.

The Army reported the use of FCC2 Enhanced Fiber Connector Cleaner and Preparation Fluid, which contains butane, 1,1,1,2,2,3,3,4,4-nonafluoro-4-methoxy, for cleaning fiber optic connectors in secure link manager assemblies and primary modem assemblies.

The MilDeps reported the use of fluorinated non-destructive testing (NDT) solvent cleaner/remover for precleaning before NDT and for removing excess surface penetrant from an inspection area before applying developer during liquid penetrant testing.

The MilDeps also reported that PFAS-containing degreasers are used to effectively remove grease, oil, tar, and other substances from military equipment to increase its operating efficiency. These degreasers leave no residue, have no flash or fire point, and serve as an alternative to legacy solvents (e.g., n-propyl bromide, trichloroethylene, tetrachloroethylene).

IV.5.9 Adhesives

The MilDeps reported the use of the following adhesives, which contain PFAS: 3M™ Super Foam Fast Spray Adhesive 74-Orange, 3M™ Hi-Strength Spray Adhesive 90 (aerosol), and 3M Scotch-Weld Epoxy Adhesive DP420 Off-White, Part A.

IV.5.10 Insulation and Foam Blowing

Fluorochemicals are components of insulation and foam blowing products used in civil and military aircraft and space vehicles/rocket motors.

IV.5.11 Resins for Specialty Materials

Fluoropolymers are used in resins for specialty high-temperature or weather-/UV-resistant composites due to their temperature-, pressure-, wear-, and chemical-resistance properties. Fluoropolymers are also used in high cleanable, high weathering and chemical resistant coatings for military assets. Many aircraft topcoats contain fluoropolymer resins due to their UV and chemical resistance properties. PFAS are not actually in the coatings themselves but are used in fluoropolymer resin manufacturing.

Moving to alternatives in under 10 years may require a return to previous methods of parts construction which produced shorter life and higher weight composites with lower performance characteristics.

IV.5.12 Specialty Filters and Membranes

Fluoropolymers are used in specialty filters and membranes (e.g., aviation filters) due to their temperature-, pressure-, and wear-resistance properties. PFAS are also found in several air filtering masks and air filtering respirators used by DoD.

IV.5.13 Fabrics, Fabric Liners, and Fabric Barriers

A variety of textiles used in uniform clothing and footwear items, tents, and duffle bags are treated with PFAS to repel water and oils while providing durability to laundering, UV light exposure, and temperature cycling. The main PFAS used on textiles are fluoropolymers, such as PTFE and short chain PFAS, known as C6 or C4 chemistries. PFAS can be incorporated as an additive mixed into individual fibers or sprayed as a coating onto finished fabrics during manufacturing or after sale and are present in/on textiles in two forms: a non-polymerized compound that can be washed out or evaporated or as a molecule integrated into a fluorine free polymer network via covalent bonds. The MilDeps reported the use of PFAS in chemical, biological, radiological, and nuclear protective equipment (the Uniform Integrated Protection Ensemble Family of Systems) and in a number of uses within health care communities.

Coretech, the biological protective fabric lining used on the Joint Biological Agent Decontamination System, includes a barrier layer for biological protection during the decontamination of aircraft. The barrier layer contains PFAS.

IV.5.14 Customized Applications

Customized applications like gyroscope suspension fluids and analytic gases and fluids for thermometric and other sensors use specialty fluorochemicals because of their pressure-resistant, wear-resistant, and temperature control properties. These applications require very small quantities of specialty PFAS and are particularly susceptible to disruptions in PFAS supply chains due to challenges in attracting manufacturers to develop low-volume commodities.

V. Conclusions

This report summarizes known direct and indirect uses of PFAS that are critical to the national security of the United States, but it is not comprehensive. Also highlighted are the challenges and costs related to finding and qualifying alternatives to existing PFAS materials in sectors of strategic importance to DoD. The information contained in this report is limited to what was available at the time of its drafting. As such, the information presented represents a fraction of the mission critical PFAS uses due to a lack of transparency in the chemical composition in consumables and articles. In addition, there is significant uncertainty regarding the presence of PFAS in products that make up a complex value chain. A more complete understanding of PFAS essential uses would require an extensive and complex evaluation of the market, a gap analysis of current requirements for manufacturer-provided product information, and illumination of the value chain of products.

PFAS are critical to DoD mission success and readiness and to many national sectors of critical infrastructure, including information technology, critical manufacturing, health care, renewable energy, and transportation. DoD relies on an innovative, diverse U.S. industrial economy. Most of the structurally defined PFAS are *critical to the national security of the United States*, not because they are used exclusively in military applications (although a few are) but because of the civil-military commonality and the potentially broad civilian impact. This report provides details on what is currently known about direct and indirect mission critical PFAS uses that could impact mission readiness if the substances are no longer available.

Emerging environmental regulations focused on PFAS are broad, unpredictable, lack the specificity of individual PFAS risk relative to their use, and in certain cases will have unintended impacts on market dynamics and the supply chain, resulting in the loss of access to mission critical uses of PFAS. These market responses will impact many sectors of U.S. critical infrastructure , including but not limited to the defense industrial base. Collectively, international and U.S. regulatory actions to manage PFAS' environmental impacts and identify and eliminate PFAS from the market, and the resulting market changes, pose risks to DoD operations and the defense industrial base supply chain. In addition, impacts to the global PFAS supply chain will present risks to the DoD Foreign Military Sales program and to North Atlantic Treaty Organization interoperability.

The Department will continue to oversee coordinated lines of effort to expeditiously identify essential uses of PFAS, prioritize actions according to vulnerabilities to national security, and address mission readiness associated with the potential loss of access to PFAS. Actions include:

- Implementing DoD PFAS policy directing the DoD Components and MilDeps to determine the PFAS content in DoD weapon systems, to the extent feasible, and enabling continued access to mission critical uses, while encouraging safe use by DoD personnel and adoption of PFAS-free alternatives.
- Engaging with industry to identify PFAS content in other materials commonly used within the DoD to assess potential obsolescence risks and potential PFAS alternatives.
- Engaging with industry and federal agencies during routine meetings to assess obsolescence risks, mission criticality, and potential PFAS alternatives.
- Investing in research, development, and qualification efforts required to demonstrate conformance with Military Standards or Specifications.
- Collaborating across the Federal Government to develop a long-term research plan for the most challenging applications where it will take a decade or more to find viable replacements.
- Investing in research to support advanced manufacturing approaches by improving purification, deconstruction technologies, scale-up of sustainable materials design and manufacturing, and circularity for the most critical and irreplaceable PFAS.

Concurrent with efforts to identify essential uses of PFAS, the Department is phasing out non-essential and non-critical PFAS uses in accordance with NDAA requirements where there is no mission impact (e.g., in food packaging, cookware, furniture, personal protective firefighting equipment). Additionally, per the 2023 U.S. Government Accountability Office (GAO) recommendations,[11] the Department is developing an approach to implement the April 2023 prohibition for military exchange resale procurements. The Department is also updating DoD Instruction 4105.72, *Procurement of Sustainable Goods and Services*, to include procedures specifically targeted to implementing the provisions of Executive Order 14057, *Catalyzing Clean Energy Industries and Jobs Through Federal Sustainability*, with respect to limiting the procurement of items containing PFAS.

Eliminating PFAS from non-essential uses is an important step toward addressing public concerns and protecting human health and the environment. Mission critical PFAS uses provide significant benefits to the framework of U.S. critical infrastructure, and national and economic security. DoD will consider future policy actions to manage non-essential and essential PFAS uses and will implement these actions with the intent of protecting human health and the environment while ensuring no adverse impacts to U.S. critical infrastructure and national security.

If future PFAS legal and regulatory frameworks ignore the OECD caution on the use of its PFAS definition and seek to broadly restrict the use of PFAS based on chemical structure, there could be extensive economic, industrial competitiveness, and quality-of-life impacts to U.S. society. The PFAS universe is structurally and physiochemically diverse and subgroups of PFAS may be more or less stable, persistent, and/or bioaccumulative compared to well-studied PFAS such as perfluorooctane sulfonate and perfluorooctanoic acid.[12] Congress and the Federal regulatory agencies should avoid taking a broad, purely "structural" approach to restricting or banning PFAS. It is critical that future laws and regulations consider and balance the range of environmental and health risks associated with different individual PFAS, their essentiality to the U.S. economy and society, and the availability of viable alternatives.

Appendix: Summary of Known Mission Critical PFAS Uses

PFAS	Application	Functionality	Availability of Alternatives	Time Frame / Cost to Develop and Qualify Alternatives*
Kinetic Capabilities				
Fluoropolymers (e.g., Teflon™) Fluoroelastomers (e.g., Viton™)	Ingredients in binders and resins used in PBX, pyrotechnics, and propellant components that are used in a variety of applications across the DoD munitions portfolio.	High temperature resistance	NA*	NA
PFAS	Used in energetic slurry processing.	Enables high levels of mixing between key energetic components.	NA	NA
Fluorinated performance fluids (e.g., 3M™ Fluorinert™ fluids)	Enable energetics laboratory research. Are critical for developing and transitioning new energetic materials.	NA	NA	NA
Energy Storage and Batteries				
Fluoropolymers (e.g., polytetrafluoroethylene (PTFE)) Polyfluoroalkyl acids (PolyFAAs)	Multiple subcomponents in modern Li-ion batteries: electrolyte solutions, cathode binders, separator coatings, casing materials, and gaskets.	Serve as heat transfer material or insulation. Provide weather-resistance, UV light-resistance, and deterioration-resistance properties.	NA	Fully eliminating PFAS from energy storage in the U.S. economy would likely take 10+ years.
PFAS	Battery manufacturing: filters and other components essential to production.	NA	Possibly available	Time and cost to identify and qualify alternatives would be significant and have ripple effects throughout the economy.
Microelectronics and Semiconductors				
Fluoropolymers Fluoroelastomers PolyFAAs Other PFAS	Semiconductor fabrication: etching materials and masks in photolithography processes; cleaning gases.	Dielectric, heat transfer, and insulation functionalities.	Currently no alternatives to PFAS for photolithography.	NA

Appendix: Summary of Known Mission Critical PFAS Uses

PFAS	Application	Functionality	Availability of Alternatives	Time Frame / Cost to Develop and Qualify Alternatives*
Fluoropolymers	Semiconductor manufacturing equipment and factory infrastructure: equipment components (e.g., tubing, gaskets, containers, filters) and lubrication (various oils and greases).	Heat and chemical resistance, and chemical inertness.	Currently no alternatives for some applications in semiconductor manufacturing equipment. Replacing most PFAS uses in semiconductor fabrication would require industry-wide re-tooling and other process innovations. Some might be achievable within 10 years, but many would not.	Development of alternatives for some uses may require the invention of novel chemistries and processes. Due to the extremely complex qualification process, it would take another 15 years to deploy alternatives, once developed, in high-volume manufacturing. Replacing PFAS in semiconductor fabrication could be a 25-year effort and may not succeed in all respects if alternatives cannot be identified or qualified at the microchip level. Replacing PFAS has the potential to initiate costly requalification of specific components. Example: radiation hardened microelectronics applications typically mandate requalification if a manufacturer substantively alters the fabrication process, which can easily exceed $10 million.

Appendix: Summary of Known Mission Critical PFAS Uses

PFAS	Application	Functionality	Availability of Alternatives	Time Frame / Cost to Develop and Qualify Alternatives*
PTFE PFA	Microelectronics applications: base laminate materials used in many RF and microwave circuits.	Provide unique properties related to isolating RF and microwave signals. Used in radar, antenna, guidance systems, 5&6 G infrastructure, and other network/ transmission applications.	There is no drop in alternative material. Any material replacement for fielded systems would require redesign of the printed board and potentially the electronic system to account for material property differences. Fielded systems that have been redesigned may require requalification.	Developing and or identifying suitable alternative materials and qualifying them could be a forward-looking action for all future DoD systems. This however does not address sustainment of existing systems. There will continue to be a need to have PTFE laminate materials available for system sustainment until all systems currently designed with PTFE are retired.
PFAS	Manufacture of printed circuit boards (PCBs): vapor phase solder and flux remover products.	Vapor phase soldering process is used for PCB assemblies with high thermal mass, fine-pitch structures, and temperature-sensitive components to minimize risk to materials, structures and components. The material stability and flame retardant qualities are well suited for the enclosed high temperature operation of the process.	It is unknown if there are suitable materials that can be used, however it is likely that current equipment may need to be replaced or modified to accommodate the replacement materials.	Developing and evaluating new materials could take 5 years or more. Equipment replacement would add time and have a cost impact.
PTFE	PCBs: cable jackets used in PCB connectors.	Used because it has excellent fire, smoke, and chemical resistance. Wide temperature range -200 to 260C constant use and up to 450C for peak exposure.	It is unknown if there are suitable replacement materials for all of the applications for PTFE wire jacket material. PTFE is higher cost than some other wire jacket materials. When it is selected for use there are typically no other suitable replacement materials.	Qualification of alternatives will be both costly and time consuming. Many materials will require new UL or other certification body approval before they can be implemented. Many current products are MilSpec certified.

Appendix: Summary of Known Mission Critical PFAS Uses

PFAS	Application	Functionality	Availability of Alternatives	Time Frame / Cost to Develop and Qualify Alternatives*
Castings and Forgings and Strategic and Critical Minerals				
Specialty fluorochemical gases and fluids	Advanced metalworking, casting, and fabrication processes used in the production of advanced metal parts throughout U.S. industry, including military-specific parts.	Temperature and wear resistance.	NA	Moving to alternatives in under 10 years may require returning to previous construction methods and may make construction using certain alloys impossible.
PTFE, PVDF, other PFAS	Mold release chemicals and release films typically used in composite manufacturing processes.	Prevent composites from strongly adhering to mold hardware.	NA	NA
Refrigeration and Air Conditioning, Cooling, Electronics Thermal Control				
HFOs	Next-generation refrigerant alternatives (to HFCs) used in civil and military cooling and thermal control applications.	NA	Known non-PFAS alternatives (e.g., hydrocarbon or ammonia alternatives) pose flammability, toxicity, or high-pressure concerns.	NA
Fire Suppression in Aircraft and Ground Combat Vehicles				
Fluorochemical specialty gases	"Clean agent" fire suppression in aircraft and ground combat vehicles.	NA	Most known clean agent, low-corrosion, low-weight, low-toxicity alternatives will likely be classified as PFAS, broadly defined.	NA
Aqueous Film Forming Foam (AFFF)				
PFAS	AFFF use to combat Class B (flammable/combustible liquid) fuel spill fires on mission critical ocean-going vessels employed by DoD and the Military Services.	MIL-PRF-24385 qualified AFFF provides the capability to rapidly control and extinguish shipboard fires.	Current F3s have significant limitations compared to AFFF that preclude their use on DoD ocean-going vessels, including the U.S. Navy fleet.	NA

Aerospace, Security and Defence Industries Association of Europe (ASD) COMMENTS ON THE ANNEX XV RESTRICTION REPORT FOR PER- AND POLYFLUOROALKYL SUBSTANCES (PFAS)

Reference: ECHA Public Consultation on the Annex XV restriction report of 22 March 2023 for Per- and polyfluoroalkyl substances (PFASs)[1]

This is the joint contribution of the Aerospace, Security and Defence Industries Association of Europe (ASD) – to the ECHA Public Consultation on the Annex XV restriction report of 22 March 2023 for PFAS.

We are submitting detailed information specifically for Q6 including case studies to illustrate PFAS usage by this sector.

[1] Available at https://echa.europa.eu/restrictions-under-consideration/-/substance-rev/72301/term.

1 Summary

Who we are: ASD is the voice of European Aeronautics, Space, Security and Defence Industries, directly and indirectly representing around 3,000 companies. It has 22 major European companies as direct members and 23 National Associations active in 18 European countries. ASD members together employed 879,000 people and generated a turnover of €238 billion in 2021. See our webpage for more details: https://www.asd-europe.org/.

In this document, we submit our input to Q6. We provide information on identified uses of PFAS chemicals in A&D products, the types of PFAS and our assessment of how these uses have been considered by the dossier submitters in the proposed restriction and the extent to which they are in scope of proposed/potential derogations.

Table 1 gives details of the uses reported by ASD members with details of the PFAS type and a best guess assessment of which of the application areas described in the restriction report they may be assigned to. For each reported use, we then assessed whether they may be in scope of a proposed/potential derogation (details given in Annex 1). From this assessment, we see that while some of the A&D uses were assessed, a very significant number of uses were not assessed and not unsurprisingly are also not covered by any derogation. We also see that in principle, some of our uses were assessed but the dossier submitters did not include them in the proposed/potential derogations.

In terms of the derogation periods given in the proposed restriction, we also see that the maximum time period is 12 years. In the assessment of available alternatives for the uses assessed (Annex E of the restriction report), we can also see that the dossier submitters did not consider the specificities of our sector when determining the time needed for substitution.

In this report, we provide details of these specificities (chapter 2.2) and show that when they are taken into account, the impact risk option proposed (RO2) would be catastrophic both for our sector and the wider functioning of the EEA in terms of aviation and defence capability (chapter 2.3).

PFAS chemicals and in particular fluoropolymers are integral to the production, operation and MRO of A&D products. A given product may have many 1000's of PFAS containing parts integrated into the components, sub-systems, systems, etc. that make up the product. The driver for their use is their high performance in harsh/extreme operating conditions that underpin the safety and reliability of A&D products. Due to the formal quality management processes in place to ensure safety and reliability, substitution is lengthy even when potential alternatives are available. There are no potential alternatives available that can fulfil the performance requirements. Maintenance of in-service A&D products must also be done with spare parts as per the original approved design over the entire product service. Depending on the product, this can be 40+ years (e.g. aircraft) or longer (e.g. naval vessel). Changes in the production of the spare parts would trigger the need for requalification and recertification and likely redesign before the part could be taken into use. This is lengthy and it can also be that redesign is not technically feasible.

Due to the ubiquity of PFAS (primarily fluoropolymers) in the production, operation and MRO of A&D products, the scale of the substitution requirement that would be triggered by the proposed restriction has no precedent. The dossier submitters' assessment did not consider the specificities of the A&D sector and the derogations as given are inadequate both in coverage and duration. Due to the complexity of A&D products and the formal quality management systems in place, non-availability of even a limited number of parts will stop production of new products and scheduled maintenance of in-service products. This means that the impact of the restriction would be felt already 18 months after the entry into force as all uses are not covered by a derogation. The impact would be quite simply catastrophic. The restriction as proposed does not have a plausible non-use scenario when our sector is included.

We ask the dossier submit to revise their proposal to include our sector; specifically

- Exclude fluoropolymers (and the precursor chemicals necessary for their manufacture) from the scope of the restriction given their ubiquity in A&D products and the absence of alternatives that fulfil the performance requirements for reliability and safety
- Include a sector derogation for the use of PFAS chemicals necessary for the production and operation of A&D products with a review clause to allow for an extension/renewal of the derogation if needed due to the non-availability of suitable alternatives
- Exclude the use of PFAS chemicals on their own, in formulations and in articles that are necessary for the MRO of existing products
- Include a time-unlimited derogation for specific PFAS chemicals used fire suppression systems (see case study 5 in Annex 2)

We also note that the reporting requirements on manufacturers and importers of PFAS or PFAS containing articles as well as formulators of PFAS containing mixtures relying on derogations (paragraphs 7 & 8) did not consider the specificities of our sector. Due to both the complexity of our products and our global supply chains (see chapter 2.2), it is not possible to collect, compile and report the information required under paragraph 7 within 18 months of the entry into force. The site specific management plans requirements given in paragraph 8 also cannot be implemented within 18 months of entry into force as the users will be need to collect information from all tiers of their supply chain and map PFAS in the 1000's of parts, components, systems etc. that make up A&D products. At least 5 to 10 years would be needed to be compliant with such requirements.

In addition, we highlight that the restriction refers to ppb levels in articles (paragraph 2) – the challenges associated with complying with the requirement were not considered by the dossier submitters as apriori to verify this, we would need to test all articles. This is not feasible for A&D products as 1000's of parts/components would need to be tested. In addition, standard test methods are not available for the range of articles that would need testing with this level of detection.

2 Overview of PFAS usage by the A&D sector

2.1 Use identification and assessment of derogation suitability

A soon as the restriction proposal was available on the ECHA website, ASD members initiated new activity to identify any further PFAS uses and to understand the impact of the proposed restriction on their sector and the extent of coverage of the proposed (5a-5t, 6a-6f) and potential (5u-5ee, 6h-6o) derogations. As outlined in our reply to Q2, PFAS chemicals are integral to the production, operation and MRO of A&D products. For example, a given product (e.g. a commercial airliner) will contain many 1000's of individual fluoropolymer parts/components integrated to subsystems, systems and assemblies.

A questionnaire with pre-defined questions was circulated between ASD members, with fields for free text answers. ASD members completed the questionnaires based on their current knowledge of where PFAS chemicals are used in the products and supply chains. Due to the limited time available, it was not possible to complete an exhaustive supply chain investigation. The aim was to collect a sector-wide first understanding of uses and to map coverage by the proposed and potential derogations as a first step in determining the impact of the proposed restriction. This exercise is not intended to be exhaustive or definitive. It was done solely in the scope of the restriction proposal and considering the applications identified by the dossier submitters (Annex A to the restriction dossier).

The questionnaire had fields to report uses by "application area/main use", the type of PFAS used and their understanding of whether each identified use may be covered by a proposed/potential derogation. ASD members reported uses in the "application area/main use" fields according to their products.

The completed questionnaires from each member were compiled to yield a wide dataset covering uses of ASD members and their supply chains. Duplicates for "application area/main use" were merged. An external contractor used expert judgement to assign reported uses to the use categories defined by the dossiers' submitters in Annex A of the proposed restriction dossier. The dataset was then used to extract details of the types of PFAS chemicals reported for each application area/main area. The contactor used expert judgement to categorise the PFAS reported in use by ASD members to particular groups; fluoropolymers, fluorinated gases, unspecified PFAS, fluorinated alkene or fluorinated organic fluids). The assignment of the reported PFAS to a PFAS type is given in Annex 1. The reported PFAS for each application area were grouped by types given in Table 1. The responses to the questionnaire depend on the products made by the member (e.g., aircraft, engines, landing gear, defence systems). There are many commonalities between the products since fluoropolymer PFAS are ubiquitous material for seals, gaskets, sleeves, tubing, cables, hosing, bearings, bushings and as components of lubricants, sealants and hydraulic fluids.

From Table 1, it can be seen that a very extensive set of application areas/main areas have been reported across the sector and that many of these cannot be assigned to a restriction use category included in Annex A by the dossier submitters. These are reported as "miscellaneous" in the Table. It can also be seen that fluoropolymers are the most common PFAS type. Note that the assignment of an A&D reported use to a restriction use category was a best guess based on current understanding of Annex A of the restriction report. The sub-uses given in Annex A for "transport" are not extensive and "defence industry" sub-uses are not given.

Some uses which have been categorised under "Applications of fluorinated gases" use 2-bromo-3,3,3-trifluoroprop-1-ene (CAS 1514-82-5, EC 627-872-0), which is a liquid at room temperature and pressure, but due to its low boiling point and high vapour pressure, is considered a gas in use. The fluorinated alkene reported was TFE (tetrafluoroethylene, CAS 116-14-3, EC 204-126-9). It is expected that this will be in the polymeric form in its final use but was reported separately by ASD members.

Table 1. Alignment of use categories as stated by the dossier submitter (Annex A) with those reported by ASD members for each PFAS type

Possible restriction Use Category (& sub-use) (Annex A)	Sub use identified by ASD members	Fluoropolymer	Fluorinated Alkene (non polymeric)	Fluorinated organic fluids (non polymeric)	Fluorinated gases	Unspecified PFAS
Applications of fluorinated gases	Cooling agents			x

* "transport" does not cover many defence and security products (weapons, munitions, launchers)
** The assignment was a best guess focussing on "packaging" – details in Annex A are quite limited

Derogation assessment: Information on possible derogation coverage was then extracted from the dataset. In this context, "coverage" solely means that the contractor could make a link between the reported use and a derogation (i.e. the use may be in scope of the derogation). The contractor used the information reported by ASD members in their completed questionnaires and expert judgement based on the content of the dossier and the Q&As from the ECHA webinar. Expert judgement/best guess was used to assign each application area as "unassessed" or "assessed/partially assessed" by the dossier submitter and to determine where applications could perhaps fall under a proposed/potential derogation.

Note that as the dossier submitters did not include aerospace, defence and security as application areas in their assessment, coverage is very limited and open to interpretation.

Details of the derogation assessment are given in Annex 1. In terms of A&D areas assessed by the dossier submitters and possibly covered by a proposed derogation, 5-k, 5-m and 5-s were the most assigned (see Table 15). Of the ASD application areas considered to be "partially assessed" by the dossier submitters, the potential derogation 6-o "transport" was the more assigned by the contractor (see Table 16). Note that this is using a very wide interpretation of "transport" – many defence and security uses are not "transport" and they will not be covered. For two ASD application areas that were assessed by the dossier submitters, release agents and release foils, it is open to interpretation if they are covered by the proposed derogation 5-s "*lubricant*". The contractor assigned these two applications separately as "5-s?" – see Table 17. However, a **significant number of ASD application areas** were considered to be **either fully or partially assessed** by the dossier submitters but **not assignable to** either **a proposed/potential derogation** (see Table 18). A **significant number of ASD application areas** were **not assessed** by the dossier submitters and are mostly **not assignable to a proposed or potential derogation** (see Table 19 (red)).

From this investigation into ASD member uses, ASD has further confirmed that PFAS chemicals are ubiquitous in the production, operation and MRO of A&D products. Fluoropolymers are the most widely reported PFAS type as articles (seals, cables, etc.), integrated into articles (paints, coatings, sealants, etc.) or components of mixtures (e.g. lubricants, cleaning agents) across all A&D products. When assessing identified ASD member uses of PFAS against the scope of the proposed/potential derogations, it is clear that that there is insufficient coverage for the vast majority of its application areas.

From the use and derogation assessment, it is clear that if the restriction (RO2) came into force as proposed, the impact on the sector would be significant and would already be apparent within the 18 month transition period, since ca. half of the PFAS uses identified to date would not be covered at all by either a proposed or potential derogation. For those uses that could be covered by a proposed/potential derogation, and assuming these uses could even viably continue in the absence of the non-covered uses, the A&D sector would need to rely on a scattered and incomplete set of derogations, with expiry dates that do not consider the challenges and specificities for developing and introducing alternatives in the sector.

Such a situation, where some A&D uses are not derogated for and others are sporadically covered by multiple non-A&D specific derogations with short (12 years and less) expiry periods would lead to non-use scenarios being realised. Even if one PFAS-reliant component or formulation, critical to manufacture or MRO of an A&D product is no longer available (e.g. due to lack of clear derogation), the product manufacture and in-service support would cease. Taking civilian aviation as an example, this would mean grounding of aircraft. We see that this has not been considered by the dossier submitters.

In terms of derogation periods, particularly for fluoropolymers (which may never be replaced with less 'persistent/resilient' alternatives), 5 or even 12 years is inadequate for the A&D sector, even if there were potential alternatives available, due to the strict qualification and certification requirements that have to be met before a new alternative can be safely introduced and the long product service lives together with the associated need for spare parts/legacy spare parts to be available for decades. It would take decades for a full phase out if suitable alternatives could even be developed. The substitution requirement would impact thousands of parts, components, sub-systems etc. in all A&D products on a scale that has no precedent for this sector.

2.2 Specificities of ASD products

As outlined in our reply to Q1, PFAS chemicals are used in the production, operation, and maintenance of A&D products and/or in the manufacture of component parts (articles), sub-assemblies and formulations (mixtures) in A&D supply chains. This means that the impact of the restriction needs to consider production, operation and MRO activities.

2.2.1 High performance in harsh/extreme operating conditions is a key requirement for safety and reliability of A&D products

From our use identification to date, it is already clear that PFAS chemicals are ubiquitous in A&D products. Fluoropolymers in particular are integrated at every level of the supply chain relating to the production, use and maintenance, repair and overhaul (MRO) of A&D products. Due to their unique combination of properties (chemical inertness, thermal stability over a wide temperature range, non-stick and low friction properties, electrical insulation, weather and UV resistance, high resistance to corrosive liquids and gases,, mechanical strength and durability) they are used in seals, sealants, gaskets, lubricants, bearings, bushings, etc. the parts, components and systems that make up A&D products. The drivers for their ubiquitous use stem from their high performance in harsh/extreme operation environments that underpin the safety and reliability of A&D products. They have been integrated into A&D products due to their performance and an A&D product will have 1000’s of PFAS containing parts integrated into components and systems. There are formal quality management systems in place to qualify and certify/approve A&D production, operation and MRO. This means that once a product is approved, there are formal change management protocols that must be followed for any change. This means that a substitution requirement to change all current PFAS containing parts has to follow the quality management systems in place to ensure continued safety and reliability of A&D products.

2.2.2 Complexity in terms of number of parts

A&D products are generally very complex assemblies of parts, components, sub-systems and systems. For example, a single product such as a tank or air defence system contains many thousands of parts, utilising an exceptionally wide range of materials and technologies in the engines, structure, wheels, radio communications, controls, fuel system, lubrication systems, hydraulic systems, munitions, CBRNE protection, etc.. Hydraulic systems will have PFAS containing hydraulic fluids, hoses, seals, gaskets, filters and cables. In an aircraft such hydraulic systems are then used in braking systems, landing gear, wing flaps, flight-control surfaces, engine pumps, air turbines, and many other area. A single major platform such as a ship or aircraft can have millions of parts, many of which are complex assemblies. Figure 1 illustrates that products like commercial aircraft are assembled from parts that are themselves made up of thousands of parts. It has been estimated that around 400,000 - 500,000 PFAS-containing components are likely to be present in a smaller short-haul commercial aircraft, whilst in larger aircraft the number of PFAS-containing components will likely be in excess of 1 million.

2.2.3 Illustrative examples of the diversity of A&D uses of PFAS in a diversity of A&D products

20 case studies are given in Annex 2 illustrating the use of PFAS in A&D products, and providing a thorough explanation on the reasons/ needs and the status of alternatives. These examples are not exhaustive and many other uses of PFAS chemicals are also still required. Some highlights are given below.

For example, a **commercial airliner** will have many thousands of integrated fluoropolymer seals, gaskets, sealants, coatings, cables, connectors in its gas turbine engines, landing gear, fuel systems, brake systems and electronic systems. Fluoropolymer seals are used in various critical applications within gas turbine engines, such as sealing combustion chambers, fuel systems, lubrication systems, hydraulic systems, and other high-temperature and high-pressure components. The specific choice of fluoroelastomer seal depends on the operating conditions, fluid compatibility, and temperature requirements of the engine component (see case studies 3, 14). **Gas turbines engines** in turn have applications in a very broad range of fields – the major ones are aviation, oil and gas, marine propulsion, power generation and industrial applications. PFAS containing lubricants and hydraulic fluids are integral to the functioning of safety critical components like aircraft gas turbines (jet engines), including actuators, flight control systems and landing gear systems, maritime gas turbine, combustion engines (see case studies 7, 14) .

Lubricants are another example. Fluoropolymers are very widely used as lubricants for bearings, valves, actuators, regulators, gears and gearboxes, gear chains, mechanical devices (like hatch opening) and fasteners in general. **Electronic systems** also have integrated fluoropolymer components due to their inertness, light weight, mechanical strength, and durability (see case study 18). **Energy sources** like Li-ion batteries and hydrogen fuel cells also have integrated fluoropolymer components (see case study 6).

Non-polymeric PFAS are used in the operation of A&D products. For example, commercial airplanes, military vehicles, naval vessels including aircraft carriers and submarines use **clean agent fire suppression systems**. Clean fire suppression systems are designed to rapidly extinguish the fire without leaving residues that damage equipment or cause harm to humans breathing them in. PFAS gases have generally replaced or are about to replace halon as the fire suppression agent. Halon was banned under the F-gas Regulation and Ozone Depleting Substances (ODS) regulations. It was also banned for non-essential uses since 2003 and banned for essential uses by 2040. For aircraft fire extinguishers systems and other A&D uses, the replacement of halon (as required by the Montreal Protocol and associated regulations) has been staged over time, some systems being already addressed/retrofitted, some others on track for approval in 2024 - in most of the cases, the halon replacements are PFAS chemicals (see case study 5).

PFAS chemicals are also used as heat-transfer fluids in **refrigerant systems**. For example, in defence platforms, including jet fighters, surveillance platforms, transports, helicopters, naval ships, submarines and land vehicles, they are used in weapon systems to cool high output electrical and electronic equipment in addition to air conditioning, general equipment cooling and food preservation. In commercial aircraft, refrigerant systems are used for cabin air conditioning, avionics cooling, galley cooling, cargo hold cooling and equipment cooling (see case study 4).

Other PFAS chemicals are used in operation and maintenance activities to modify surfaces to repel rain and dirt. For example, they are used as rain repellent agents in fluids applied to windscreens in aircraft, military aircraft canopies, defence platforms like aircraft carriers, etc. They impart water repellence to windscreen surfaces ensuring good visibility under all weather conditions. They are also used in cleaning fluids to prevent rainwater sticking to surfaces leading to ice formation at high altitudes and changes to the weight and balance of the aircraft during flight. Another example of their use is in the technical textiles coating mainly used in the land defence vehicles and tanks, aircrafts, etc. for their fire and smog resistance properties and as water and oil repellence at the same time.

More details are given in Section 2.3.

2.2.4 Very long service lives and availability of spare parts and materials for operation and MRO

Products typically have decades long service lives meaning that a continuous supply of parts and material must be available for their operation and also in maintenance, repair and overhaul (MRO) until the end of service life. The latter also particularly relates to ships and submarines including for lay-up prior to decommissioning. All spare parts and materials are generally required to be as per the original design specification in all key attributes including physical, chemical, surface wear, life, reliability and compatibility with adjacent materials and components.

2.2.5 Complex multi-tiered supply chains

Due to the complexity of the products, each OEM will deal with hundreds of suppliers for each product/platform type. For some suppliers, production will be based on customer (OEM) drawings. Others will have their own designs and supply chains using a variety of custom and off-the-shelf commercial components. A simplified two region supply chain diagram is given in Figure 2 to illustrate the complex interrelationships and many levels of the global supply chain.

Figure 1. Illustration of the complexity of A&D products (adapted from Figure 8 in the ASD Sectoral Guidance for WFD/SCIP implementation[3])

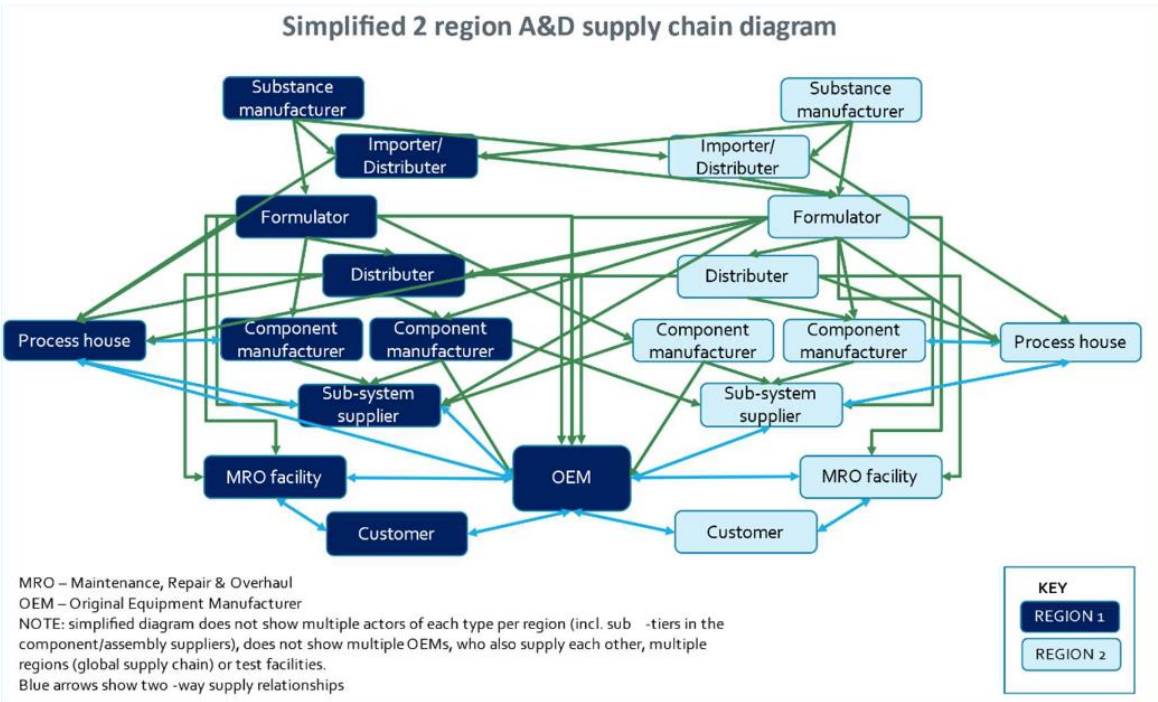

Figure 2. Simplified 2 region A&D supply chain showing the interdependences between the different tiers (reproduced with permission from the ADCR authorisation applications4 for CrVIs for the A&D sector)

[3] ASD Sectoral Guidance for WFD/SCIP implementation available at https://www.asd-europe.org/sites/default/files/2022-08/ASD%20Sectoral%20Guidance%20for%20WFD-SCIP%20implementation0505.pdf

[4] ADCR application for authorisation for continued use of hexavalent chromates; Application ID 0327-01 "*Chemical conversion coating using chromium trioxide, sodium dichromate and/or potassium dichromate in aerospace and defence industry and its supply chains*" available on the ECHA website at https://echa.europa.eu/en/applications-for-authorisation-consultation/-/substance-rev/74108/term

2.2.6 Formal quality management systems in place to ensure safety and reliability of A&D products

A&D products are subjected to some of the most aggressive environments around the world. They must operate successfully in extremes, not limited to altitude, temperature, pressure, and precipitation, while having to fulfil the highest possible technical reliability and safety requirements. Formal quality management systems are in place to ensure safety and reliability of A&D products throughout their service lives. For example, to ensure aircraft safety, comprehensive airworthiness regulations[5] have been in place in the European Union (as well as around the world) for decades. These regulations require qualification of all materials and processes according to a systematic and rigorous process to meet stringent safety requirements that are ultimately subject to independent certification and approval. Such rigorous testing and qualification processes are required to assure that any changes do not compromise the integrity of the affected components or the safety of the product as a whole.

Parallel requirements[6] are in place to ensure airworthiness for defence systems in Europe. Ground and sea-based defence systems are subject to similar rigorous qualification requirements. They operate in extreme environments over many years. In the defence sector, many national, European and NATO standards are obligatory and must be reached to be compliant with the NATO requirements settled by the allies in the international agreements. Space systems must also meet the highest specifications for consistent reliability and performance in extreme environments over many years, since repair or maintenance is practically impossible once the technology is launched.

This means that every alternative for an existing use must be successfully qualified (evaluated and tested) in the context of the whole system/sub-system. This has to be demonstrated for every existing use to be replaced, even if the alternative is the same. Once qualified, the system must be revalidated to maintain certification of the product (aircraft, vessel, vehicle, etc.). Certification is strictly controlled by regulatory bodies in the EU and other jurisdictions, in both the civil aerospace and military domains (European Aviation Safety Agency (EASA), the US Federal Aviation Administration (FAA) and their military counterparts).

Alternatives can only start to be used once they have successfully passed the qualification and certification stages. This means that substitution is a lengthy process. The specificities of the substitution process for the A&D sector are described in detail in the ADCR authorisation applications – see for example chapter 3.1.2 of the AoA-SEA report of the application requesting authorisation for continued use of hexavalent chromates in conversion coatings[4].

The scale of the substitution effort that would be required, if new materials are ever developed to replace PFAS (but in particular fluoropolymers), has no precedent. Thousands of formulations, parts, components, systems etc. across all A&D products would be affected.

Note that one of the challenges is to find suitable substitutes that fit with the existing product design. These are more or less frozen as they are tied to the type certification, making substitution technically and/or economically impractical. The "form, fit, function" requirements, that alternatives have to comply with, may mean that a complete redesign could be needed, which may in turn impact on product characteristics such as weight and adversely impact environmental performance. Retrofitting in-service

[5] E.g. European Union (EU) Regulation No 216/2008 and the EASA CS-25 and EASA CS-E in the EU

[6] The European Aviation Requirements (EMARs) established by the European Defence Agency (EDA) Airworthiness Authorities (MAWA) Forum

products also has temporal, logistical & economic challenges. For example, one OEM has design responsibility for a customer fleet of 12000 in-service civilian aircraft.

2.3 A&D uses of PFAS chemicals (Missing uses (Q6))

Based on the use mapping reported in section 2.1, ASD see that the specificities of their A&D sector have not been considered by the dossier submitters (variety of different A&D products concerned, number of parts and products concerned, strict qualification/certification requirements, long service life requiring parts to be available for decades, complex supply chains). To be clear, the potential derogation “transport” (6-o) is not adequate for the A&D sector as not all uses would be covered and the time limit of 12 years is insufficient.

For this reason, ASD provide information on A&D sector uses of PFAS in its reply to Q6 and request A&D to be considered as a sector in its own right, when determining derogations.

2.3.1 Tonnage and emissions – PFAS uses by the A&D sector (ECHA Q6a)

ASD members are typically OEMs and system integrators and the PFAS will generally be used by the members but also throughout their upstream suppliers (parts, components, systems, sub-systems providers), service providers (MRO providers) and customers (airline companies, defence forces and their service providers). It is therefore very challenging to estimate likely tonnages and emissions.

Types of PFAS: Based on the identification of PFAS uses by ASD members to date, polymeric PFAS are the most widely used PFAS type and are integrated to the parts and components that are ultimately assembled into the A&D products. Ca. 80 % of the reported uses (by count) given in Table 1 refer to polymeric PFAS and most refer to articles. As downstream users of fluorpolymers, ASD members do not have access to emissions data relating to their manufacture and end-of-life (EoL). We refer the dossier submitters to information submitted by the Fluoropolymers Product Group (FPG)[7] on manufacture and to the Conversion report on fluoropolymer waste[11]. The remaining 20 % of reported uses cover all non-polymeric PFAS.

Intentional release during use phase: For emissions, ASD have no reliable estimates at this time. Looking at the types of PFAS and where they are used in practice, ASD can differentiate between those where there is intentional release during the use and those where there is not and it is clear that there are only a few cases with intentional releases.

For polymeric PFAS integrated to parts/components in seals, gaskets, cables, sleeves, tubing, linings, and similar, there is no intentional release to the environment during use. The inertness and durability of polymeric PFAS is the driver for their use in these kinds of products.

For non-polymeric PFAS, there will be intentional release where that is intrinsic to the functioning of the system (e.g., as the fire suppression agent on the rare occasions they are used for purposes of safety (confirmed or suspected fire), this has been estimated to be ca. 4 tons per year (with +3% increase – i.e. ca. 0.150 metric tonnes - as per forecasted fleet growth – see case study 5) and no intentional release for uses as refrigerants, heat transfer fluids and hydraulic fluids.

Manufacturing stage: Due to the length and complexity of supply chains for the many parts affected it is not possible to provide additional information at this time regarding emissions during parts manufacture.

[7] Fluoropolymer Product Group (FPG) website available at https://fluoropolymers.plasticseurope.org/index.php/about-us

We refer the dossier submitters to the comments submitted by the FPG (#6418) on "*Health and Safety Directive (OHS) together with the implementation of responsible manufacturing and EoL risk-management practices*" for the position of the manufacturers. Our understanding is that for fluoropolymers in particular where there is no expected release during service life, it could be considered that any risks in the manufacturing and waste phases be addressed through the Industrial Emissions Directive and occupational health and safety measures.

A supplier of fluoropolymer seals and other parts for aerospace engines shared their estimates for emissions from the manufacture of their fluoropolymer parts used in aerospace engines at their site. The emissions are very low (< 0.3 kg /year to water and negligible to air during manufacture). These emissions can be effectively regulated under the Industrial Emissions Directive (see comments submitted by DuPont[8]).

Table 2. Preliminary estimates for breakdown of PFAS use by type and potential for emission during use from the use assessment

	Polymeric PFAS	**Non-polymeric PFAS**
% of PFAS type in A&D uses (estimate*)	Ca. 80 %	Ca. 20 %
Intentional releases to the environment during use	No, for most uses where the polymer is integrated to a part/component– there is no release for the service life of the part.	Yes, for some uses where release is a required function (fire suppression – see details in case study 5 in Annex 2 No, for other uses (e.g., refrigerant systems with leak controls)

* by count from the preliminary use mapping done – see Table 1

Emissions at end-of-life stage: Emissions depend on the type of PFAS and the specific use. The following details are based on civil aviation practices. Similar processes are anticipated in military equipment such as military aircraft in such cases where there is end of life disposal. It should be noted that the end-of-life management of military equipment is a highly sensitive subject for national security reasons and no information is provided on that in this report.

End-of-life A&D products e.g. aircraft, defence vehicles are valuable assets due to the parts and materials contained even after service life measured in decades. See for example the information on recycling of specific aircraft on OEM websites[9] and providers who specialise is aircraft recycling.[10] Dismantling includes decontamination/depollution steps to separate out hazardous waste including all chemicals and fluids which are then sent to appropriate hazardous waste treatment facilities. Some of these will include PFAS. As shown in the sectoral use mapping (Table 1), fluoropolymers are the dominant PFAS type and are generally integrated in articles such as seals, O-rings, fluid systems, cables and structures, etc.. As outlined in the Conversio report on fluoropolymer waste, the focus of aircraft dismantlers and recyclers is to extract valuable and reusable parts as well as recovery of metal fractions such as skeleton and cladding.

[8] Socio-Economic Impact Assessment for the use of PFAS within the Aerospace Supply Chain, Final Report prepared for DuPont by RPA, submitted via the webform on 09.08.2023
[9] https://aircraft.airbus.com/en/newsroom/news/2022-11-end-of-life-reusing-recycling-rethinking
[10] https://www.tarmacaerosave.aero/aircraft-recycling

Non-recyclable materials are mainly incinerated for energy recovery operations. Only a small share of plastics, incl. a small share FP materials, is landfilled, e.g., in the UK or in France.[11]

Aircraft storage, recycling and disposal is a specialised activity and is managed as a service.

Land defence vehicles storage, recycling and disposal is a specialised activity and is managed as a service with MoDs.

Emissions at end-of-life from the decommissioning of fire suppression equipment are extremely low as most of the agent is recovered and reused to service other equipment.

2.3.2 Key functionalities driving the use of PFAS chemicals in A&D products (ECHA Q6b)

The key functionalities will depend on the driver for using the PFAS chemical in parts, components, sub-systems, assemblies and products. ASD members differentiated between polymeric PFAS and non-polymeric PFAS in their description of key functionalities requirements. Depending on the A&D product, their key functionalities are determined by the operating environment and conditions of use of the affected formulation or article within a product.

To illustrate the diversity and complexity of PFAS use across A&D products, some examples are given in Table 3. (typical fluoropolymer articles), Table 4 (formulations containing fluoropolymers) and Table 5 (non-fluoropolymer uses). As A&D products were generally not considered by the dossier submitters in their assessment, the examples aim to explain the where and why for PFAS usage.

[11] Fluoropolymer waste in Europe 2020, End-of-life (EOL) analysis of fluoropolymer applications, products and associated waste streams Conversio report 2022-07-19 available at https://www.ft.dk/samling/20222/almdel/euu/spm/49/svar/1951975/2698345.pdf

Table 3.Overview of typical fluoropolymer parts used in the production and MRO of A&D products, the drivers for the use and examples

Common fluoropolymer components	Description	Driver for why it is made from a fluoropolymer	Examples of fluoropolymer parts integrated to components/systems
Bearings and Bushings	Parts in mechanical systems that allow free rotation between a shaft and surrounding structure with minimal axial or radial movement.	- Higher thermal capabilities; - Reduced friction and wear, - life extension and performance i.e., lower friction less power losses Bearings in aircraft control levers are given an illustrative example. In an aircraft environment, where heat and chemical resistance as well as excellent wear characteristics are required, PTFE containing bearings or PTFE containing films are used at the interfaces of moving parts where low friction is required and other methods such as lubricants which require associated regular maintenance are not feasible. For example, the flap lever controls the high-lift system during take-off and landing. In addition to various sensors in the wings and redundant computer systems, the high-lift system is controlled manually by the pilot. The necessary, so-called Flaps Lever is situated in the cockpit and is the man-machine interface of the system. The Flaps lever is mounted in its pivot point in bearing shells, containing polytetrafluorethylene (PTFE) thus to minimize friction of the bearing. Due to the fact that the adhesive and the gliding friction are equally low with PTFE, the so-called stick-slip-effect is prevented, which is crucial for precise operation of the Flaps lever by the pilot.	 Use of PTFE bearings in aircraft control lever These parts are used at every intentionally moving interface. In aircraft this includes, flaps, slats, rudders, ailerons, doors, landing gear, fire escapes, switches, levers etc. In other products, these includes drive trains, turrets, anchorage and mooring systems, missile loading systems, cargo management, cranes. Exact material choices depend on operating conditions. See case Table 11. 12 and case study 8 in Annex 2.
Hydraulic hoses	Flexible pipes that allow transfer pressure through an incompressible fluid, with minimal expansion or flexing under extremely high fluid pressures	Performances related to aging (aeronautical requirement related to lifetime) - large range of temperature (-55°C to 232°C) - large range of pressure: full vacuum to 10 000 PSI - Compatibility with almost all fluid (fuel, hydraulic, …) - Compatibility with oxygen system (breathable) - mechanical performance mix: flexibility & tensile/ pressure properties - All specifications (standard and customer) require PTFE for hose construction As a specific example from the aviation sector, hoses in the aircraft are used to contain and convey hydraulic fluids, oils, fuel, greases, lubricants, anti-icing and de-icing agents, cleaning agents, oxygen, extinguishing agents and multiple other flight safety critical substances.	 Schematic of aircraft fuel and hydraulic systems

Common fluoropolymer components	Description	Driver for why it is made from a fluoropolymer	Examples of fluoropolymer parts integrated to components/systems
		Hydraulic hose lines act as links to ensure the transmission of energy in hydraulic systems. If they fail, the entire system is affected and machine failures are the result. Certification co-dependencies: as of today certification requirements make it so hydraulic fluids are phosphate ester based for fire resistance. As a result, hydraulic hoses must be resistant to phosphate ester.	 Schematic of CRES (corrosion resistant steel) hose material structure/layers Every hydraulic system has integrated hydraulic hoses. Hydraulic controls are used for high-force mechanical actuation for wing and rudder controls, thrust reverser movement, landing gear, gun turret and torpedo operating systems, crane and mooring systems. See Table 11 and case study 2 in Annex 2.
Seals (including O-rings and gaskets)	**Gasket**: Packing material between two relatively static surfaces to prevent leakage. **O-Ring**: A circular seal or gasket preventing liquids or gases from mixing or escaping to atmosphere	**Seals**: Use in aggressive environment: fluids (e.g. engine oil), space (extreme temperature and pressure) **Gaskets:** Chemical resistance (oils, greases, fuels) Thermal resistance (205°C / continuous) Resistance to ozone and oxygen For example**,** fluorocarbon and PTFE seals used in multiples parts of gas turbines. There are no alternatives that met the temperature and material compatibility requirements. Fluorocarbon and fluorosilicone seals are standard for fuel system sealing. There are no alternatives that have temperature and compatibility capability. Inability to use fluorocarbon seals would additionally prevent the use of sustainable fuels where the biggest compatibility challenges exist. Aircraft and other A&D products are required to operate in a wide temperature range of -56 to 80°C, in some areas the temperature may go up 220°C (engine fuel feed lines and recirculation). Seals and sealing solutions have to be suitable for use under these extreme temperatures. In particular, fuel seals and fittings must remain pliable at the coolest temperatures, to cope with flexure in the airframe from air movements and aircraft manoeuvres to avoid leaks. They also need to be oxygen, ozone, fuel and	 Photos of O-rings and parts with fitted seals

Common fluoropolymer components	Description	Driver for why it is made from a fluoropolymer	Examples of fluoropolymer parts integrated to components/systems
		oil resistant. Due to very specific technical requirements and extreme operating conditions, there are only two fluorinated rubbers which can offer the properties and characteristics needed to be used for aircraft seals and sealings solutions: Fluorinated silicones (FMQ) and fluorinated carbon rubbers (FKM). All the main groups of fluorinated rubbers possess very enhanced properties over traditional oil resistant rubbers, the key ones being the high resistance to swelling and mechanical strength. Fluorinated silicone rubbers (FKM) have a very extended temperature range -45 to +225°C and consequently extreme resistance to long term oxidation, aging and perishing.	Seals are used in gas turbines compressors and turbines to separate primary gas flows and cooling air, in air bleed valves, oil pumps, fuel pumps. oil and fuel filters, fuel delivery systems, fuel and oil temperature or pressure transducers, every fuel or oil pipe joint, shut-off valves, control valves, gearboxes. Across aircraft systems, seals are used through the hydraulic system including hydraulic pumps, pipe joints, filters, actuators for landing gear, flaps, rudders and ailerons. Seals are found around cargo doors and passenger doors, windows, electrical connectors, access panels. In other applications seals are used to protect all kinds of marine systems from sea water entry, and for the integrity of all manner of systems including fuel, lubrication, and hydraulic systems and to protect electronic and other systems from corrosion. See Table 11 and case study 3 in Annex 2
Sleeves	A protective tube that fits over a wire, pipe or other part to protect it from abrasion or to prevent electrical short circuits.	**Shrink sleeves:** - Heat and chemical resistance; - Insulation - Dielectric properties - Thermal resistance - Fire resistance - Mechanical protection - Chemical resistance **Sleeves:** - Excellent mechanical strength and toughness, stiffness, - high dielectric strength, - abrasion resistance, - creep resistance, - high purity, - chemical inertness, - low flammability & low moisture absorption.	Sleeves in electrical wiring provide insulation and protection for individual wires in electrical joints. Electrical and electronic systems are everywhere in modern A&D equipment, with many thousands of electrical joints per product system. Sleeves may also be used around oil or fuel pipes wherever there is a risk of rubbing and abrasion to protect against leaks or fire.
Sealants, adhesives and tapes	Adhesives and sealants stick to surfaces and may be used for a range of purposes including prevention of fluid	**Sealants**: PFAS contribute to the high temperature stability and fuel resistance (high chemical stability) of fluorocarbon sealants. **Adhesives**: High Strength, Chemical, thermal, water, and electrical resistance (insulating and dielectric properties), low coefficient of friction, chemically inert, high wearability and adhesion strength, cohesion (drip-resistant)	These products may be used in complex assemblies at joints or mating surfaces where there is a risk of air or fluid leaks and where disassembly is not needed, including in electronic assemblies, fuselage structures and wing structures.

Common fluoropolymer components	Description	Driver for why it is made from a fluoropolymer	Examples of fluoropolymer parts integrated to components/systems
	leakage between parts and mating surfaces. Tapes comprise a surface material together with an adhesive to provide a protective surface.	**Tapes**: protect parts from dust and aggressive chemicals (e.g., lubricants, fuels, electrolytes) thus ensuring functionality and reducing service intervals; prevent leakage, resistant against heat, pressure and corrosive chemicals and also have a low friction coefficient For A&D products, fluoropolymers are crucial in ensuring that high-performance sealants, mastics and resins, and gaskets and moulded products: - Provide reliable sealing over the long lifetime of A&D products (can be 40+ years) operating in hostile environments. - Seal pressurised cockpits and cabins in aircraft subjected to rapid changes in pressure differentials, noting that the pressure differential is especially great at high altitude - thus maintaining a safe environment for crew and passengers. - Prevent leakage of fuels, oils, coolants from high-pressure systems subject to high stress environments/vibration, extreme temperatures and rapid temperature fluctuations. - Prevent ingress of fluids, dirt and debris to A&D products operating in hostile/extreme environments. - Withstand exposure to fuels, engine oils, hydraulic fluids and chemicals that may cause deterioration in sealing properties upon contact. For example, sealants are used to seal airframes, panels, and other structures both in civil and military aircraft. Aerospace sealants have a significant impact on airframe functionality, operational performance, and maintainability. Tapes increase aircraft surface life because they effectively protect aircraft panels from vibration, corrosion, aggressive fluids, and more.	See Table 11 and case study 3 in Annex 2.
Cables and connectors	Electrical cables together with electrical connectors which connect electronic devices with each other and to key sensors and actuators.	**Cable insulation**: Combination of safety requirements: - temperature resistance (55°C to 260°C); - chemical resistance; - Resistant to fungal attack - mechanical resistance (abrasion, cut-through); - flexibility; - excellent dielectric properties; - arc tracking resistance;	Cables provide a nervous system-like network of reliable signal transmission within all A&D products to control communications, safety, and mission critical systems, such as flight controls, radar, and survivability equipment (depending on the product). For example, a single aircraft, satellite, or vehicle will have numerous cables and cable assemblies, each with unique performance requirements based on its specific use in a complex system.

Common fluoropolymer components	Description	Driver for why it is made from a fluoropolymer	Examples of fluoropolymer parts integrated to components/systems
		- flame Retardant **Co-axial cables**: - Resistance to soldering operations; - good resistance to solvents; - low moisture absorption; - uniform electrical properties over frequency For examples, specifically for cables in civilian airliners, ca. 50 000 km of cable are mounted each year in aircrafts by one OEM. All of these cables contain PFAS. More than 95 % of this volume (up to 49 000 km) are specified by the European standards EN2267-009, EN2267-010 and EN2714-013. Those specifications require the cables to be able to operate in temperatures between -55°C and 260°C. Fluoropolymers, and especially PTFE is the only currently known material to be able to operate efficiently cable insulation and flexibility in those temperature ranges during the whole lifecycle of the aircraft (40 years and up). Cables also need to be resistant to external contamination in case of failure of another system (fuel for example). Failure in the electrical system could lead to severe consequences and those requirements are thus essential to be met for safety and certification of the Aircraft.	 As a specific example, aircraft signal, power wires and cables systems are used all over the aircraft. The schematic shows the complex and wide electrical structure of the aircraft (engines are excluded in the schematic). Electrical system include communications, flight controls, engine controls, land controls, radars, weapon systems, power supplies, entertainment systems, lighting, flight recording systems (“black box”), telemetry and sensing systems, actuators. See Table 11 and case study 1 in Annex 2.

Table 4. Common polymeric PFAS containing mixtures used in the production, operation and MRO of A&D products, the drivers for the use and examples

Common fluoropolymer containing mixtures	description	Driver for why fluoropolymers are included	Examples of A&D uses
Lubricants	Materials and liquids which reduce friction between rubbing surfaces	Temperature resilience; chemical inertness; very low friction coefficient; resistance to harsh environment; Low outgassing; Lubricant operating with oxygen - Inert to oxygen; Key functions relate to the lubricant as a whole, not just to the PFAS component and include temperature stability and lifetime. It must retain its coefficient of friction over the full temperature range. Many components use these products to ensure that safety critical features are maintained. In A&D products, lubricants are used in production, operation and MRO to prevent sticking of surfaces in all use conditions. Aerospace applications have some of the most demanding requirements when it comes to lubrication. Compared to automotive applications, for example, the temperature ranges where a single lubricant must perform are considerably broader. Military aerospace applications can involve even greater extremes, in addition to other requirements, such as long storage life. Component failures in aerospace applications can be catastrophic, not only in terms of the capital costs of the parts themselves, but also because of the ancillary costs of repair and safety risks they engender.	Aircraft gas turbines (jet engines), including actuators Aircraft flight control systems Aircraft landing gear Maritime gas turbines Combustion engines Bearings – plain, roller, sliding Valves, actuators, regulators Gears, gearboxes Chains Friction reduction in various mechanical devices Door / hatch / window opening mechanisms Fasteners – screws, bolts, nuts, etc. See Table 11 and case study 10 in Annex 2.
Coatings	A coating that modifies the surface to give specific properties e.g. non-stick, corrosion resistance, abrasion resistance	Surface modification to prevent foreign particles sticking to the surface in all conditions of use For example, the requirements for coatings used in military aircraft systems, specifically in protecting aircraft parts, radomes and leading edges from abrasion and rain erosion during flight, are highly demanding. Operating in mission environments characterized by supersonic speeds, high altitudes, rain, UV-radiation and friction-induced high temperatures, military aircraft face significant challenges. Sprayable coatings are essential for providing effective protection against rain erosion and abrasion, aerodynamic heating, thermal flash exposure, and weathering. PFAS, particularly in the form of FKM (fluoroelastomers) and PTFE (polytetrafluoroethylene), play a critical role in meeting the functional requirements of these coatings. They possess unique properties such as heat resistance exceeding 200°C, wear resistance, lubricating properties, elasticity for shock absorption, and excellent aircraft fluid resistance, making them indispensable for military aircraft applications.	 naval carrier with a radome Weather-resistant structures, marine systems subject to salt water attack, hydraulic pumps and actuators. See Table 11. 1 and case studies 11 and 19 in Annex 2

		In defence products, for example the surface protection system used in rail launchers is essential to their performance and longevity. The current state-of-the-art solution involves hard anodizing-based protection with a PTFE sealing to reduce wear. This combination provides a range of exceptional properties that are critical to meeting the demanding requirements of rail launcher applications.	
Release films	Release films allow for the removal from the composite part of other process materials such as breather fabric and flow media.	ETFE, PTFE, and FEP-based mold release films play a vital role in aircraft and aerospace craft manufacture, offering the cleanest, most consistent release performance possible. The molding of composite structures is essential in improving the ratio of strength-to-weight and resistance to corrosion and fatigue. For example PTFE coated fibreglass fabric is used in various composite manufacturing processes. It is applied directly to the mold and product allowing for an easy and clean release after the curing process of aircraft composite.	 Photo of aircraft composite part with release film Composite parts are superior to traditional metals, including aluminum, due to higher strength, lower weight, and excellent resistance to flex fatigue and exposure to environmental extremes such as heat, cold, humidity, and pressurization. Release films are used in the manufacture of aircraft composited components like helicopter rotor blades, satcom and weather radomes, structural components like tail sectors, wire harness protective insulation.
Pyrotechnic mixtures	Pyrotechnics play a crucial role in defence by providing various effects, including illumination, signalling, and smoke generation	Fluoropolymers are used in pyrotechnic flares as their complex chemistry provides spectral output which can mimic the heat signatures of the aircraft jet exhaust.	Pyrotechnic flares used as anti-missile countermeasures for aircraft are essential to mission capability, and PFAS polymers help produce the required spectral output to decoy missiles away from the aircraft. The fluoride ions from the PFAS increase the brightness of the signal, to reach the specific illuminating effect.
Energetic materials	An energetic material, often referred to as an explosive	Certain fluoropolymers are included in energetic compositions because they provide functionality to the materials. A number of explosive compositions include	Polymer-bonded explosives in military weapons and munitions (see case study 20 in Annex 2)

	material, is a substance that contains a large amount of stored energy that can be released rapidly in the form of an explosion. These materials are designed to release this energy when subjected to certain stimuli such as heat, shock, friction, or electrical impulses. Energetic materials are used in various applications, including military and industrial uses, mining and propulsion systems.	fluoropolymers which act as a binder for pressed pellets,-the high-density coating enables an effective energy transfer within the explosive material. The chemical stability of the binder also ensures dimensional stability and performance of the explosive composition over time.	

Table 5. Uses of non-polymeric PFAS in A&D products, the drivers for the use and examples

Non-polymeric PFAS uses	Description	Driver for PFAS use	Examples of A&D uses
Hydraulic fluids	Incompressible liquids which transfer force through hoses to actuators driving flight surfaces or other mechanisms, operating at high pressure.	- Anti-corrosion; - temperature resilience; - chemical stability; An example case study for aviation related hydraulic systems is given in the appendix and summarised in Table 11. Aviation hydraulic systems are used to control many parts of an aircraft. This includes the aircraft brakes and landing gear, the movement of flight control surfaces, pitch and yaw to move the aircraft up, down, left, and right, and parts of the wings for controlling lift and speed. All these systems are operated and lubricated by a common oil, which is a fire-resistant phosphate-ester based hydraulic fluid (PEBHF). PEBHFs are hydraulic system lubricants based on the esters of phosphoric acid. They have been the exclusive hydraulic fluid used for commercial aircraft for many decades because of their unique combination of fire resistance and low-temperature performance. The fire resistance properties are required to provide aircraft and passenger safety. The low-temperature performance properties are needed to ensure trouble-free operation of aircraft hydraulic systems, such as steering, under cold atmospheric conditions. Because of their chemical and electrical properties, phosphate ester fluids in high-pressure hydraulic systems without the use of a corrosion inhibitor additive can lead to rapid electrochemical erosion and ultimately failure of precision hydraulic system components, disrupting aircraft control. To prevent these failure modes, corrosion inhibitors for PEBHFs must increase the electrical conductivity of the phosphate ester fluid by dissociating into ionic charge carriers. The use of fluorinated compounds decreases the association energy of the ions and permits this to happen. Critically, the erosion inhibitor must be stable under harsh service conditions. Non-fluorinated erosion inhibitors were attempted many decades ago, and all	Aircraft flight control systems, actuators for flying surfaces Aircraft landing gear Actuators in defence systems. These include, but are not limited to steering mechanisms, munitions loading systems, turrets.  See case Table 11 and case study 7 in Annex 2

Non-polymeric PFAS uses	Description	Driver for PFAS use	Examples of A&D uses
		showed poor performance even in older, less severe system designs. Over 200 alternatives to PFAS have been tested in PEBHFs over 3 decades, and all have had challenges in one or more areas. To date, no potential replacement has been identified.	
Fire suppression clean agent	A clean agent is a gaseous fire suppressant that is electrically non-conducting and that does not leave a residue upon evaporation. This is ideal when protecting high value items like historical artifacts or sensitive electronic equipment. The umbrella term "clean agents" includes both halocarbon agents and inert gas agents.[12]	Fire suppression without residues (which can damage equipment in ways that can compromise safety); Chemical stability; Fire suppression at low concentration - Safe to breathe in - replacement for halon Fire extinguishers in aircraft are given as an example. Aircraft fire extinguisher systems are currently composed of build-in systems protecting four areas: - propulsion system (engines) - auxiliary power unit (APU – small gas turbine and aimed at providing energy for function other than propulsion) - cargo - cabin lavatories, plus, cabin & cockpit areas that are fitted with portable fire extinguishers The fire suppression agents have been HFCs regulated under Ozone Regulation and Montreal Protocol and substitution efforts to phase out banned HFCs has been ongoing for decades. However all substitutes are PFAS chemicals as the only alternatives that fulfil the level of safety required for airworthiness.	 Cockpit fire extinguisher Fire extinguishers are used in aircraft cockpit/passenger areas, cargo holds, and around engines and auxiliary power units. They are also used in Submarine / ship use due to confined spaces? See case Table 11 and case study 5 in Annex 2.
Refrigerant agent	Heat transfer fluids, or refrigerants, are used in refrigerant systems to absorb heat in the evaporator, release heat in the condenser, and facilitate the heat exchange process between various components. They undergo phase changes from gas to liquid and vice	- chemically inert; - non-flammable; - high dielectric strength and electrical resistivity; - evaporate without leaving residues;	

[12] https://www.gaseousfireextinguishers.com/

Non-polymeric PFAS uses	Description	Driver for PFAS use	Examples of A&D uses
	versa, allowing for efficient heat transfer and enabling the cooling or heating effect desired in the system	- broad operating temperature range; As a specific example of an A&D use, use in aircraft cooling systems is included as an illustrative case study (Table 11) HFC refrigerants are used in equipment specifically designed for use on aircraft installations and have an operation envelope to meet high safety and reliability standards. A basic principle of aircraft systems design is to avoid by design any event that could impose a risk to the safe operation of the aircraft. HFC refrigerant R-134a, which is used on aircraft, is non-toxic, non-flammable and thus intrinsically safe. Airworthiness certification of equipment is based on non-flammability classification of the refrigerant.	Galley Cooling - Air Chiller  Supplemental Cooling -Vapor Cycle Refrigeration Unit See case Table 11 and case study 4 in Annex 2.

Examples of key functionalities for specific A&D uses are given in Table 6, Table 7 and Table 8 together with information on the availability of alternatives. The details are taken from case studies given in Appendix 1 and from information available from suppliers (see summaries in Table 11). Due to their unique combination of properties that make them ideally suited to uses in harsh environments with high reliability requirements, there are generally no suitable alternatives available for fluoropolymer uses. Prior to this restriction proposal, there was no concern relating to the use of fluoropolymers in A&D and no driver to develop substitutes apart from their high costs. For non-polymer PFAS uses in fire suppression systems and refrigerants, PFAS chemicals substitute earlier HFC gases that are regulated under the Montreal Protocol and Ozone Regulation. However due to the qualification and certification requirements and the long service life of A&D products, substitution is still ongoing.

Details of what substitution would involve in practice in terms of identification of alternatives, qualification and certification are given in the next section.

2.3.3 Companies/parties in the sector impacted by the proposed restriction (ECHA Q6c)

A&D supply chains are complex and multi-tiered. The proposed restriction impacts hundreds of thousands of parts and components at all tiers of the supply chain, since if a qualified part is not available, it has a knock-on effect for each subsequent tier upstream. The non-availability of qualified parts would impact production of new products and maintenance of existing products in the EEA. It would also impact A&D customers from commercial airlines to Ministries of Defence in terms of the operability of A&D products in the EEA and their maintenance in terms of availability of spare parts and legacy spare parts. It would impact 3rd party MRO service providers who would not be able to source components containing PFAS in the EU. It would impact air transport (passengers, cargo) and the operational readiness of EEA defence forces as products and spare parts would not be available in the EEA and would also not be able to be sourced from outside the EEA.

Table 6. General key functionalities of polymeric PFAS and examples for specific uses

Polymeric PFAS	General	Seal in a gas turbine engine	Cable insulation in A&D products	Valves & seals in the manufacture of explosives	Printed circuit boards and assemblies integrated into electronic systems	Coating for the radome housing communication and weather antenna
Key functionalities	Durable, stable and mechanically strong in harsh conditions in a variety of sectors including but not limited to automotive, aerospace, environmental controls, energy production and storage, and electronics, stable in air, water, sunlight, chemicals and microbes; Chemically inert, Non-wetting, non-stick, and highly resistant to temperature, fire and weather	Provide thermal stability and resistance to vibration and to chemicals that may cause deterioration in sealing properties upon contact. e.g., PTFE lip seal Tight sealing, even under high pressure in excess of 35 Bar; Ability to run at temperatures far above or below elastomer rubber lip seals (with typical temperature ranges from -53 °C to 232 °C); Elastomer coatings on the seal's outer diameter make for easy installation without damaging mating hardware; Available in custom designs and a wide range of sizes and materials; Inert to most chemicals; Withstands high speed between moving surfaces in excess of 35 metres per second;	High performance over the long lifetime of A&D products (can be 40+ years), particularly where reliable, high-volume data transmission in harsh environments is essential; Low dielectric constant confers excellent electrical insulation; Flexible, resistant to cracking/degradation when subjected to high stress environments/ vibration; Allows wires in wiring harnesses to slide against each other and against harness fasteners, thus reducing stress/chafing when exposed to vibration or during maintenance; Resistant to high temperature environments and rapid temperature fluctuations; flame retardant; UV resistant.	Be chemically inert having a high strength whilst retaining elasticity, and with a relatively long life when exposed to chemicals	Low dielectric constant confers excellent electrical insulation; Heat resistance; Chemical resistance; Non-stick and low frictional properties; Resistant to water, oil and chemicals; See case study 18 in Annex 2.	Transparency to radio waves at relevant wavelengths; Weather resistance: Electrical insulation; Mechanical strength and durability; Chemical resistance. Specific example: Active Phased Array Radar in Naval applications operate in harsh and challenging environmental conditions. To protect the array, a radome is required that protects the radar system and withstands all environmental loads while also being transparent for X-band microwaves. The short wavelengths of X-band are needed for high resolution imaging for target identification. These short wavelengths require specific radome materials. See case study 19 in Annex 2.

Polymeric PFAS	General	Seal in a gas turbine engine	Cable insulation in A&D products	Valves & seals in the manufacture of explosives	Printed circuit boards and assemblies integrated into electronic systems	Coating for the radome housing communication and weather antenna
		Low friction and ability to address rotating equipment and vibration for longer life; Compatible with most lubricants and able to run in dry or abrasive media.	Resistant to water, oil and chemicals;			The only material that combines these conflicting properties is a fibre reinforced fabric with PTFE.
Availability of alternatives	There are no general alternative for fluoropolymers that have a comparable range of key functionalities. Note it is uncertain if alternatives can ultimately be innovated that would not be equally "persistent" as durability and inertness are technical performance requirements for operation in harsh/extreme conditions of use to ensure safety and reliability of A&D products.	There are no alternatives that fulfil the performance requirements. See Table 11. and case study 3 in Annex 2. The requirements for the A&D sector were not considered by the dossier submitters in the assessment of alternatives (Table E.113 in Annex E) under the "transport" use.	Currently no alternatives are available or known to be able to operate under the harsh conditions and over such a long lifecycle. See case Table 11. and case study 1 in Annex 2 This use (Annex A) and the availability of alternatives (Annex E) was not considered by the dossier submitters in their assessment.	Currently there are no viable alternatives to the fluoropolymer-based valves and seals used on equipment used in the manufacture and processing of explosives which provides the resilience and relative inertness to corrosive high temperature chemicals, and enables a high level of safety for processing of explosives and in the manufactured ammunition. See case Table 11 and case study 11 in Annex 2 This use and the availability of alternatives was not considered by the dossier submitters in their assessment (Annex A and Annex E).	There are no alternatives available that have the range of properties required for applications with high performance requirements in terms of safety and reliability. The requirements for the A&D sector were not considered by the dossier submitter in the assessment of alternatives (Table E.218 in Annex E)	No alternatives available with the range of properties needed. For the specific example of naval carriers, due to the environment and reliability requirements, materials in naval radar construction have to undergo and pass extensive qualification and testing. No alternative to PTFE coated fiber reinforced fabric is available to date for X-band radome material with required phased array radar performance which meets Naval environmental requirements. This use (Annex A) and the availability of alternatives (Annex E) was not considered by the dossier

Polymeric PFAS	General	Seal in a gas turbine engine	Cable insulation in A&D products	Valves & seals in the manufacture of explosives	Printed circuit boards and assemblies integrated into electronic systems	Coating for the radome housing communication and weather antenna
						submitters in their assessment.

Table 7. General key functionalities of non-polymeric PFAS uses in fire suppression and refrigerants with examples for specific uses

PFAS-gases	General	Aircraft fire suppression systems in 4 areas (engines, auxiliary power unit, cargo, cabin lavatories plus cabin & cockpit areas that are fitted with portable fire extinguishers)	Refrigerant HFC R-134a in aircraft installations	Heat Transfer Fluid Galden® HT in supplemental cooling system aircraft
Key functionalities	Chemically inert over a broad range; non-flammable; evaporates without leaving residues; Broad operating temperature range; Safe for humans to breathe at the concentrations used; Dielectric properties	Fire suppression without residues (which can damage equipment in ways that can compromise safety); Chemical stability; Fire suppression at low concentration - Safe to breathe in - replacement for halon Certified for use on aircraft according to airworthiness regulations See case study 5 in Annex 2	HFC refrigerant R-134a, which is used on aircraft, is non-toxic, non-flammable and thus intrinsically safe. Airworthiness certification of equipment is based on non-flammability classification of the refrigerant. Certified for use on aircraft according to airworthiness regulations See case study 4 in Annex 2	Galden® HT is used as heat transfer fluid in order to remove heat from the galleys and avionics. The physical properties of Galden® HT, being non-flammable, non-conductive and non-toxic in this application, make it intrinsically safe for use on aircraft applications. Certified for use on aircraft according to airworthiness regulations See case study 4 in Annex 2.
Availability of alternatives	Substitution for HFCs covered by the F-gas regulation has been ongoing for more than 20 years – however many of the substitutes are PFAS	PFAS are alternatives for Halon 1301. Halon 1301 (Bromotrifluoromethane) is the most effective fire extinguishing agent, but because of its high ozone depleting potential, the production of Halon 1301 was banned in 1994 as part of the Montreal Protocol. Most Halon 1301 alternatives (HFC-125 (Pentafluoroethane), 2-BTP (bromotrifluoropropene), NOVEC 1230 (Perfluoro(2-methyl-3-pentanone), CF3i	Alternatives for R-134a are available in the market for stationary and domestic applications as well as for vehicles and ground transport. These alternatives are either HFC (e.g. R-1234yf), natural (flammable) fluids like propane, isobutane, or Carbon Dioxide (CO_2). These are not currently suitable for aerospace / aircraft applications. Replacing the current refrigerant is extremely difficult in the short and mid-term refrigerant	Alternatives for use on aircraft are available. In fact, Galden® HT is not used anymore, in new aircraft types. For example in the A350 system a water-based Propylene-Water Glycol mixture is used, mainly due to weight reasons. However, additional design precautions are needed mainly due to the electrical conductivity, which could result in a risk in the case of leakages.

PFAS-gases	General	Aircraft fire suppression systems in 4 areas (engines, auxiliary power unit, cargo, cabin lavatories plus cabin & cockpit areas that are fitted with portable fire extinguishers)	Refrigerant HFC R-134a in aircraft installations	Heat Transfer Fluid Galden® HT in supplemental cooling system aircraft
		(Trifluoroiodomethane)) and all Halon1211 (Bromochlorodifluoromethane) alternatives (2-BTP and HFC-236 (Hexafluoropropane)) are PFAS. Assuming a non-PFAS Halon alternative is selected, a minimum of 15-20 years would be required for a complete transition. See Table 11. and case study 5 in Annex 2 The alternatives listed in Appendix E.2 to Annex E are not suitable for these uses.	on certified aircraft as no suitable refrigerants are on the market that have the same behaviour in terms of physical properties, e.g., are neither toxic nor flammable. It is technically possible to design, develop and build new equipment using natural refrigerants like propane and isobutane. However, the OEM needs to demonstrate the same safety level as today considering the flammability classification of the equipment. It may be possible that additional design precautions or means need to be installed on aircraft to enable safe operation of the equipment. This includes ventilation of installation areas, protection of electrical equipment, or relocation of the equipment. See Table 11 and case study 4 in Annex 2. The alternatives listed in Appendix E.2 to Annex E are not suitable for these uses.	Replacing Galden® HT on in-service aircraft is not possible, since extensive changes are needed on the equipment. If it can not be used, in-service aircraft will be grounded. See Table 11 and case study 4 in Annex 2 The alternatives listed in Appendix E.2 to Annex E od the restriction report are not suitable for these uses.

Table 8. General key functionalities of other non-polymeric PFAS and examples for specific uses

	Component of hydraulic fluid in aircraft hydraulic systems
Key functionalities	Corrosion inhibition in all conditions of use; fire resistant Aviation hydraulic systems are used to control many parts of an aircraft. This includes the aircraft brakes and landing gear, the movement of flight control surfaces, pitch and yaw to move the aircraft up, down, left, and right, and parts of the wings for controlling lift and speed. All these systems are operated and lubricated by a common oil, which is a fire-resistant phosphate-ester based hydraulic fluid (PEBHF). PEBHFs are hydraulic system lubricants based on the esters of phosphoric acid. They have been the exclusive hydraulic fluid used for commercial aircraft for many decades because of their unique combination of fire resistance and low-temperature performance. The fire resistance properties are required to provide aircraft and passenger safety. The low-temperature performance properties are needed to ensure trouble-free operation of aircraft hydraulic systems, such as steering, under cold atmospheric conditions.
Availability of alternatives	Over 200 alternatives to PFAS have been tested in PEBHFs over 3 decades, and all have had challenges in one or more areas. To date, no potential replacement chemistry has been identified with adequate stability to survive in phosphate esters in aircraft service. See Table 11 and case study 7 in Annex 2 Table E.133 in Annex E states that there are no non-PFAS alternatives available and that more than 10 years are needed for substitution. However, the assessment did not consider the specificities of the A&D sector.

2.3.4 Availability of suitable alternatives to PFAS chemicals in the A&D sector (ECHA Q6d)

PFAS chemicals are integral to the production, operation and MRO of A&D products due to their high performance in harsh/extreme operating conditions that underpin the safety and reliability of A&D products. Their high performance stems from their unique combination of properties and there are generally no suitable alternatives available that fulfil the performance requirements. Due to the formal quality management systems in place to ensure product safety, alternatives that fulfil the performance requirements would need to be identified and then taken through the strict qualification and approval processes before taking them into use. Scheduled maintenance and repair also requires the availability of spare parts that are produced as per the approved product over its entire service life. This can be decades depending on the product (e.g. 40+ for an aircraft, 40+ for a naval vessel). Any changes in the production of the spare parts also need to follow a requalification and recertification process before they can be taken into use. A redesign is likely to be needed meaning it is very lengthy as it would involve retrofitting all in-service products.

One of the key challenges with this proposed restriction is the scale of the substitution requirement it would trigger. As can be seen from the Tables above, fluoropolymers in particular are ubiquitous in A&D products. Substitution efforts would need to be balanced against all other ongoing R&D activities and substance replacement workstreams. It would also impact ongoing activities like the transition from internal combustion engines to hydrogen, as fluoropolymers are integral to the hydrogen transition (see contribution from Hydrogen Europe[13]) and MEA (more electric aircraft). Additionally fluoropolymers are necessary for the transition to sustainable aviation fuel, which would also be impacted.

The dossier submitters included an analysis of alternatives for the application areas and sub-uses they considered in their assessment. Defence and security was not included in their assessment and defence use are not generally covered in Annex A or Annex E of the dossier or if they are covered (e.g. lubricants), the specificities of defence products were not considered in the availability of alternatives or the time

[13] https://hydrogeneurope.eu/wp-content/uploads/2023/02/Hydrogen-Europe-position-paper-on-PFAS-ban_v12_FINAL.pdf

needed for substitution. For other A&D products, a limited number of uses could be under the scope of "transport". However, the dossier submitters concluded for uses under "transport " in Table E.121 in Annex E

> […] *that a 12 year derogation could be appropriate for PFAS use in transport (including automotive, aircraft, rail, marine, and aerospace industries) where the substances are affecting the proper functioning related to the safety of transport vehicles, and affecting the safety of operators, pasengers or goods. Shorter transition periods would not reflect the current state of the industry with respect to PFAS use, with many uses having no satisfactory identified alternatives at the present time.*
>
> *In light of the broad use scope and the weak evidence base to narrow down the scope for a derogation, such a derogation is not proposed at this point but marked for reconsideration. A derogation might be proposed at a later stage if additional information on (e.g.) the rationale for continued PFAS use in specific applications and the quantities of PFAS used in those applications is provided*. […]

We highlight that the dossier submitters did not consider the specificities of our sector where there are no alternatives that fulfil the performance requirements needed for safety and reliability of A&D products. 12 years is not adequate to develop new materials and subsequently phase out all the uses of fluoropolymers in A&D products. Noting that it is not currently foreseen that alternatives, that are not also considered persistent, may ever be found for fluoropolymer applications, since reliability/durability is a primary reason they are used in A&D applications.

Taking lubricants and hydraulic fluids that are ubiquitous in A&D products as illustrative examples, reformulation requires identification of alternatives that fulfil the performance requirements for **each use**. The testing of each lubricant and fluid, followed by qualification and certification for use across each application in all A&D products may take from 3 to 10+ years per formulation, depending on complexity, **after** a reformulated alternative has been developed by formulators. It is important to note that if reformulated lubricants and hydraulic fluids do not meet performance specifications and pass qualification testing, they cannot be used. In ASD's earlier submission in the call for evidence in 2021, an ASD member highlighted the risk of incompatibility between lubricants. Two incompatible greases were used in the same aircraft system and as a consequence, the mixed greases solidified and the system seized. This highlights the criticality of ensuring that even changes that may seem 'minor' at the formulation level, are adequately tested and qualified prior to being allowed to be used for A&D products.

Taking an example of ongoing substitution efforts, the A&D sector has been working for more than 30 years to replace hexavalent chromium compounds. The challenges faced with alternatives development for this sector was summarised by the Global Chromates Consortium for Aerospace (GCCA)[14] as follows (related to their application for authorisation to continue use of these chemicals after the given sunset dates):

> *"Aerospace and defence products operate and carry people in extreme environments over extended timeframes, while having to fulfil extremely challenging technical, reliability, and safety requirements. To ensure the safety and reliability of aerospace products, comprehensive*

[14] "Aerospace & Defence Qualification Process Impacts on Ability to Substitute Cr(VI) Substances" from Global Chromates Consortium for Aerospace (GCCA) available at https://www.ramboll.com/-/media/files/reh/GCCAAerospaceDefenceQualificationProcessImpactsonAbilitytoSubstituteCrVISubstanceswhitepaper

airworthiness regulations have been in place globally for decades. These regulations require a systematic and rigorous framework to be in place to qualify all materials and processes to meet stringent safety requirements that are subject to independent certification and approval through EASA and other agencies requirements. Air, ground and sea-based defence systems, and also space systems, are subject to similar rigorous qualification requirements. Changes to Aerospace and Defence hardware offer unique challenges that are not seen in other industries."

The illustration given in Figure 3 (adapted from the GCCA paper[14] in the ADCR authorisation applications[4]) provides a simplified overview of alternatives development steps and typical timelines. Note that as PFAS chemicals, in particular fluoropolymers, are ubiquitous in A&D products, **the substitution challenge is far more complex as substitution impacts multiple chemicals, multiple parts integrated into multiple components that are in turn integrated into the sub-systems and systems that make up the products**. An illustration of the testing requirements going from components to subsystems to systems from the ADCR authorisation application reports[4] is given in Figure 4.

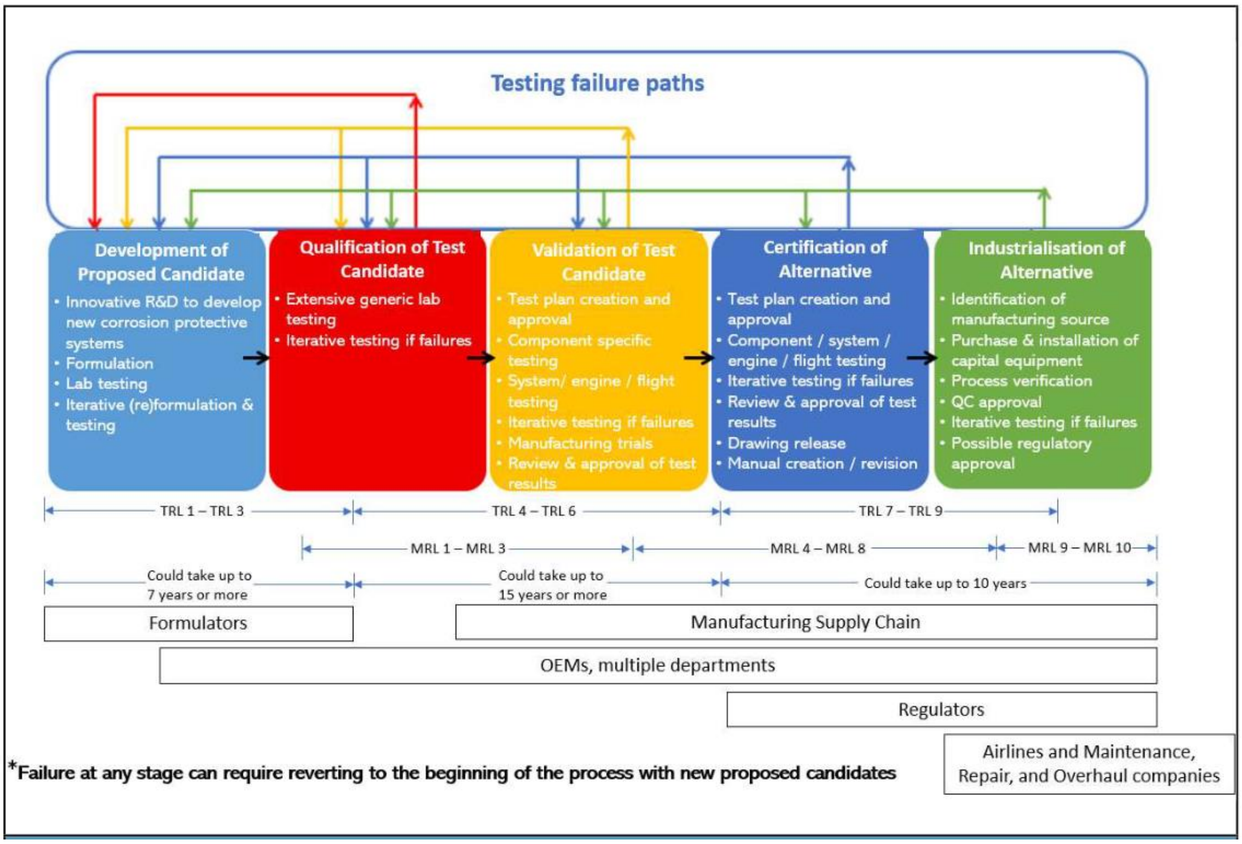

Figure 3. Schematic showing the key phases of the substitution process; Typical TRLs and MRLs associated with each stage, and the entities involved in each stage, are also shown. Note that failure of a proposed candidate at any stage can result in a return to a preceding stage including TRL 1. Note that failures may not become apparent until a late stage in the process. – adapted from the GCCA paper on Aerospace & Defence Qualification Process Impacts on Ability to Substitute Cr(VI) Substances & Joint Analysis of Alternatives and Socio-Economic Analysis, Authorisation application 0203-0242 (reproduced from ADCR authorisation application[4])

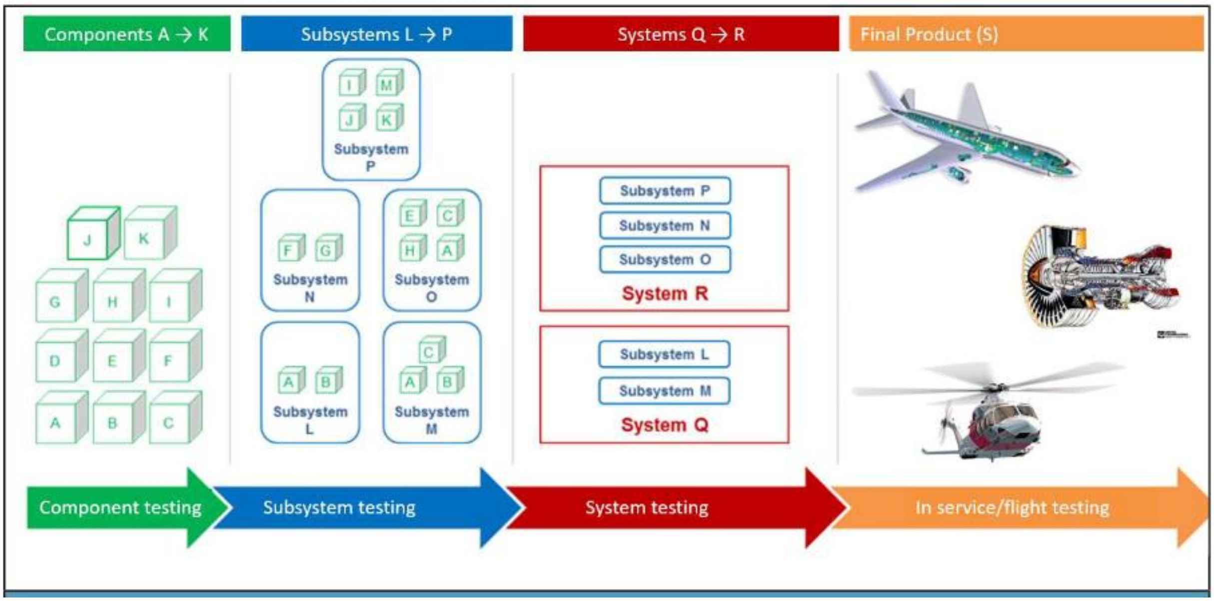

Figure 4. Assessment requirements in the implementation of alternatives (reproduced from the ADCR authorisation application[4] and based on the GCCA paper on "Aerospace & Defence Qualification Process Impacts on Ability to Substitute Cr(VI) Substances"[14]

When looking to qualify new alternatives to replace undesirable substances used in formulations and materials e.g., adhesives, sealants, resins, lubricants etc., A&D companies must ensure that the functional requirements performed by the formulation are met. The focus when determining the necessary requirements for alternatives is not typically driven by the function of any individual constituent substance per se, but on the function of the formulation as a whole in which those substances are being used (for the case where PFAS is a component of a formulation).

Thus, when providing information on the technical functions that are necessary for any alternative, information that may be provided from A&D companies is often focused on the required functions for a replacement formulation rather than a replacement substance. Furthermore, this will vary according to the different OEMs, products and parts where a replacement needs to be used, even for the same formulations. A schematic illustration of the path to successful reformulation of a formulation certified for use in commercial aircraft from the ADCR 2023 authorisation application[4] for A&D uses of CrVI compounds is given in Figure 5.

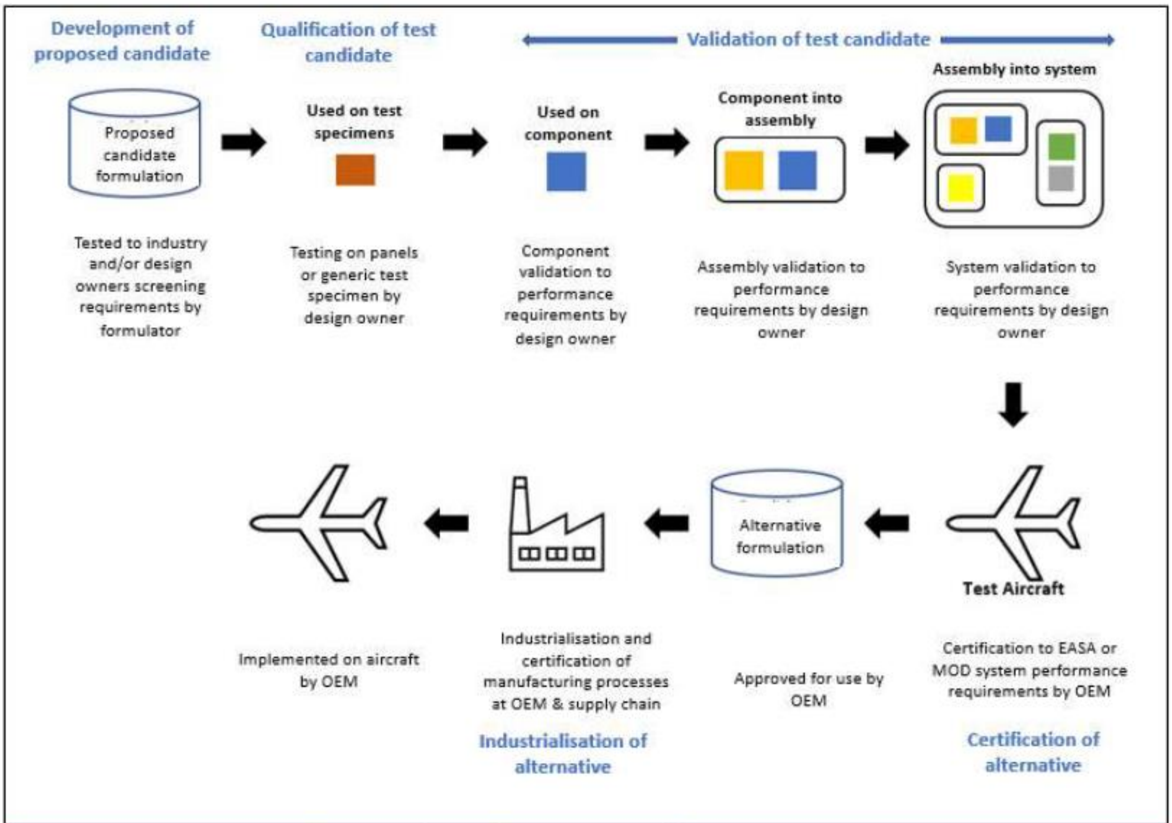

Figure 3-4: Process to Certify a Formulation for use on Aircraft
Formulations used in production have completed this process. New or reformulations must follow same process for use in production.
Source: ADCR member

Figure 5. Overview from the ADCR authorisation application[4] illustrating the complexity of reformulation must consider the overall functioning of the formulation and not solely the component substituted.

Note that with alternatives development and qualification, success is not guaranteed. If alternatives fail any part of the testing criteria, the process restarts, substitution timelines will exceed any originally anticipated timeline. Resource constraints can prevent testing/trialling multiple alternatives simultaneously (since whilst the cost/resource is less for performing multiple trials than if done separately, it is still higher than if one trial is done and it works)

An additional aspect specific to the A&D sector is the long lifetime of the products. This means that spare parts made according to the approvals in place at the time an A&D product was certified must be used in MRO, unless a replacement is qualified and certified under an exhaustive and robust process. This means that spare parts must be available for decades and also legacy spare parts must be available to support operation after the aircraft ends production. This also means storage facilities for such spares must be in place (and of adequate environmental/ cleanliness standards and maintain suitable QC standards). Non-availability of a sufficient number of spare parts means that the aircraft is grounded. The ADCR consortium authorisation applications for continued use of CrVI for various surface treatments illustrate the impact of the non-availability of parts on the ability to produce an aircraft[4] (see Figure 6).

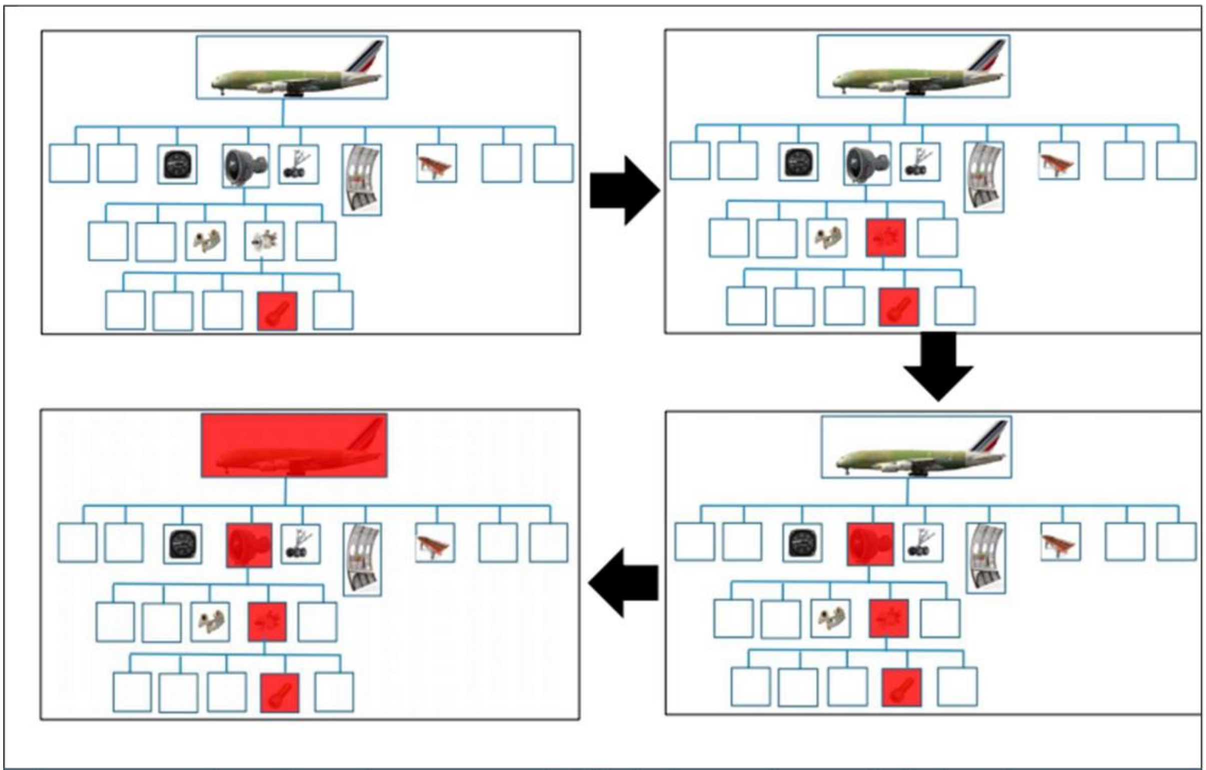

Figure 5–1: Interdependency of component availability in the manufacture of a final product

Figure 6. Schematic from an ADCR authorisation submission (March 2023) illustrating the interdependency of component availability in the manufacture of the final A&D product (in this case, a commercial airliner[4]

2.3.4.1 Frameworks to understand the "readiness" of an alternative for commercial deployment and market acceptance

To ensure a common understanding of the path to commercial deployment of a new technology, ASD share details on the frameworks that are used to describe the stages and milestones involved. Evidence of successful lab scale results does not imply ultimate successful field testing or commercial deployment. Commercial deployment in turn does not imply market acceptance.

Technology readiness levels (TRLs 1-9) give a framework to describe the stages from "proof of concept" to successful industrial deployment. These were developed by NASA for the space program in the 1970's and are now integrated into EU funding programs since the 2014 Horizon 2020 program[15]. **Manufacturing Readiness Levels**[16] (MRLs 1-10) are also widely used with assessments of innovation readiness and are designed to assess the maturity of a given technology, system, subsystem, or component from a manufacturing perspective. They were developed by the US Department of Defence (DoD) to assist decision-makers (at all levels) with a common understanding of the relative maturity (and attendant risks) associated with manufacturing technologies, products, and processes being considered to meet DoD requirements. Manufacturing readiness and technology readiness go hand-in-hand. In conjunction with TRLs, MRLs are key measures that define risk when technology or process is matured and transitioned to commercial production.

[15]Horizon Europe NCP Portal, TRL Guidance notes available at https://horizoneuropencpportal.eu/store/trl-assessment

[16] Manufacturing Readiness Level Definitions available at https://acqnotes.com/acqnote/careerfields/manufacturing-readiness-levelmanufact

Note that this framework applies for each and every application.

Table 9.Technology Readiness Levels (source EU Commission H2020 programme)[17]

G. Technology readiness levels (TRL)

Where a topic description refers to a TRL, the following definitions apply, unless otherwise specified:

- TRL 1 – basic principles observed
- TRL 2 – technology concept formulated
- TRL 3 – experimental proof of concept
- TRL 4 – technology validated in lab
- TRL 5 – technology validated in relevant environment (industrially relevant environment in the case of key enabling technologies)
- TRL 6 – technology demonstrated in relevant environment (industrially relevant environment in the case of key enabling technologies)
- TRL 7 – system prototype demonstration in operational environment
- TRL 8 – system complete and qualified
- TRL 9 – actual system proven in operational environment (competitive manufacturing in the case of key enabling technologies; or in space)

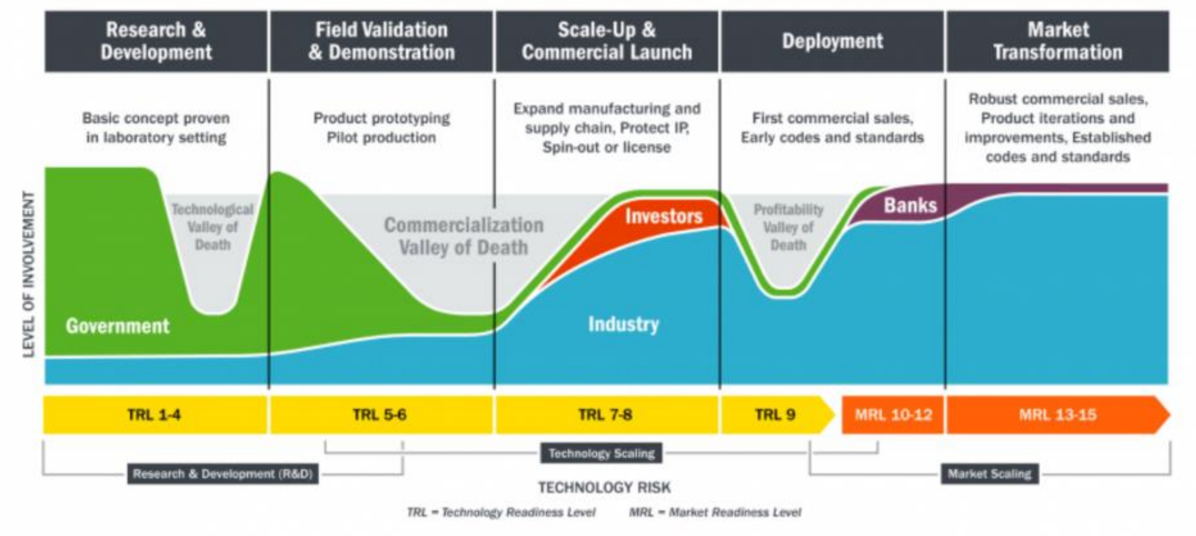
Table 10. MRL frameworks developed for the assessment of the readiness of an innovation for commercial deployment (TRL) and the readiness in terms of actual manufacturing in commercial production (reproduced from [16])

MRL	Definition
1	Manufacturing Feasibility Assessed
2	Manufacturing Concepts Defined
3	Manufacturing Concepts Developed
4	Capability to produce the technology in a laboratory environment.
5	Capability to produce prototype components in a production relevant environment.
6	Capability to produce a prototype system or subsystem in a production relevant environment.
7	Capability to produce systems, subsystems or components in a production representative environment.
8	Pilot line capability demonstrated. Ready to begin low rate production.
9	Low Rate Production demonstrated. Capability in place to begin Full Rate Production.
10	Full Rate Production demonstrated and lean production practices in place.

More recently, "**Market Readiness Levels** (MRLs 10-15)" have also been introduced by the US DoD to take into account that market transformation is also staged. The stages and milestones that need to be achieved to move from R&D to commercial production to market acceptance are illustrated in Figure 7.

[17] Technology Readiness Levels taken from H2020 work programme available at https://ec.europa.eu/research/participants/data/ref/h2020/wp/2014_2015/annexes/h2020-wp1415-annex-g-trl_en.pdf

These frameworks illustrate that commercial deployment and market transformation is staged.



Tech-to Market Process: Technology readiness is commonly measured on a nine-point scale referred to as Technology Readiness Level (TRL). TRLs are used to consistently identify technology development stages across technology types. Market Readiness Levels (MRLs) refer to the readiness of a market to accept and adopt a new technology.

Figure 7. Visualisation of the path from innovation to market that also considers "Market readiness Levels" (from https://www.energy.gov/eere/buildings/technology-market)

Examples of specific PFAS uses in A&D products are given in Annex 2 to highlight the particular challenges faced with substitution. Summaries are given in Table 11. Note the use cases are intended to be illustrative on the PFAS use, the availability of alternatives for that specific use and derogation assessment as per the proposed restriction text. They are not intended to be exhaustive.

The examples may refer to a specific product. The assessment of which derogation may be assigned to the use is specific to the product. For example, hosing in aircraft (case study 2 in Annex 2) may be covered by 6-o but this does not imply that 6-o is generally applicable to all hosing uses in all A&D products.

Table 11. Use cases illustrating where PFAS chemicals are used, the availability of alternatives and possible derogation coverage

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
1	Aircraft signal, power wires and cables	Aircraft –all operating systems for power and communication - Electrical wiring insulation given as a specific example	Fluoropolymers	Some coverage under 6-o (12 years)	Aircraft signal, power wires and cables systems are used all over the aircraft. fluoropolymers are used in a variety of different components: cables, connectors, sleeves, conduits, shrinkable elements, connector back-shells, modules, contacts, lugs, pressure seals, tying devices, tapes, optic fibre cables and more complex elements such as electromechanical devices There are no alternatives available to replace fluoropolymers for these uses. Research, development, and implementation of alternatives could take more than a decade and require several different solutions to be developed in parallel, which would put a substantial strain on resources and is not realistic. It is uncertain if alternatives can ultimately be innovated that would not be equally “persistent” as durability and inertness are technical performance requirements. The potential derogation for “transport” (6-o) (fluoropolymers and perfluorethers) would in principle cover these uses - however the time period (12 years) is inadequate as there is no alternative available meaning that new insulation materials will need to be innovated and that substitution will be lengthy. In addition, 12 years is not adequate for MRO of existing aircraft for existing aircraft that have lifetimes of 40+ years. For these reasons, ASD highlight that the derogations are not adequate either in coverage or duration.	See case studies submitted by W.L. Gore & Associates (#6286 and 6301) and Dupont[8] for more detailed information on specific products. The dossier submitter did not consider defence or security related uses and these would not be covered by 6-o.

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
2	Hydraulic, oil, air, water (waster), bleed air and fuel hose assemblies in aircraft	Aircraft hose assemblies	Fluoropolymers	Some coverage under 6-o (12 years)	Hoses in the aircraft are used to contain and convey hydraulic fluids, oils, fuel, greases, lubricants, anti-icing and de-icing agents, cleaning agents, oxygen, extinguishing agents and multiple other flight safety critical substances. Those media are either hazardous, toxic, flammable, corrosive and/or reactive. They need to be contained and conveyed in the safest way achievable whilst also meeting the high level of performance necessary to achieve improved rigorous fuel efficiency and sustainability requirements. Different materials can be used to meet the required functions, certification and safety requirements of the products. In each case, hoses are protected with a PTFE liner to protect them from the aggressive media durably during the long lifecycle of the aircraft (40+ years). PTFE fulfils the chemical compatibility, chemical inactivity/resistance requirements meanwhile its longevity makes it viable for as long as the lifespan of the aircraft. There are no alternatives available to replace fluoropolymers for these uses and it is uncertain if alternatives can ultimately be innovated that would not be equally “persistent” as durability and inertness are technical performance requirements. The potential derogation for “transport” (6-o) (fluoropolymers and perfluorethers) would in principle cover these uses - however the time period (12 years) is inadequate as there is no alternative available meaning that new hosing materials will need to be innovated and that substitution will be lengthy. In addition, 12 years is not adequate for MRO of existing aircraft for existing aircraft that have lifetimes of 40+ years. For these reasons, ASD highlight that the derogations are not adequate either in coverage or duration.	The dossier submitter did not consider defence or security related uses and these would not be covered by 6-o.
3	Sealing solutions and seals in aircraft fuel lines	Aircraft - mostly fuel systems	Fluoropolymers	Some coverage under 6-o (12 years)	Aircraft are required to operate in a wide temperature range of -56 to 80°C. For equipment the temperature may exceed 200°C (some areas higher than 220 °C), for example for engine fuel feed and recirculation lines. Seals and sealing solutions must be suitable for use under these extreme temperatures. Fuel seals and fittings must remain pliable at the lowest temperatures, to cope with flexure in the airframe from air movements and aircraft manoeuvres to avoid leaks. They also need to be chemically resistant to oxygen, ozone, fuel and oil. Due to these very specific technical requirements and extreme operating conditions, there are only two fluorinated rubbers which can offer the properties and characteristics needed to be used for aircraft seals and sealings solutions: fluorinated silicones (FMQ) and fluorinated carbon rubbers (FKM). For high-speed seals, the anti-	See case studies submitted by W.L. Gore & Associates (#6286 and 6301 and Dupont[8] for more detailed information on specific products. ASD support the position of the European sealing association – see their case study on the use of

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
					extrusion rings contain PTFE. PTFE is needed to prevent O-ring extrusion and permit the use of seals in higher pressure settings (up to 1000 psi) which is essential in the aerospace industry. In a typical aircraft nearly all fuel seals will be affected, as well as majority of the landing gear struts. There are no alternatives available to replace fluoropolymers for these uses and it is possible that alternatives, that are not also considered persistent, will ever be found for such applications where durability/reliability under harsh conditions is a requirement. The potential derogation for "transport" (6-o) (fluoropolymers and perfluorethers) would in principle cover these uses - however the time period (12 years) is inadequate as there is no alternative available meaning that new insulation materials will need to be innovated and that substitution will be lengthy. In addition, 12 years is not adequate for MRO of existing aircraft for existing aircraft that have lifetimes of 40+ years. For these reasons, ASD highlight that the derogations are not adequate either in coverage or duration.	fluoroelastomer sealing elements in gas turbine engines.[18] The dossier submitter did not consider defence or security related uses and these would not be covered by 6-o.

[18]European Sealing Association (ESA) position statement relative to the European proposal for PFAS regulation in relation with the Sealing Industry available at https://www.esaknowledgebase.com/wp-content/uploads/2022/03/ESA-Position-Statement-on-proposed-PFAS-regulation-March-2022-1.pdf

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
4	Heat transfer fluids & refrigerants	Aircraft – cooling systems	Perfluorocarbons Perfluoroethers	Some coverage under 5-i (12 years), 5-p and 5-q (5 years); Military vehicles: 5-dd (12 years)	Refrigerants and heat transfer fluids are used in equipment specifically designed for use on aircraft installations to meet high safety and reliability standards. Refrigerant HFC R-134a is used in aircraft cooling systems. Replacing the current refrigerant in the short and mid-term on certified aircraft is extremely difficult as no suitable refrigerants are on the market that have the same behaviour in terms of physical properties, e.g., are neither toxic nor flammable. Heat Transfer Fluid Galden® HT is used as heat transfer fluid in order to remove heat from the galleys and avionics. Alternatives for use on aircraft are available and Galden® HT is not used in new aircraft. Replacing Galden® HT on in-service aircraft is difficult since extensive changes are needed on the equipment. There is no alternative solution without redesigning the equipment, mainly the pumps of the system. For refrigerants and heat transfer fluids used in aircraft cooling systems, it will take at least 12 years for substitution in new aircraft. For MRO of existing aircraft, certified equipment needs to be available up to the end of product range life. Based on the derogation mapping done since the dossier was made available on the ECHA website, it is our understanding that this is not directly covered by either a proposed or potential derogation. Potential derogation 5-dd is specific to military aircraft but not civilian. The proposed derogation 5-i for refilling and maintaining existing HVACR equipment does not cover production and there is some coverage under 5-q depending on the interpretation of "transport refrigeration". ASD highlight that the derogations are not adequate either in coverage or duration. To avoid catastrophic effects on aircraft production and MRO of existing aircraft 18 months after the entry into force, ASD request a derogation for these uses with a review clause and to limit the scope to their use in new products and exclude existing products due to recertification requirements.	
5	Fire suppression – substitutes for halon in aircraft fire suppression systems	Aircraft –fire safety systems	2-BTP (C3H2BrF3) HFC-236fa ($[CF_3]_2CH_2$) Verdagent© (blend of 2-BTP	5-m (12 years)	Fire events have always been considered as one of the most severe threats for aviation, leading industry to develop fire protection systems since the early/mid 1900s. Development of the associated safety level has been supported by the airworthiness authorities that have set up minimum standard to be reached/demonstrated and mandated it through their respective certification standards. extinguishing agents, but because of	ASD supports the position of Halon Alternatives Research Corporation (HARC) (#4457)

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
			($C_3H_2BrF_3$) and CO_2)		their high ozone depleting potential, their production was banned in 1994 as part of the Montreal Protocol with limited exceptions for critical applications such as "aviation, military and police use" and subject to phase out deadlines (Annex VI to the Ozone Regulation). However, most Halon 1301 alternatives (HFC-125 (Pentafluoroethane), 2-BTP (bromotrifluoropropene), NOVEC 1230 (Perfluoro(2-methyl-3-pentanone), CF3i (Trifluoroiodomethane)) are PFAS chemicals. All Halon 1211 (Bromochlorodifluoromethane) alternatives (2BTP and HFC-236 (Hexafluoropropane)) are PFAS chemicals. These chemicals are substitutes to Halon (1301/1211) in aircraft safety devices (fire extinguishing systems) currently regulated under the Ozone Regulation. The proposed restriction therefore impacts ongoing substitution to comply with other regulations. There are no other alternatives available to Halon 1310 and 1211 for these specifics applications. The identification of these 3 chemicals as suitable alternatives to Halon took decades. The use is covered by the proposed derogation 5-m "*clean fire suppressing agents where current alternatives damage the assets to be protected or pose a risk to human health*". However, the duration period is not adequate for time needed to identify, qualify, (re)certify alternatives in the systems. There is also no review clause meaning that use must cease upon expiry of the derogation period. This would mean a cease in aircraft production and grounding of existing aircraft due to lack of certified fire systems. MRO for existing aircraft will require availability of certified systems or re-certified systems with alternatives. ASD highlight that the derogation is not adequate in duration. They ask the dossier submitters to consider the ongoing substitution efforts, the absence of suitable alternatives and the low emissions from this use. In line with the position of the Halon Alternatives Research Corporation (HARC) , ASD request the following: • reconsider the time limit and proposed a time-unlimited derogation.	
6	Hydrogen fuel cell (PEMFC)	Aeronautical energy systems	Fluoropolymers	6-e (5 years)	Hydrogen fuelled proton-exchange member fuel cells (PEMFC) provide electrical power generated via electrolysis of air and hydrogen. This technology enables both CO2-free and NOx-free operation of hydrogen fuelled aerospace aircraft/vehicles within the EEA. For	ASD support the position of Hydrogen Council [19]

[19] Position paper from the Hydrogen council on PFAS published 31.7.2023 https://hydrogencouncil.com/wp-content/uploads/2023/07/Hydrogen-Council-White-Paper-PFAS.pdf

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
					example, aircraft are expected to use hydrogen fuel cells to create electrical power that complements the modified gas-turbine engines, resulting in a highly efficient hybrid-electric propulsion system. Fluoropolymers are integral to the production, operation and safety of PEMFCs. They are integral to membranes, gas diffusion layer, microporous layers, electrodes; sealants; bonding fasters; Housing for electrical components. There are no alternatives available and time limited derogations are not adequate. Aeronautical uses of PEMFCs have exceptionally high requirements for safety, stability and durability. Currently the only materials that fulfil these requirements are fluoropolymers. For the above reasons ASD highlight that the derogations are not adequate either in coverage or duration. Alternative risk management options are requested (e.g. exception from the restriction until such time as alternatives are available, other legislation to limit emissions and recover materials at the end of life).	
7	Hydraulic fluids (anti-corrosion agent in fire-resistant phosphate-ester based hydraulic fluid)	Aviation hydraulic systems	Potassium decafluoro(pentafluoroethyl) cyclohexanesulphonate	5-o (12 years)	Fire-resistant phosphate-ester based hydraulic fluids (PEBHFs) are used in sealed hydraulic fluid systems within passenger, commercial, and most military aircraft. Due to electrochemical erosion (a unique form of corrosion), Potassium decafluoro(pentafluoroethyl)cyclohexanesulphonate (CAS 67584-42-3) has been included as a corrosion inhibitor in PEBHFs since the 1970s and continues to be used today. To date, despite significant effort and investment, there are no alternatives available for these uses. It is possible that over the course of the derogation period, an inferior chemistry could be identified and brought forward as an alternative which may provide partial protection. However, any associated reduction in safety and reliable operation would be considered unacceptable for these critical aircraft systems. The proposed derogation: "5.o *Additives to hydraulic fluids for antierosion/anti-corrosion in hydraulic systems (incl. control valves) in aircraft and aerospace industry*" gives a derogation period of 12 years. .However based on current research and state of the art for this technology, 12 years will not be adequate since it cannot be predicted if alternatives will be successfully deployed in a given timeframe. In addition, 12 years is not adequate for MRO of existing aircraft for existing aircraft that have lifetimes of 40+ years.	ASD supports Exxon Mobil's submission to the public consultation. See also case study 15 in Annex 2

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
					For the above reasons ASD highlight that the derogations are not adequate either in coverage or duration and request the following: - Introduce a review clause in the current derogation for this use - Reconsider the time limit and the conditions of the restriction - Exclude existing products from the scope	
8	Aircraft electro-mechanical equipment	Internal bearings in aircraft control levers – Flaps lever give as an example	Fluoropolymers (PTFE)	6-o (12 years)	The flaps lever for the high-lift system in an aircraft's cockpit is a crucial control that enables the pilot to manage the position of high-lift devices on the wings. These devices, including flaps and slats, are essential for optimizing lift and control during takeoff and landing, and proper control of these devices is fundamental for safe and efficient flight operations. PTFE containing bearings or PTFE containing films are used at the interfaces of moving parts where low friction is required and other methods such as lubricants with associated regular maintenance are not feasible. Alternatives are not available and due to qualification and certification requirements, substitution will be lengthy in new products. For existing products, the re-certification requirements is not likely to be economically feasible. The potential derogation for "transport" (6-o) (fluoropolymers and perfluorethers) would in principle cover these uses - however the time period (12 years) is inadequate as there is no alternative available meaning that new materials will need to be innovated and that substitution will be lengthy. In addition, 12 years is not adequate for MRO of existing aircraft for existing aircraft that have lifetimes of 40+ years. For these reasons, ASD highlight that the derogations are not adequate either in coverage or duration. Alternative risk management options are requested.	See case study 15 for other examples.
9	Guidance section of missile systems	Defence systems	PFAS components of specialist lubricants	Possible coverage under 5-s (12 years); Otherwise no coverage	The Guidance Section is the brain of the missile. It communicates with the aircraft, acquires and tracks the target, performs guidance and autopilot functions. The Guidance Section uses special oils and greases which contain PFAS. Two example use cases given. Neither has available alternatives. This use is possibly covered by proposed derogation 5-s "*lubricants where the use takes place under harsh conditions or the use is needed for the safe functioning and safety of equipment*" depending on the interpretation of "harsh conditions" and "safe functioning	Defence uses were not assessed by the dossier submitters.

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
					/safety of equipment”. The derogation period of 12 years in not adequate as it is uncertain if alternatives will be identified and qualified by the expiry of the period. If qualified alternatives are not available, it will impact the operational readiness of defence systems. ASD highlight that the derogations are not adequate either in coverage or duration. Alternative risk management options are requested.	
10	Surface coating - defence systems	Defence systems: Rail launchers for submmunition	Fluoropolymers (PTFE)	Possible coverage under 5-s (12 years); Otherwise no coverage	Rail launchers serve a vital role in various sectors, including defence and aerospace. They are specifically designed for launching projectiles at high speeds, making them crucial for missions that require precision, accuracy, and reliability. These launchers operate in extreme conditions and therefore are subject to significant stresses and challenges. The surface protection system used in rail launchers is essential to their performance and longevity. The current state-of-the-art solution involves hard anodizing-based protection with a PTFE sealing to reduce wear. This combination provides a range of exceptional properties that are critical to meeting the demanding requirements of rail launcher applications. There are no alternatives available and R&D needs to be initiated for new materials. The unique properties and performance of fluoropolymers (PTFE), are indispensable in meeting the stringent requirements of military aircraft systems. Until feasible alternatives are available or in development, derogations are vital to ensure the safety, effectiveness, and readiness of military aircraft as well as to avoid unnecessary burdens on operational capabilities. Note it is uncertain if alternatives can ultimately be innovated that would not be equally “persistent” as durability and inertness are technical performance requirements for operation in harsh/extreme conditions of use to ensure safety and reliability of the system. This use is possibly covered by proposed derogation 5-s “lubricants where the use takes place under harsh conditions, or the use is needed for the safe functioning and safety of equipment”. The derogation period of 12 years in not adequate as it is uncertain if alternatives will be identified and qualified by the expiry of the period. If qualified alternatives are not available, it will impact the operational readiness of defence systems. In addition, 12 years is not adequate for MRO of existing aircraft for existing systems. For these reasons, ASD highlight that the derogations are not adequate either in coverage or duration. Alternative risk management options are requested.	Defence uses were not assessed by the dossier submitters.

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
11	Erosion resistant coatings, abrasion resistant coatings – A&D products	Airframe: Areas subject to abrasion and erosion (e.g. leading edges, flap / slat mechanisms)	Fluoropolymers (PTFE, KFM)	6-o (12 years)	The requirements for coatings used in military aircraft systems, specifically in protecting aircraft parts such as radomes and leading edges from abrasion and rain erosion during flight, are highly demanding. Operation of military aircraft face significant challenges in mission environments characterized by supersonic speeds, high altitude, rain, UV-radiation and friction-induced high temperatures. Sprayable coatings are essential for providing effective protection against rain erosion and abrasion, aerodynamic heating, thermal flash exposure, and weathering. There are no alternatives available that have the performance properties in coatings used in military aircraft systems, specifically in protecting aircraft parts such as radomes and leading edges from abrasion and rain erosion during flight. Operating in mission environments characterized by supersonic speeds, high altitudes, rain, UV-radiation and friction-induced high temperatures, military aircraft face significant challenges. Note it is uncertain if alternatives can ultimately be innovated that would not be equally "persistent" as durability and inertness are technical performance requirements for the harsh/extreme conditions of end-use to ensure safety and reliability of the product. This use is possibly covered by proposed derogation 5-s "lubricants where the use takes place under harsh conditions, or the use is needed for the safe functioning and safety of equipment" depending on the interpretation of "lubricant" by the dossier submitter – see ECHA Q&A from the webinar. The derogation period of 12 years in not adequate as it is uncertain if alternatives will be identified and qualified by the expiry of the period. If qualified alternatives are not available, it will impact the operational readiness of defence systems. This means that use would need to stop for production of new rail launchers and maintenance/repair of existing launchers. ASD highlight that the derogations are not adequate either in coverage or duration. Alternative risk management options are requested.	Defence or security uses were not assessed by the dossier submitters and are not covered by 6-o.
12	Aircraft engine uses	Bearings and bushings in a high pressure compressor	Fluoropolymers (PTFE)	6-o (12 years)	Fluoropolymers are very widely used in aero-engines in the form of sockets, gaskets, wedges or wear strips. For example, PTFE is used in engine components such as bearings and bushings. As a specific example, PTFE bearing and bushings are used in the high-pressure (HP) compressor of the engine. A high-pressure compressor in an aircraft engine plays a crucial role in preparing the incoming air for combustion by compressing it to a higher pressure. This compression leads to more efficient and powerful combustion, which	See also case study 8

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
					in turn generates the thrust needed to propel the aircraft forward. The function of the bearings and bushings is to improve the rotation and position of the blade for HP compressor in engines. There are no alternatives available to PTFE that fulfil the technical performance requirements (friction properties, mechanical properties, temperature resistance over a wide temperature range, chemical resistance) in the bearings and bushings. This means that R&D programs need to be started to first innovate new materials with no certainty that suitable alternatives will be identified. Once alternatives are identified, it would need to be qualified and then certified for use in the aircraft engine. For existing products, redesign would be needed for new materials and recertification. In this case, as hundreds of components in an engine have to be replaced, it would be necessary to have an alternative for each component before launching the re-certification process for the redesigned whole engine. Note it is uncertain if alternatives can ultimately be innovated that would not be equally "persistent" as durability and inertness are technical performance requirements for the harsh/extreme conditions of end-use to ensure safety and reliability of the product. The potential derogation for "transport" (6-o) (fluoropolymers and perfluorethers) would in principle cover these uses - however the time period (12 years) is inadequate as there is no alternative available meaning that new materials will need to be innovated and that substitution will be lengthy. In addition, 12 years is not adequate for MRO of existing aircraft for existing aircraft that have lifetimes of 40+ years. For these reasons, ASD highlight that the derogations are not adequate either in coverage or duration. Alternative risk management options are requested.	
13	Sealing systems and greases for extreme mobility & extreme environment suspension systems –	Suspension systems for military-specific vehicles	Fluoropolymers (FKM, PTFE, FFKM, PFPE)	Possible coverage under 6-o (12 years). Dubious whether "Transport" cover all necessary	An armored vehicle is a type of military or security vehicle that is specifically designed and built to provide protection to its occupants from various threats such as ballistic projectiles, explosives, and small arms fire. Armored vehicles have reinforced armor plating, typically made of steel or composite materials, that shields the occupants from bullets, shrapnel, and other forms of attack. Despite their added weight from armor, armored vehicles are usually equipped with powerful engines and robust suspension systems to maintain mobility on various terrains. There are no alternatives available to replace PTFE, FKM, FFKM and PFPE parts and greases that are used in the suspension systems. There are currently no promising R&D programs to guarantee possible 1:1 substitution. Key characteristics that	Defence or security uses were not assessed by the dossier submitters.

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
	defence products			military vehicles (for example, self-propelled or towed artillery)	prevent the possible use of other materials include the wide temperature range the systems are required to withstand (from -46ºC in order to fulfil NATO Standards for arctic vehicles to operating temperatures in off-road mobility of over 200ºC without degradation), low friction coefficient, compatibility with main NATO standard fluids and chemical inertness. Note it is uncertain if alternatives can ultimately be innovated that would not be equally "persistent" as durability and inertness are technical performance requirements for the harsh/extreme conditions of end-use to ensure safety and reliability of the product. The proposed 12-year derogation is considered insufficient due not only to the lack of current substitute availability which would require R&D programmes lasting more than 12-years in order to develop sealing, guiding, and bearing systems which have passed all related certifications (MIL-STD, Def-Stan), but also due to the long life of the vehicles themselves (over 40 years) which renders MRO impossible for existing vehicles with a 12-year derogation as proposed. Another key point is the consideration of "transport" wherein it is unclear that all military vehicles are included. While certain vehicles such as 4x4s and trucks are certain to be included, other vehicles such as combat systems or artillery system have a very doubtful fit in this category. For these reasons, ASD highlight that the derogations are not adequate either in coverage or duration. Alternative risk management options are requested	
14	Chemical, Biological, Radiological, Nuclear, and high yield Explosives (CBRNE) detection equipment	Security and defence	Fluoropolymers and pefluoroelastomers	Not covered	CBRNE is an acronym for Chemical, Biological, Radiological, Nuclear, and high yield Explosives. These types of weapons have the ability to create both mass casualties as well as mass disruption of society. CBRNE threat detection equipment plays a key role in ensuring the safety of military forces and help protect civilians. Current CBRNE detection technologies are strongly reliant on PFAS due to the bespoke specificities they require. There are no alternatives available. These uses are not covered by any proposed or potential derogation. This means that the use of fluoropolymers in the production of CBRNE detection equipment must stop 18 months after the entry into force of the restriction. Imports of components would also stop meaning that MRO would also stop. This would have the consequence that the industry	Defence or security uses were not assessed by the dossier submitters.

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
					would not be able to produce or maintain this equipment meaning that security and defence forces would be unable to detect potential CRBNE threats. This is not a plausible scenario. ASD highlight that the restriction as currently proposed does not have a plausible non-use scenario for these uses. Alternative risk management options are requested.	
15	Aircraft landing gear	Seals & hoses, hydraulic fluids, paints & coatings, insulation (cables and systems)	Fluorpolymers, Specific non-polymeric PFAS as additives for anti corrosion,	6-o (12 years) 5-o (12 years)	Aircraft landing gear and its actuation system are critical components that facilitate the safe takeoff, landing, and taxiing of an aircraft. Manufacturers must ensure that the strict requirements of aviation sector in terms of safety and durability are met. Components like seals and hoses, hydraulic fluids, paints and coatings and isolation material all contain PFAS. There are no alternatives available that fulfil the technical performance requirements for parts/components of landing gear and actuation systems. The potential derogation for “transport” (6-o) (fluoropolymers and perfluorethers) would in principle cover seals, hoses, insulation uses - however the time period (12 years) is inadequate as there is no alternative available meaning that new materials will need to be innovated and that substitution will be lengthy. In addition, 12 years is not adequate for MRO of existing aircraft for existing aircraft that have lifetimes of 40+ years. Hydraulic fluid use would be covered by “5.o *Additives to hydraulic fluids for antierosion/anti-corrosion in hydraulic systems (incl. control valves) in aircraft and aerospace industry*”. However, the derogation period of 12 years will not be adequate-since it cannot be predicted if alternatives will be successfully deployed in a given timeframe. In addition, 12 years is not adequate for MRO of existing aircraft for existing aircraft. Note it is uncertain if alternatives can ultimately be innovated that would not be equally “persistent” as durability and inertness are technical performance requirements for the harsh/extreme conditions of end-use to ensure safety and reliability of the product. ASD highlight that the derogations are not adequate either in coverage or duration. Alternative risk management options are requested.	See also case studies 1-3 and 7
16	SMArt artillery ammunition – defence systems	Defence - PTFE surface coating for shell gliding properties	Fluoropolymers (PTFE)	Not covered	A 155 mm SMArt (Submunition Area Denial Artillery) shell is a type of artillery ammunition used primarily for long-range artillery systems. It is a sophisticated artillery round that is capable of releasing submunitions equipped with sensors and guidance systems. PTFE surface coatings are used in the shells to reduce friction. The coating plays a crucial role in	See also case study 10 and 20.

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
		under conditions of fire			the reliable functioning of the end product, even under the most extreme operating conditions (-33 °C to +52 °C). The special sliding properties of the surface coating guarantee error-free mechanical interaction of the components that are briefly subjected to the highest loads during operation. There are no alternatives available. Note it is uncertain if alternatives can be ultimately innovated that would not be equally "persistent" as durability and inertness are technical performance requirements for the harsh/extreme conditions of end-use to ensure safety and reliability of the product. The use of PFAS in artillery ammunition is not covered by any proposed or potential derogations as the dossier submitters did not consider defence uses in their assessment. This means that 18 months after the restriction enters into force, production of the shell would stop. Imports would also stop. Supply would rely on shells in stock with no possibility of restocking once the supply is used up. This would have a security implications as these weapons systems could not be used. This has not been considered by the dossier submitters. This is not a plausible scenario. ASD highlight that the restriction as currently proposed does not have a plausible non-use scenario for these uses. Alternative risk management options are requested.	Defence or security uses were not assessed by the dossier submitters.
17	ePTFE microporous membranes to protect equipment from the effects of pressure and humidity changes	Defence	Fluoropolymers (ePTFE)	not covered	ePTFE (expanded polytetrafluoroethylene) microporous membranes are versatile materials with a unique porous structure. They are used to protect equipment from pressure variations and humidity by serving as effective barriers that control the exchange of gases and moisture between the equipment's interior and the external environment. See details in Annex 2 (confidential)	Defence or security uses were not assessed by the dossier submitters.
18	Fluoropolymers in electronic, optical and microwave equipment	Defence	Fluoropolymers	No coverage	The main products containing fluoropolymers used in electronic, optical and microwave equipment are: - printed circuit boards (PCBs) - connectors and accessories (SMA, SMB, SMP, N, etc.)	Defence or security uses were not assessed by the dossier submitters.

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
					- coaxial cables - optical cable sheaths - seals - waterproof membranes, - electronic and microwave functions, in the form of ready-to-use components such as amplifiers, dividers, circulators, etc. See details in Annex 2 (confidential)	
19	Use of PTFE in a radome for a naval multi-function radar	Defence	Fluoropolymers	Not covered	A radome on a naval vessel is a protective enclosure or cover that houses and shields radar antennas and other sensitive electronic equipment from the harsh marine environment while allowing electromagnetic signals, including radar signals, to pass through with minimal loss or distortion. See details in Annex 2 (confidential)	Defence or security uses were not assessed by the dossier submitters.
21	Fluoropolymer bonded explosives	Defence	Fluoropolymer (FPM)	Not covered	Polymer-Bonded Explosives (PBX) are a type of explosive material in which explosive particles or crystals are dispersed within a polymer matrix or binder. Fluoropolymers are used in PBX in military weapons and munitions. The chemical stability of fluoropolymer binders ensures dimensional stability and performance of the explosive composition over time. Degradation of the binder due to ageing (caused by processes such as hydrolysis, oxidation, rearrangement, chemical reaction with surrounding materials, etc.) increases the sensitivity of the explosive composition over time, resulting in unpredictable behavior that poses a safety risk. There are no alternatives available. The time required to identify alternatives and requalify the munitions and weapons is significantly longer than the time proposed for the restriction to become effective (18 month after entry into force). It is uncertain if alternatives can be identified. It would also take a considerable amount of time to industrialize the manufacturing process and increase production to meet demand. Given the unique properties of fluoropolymer-bonded explosives, there may not be a one-to-one equivalent. If R&D efforts are not able to identify alternatives, the entire explosive trains will have to be redesigned and qualified.	See case studies 10 and 16 Defence or security uses were not assessed by the dossier submitters.

#	Specific use case	Application area described in the case study	Type of PFAS	Possible derogation coverage	Key points	Other relevant information
					These uses are not covered by any proposed or potential derogation. This means that the use of fluoropolymers in the production of the concerned weapons and munitions must stop 18 months after the entry into force of the restriction. Imports of the concerned weapons and munitions would also stop. The proposed restriction would cripple the ability to supply armed forces as needed, which would reduce the defence capabilities of Member States as ammunition stocks would likely be depleted long before alternatives are available. This is not a plausible scenario. ASD highlight that the restriction as currently proposed does not have a plausible non-use scenario for these uses. Alternative risk management options are requested.	

2.3.5 Non-use scenario & socio-economic impact of the current restriction proposal (ECHA Q6g)

The impact of the proposed restriction would be exceptionally severe on the A&D sector.

With Restriction Option 1 (RO1) where all PFAS chemicals are banned with no derogations, the economic impacts would be severe and detrimental to the functioning of the EEA both in terms aviation (passenger, cargo, military) and national and European Defence and security.

With RO2 (all PFAS chemicals are banned with time limited derogations for uses by specific sectors/applications), the impact will depend on the eventual coverage of the derogations for uses of PFAS chemicals needed for the production, operation and MRO of A&D products. If the derogation coverage is not complete and/or the expiry periods are not sufficient, the impact could be as severe as RO1. It would affect A&D companies, their supply chains, third-party MRO facilities, customers (including airlines and defence agencies) and those who rely on the products and services provided by the A&D industry. Our use identification and potential/proposed derogation assessment further demonstrates that coverage for A&D uses is not well considered or provided for currently.

In this section, we discuss non-use scenarios for the aviation and defence sectors and consider the impact on the non-availability of qualified parts/components etc. when the restriction comes into force and derogations expire. To provide an appreciation for quantification of the anticipated SEA impacts, we refer to the recent authorisation applications submitted by the A&D sector for the continued use of a limited number of hexavalent chromium compounds CrVI for a limited number of surface treatment of parts/components in the production, operation and MRO of A&D products.[4] We referred to their socio-economic impact assessment to get an illustrative understanding of the wider economic consequences of non-use scenarios. However, it must be recognised that impacts would be even greater, since import of PFAS-containing articles would be prohibited and so any non-use scenario allowing for continued import of articles manufactured outside the EEA, could not be considered in the case of PFAS. For RO2, neither use nor import is allowed. The impacts are summarised in Table 12.

Table 12. Non-use scenario when qualified and certified alternatives are not available for A&D products and the wider economic impact

	Non-use scenario when qualified and certified alternatives are not available (RO1 or RO2 with incomplete/non-aligned derogations)
Aviation	• Production of aircraft/and or aircraft equipment in the EEA stopped • Imports of aircraft to the EEA is stopped (as import of an article containing PFAS is not allowed) • Operation of aircraft and components, including spares containing PFAS components would not be stopped for existing aircraft in use at the time of expiry or other aircraft 'visiting' the EEA • Scheduled maintenance operation activities involving replacing PFAS components in the EU stopped and relocated outside the EEA, only where possible • Aircraft requiring repairs/replacement PFAS parts effectively 'grounded' in the EEA. • Premature retirement of aircraft that can no longer be maintained or repaired. • Operation activities involving PFAS stopped in the EEA (e.g., safety critical window cleaning fluid) • Impacts to production of aviation products in other regions including UK and US, where customers are currently reliant on EU based manufacture or assembly of certain components (global supply chain)

Defence (non-aviation uses)	• Production of defence products stopped in the EEA • All imports of defence products and components, including spares to the EU stopped • Defence equipment requiring repair/replacement parts effectively 'grounded' • Scheduled maintenance of defence assets that require the use of PFAS-containing parts shifted outside the EEA only where possible (in most cases this will not be possible due to security considerations for defence applications) • Premature retirement of defence equipment that can no longer be serviced/repaired • Operation of existing defence products containing PFAS would not be stopped – but production, maintenance and repair would shift outside the EEA only where possible (in most cases this will not be possible due to security considerations for defence applications) • Impact production of defence products in other regions including UK and US, where reliant on EU based manufacture or assembly of certain components (global supply chain)
Wider economic impacts	• Cease in both production and import of A&D products within the EEA • Cease in delivery of spare parts to the EEA (leading to reliance on offshore maintenance services for A&D products used in the EEA) only where possible (in most cases this will not be possible due to security considerations for defence applications) • Inability to service and repair existing A&D products in the EEA or to import repaired and refurbished PFAS-containing components to the EEA – aircraft would be grounded, including defence fleets (with direct impact on national security) • No new A&D products could be imported or produced in the EEA • Loss of functioning A&D equipment in EEA • Premature retiring from service of A&D equipment in EEA • The EEA neither develops innovative new PFAS-reliant products nor benefits from those developed outside the EEA • Remaining existing products reach end of service life and cannot be replaced • EEA aviation sector no longer viable • MoDs cannot procure defence systems • National security is compromised as operational readiness is not possible • Passenger and cargo air transfer relies on depleting and aging stock with all MRO scheduled to be done outside the EEA (leading to increased costs) • Airlines cease business as costs are too high and cannot be passed on to passengers or by increased freight charges • Massive loss of jobs across multiple sectors that rely on the A&D sector • Closure of EEA-based facilities • Loss of strategic innovation and technology development in the EEA

The economic impacts would include:

- Loss of profits – OEMs, suppliers, airlines, repair and maintenance facilities, etc.
- Business closures and lost jobs
- Costs associated with unused stock disposal
- Costs for relocation of work outside of EEA – OEMs, suppliers, repair and maintenance facilities, etc. (only in cases where this is even possible)
- Penalties for failures to meet contracts (e.g. where servicing cannot be completed leading to aircraft being grounded)
- Economic consequences of commercial and freight aircraft groundings and flight cancellations
- Market distortion for aviation services (no EEA based airline companies)
- The EEA ceases to have functioning aviation and defence capabilities due to its inability to procure new products or maintain existing products

- Market distortion of global innovation and technology development to favour locations outside the EEA

The wider consequences are given in the Table above. The consequences would be catastrophic and are not plausible**.** The EEA would cease to have functioning aviation and defence capabilities as production and MRO would all need to be done outside the EEA. Imports would not be possible. All technology development, innovation, investment etc. would move outside the EU and the European defence would rely on other military countries (US, China, others) or must be stopped. This is simply not a plausible scenario.

The 2023 ADCR submission for chromate re-authorisation for the A&D supply chain assessed the economic impact of the non-availability of conversion coatings based on hexavalent chromium compounds on A&D companies[20]. The non-use scenario is similar since without conversion coatings, a significant proportion of production and all MRO activities would cease in the EEA. Whilst the conversion coating non-use scenario allows for relocation and import of articles back to the EU, in the case of PFAS, any relocation of activities would only be able to serve non-EU markets and so the actual realised impacts for the PFAS case would be much more severe. Table 13 gives quantitative estimates for the impact on A&D companies (in the context of the 12 year review period applied for and a 4 % depreciation (UK figures included due to an equivalent authorisation requirement under UK REACH, but there would also be some impact on this market due to UK dependencies on EU-based production of parts)). The non-use scenario in this case would mean that all production and MRO relocates giving a higher impact.

[20] ADCR application for authorisation for continued use of hexavalent chromates; Application ID 0327-01 "*Chemical conversion coating using chromium trioxide, sodium dichromate and/or potassium dichromate in aerospace and defence industry and its supply chains*" available on the ECHA website at https://echa.europa.eu/en/applications-for-authorisation-consultation/-/substance-rev/74108/term

Table 13. Extract from the ADCR submission[4] for the re-authorisation of CrVI based conversion coatings in the A&D supply chain giving the impact on A&D companies

Table 5-8: Summary of economic impacts under the non-use scenario (12 years, @ 4%)		
Economic operator	**Quantitative**	**Qualitative**
Applicants	• Not assessed	Lost profits to applicants in both the EEA and UK are assessed in the Formulation SEA
A&D companies	• Lost operating surplus EEA: €29.6 – 70.5 billion over 12 years (€3.1 – 7.5 billion over one year) • Lost operating surplus UK: €4.7 – 28.0 billion (€0.5 – 2.9 billion over one year)	Relocation costs, disruption to manufacturing base and future contracts, impacts on supply chain coherence, impacts on future growth in the EEA and UK sectors, loss of skilled workforce, impacts on R&D (and potential to deliver new more sustainable technologies)
Competitors	Not anticipated due to sectoral coverage of the application	Not anticipated due to sectoral coverage of the application
Customers and wider economic effects	Not assessed	• Impacts on airlines, air passengers, customers, cargo and emergency services, and thus society as a whole • Impacts on military forces' operation capacity and mission readiness • Lost output/value added multiplier effects due to impacts on civil aviation and loss of defence sector spending • Loss of spin-off effects – innovation and new technologies

The authorisation application reports also considered related aspects; the impact on military forces and companies acting as suppliers to the military forces. It was not considered plausible that the EEA defence forces would rely entirely on non-EEA suppliers, and it was considered that use would continue via defence exemptions. Obsolescence risk was also considered as if solely defence uses are allowed, many suppliers would not have sufficient turnover to remain profitable.

The report highlighted the contribution the defence sector makes to the EEA economy:

> *"Companies in the European defence sector represent a turnover of nearly €100 billion and make a major contribution to the wider economy. The sector directly employs more than 500,000 people of which more than 50% are highly skilled. The industry also generates an estimated further 1.2 million jobs indirectly. In addition, investments in the defence sector have a significant economic multiplier effect in terms of creation of spin-offs and technology transfers to other sectors, as well as the creation of jobs."*

The report highlighted that this multiplier effect would be lost if companies relocate outside the EEA.

Based on the sector wide quantitative assessment done for the same sector for a very limited number of coatings and where imports are not restricted, it can be seen that impact of the non-use scenario is severe. In this case, due to the number of chemicals within scope and the ubiquity of their use in the production, operation and MRO of A&D products, the impact of RO2 would be catastrophic. RO2 would shut down production of new products, stop MRO of existing products, stop the import of products, components, parts etc. The wider economic consequences go beyond lost jobs but would in effect stop all EEA based production of A&D products, stop their imports, stop MRO of existing products, stop import of components, parts etc. Taking civilian aviation as an example, this would mean that aircraft could fly in the EU but could not be produced, serviced or imported in the EEA. Taking national security as an example, existing defence products (aircraft, naval vessels, land vehicles, munitions, weapons) could be operated but not serviced due to lack of spare parts. Existing stocks once depleted could not be replenished. New products/parts could neither be produced nor imported in the EEA. Defence forces would be unable to respond to security threats. These non-use scenarios are not plausible.

ASD ask that the dossier submitters revise their proposal and propose more appropriate and proportionate regulatory risk management measures that explicitly take the specificities of the A&D sector into account and the wider aspects on the functioning of the EEA.

Appendices

Annex 1. Assignment of the specific PFAS reported by ASD members in their questionnaires to PFAS types for the use and derogation assessment

Table 14. Details of the assignment of PFAS reported by ASD members to PFAS types for the use and derogation mapping (see Tables 1, Tables 15-19)

Type of PFAS	Abbreviation	Trade Name(s)	Chemical Name	EC No	CAS No
Fluoropolymer	PFPE		1-Propene, 1,1,2,3,3,3-hexafluoro-, oxidized, polymd.	615-044-1	69991-67-9
	ECTFE		poly(ethene-co-chlorotrifluoroethene); poly(1-chloro-1,2,2-trifluorobutane-1,4-diyl)	polymer	25101-45-5
	ETFE	Tefzel	poly(ethene-co-tetrafluoroethene); ethylene tetrefluoroethylene	polymer	25038-71-5
		Ethene, 1,1,2,2-tetrafluoro-, oxidized, polymd	Ethene, 1,1,2,2-tetrafluoro-, oxidized, polymd; fomblin m15 pfpe	polymer	69991-61-3
	FEP	Teflon FEP; Neoflon FEP; Dyneon FEP	fluorinated ethylene propylene; Tetrafluoroethylene-hexafluoropropene copolymer; Fluorinated ethene propene copolymer	polymer	25067-11-2
	FEPM		Tetrafluoroethylene propylene copolymer	polymer	unknown
	FFKM	Kalrez, Technoflon PFR; Dyneon PFE; DAI-EL GA; Chemraz	perfluoroelastomeric compounds	polymer	multiple
	FKM	Viton, Viton E	family of fluorocarbon-based fluoroelastomer materials	polymer	multiple
		Fluoropolymers	unspecified fluoropolymers	unknown	unknown
		fluorosilicone	fluorosilicone rubber	polymer	unknown
	FPM	Viton	family of fluorocarbon-based fluoroelastomer materials	polymer	multiple

	FVMQ		fluorovinylmethylsiloxane rubber; fluorosilicone rubber	polymer	unknown
		Nafion	Perfluorosulphonic acid-PTFE copolymer	polymer	66796-30-3
		Nedox	(range of surface coating products)	polymer	multiple
		NOVEC 1700 (active)	Fluorinated acrylate polymer	polymer	unknown
	PCTFE		Polychlorotrifluoroethylene	polymer	9003-83-9
			Perfluoroalkane sulfonyl (meth)acrylate polymers	polymer	unknown
			Perfluorocarbon elastomer	polymer	unknown
		Perfuoroelastomer	Perfluoroelastomer	polymer	unknown
	PFA		perfluoroalkoxyl polymer	polymer	unknown
	PFPE	Krytox	perfluoropolyether	polymer	unknown
	PTFE	Teflon; Arlon; Avalon; Turcon; Formulations containing PTFE include: Alexol Stabox; Magnalube G; Microflon M2; PEEK / FC containing PTFE; Polyimide + PTFE	polytetrafluoroethylene	polymer	9002-84-0
	PVDF		Polyvinylidenefluoride; Polyvinylidenedifluoride; poly(1,1-difluoroethylene)	polymer	24937-79-9
	PVDF-HFP		Polyvinylidenefluoride; Polyvinylidenedifluoride; poly(1,1-difluoroethylene) and Hexafluoropropylene	polymer	24937-79-9 and 116-15-4 polymer
			Tetrafluoroethylene-hexafluoropropene copolymer	607-524-4	25067-11-2
		Tufram	(range of surface coating products)	polymer	multiple

Fluorinated Alkene (non polymeric)	HFP	freon R 1216; halocarbon R 1216; fluorocarbon 1216	Hexafluoropropylene; Perfluoropropene; Perfluoropropylene	204-127-4	116-15-4
	TFE		Tetrafluoroethylene	204-126-9	116-14-3
Fluorinated organic fluids (non polymeric)	2-BTP	Halotron BrX	2-bromo-3,3,3-trifluoroprop-1-ene	627-872-0	1514-82-5
		Caldene TME	reaction mass of 1,1,1,2,2,3,3,4,4-nonafluoro-4-methoxybutane; 1,1,1,2,3,3-hexafluoro-3-methoxy-2-(trifluoromethyl)propane	425-340-0	163702-05-4
		DuPont™ Vertrel®	HFC-based products	unknown	unknown
		FK-5-1-12; Novec 1230	Dodecafluoro-2-methylpentan-3-one; 1,1,1,2,2,4,5,5,5-nonafluoro-4-(trifluoromethyl)-3-pentanone	436-710-6	756-13-8
	HFC	HFC	unspecified Hydrofluorocarbons	unknown	unknown
		HFC-43-10mee	(S,S)-1,1,1,2,2,3,4,5,5,5-decafluoropentane;reaction mass of: (R,R)-1,1,1,2,2,3,4,5,5,5-decafluoropentane	420-640-8	138495-42-8
	HFE	HFE	unspecified Hydrofluoroethers	unknown	unknown
	HFE-7300		Pentane, 1,1,1,2,2,3,4,5,5,5-decafluoro-3-methoxy-4-(trifluoromethyl)-	459-520-5	132182-92-4
		Methyl Nonafluorobutyl Ether	Methyl Perfluorobutyl Ether; Butane, 1,1,1,2,2,3,3,4,4-nonafluoro-4-methoxy-; 1,1,1,2,2,3,3,4,4-nonafluoro-4-methoxybutane	829-015-8	163702-07-6
		Novec 71 IPA, NOVEC 1700 (solvent); Promosolv DR1	Methyl perfluoroisobutyl ether; reaction mass of 1,1,1,2,2,3,3,4,4-nonafluoro-4-methoxybutane; 1,1,1,2,3,3-hexafluoro-3-methoxy-2-(trifluoromethyl)propane	422-270-2	163702-08-7 and 163702-07-6

		NOVEC 7500	3-ethoxy-1,1,1,2,3,4,4,5,5,6,6,6-dodecafluoro-2-trifluoromethyl-hexane	435-790-1	297730-93-9
		Perfluoroalkyl ethers / alkanes + aromatics		unknown	unknown

TULAC	Fire resistant glass cloth		x						x										

Of the ASD application areas considered to be "partially assessed", "6o-transport" was the more assigned derogation (see Table 16). Note that this is using a very wide interpretation of "transport" – many defence uses are not readily "transport".

Table 16. ASD application areas considered to be "partially assessed" by the dossier submitter AND possibly covered by potential derogation 6o

		Unassessed	Assessed		Potential Derogations			Proposed Derogations

1 General Comments

1.0 Introduction and Summary

Founded in 1919, AIA is the premier trade association representing over 320 major aerospace and defense manufacturers and suppliers and more than 2.2 million employees. Among its members are the United States of America's leading manufacturers and suppliers of civil, military, and business aircraft, helicopters, unmanned aerial systems, missiles, military airborne, ground-based and naval systems, space systems, aircraft engines, material, and related components, equipment services, and information technology. AIA is pleased to provide the following comments on the proposed PFAS restriction.

Both fluoropolymers (e.g., PTFE, PFA, PVDF, etc.) and non-polymeric PFAS are used in the Aerospace and Defense (A&D) industry in a wide variety of critical applications that are further detailed in this document. The properties of PFAS are commonly unmatched by other materials, and the products containing them are often required for the safe, reliable and effective operation, maintenance and repair of today's commercial and military aircraft and many other A&D products, including critical military equipment. Further, a review of other submissions from the A&D value chain in response to the proposed restriction also reveals a wide dependence on PFAS in developing products for the A&D industry, even for products that do not contain PFAS. Further, we conclude from our and suppliers' information that feasible alternatives are not currently available for most of those uses, and in many cases will not be available for the foreseeable future. In our industry, many uses of PFAS have been formally approved and certified for the functions and capabilities they provide. We also believe that proposal significantly underestimates the socioeconomic costs that the restriction will have on the REACH member states without significant revision. Finally, the A&D industry is very concerned about the continued availability of products and materials needed to manufacture and support industry products, and ensuring those products continue to meet the stringent product performance, safety and reliability requirements demanded by its customers and other stakeholders, including regulatory bodies.

AIA proposes the following changes be made in the restriction proposal as justified by the information presented here:

Derogations for PFAS

In Section 1.8, we propose a derogation for all uses and sub-uses of PFAS chemicals for the aerospace and defense sector;

The derogation should include technology readiness evaluations to determine whether alternatives are available for any uses and sub-uses and what appropriate adjustments should be made to the duration of the derogations.

Aerospace Industries Association of America, Inc.
1000 Wilson Boulevard, Suite 1700 | Arlington, VA 22209-3928 | 703.358.1000 | www.aia-aerospace.org

Exemption/exclusion for fluoropolymers

As explained in Section 1.5 we fully support removing or exempting fluoropolymers from the scope of the restriction;

The derogation should include low molecular weight PFAS chemicals used for producing fluoropolymers.

Chemical identifiers

In Section 1.3, we strongly suggest that an explicit list of chemical identifiers (CAS numbers) be provided for the PFAS covered by the restriction.

Repair as produced

In Section 1.8, we support the repair as produced principle where products should be allowed to be repaired as originally designed and produced.

1.1 Information on PFAS uses in the aerospace and defense sector

AIA wishes to highlight additional and complementary information about PFAS use in the A&D sector. Much of this information is found in comments submitted directly by other organizations. Where possible these comments are cited in Table 1 and elsewhere in this submission where they are specifically relevant. We also want to highlight comments submitted by Aerospace, Security and Defence Industries Association of Europe (ASD, Submission # 4419 and their follow-on submission), the US Chamber of Commerce (Submission # 6288), American Chamber of Commerce to the European Union (AmCham EU, Submission # 4584) and a white paper developed by International Aerospace Environmental Group (IAEG).

IAEG commissioned a report this year to highlight the uses of PFAS within the A&D industry and illustrate the complexities facing this sector with regard to the identification and understanding of PFAS uses across the supply chain, and the challenges facing the industry in terms of finding substitutes to PFAS across this wide range of applications. Many members of AIA (and ASD) contributed data to the report. In particular, this report aims to:

- Highlight and map the key uses of PFAS within the A&D sector that are covered under the proposed restriction proposal (both in relation to 'transport' and other related sectors), as well as uses that are not explicitly discussed in the restriction proposal.
- Identify the 'critical' uses of PFAS in the A&D sector, where alternatives may not currently meet specific performance or safety standards.
- Illustrate the challenges in identifying if and where PFAS are used in specific products or components and the complexity of the A&D supply chain.

The upcoming report will be found at the IAEG website at https://www.iaeg.com/workgroups/wg5/activities.

1.2 Risk of obsolescence and disruption of A&D supply chains

The potential for regulatory-driven obsolescence (even for exempted and derogated uses) is a real concern for companies in the A&D industry, with the result of significant socio-economic cost to the EU member states. As mentioned elsewhere, many organizations in the A&D supply chain have identified significant risks from the proposed restriction on their ability to continue to supply to the EU and global markets. Suppliers to the industry may make decisions to remove PFAS substances (including products made from those substances) from the market for various reasons. These can include compliance with anticipated regulations that have not yet entered into force, lack of continued marketability/profitability for PFAS-containing products or limiting their own risks and liabilities associated with continued production and/or processing of PFAS such as with 3M's recent decision to exit the market on all PFAS products.[1] While we recognize that these are decisions that individual companies may make, our concern is that such decisions may be made without full regard to the downstream impacts on customers that rely on these products. Ultimately, aerospace and defense suppliers and companies would be required to mitigate such cases of obsolescence in a manner that could include temporary stockpiling, reformulation, replacement with qualified materials, relocating work outside of the EU/EEA, redesigning, requalifying and recertifying end products.

Further mitigation would not necessarily result in phasing out PFAS. In the simplest of cases companies may switch to a product from another supplier that may already be qualified. If there is not an existing qualified alternative, they may need to qualify an alternative from another source, and this may very well be another product that contains PFAS. In fact, it may be easier to qualify a PFAS-containing alternative, especially when it is the same PFAS chemical, because the products will have similar properties and demonstration of interchangeability will be less time consuming. Thus, given the choice between qualifying a PFAS vs. a non-PFAS candidate alternative, the PFAS option could be chosen to maintain business continuity.

1.3 Difficulty identifying PFAS

While we are just beginning to understand our dependence on substances within the scope of the proposed restriction, tracing chemical substance content information and transparent communication of that information is extremely challenging. For "downstream" manufacturers of complex articles with global, multi-layered supply chains such as those in the A&D industry, this means tracing substance information through many levels of the supply chain, starting with parts manufacturers through to the complex assemblies used in our products. The A&D industry includes thousands of global subcomponent suppliers, including numerous small-to-medium sized companies. In order to determine the chemical composition of these subcomponents, the suppliers must be able to reliably collect and accurately report data on substances used in each specific subcomponent as well as in its manufacturing process at each level of the supply chain. This challenging situation is compounded by the fact that spare parts are routinely produced several years in advance of their use, where the precise understanding of their composition was not available at that time of their manufacture. Further, while process and tools to obtain and use composition data have been under development by the industry for several years, adoption in the global supply chain has not fully developed and significant gaps in such data remain.

[1] https://news.3m.com/2022-12-20-3M-to-Exit-PFAS-Manufacturing-by-the-End-of-2025

Further, the presence of PFAS in chemical products has not been consistently covered by chemical information contained on safety data sheets (SDS) for materials used in the supply chain. In many cases, individual PFAS are still not widely recognized as hazardous, are present below applicable cut-off thresholds and/or are proprietary substances. If a PFAS is not explicitly listed in an SDS (which is common in our experience) with a commonly-recognized identifier (Chemical Abstract Series "CAS" Numbers are the most-commonly used numerical identifier to accurately identify substances worldwide) then the identification throughout the supply chain is extremely challenging, including where substances are processed into articles. If the lack of PFAS identification through the supply chain is not addressed on a global scale, then PFAS content reported through the supply chains for our products will always be incomplete.

Factors that affect a company's ability to connect with and obligate members in global supply chains to collect information for a finished industry product include local regulatory requirements and industry best practices, contractual obligations and agreements between and among members in the supply chain, the number and locations of those members, the types of equipment (e.g., military or commercial), and time (e.g., the number of years in the data call, the amount of time to complete a data call). Supply chain members face challenges to reliably collect and accurately report composition data because of the typical complexity of the articles produced by the industry (e.g. aircraft), the availability of the information, and often limited use of product chemical content data for articles by actors in the supply chain. Stockpiled supplies and replacement parts (i.e., historical supply) add layers of complexity and complication given that supply chain partners regularly change and may no longer have contractual obligations to provide information, and/ or components, complex assemblies and finished articles may have changed chemical content over time.

In practice some A&D companies report that it takes typically around 24-36 months after a substance has been added to the EU REACH Candidate List for data on those substances in industry hardware (articles) to be received from the majority of the global article supply chain. In the case of requests for PFAS to be declared at much lower levels (0.1% for the Candidate List vs. 25 parts per billion threshold in this restriction proposal), we anticipate that it will take much longer to obtain such information from the global supply chain. The large number of substances in scope of this proposal will further extend the time. In addition, if testing is identified as necessary to determine the PFAS content of articles, laboratory testing availability, capability, and capacity (and possibly costs) of suitable tests are also considerations that will lead to longer timeframes for compliance with proposed restriction limits.

Further, basing a restriction on a definition and not explicitly-defined chemical identities (including CAS numbers) will make it extremely difficult for article manufacturers sourcing from many supply chains to understand their dependence on PFAS (including for PFAS in production equipment/ materials that don't appear in supplied products), as many suppliers may not be able to identify a PFAS even when it is reported in an article declaration or an SDS. This difficulty will be exacerbated for goods sourced from non-EU suppliers. The lack of PFAS identifiers will also make consistent enforceability nearly impossible, even though "enforceability" is a requirement of REACH Annex XV (under the section titled "Justification for Restrictions at Community Level") for justifying the need for an EU-wide restriction. **Thus, we strongly suggest that an explicit, comprehensive list of chemical identifiers (CAS numbers) be provided for substances within the scope of the final restriction.**

Aerospace Industries Association of America, Inc.

1.4 Appropriateness of Regulating All PFAS Identically

We agree with the many comments already submitted that the identical regulation of over 10,000 species of PFAS is inappropriate from both regulatory and risk management standpoints. As a class of substances, PFAS have extremely wide set of chemical properties and functionalities and environmental and human health impact profiles. As such, many PFAS do not meet the criteria that support restriction being the best option to manage risk. Further, we believe that many types of PFAS provide significant benefits to society at minimal risk and therefore should not be covered by the restriction. Certainly, regulatory responses for groups of PFAS exhibiting similar properties have been successfully used to control risks (e.g., the recent addition of perfluorohexane sulfonic acid (PFHxS), its salts and PFHxS-related compounds to the EU POPs regulation), and we encourage that approach be continued in a risk-informed and prioritized fashion. Because of the broad and unprecedented proposed approach to restrict such a large and diverse group of chemicals with many critical uses, many derogations will need to be granted (even with limited existing data) for essential uses, often with only rough estimates of the time needed until replacements might be available. We see that these points have also been made by numerous other commenters and we concur with those comments.

AIA is also very concerned with the implications that the proposed restriction might have on imports to the EU from the US and other EU trading partners. As indicated in this response, AIA (including through many A&D industry suppliers) has identified multitudes of instances where the use of PFAS is essential to the proper operation and support (maintenance and repair) of A&D products, with no alternatives that provide the same levels of effectiveness, safety, and reliability needed to properly conduct air travel, military missions and a wide variety of other socioeconomic functions supported by our industry. However, there are currently no consistent regulatory drivers across many trading partners and EU allies requiring the comprehensive identification of PFAS use; in fact, there are disagreements between countries and other entities as to what even constitutes a PFAS. As a result, efforts to identify PFAS uses have only just recently been initiated in the US and other regions and there is significant risk that critical uses have not have yet been fully identified. As a result, AIA is concerned that the envisioned restriction (if not appropriately and carefully amended) may create barriers to the free trade in commodities and materials where PFAS use is not fully characterized, including those that are essential for the proper functioning and security of EU society.

AIA is also concerned that the proposed restriction of fluorinated gases under Annex XVII is creating confusion and concerns of “double regulation” for “F-gases” - hydrofluorocarbons (HFC), hydrofluoroethers (HFE) and hydrofluoroolefins (HFO), many that are currently essential and are needed for continued use under the HFC phase-down schedules agreed to in the Kigali Amendment to the Montreal Protocol. To prevent this situation and ensure consistent regulation, it is our recommendation that F-gases subject to other regulatory instruments (e.g., the EU F-Gas Regulation) be excluded from the scope of the proposed PFAS restriction.

1.5 Fluoropolymers Are of Low Concern

Polymeric PFAS, generally referred to as fluorinated polymers, include fluoropolymers, perfluoropolyethers (PFPE), and side-chain fluorinated polymers (SCFP). Although fluoropolymers fit the PFAS structural definition, they have been shown to be thermally, biologically, and chemically stable; have very low water solubility and are considered to be nonmobile, nonbioavailable, and

Aerospace Industries Association of America, Inc.
1000 Wilson Boulevard, Suite 1700 | Arlington, VA 22209-3928 | 703.358.1000 | www.aia-aerospace.org

nonbioaccumulative (Henry et al. 2018)[2]. In this study, four major fluoropolymers were demonstrated to meet the criteria as Polymers of Low Concern (PLC) as set by the Organisation for Economic Co-operation and Development (OECD). Following the analysis presented by Henry et al., 2018, 14 additional commercially manufactured fluoropolymers have recently been shown to also meet the PLC criteria (Korzeniowski et al. 2023)[3]. Taken together, these two studies covered ~ 96% of the global fluoropolymers market and can be considered to be representative of the low environmental and toxicological concern posed by these materials.

Considering this, and as described in the previous section, fluoropolymers generally meet the criteria as persistent but do not pose the toxicity risk warranting restriction. As a result, **we fully support excluding fluoropolymers from the scope of the proposed restriction**.

Since fluoropolymers are produced from the polymerization of low molecular weight PFAS constituents, a **derogation will also be required for the low molecular weight PFAS constituents required to produce fluoropolymers**, with appropriate controls in place to minimize the impact of these low molecular weight PFAS constituents on the environment.

1.6 Uses and Sub-uses:

AIA has compiled a list of PFAS uses and sub-uses from available sources including AIA member queries, IAEG WG5 data, information from other sectors and companies, literature searches, internal engineering records, safety data sheets, etc. As cautioned elsewhere, we are not confident at this stage that the list is comprehensive and as such should be considered indicative. Table 1 PFAS uses and sub-uses of the A&D sector identified by AIA." For each use, AIA has also broadly identified the type of PFAS (e.g.,., whether it is polymeric on non-polymeric).The table also contains information on whether AIA has identified a relevant proposed or potential derogation. Where these have been identified, the identifying paragraph and sub-paragraph of the restriction proposal (RO2) are listed. The text of each potentially applicable derogation is identified following the table. Finally, we list any supporting comments that AIA would like to draw attention to and that could provide more information on the use are included. For some uses additional information is available and included in Section 2 and a cross reference is provided to the specific section for those uses.

1.7 Alternatives and Substitution Timelines

Noting that the identification of aerospace and defense uses is still ongoing, a full assessment of the availability and suitability of alternatives is only at the beginning stages. A detailed analysis must be completed for each use and sub-use.

The continued use of various PFAS chemicals (including FPs) in aerospace and defense products is desirable as these uses are a small fraction of the global utilization of PFAS chemicals yet provide significant societal benefit. Today, there are no known substitutes for PFAS chemical materials with their unique properties partly because the alternatives will also be persistent in nature and will also result in poorer performance overall. Finally, the diminution of functional characteristics is unwarranted and will lead to other unintended consequences especially in aerospace and defense applications where their use is much needed. (A&D products operate in extreme environments, over extended time frames, while having to fulfill significant safely, reliability and technical requirements. Global airworthiness regulations ensure A&D products' safety and reliability. These regulations require a systematic and rigorous framework to be in place to qualify all materials and processes to meet stringent safety requirements that are subject to independent certification and approval through EASA (European Union Aviation Safety Agency), Federal Aviation Administration (FAA) and other national agencies. Air, ground and sea-based defense systems, and also space systems, are subject to similar rigorous qualification requirements. Meeting approvals requires validation and certification of all products used.

Because PFAS-containing products have proven reliable in safety critical A&D applications, the industry has not needed to develop or seek alternative products and materials. The state of available alternatives today is similar to that for hexavalent chrome uses in the late 1980s, when the aerospace and defense sector first started alternative development efforts – alternatives are still not available for all hexavalent chromium uses over 30 years later. While some uses may be fully substitutable in a shorter time, it is not possible to predict with certainty which ones. Given the widespread uses of polymeric and non-polymeric PFAS in the A&D sector, and the extensive validation, certification and industrialisation work OEMs undertake for all affected specifications, components and products, it will take a lengthy (and currently unknown) period of time to identify and implement substitutes.

To help convey the challenges involved in alternatives development and deployment for A&D uses, we call your attention to a paper produced by the Global Chromates Consortium for Aerospace's (GCCA), titled Aerospace & Defence Qualification Process Impacts on Ability to Substitute Cr(VI) Substances which is attached to this submission. Although the GCCA paper was written to support hexavalent chromium Authorisation applications, the qualification and certification processes described are also applicable to substitution of other substances, including PFAS within the A&D industry. The following illustration included in that paper supports the length and uncertainties of the substitution timeline discussed in the previous section.

Aerospace Industries Association of America, Inc.
1000 Wilson Boulevard, Suite 1700 | Arlington, VA 22209-3928 | 703.358.1000 | www.aia-aerospace.org

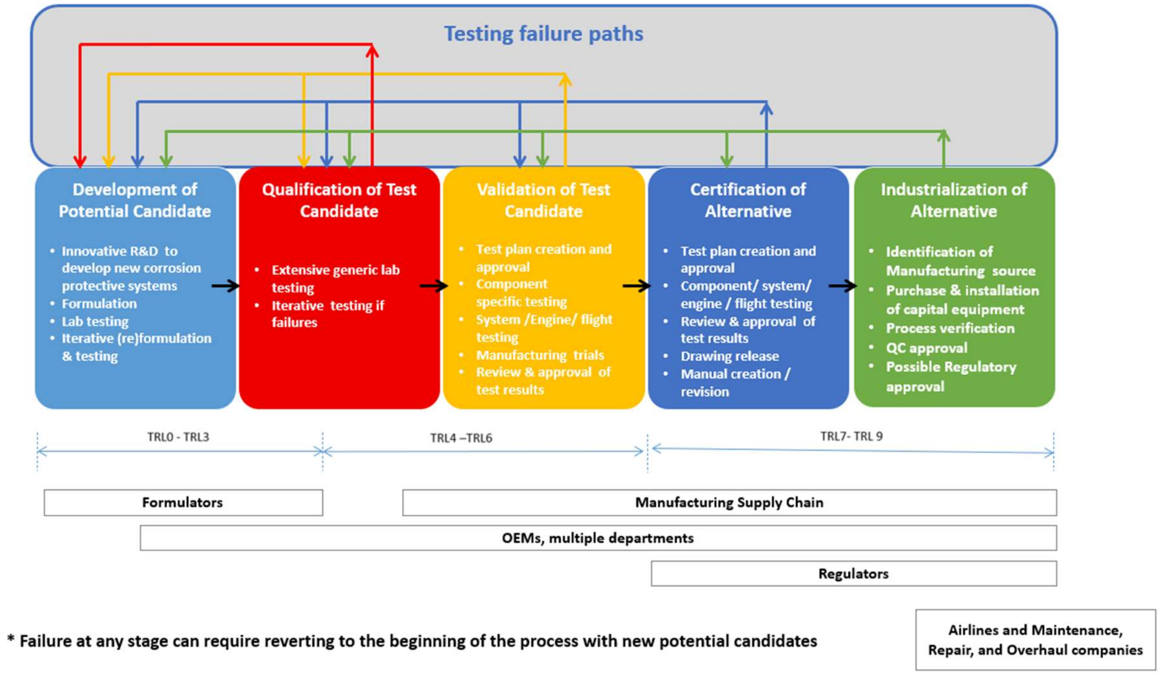

Figure 1. Illustration of the development, qualification, validation, certification and industrialisation process required in the aerospace industry – adapted from the GCCA paper on Aerospace & Defence Qualification Process Impacts on Ability to Substitute Cr(VI) Substances[3].

The GCCA paper provides the following important statement: "The complex relationship between each component and its performance requirements within its own unique design parameters requires certification of each substitution individually (see Figure 2). Qualification in one particular application does not guarantee that use in another application is qualified. Every application must be individually assessed to determine that requirements are met. This process must be independently replicated across all A&D products by each A&D company. A&D products (e.g. a specific aircraft model) may be in service for 30-50 years (even longer in defense uses), requiring maintenance, repair and spare parts over their entire service lives. Any changes to these parts or processes must be fully validated and certified to ensure safety and performance are not compromised."

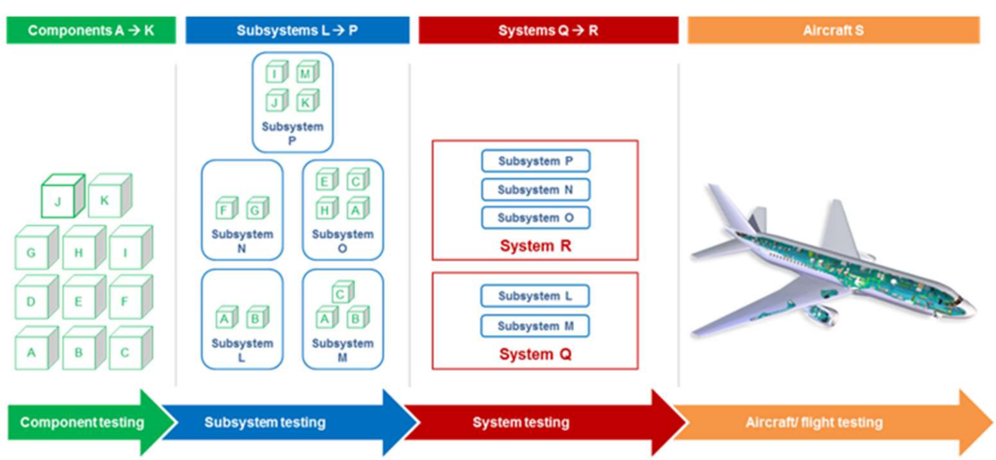

Figure 2. Systems assessment and validation overview, taken from the GCCA paper on Aerospace & Defence Qualification Process Impacts on Ability to Substitute Cr(VI) Substances[3].

The R&D process for finding suitable PFAS-free alternatives to the articles and formulations described in this comment will be robust but complicated. Our industry is still in the early stages of initiating R&D processes to find PFAS-free alternatives. Safety and quality considerations will be paramount given the nature of our industry. The R&D processes will require collaboration between major material suppliers, designers, and parts manufacturers. A key complicating factor is that once suitable PFAS-free alternatives have been identified within the industry, certain PFAS substitution efforts will almost certainly require the approval of the EASA and the U.S. FAA. Such approval processes can take many months if not years.

If viable PFAS alternatives can be identified, best case replacement efforts would require at least 0.5 year of research and require at least €186,000 ($200,000 USD) per material, with a likelihood of successful completion of 75%. Once developed, these formulations would need to go through validation, testing and certifications processes

If no viable PFAS alternatives exist, requiring the development of new materials, a more extensive research effort will be required. This effort would include the following, with the following costs attributable for one member company of our organization:

- *i)* New material discovery, manufacture, and scale up *(€3.7-5.6MM; $4-6MM USD)*
- *ii)* Application development, including material handling, formulation, manufacturing set up, part design, and manufacture *(€75MM; $80MM USD)*
- iii) Extensive testing to ensure the materials, formulations and articles have the critical quality requirements required for the application *(€45-60MM; $48-64 MM USD)*
- iv) Certification and component testing (*€1-3MM; $2-3MM USD)*
- *v)* Change in Design (CID) processing, including engineering and regulatory reviews (*€2MM; $3MM USD)*

For one member company of our organization, the overall research effort is expected to last at least 10 years and cost at least €136-187 MM ($145-200 MM USD).

To reiterate, given the strict qualification and certification requirements in place for A&D products, substitution, of PFAS chemicals would mean that many hundreds of thousands of parts designed, integrated, approved and certified for aviation and other A&D systems would need to go through a requalification process if and when suitable alternatives have been identified. The scale of the substitution effort that would be required based on the current restriction proposal has no precedent as thousands of formulations, parts, components, systems etc. across all A&D products would be in scope. Technical and monetary resources currently engaged in substituting other heavily regulated materials of concern such as hexavalent chromium will get diverted, thus hindering their progress.

The aviation industry has committed to achieving net-zero flying carbon emissions by the year 2050 and increased use of Sustainable Aviation Fuel (SAF) is one of the key enablers being actively pursued. Aerospace OEMS are evaluating and qualifying new SAF pathways for unrestricted use in commercial and military engines. Both blended and 100% SAF are currently being tested for their compatibility with the materials currently in use for aircraft engine oil and fuel systems. These include the seals, O-rings, gaskets, and hoses discussed in section 2.4. If new material is introduced to replace polymeric PFAS, all the testing will need to be repeated in order to ensure compliance with airworthiness regulations. This will be a major setback for the net-zero by 2050 goal.

1.8 Socio economic analysis (SEA) issues

In this section, AIA considers the socioeconomic impacts of a restriction on PFAS as currently proposed where derogations cover some, but not all, aerospace and defense uses. It might be worthwhile to consider the nature of the A&D industry within the REACH member states. The European Commission has summarized the economic impact of aerospace within Europe as follows:

> Air transport makes a key contribution to the European economy, with more than 100 scheduled airlines, a network of over 400 airports, and 60 air navigation service providers. The aviation sector directly employs between 1.4-2 million people and directly or indirectly supports 4.7-5.5 million jobs. Aviation directly contributes more than €110 billion to the European gross domestic product (GDP). Some 900 million passengers departed or arrived at EU airports in 2014. Linking people and regions, air transport plays a vital role in the integration and the competitiveness of Europe, as well as its interaction with the world.[5]

The socioeconomic impacts of the PFAS restriction will clearly depend on its scope as the discussion below explains.

RO1 option – a full PFAS ban: The Annex E report concludes the following with regard to the cost impacts of a total PFAS ban on the Transport sector without appropriate derogations:

> In the event of a full ban, there would be significant disruption to the industry leading to very high producer surplus losses including business closures, which would also lead to substantial employment losses. In the event that it is possible to produce vehicles, there is also a strong likelihood of consumer surplus losses through the sale of vehicles with limited capabilities and reduced reliability.[6]

While this language is direct and alarming, we do not believe it sufficiently captures the scale of costs that the proposed restriction would impose on the REACH member states. The proposed restriction as written would prevent the use or placing on the market of PFAS above certain concentrations in articles. While the restriction's applicability to new articles may be more straightforward, the biggest impact of the restriction would be on aircraft engines flying in and out of the REACH member states. These aircraft—some with 30+ year lifecycles (where PFAS contributes greatly to this longevity due to the strength of the C-F bond) —will continue to require new or refurbished parts that contain PFAS. Removing all PFAS-containing components from these aircraft will require a massive multi-year

[5] See European Commission, Internal market, available at https://transport.ec.europa.eu/transport-modes/air/internal-market_en

[6] Table E.121; page 372.

retrofitting effort. A total PFAS ban within 18 months without appropriate derogations would prevent existing aircraft from getting necessary maintenance and service within the REACH member states. It is not exaggeration to say that this would result in nothing short of a significant disruption, if not a near complete shutdown, of air travel to, from, and among the REACH member states.

Simply put, if no derogations are provided for A&D or other safety critical aspects of the Transport sector, air travel within the REACH member states would not be able to occur compliantly for many years, putting the entire A&D industry within Europe at grave risk. It is not unreasonable to compare such a scenario to the economic impacts of the COVID-19 pandemic impact on the aerospace industry, where global travel slowed to a halt and flights were grounded worldwide. According to a 2023 study by the International Civil Aviation Organization, the pandemic caused total passenger revenues in Europe to decrease €92 billion ($100 billion) in 2020, €81 billion ($88 billion) in 2021, and €37 billion ($40 billion) in 2022, vs. 2019 figures.[7] These figures do not account for the massive job losses and other downstream costs to the EU economy. In short, the restriction as proposed without amendment (including an appropriate derogation accounting for transport safety) would create catastrophic economic impacts on the REACH member states.

RO2 – a PFAS ban but with the proposed derogations, but without the proposed derogation under reconsideration in 6.o: We believe that the discussion above applies nearly equally to the RO2 option without significant revision and without inclusion of a derogation accounting for safety in Transport. The most severe impacts would occur earliest at the time the end of the 18-month transition period when no parts or products containing PFAS or fluoropolymers without a derogation would be allowed to be introduced to the EU market. In the case of A&D products, where every part and component are essential, this means that any one component containing PFAS that cannot be replaced would stop delivery of the entire aircraft or product. In reality, of course, this would be numerous parts and components. However, when considering individual parts and components, such as spares, parts not containing PFAS would be unaffected. But parts containing PFAS and covered by a derogation could still be imported, and those not covered could not be. This situation would shift over time if some PFAS uses are able to be substituted, but at 6.5 years the first tranche of derogations expires and increases the number of parts that cannot be imported. The situation repeats again at 13.5 years with the last tranche of derogations expiring. Of course, the future availability of qualified, validated and certified alternatives for any specific use is not known today, but we can predict with high confidence that there will be some (and probably many) uses where there will not be available alternatives and there will be many PFAS containing parts (especially those with fluoropolymers which we expect to be especially difficult if not impossible to substitute) remaining that could not be imported. Thus, at 13.5 years no PFAS containing spare parts and no products/aircraft could be imported into a REACH member state. Through this entire timeline AIA member companies would be able to continue providing products to customers outside of the EU, but inside the EU newly produced aircraft would be unavailable except for foreign owned aircraft landing at EU airports. It would also place sharp limits on EU military

[7] See ICAO, Effects of Novel Coronavirus (COVID-19) on Civil Aviation: Economic Impact Analysis (April 27, 2023), slide 65, available at https://www.icao.int/sustainability/Documents/Covid-19/ICAO_coronavirus_Econ_Impact.pdf.

interoperability with international treaty partners that rely on fluoropolymers and other PFAS in their defense equipment.

Let's also consider the uses of PFAS. AIA member companies do have some of their own operations based in the EU as well as significant networks of suppliers that produce parts and components (and sometimes full finished products) for products and aircraft that are produced in the US. At the end of the 18-month transition period all uses of PFAS in the EU without applicable derogations would have to cease. However, these same processes could still be performed in the US or other non-EU countries, and AIA member companies would evaluate moving these production processes out of the EU. Shifting large quantities of work would not be done cheaply, so this would be a significant economic impact. Similar to the previous case with importation of PFAS containing parts, there would be two more tranches of activity at 6.5 and 13.5 years when derogations expire for uses without available alternatives.

The situation is similar for maintenance, repair and overhaul (MRO) of aircraft. Non-derogated maintenance activities currently done in the EU would have to shift outside of the EU to continue using PFAS where there are not available alternatives. More maintenance activity would have to shift as derogations expire at 6.5 and 13.5 years. It is unclear under this restriction proposal if a repair that incorporates PFAS into the product (e.g. replacement of a PTFE rub strip) without a derogation would prevent the return of the repaired product/aircraft to service in the EU. In this regard **AIA supports the repair as produced principle where products should be allowed to be repaired as originally designed and produced** (Orgalim)[8].

1.9 Sectors

This comment provides information relevant to the aerospace and defense sector. In the restriction report, A&D is combined with the transport sector. While there are many similarities between A&D and the broader transport sector, products in the A&D sector must meet exacting performance requirements and operate in more extreme environments. Change processes for A&D products are also highly regulated and deliberate to ensure continuity for product performance and safety. For these reasons A&D will likely require different, most likely more and longer, derogations than the rest of the transport sector. Thus, **we suggest that aerospace and defense should be treated as a distinct sector.**

A&D also relies on products from other sectors to be integrated into A&D products. AIA is aware that many of these sectors have already made comments or are planning to make comments to this restriction proposal. We are also aware of individual companies in said sector making supplemental comments. In many cases these comments identify the reliance of A&D (and other sectors) on their products. AIA wishes to emphasize that where a sector does not identify reliance of A&D on their products does not necessarily mean there is not a reliance on their product. It is also important to recall that timelines for A&D to adopt potential alternatives can be very long and potentially exceed estimates of the sectors upon which we rely.

1.10 Emissions and Recycling in the End of Life Phase

The Aircraft Fleet Recycling Association (AFRA) establishes standards and best practices which it uses as a basis for its accreditation program for aircraft disassembly and aircraft materials recycling.[9] Similarly, Tarmac Aerosave is an independent European company actively engaged in decommissioning and recycling.[10] More information about both programs is described in the International Civil Aviation Organization (ICAO) 2019 Environmental Report.[11] Aircrafts are considered valuable assets even at the end-of-life due to the specialized, high performance material contained in them. Comments submitted to this consultation by ASD, provide more information on how commercial aircrafts are stored, recycled and disposed at the end of life. The end-of-life management of military equipment is even more closely managed as is a highly sensitive subject for national security reasons.

1.11 Proposed derogations

With regard to derogations, AIA acknowledges that derogations are proposed for some PFAS uses that are relevant to the aerospace and defense sector. However, not all aerospace uses or sub-uses of PFAS have derogations in the restriction proposal. The list of uses and sub-uses identified by AIA in section 1.5 identifies which uses appear to be "covered" by a derogation and would thus have an additional 5 or 12 years to fully implement alternatives. Many uses, especially of non-polymeric PFAS, do not appear to correspond to any applicable proposed derogation at all. These uses would then have to cease at the end of the transitional period. It appears that most polymeric PFAS uses would fall under a potential 12 year derogation [6.0] under consideration for the broader transportation sector. It is not guaranteed that any of these potential derogations would provide sufficient time to make substitutions in an orderly and carefully controlled manner that is necessary for all our products.

AIA also wishes to reemphasize the importance of highly deliberate change processes that ensure continued operational safety of aerospace and defense products. As described in Section 1.4 substitution timelines can take many years to ensure that all performance requirements are satisfied. Failure to do so can lead to catastrophic results. In the case of substituting PFAS we will need to perform this process many times over for each use that needs to be substituted. We do not yet even know the number of changes (we are still in the process of identifying all uses, and a preliminary listing of uses is provided in Section 1.6 that addresses the specific information request on sectors and (sub-) uses) that would need to be done as a result of this proposed restriction, nor do we have an idea how long each individual substitution would take. But we can say with certainty that 18 months would not be long enough to bring all required aerospace and defense changes through all stages of the process. Where there are longer derogations proposed it is improbable that some substitutions could be completed.

Aerospace Industries Association of America, Inc.
1000 Wilson Boulevard, Suite 1700 | Arlington, VA 22209-3928 | 703.358.1000 | www.aia-aerospace.org

The question then becomes how long would the aerospace and defense sector require to complete substitutions for each use or all uses. This, unfortunately, is unknown at this point. We simply lack all of the information needed to respond here. Among the unknowns:

- Uses and sub-uses of PFAS in the supply chain
- Identity of non-PFAS candidate alternatives to test for each use and sub-use
- Resources required to adequately evaluate all substitutions;
- Whether any particular substitution will be an interchangeable global change or need to be done on a part by part basis

Since the neither the generic 18-month transition period nor the fixed duration derogations are sufficient for aerospace and defense uses and sub-uses, **we propose that a derogation be included for all uses and sub-uses of PFAS chemicals in the aerospace and defense sector**. **The derogation should include technology readiness evaluations to determine whether alternatives are available for any uses and sub-uses and what appropriate adjustments should be made to the duration of the derogation.**

1.12 Potential Derogations Marked for Reconsideration

While we strongly urge the inclusion of a derogation specific to the A&D sector as described above in section 1.9, **we also strongly support the inclusion of the following potential derogation marked for reconsideration: 6.o, "**applications affecting the proper functioning related to the safety of transport vehicles, and affecting the safety of operators, passengers or goods until 13.5 years after EiF." We respectfully provide the following information in support of this potential derogation.

As discussed above, the annual tonnage and emissions of PFAS associated with this sub-use is not possible to quantify at this time. In summary though, we believe that PFAS plays a critical role in ensuring the safety of various components in aircraft and defense.

As explained elsewhere in these comments, the types of PFAS that we have identified serve critical safety functions of heat and fire resistance, fluids chemical resistance, vibration resistance, corrosion resistance, and wear resistance. Many of their uses are described in Table 1 above. Their use qualifies as "applications affecting the proper functioning related to the safety of vehicles, and affecting the safety of operators, passengers or goods."

We estimate that this restriction would directly affect hundreds of different companies in the aerospace industry, including aircraft engine manufacturers and their supply chains, with resulting indirect impacts on airframers, airliners, and their customers. The total number of companies within our industry estimated to be affected by the restriction is estimated to be in the thousands.

We wish to provide comments on the alternatives and cost impact of the proposed restriction on the A&D portion of the Transport sector and particularly on the PFAS sub-use relating to applications

Aerospace Industries Association of America, Inc.
1000 Wilson Boulevard, Suite 1700 | Arlington, VA 22209-3928 | 703.358.1000 | www.aia-aerospace.org

affecting the proper functioning related to the safety of vehicles.[12] The Annex E report concludes the following with regard to the availability of alternatives to PFAS within the Transport sector:

> The transport sector has an extremely high dependence on PFASs, including use in complex products (e.g. seals, O-rings and gaskets in engines). The properties of PFASs can provide input to the design of such products, with the result that drop-in substitutes will not always be available. Even where they are, testing and certification procedures would need to be followed. It is therefore concluded that a full ban is not feasible for the transport sector and that substitution potential is low.[13]

We agree with this statement but wish to reiterate that for the formulations and articles discussed above, there are currently <u>no</u> available PFAS-free alternatives for such products on the EU market (or elsewhere globally) that we have yet been able to identify. The concern is particularly acute in the context of aerospace servicing and manufacturing given the rigorous safety and qualification process that are required of any changes to engine design and specification. Please see the discussion in Section 1.8 concerning the socioeconomic impacts of a restriction without inclusion of this potential derogation. As described in Section 1.5 alternatives for fluoropolymers (and PFAS) are not available because R&D into potential alternatives has only just begun. This will be a complex and expensive process. As alternatives are not yet available we do not have information to provide regarding cases where substitution is technically and economically feasible or where substitution is not technically or economically feasible.

2 Aerospace PFAS Use Examples

The following section provides more commentary on several of the uses and sub-uses presented in Table 1. Where possible, we have added information on describing the use(s) in A&D applications, key functionalities, the current state of knowledge on alternatives and adequacy of any potential derogations. It is noted that not all uses in Table 1 are covered here and those not included should not be considered as less important to the A&D sector.

2.1 Fire Suppressing Agents

In general, there are many classes of fire suppressing agents including water, inert gases, carbon dioxide, and vaporizing liquids (referred to as Clean Agents in NFPA nomenclature. Clean agents extinguish fires rapidly, leave no residue, are efficient (i.e., they have excellent space/weight characteristics) and are safe to use where humans are present. For this reason, they are required for protection of high-value assets, e.g., computer rooms, nuclear power plants, aviation and military applications.

There are two main approaches to extinguish fire: either fill the entire space with the required amount of fire extinguishing agent, a process known as "total-flooding", or directing the fire extinguishing agent at the source of the fire (if it is known), a process called "local application or streaming".

A class of halogenated hydrocarbons or halons were identified as particularly effective in a joint study by Purdue University and the US Army[14]. Halons were fully commercialized in the 1970's and formed the mainstay of clean agent fire protection of over 20 years until they were implicated in ozone depletion. Under the Montreal Protocol, production of halons ceased in 1993 in developed countries and 2010 in developing countries.

For total flooding applications bromotrifluoromethane (CF3Br, Halon 1301) was preferred, whereas for local application bromochlorodifluoromethane (CF2BrCl, Halon 1211) was preferred.

However, the need for fast, effective, clean agents had not gone away and the fire protection industry has been developing alternatives to halon for the last 30 years. Alternatives including HCFCs, HFCs, inert gases, and a perfluoroketone were developed as clean agents for total-flooding applications and HCFCs, HFCs and 2-bromo-3,3,3-trifluoropropene were developed as streaming agents.

More recently, HCFCs are subject to a phase-out under the Montreal Protocol, and since the issue of global warming, HFCs are being phased down, e.g., under the EU F-gas regulations.

This leaves aerospace and military fire protection in a difficult situation. The proposed PFAS regulations remove all candidate agents, apart from halons, CF3I and HFC-23. The specific implications for aerospace and military fire protection applications are discussed in the following section.

---

[14] Purdue Research Foundation and Department of Chemistry. "Final Report On Fire Extinguishing Agents for the Period September 11, 1947 to June 30, 1950." Purdue University, West Lafayette, IN, July 1950.

2.1.1 Fire extinguishers used on-board aircraft

2.1.1.1 Description of Use

In commercial aircraft fire suppression agents utilizing Bromochlorodifluoromethane (Halon 1211) or Bromotrifluoromethane (Halon 1301) have been used in 4 main systems described below.

Application	Historic Use	Replacement
Handheld	Halon 1211	The most common non-halon handheld fire extinguisher agent that is in use on commercial airplanes is 2-BTP (CF3CBr=CH2). Replacements have been ongoing since 2019. 2-BTP is PFAS according to the definition in this restriction proposal. The only non-PFAS alternative would be to revert to using Halon 1211. However, this would be in contradiction of the EC Regulation 1005/2009 as amended by (EU) 744/2010.
Cargo	Halon 1301	A blend of CO2 and 2-BTP is the leading candidate for cargo applications. 2-BTP is a PFAS according to the definition in this restriction proposal. Non-PFAS alternatives in the form of water mist plus inert gases or inert gases alone have been evaluated but these approaches would entail significant space and weight penalties as well as a more complex certification approach.
Lavatory	Halon 1301	HFC-227ea (CF3CHFCF3) and HFC-236fa (CF3CH2CF3) have both been used as replacements for Halon 1301 in lavatory waste compartment fire protection[15]. (PFAS) There are no other clean agents that are not classed as PFAS. CF3I is precluded owing to its toxicity profile. The only non-PFAS alternative would be to revert to using Halon 1301. However, this would be in contradiction of the EC Regulation 1005/2009 as amended by (EU) 744/2010.
Propulsion	Halon 1301	CF3I is the top candidate for propulsion applications. (Not PFAS)

The ozone depletion and global warming potential of the traditional CF3Br (Halon 1301) suppression agent necessitated the development of suppression agents. The alternative agents have not as yet been successful at suppression in all circumstances, but the one thing they all have in common are carbon-fluorine bonds. This is of particular importance for fire suppression because even after the donation of a more loosely-bound halogen like iodine or bromine to the catalytic flame suppression reaction, the base molecule must remain stable in the hot environment. The base molecule must also have little or no bonded species that can be oxidized to CO2 and water as this would promote rather than suppress flame. The combination of carbon-fluorine bonds (with their inherent stability) and carbon bonded to another catalytic halogen (e.g., bromine), provides suppression of flames which are the primary driver of fire spreading to new fuel sources.

For gas phase fire suppression chemicals to work they must either absorb heat or release an atomic species that will catalytically quell the flame front, or both. The binary agents are combinations of these two methods using CO2 to absorb heat and a molecule that will release bromine atoms (the catalytic

[15] https://www.icao.int/Meetings/a41/Documents/WP/wp_096_en.pdf

agent). The molecule that releases bromine at the flame front must be stable enough to survive the trip to the flame front at high temperature. Current methods include the use of chemicals such as 2-BTP (2-bromo-3,3,3-trifluoroprop-1-ene), here the inherent strength of the carbon-fluorine bond is utilized to gain enough molecular stability to release the bromine at the flame front. There are still two hydrogen-carbon bonds that can be oxidized in the fire which is why this chemical cannot be used on its own (i.e., without CO2). Without carbon dioxide the 2-BTP is oxidized in the gas phase by gas phase fuel fires; which is not acceptable for mixed fuel fires such as aircraft cargo fires.

2.1.1.2 Key functionalities

Required functionality generally includes the following.

- Ability to extinguish fires,
- material compatibility (e.g. with materials found on aircraft),
- toxicity,
- low ozone depletion,
- low global warming potential
- weight

2.1.1.3 Availability, technical and economic feasibility, hazards and risks of alternatives

The only current alternative for 2-BTP would involve reverting to Halon 1211 for handheld fire extinguishers. As previously stated, Halon is not an acceptable nor available alternative.

- Subject to Montreal Protocol,
    - Ozone-depleting substance
    - High global warming potential
    - Global production has ceased
    - Subject to phaseout in 2025 under EC Regulation 1005/2009 as amended by (EU) 744/2010.
- Limited available global supply

2.1.1.4 Status of R&D where alternatives not available

Fire suppression is also an example of there not being a universal answer when seeking a chemical solution to an environmental problem. In the last four years several experiments in a full-scale fire suppression test facility have shown that a different set of chemical constraints are important to the function of fire suppression materials.

Two "not-in-kind" technologies have been extensively evaluated.

Inert gas, either used alone or combined with water mist has been shown to be capable of extinguishing the types of fires encountered in cargo compartments. However, the space and weight requirements for a high-pressure inert gas system are prohibitive. An AIA member company has proposed inert gas on numerous responses to Requests for Information (RFIs) or Requests for Proposal (RFPs), and on each occasion the aircraft OEM was not able to integrate the much larger and heavier system into the airplane. Inert gas systems have also not been tested to the latest FAA/EASA Minimum Performance Standard test.

CF3Br vs. CF3I has been extensively investigated. Iodine is next down in the halogen column from bromine. The C-I bond is less robust and thus the CF3I molecule has a much shorter half-life in the atmosphere (on the order of days). However, one step down the periodic table was too large a jump in bond strength. CF3I failed to suppress a smoldering cargo fire and decomposed via several free radical mechanism to CO2, I2 and HF (hydrofluoric acid) which is not the desired outcome. For liquid fuel fires CF3I is quite effective when applied directly on the fire, and it can also suppress fires caused by exploding aerosol cans in the cargo hold of an aircraft. But it cannot control a smoldering fire due to the low bond energy of the C-I bond.

Binary fire suppression agents are now being tested. These combine CO2 and other agents to achieve desirable performance in the case of a fire, but they weigh more and require more complex suppression system designs that are also heavier than those for a single component suppression agent. However, the blend of 2-BTP/CO2, as noted above, is the leading agent to replace Halon 1301 in cargo compartments.

While CF3I is a non-PFAS alternative being explored for propulsion applications it has been ruled out for cargo applications. It was evaluated thoroughly in 2019, and failed the smoldering fire test. It has not been considered as a candidate an alternative for handheld or lavatory applications because of its toxicity profile. Handheld and lavatory fire protection applications are in areas where people are present, and the use of CF_3I would exceed maximum safe concentrations.

2.1.1.5 Information on substitution where alternatives are available

The only area of fire protection where a non-PFAS is being considered is that for propulsion / APU, where CF3I is one of the agents being evaluated. CF3I has passed the minimum Performance Standard

2.1.1.6 Socio-economic impacts

The proposed restriction includes a derogation for “clean fire suppressing agents where current alternatives damage the assets to be protected or pose a risk to human health until 13.5 years after EiF”. This will have the effect of delaying the eventual outcome of a non-use scenario. The continued use of Halon 1301 would create a crisis of its own, as global supplies are projected to run out as soon as the mid-2030s. This would leave airlines with two very untenable choices – continue to use Halon 1301, which would require a change to the Montreal Protocol to allow new production as recycled Halon 1301 can no longer address demand, or switch to the 2-BTP/CO2 blend, which would be restricted and require removal in approximately 2038. The two are not interchangeable without a significant airplane modification. The uncertainty created by the proposed restriction will prevent adoption of the halon alternative, which will increase the chance of a requirement to produce new Halon 1301 or ground the European airline fleet.

2.1.2 Conclusion and adequacy of proposed/potential derogations

Substitution of Halon fire suppressants has been time consuming and difficult to complete. Original development efforts began in 1990 for all 4 main applications. Lavatory applications were successfully substituted starting in 2006. Substitution of handheld fire extinguishers began in 2019. As noted previously, efforts for cargo and propulsion are still ongoing meaning the overall substitution timeline to

Aerospace Industries Association of America, Inc.
1000 Wilson Boulevard, Suite 1700 | Arlington, VA 22209-3928 | 703.358.1000 | www.aia-aerospace.org

move away from Halon will be greater than 25 years, assuming the current candidates are successful. Considering the challenges and time duration to get to this point, it is not unreasonable to conclude that substitution with non-PFAS, non-Halon, alternatives meeting all requirements would take much longer than 13.5 years, if an alternative can be identified at all. Recalling the bond energies carbon-fluorine compared with other carbon-halogens, new non-fluorinated chemicals with low GWP are not currently foreseen and 13.5 years is inadequate. We cannot predict if or when a new candidate will become available to test, so it would not be prudent to suggest a different duration. We also acknowledge that requesting a permanent derogation for this use may not be palatable for certain parties. Rather, we would suggest an open-ended review period with periodic technology review checkpoints.

2.1.3 Fire extinguishers used in military fighting vehicles

Many of the arguments presented in Section 2.1.1 above are equally applicable to military vehicle fire protection, so will be summarized briefly here. The requirements for military applications are in some ways more demanding and HFCs remain the only viable extinguishing agent type, other than halons, for military vehicle protection.

In the military environment large fast-growing fires can be encountered. In the case of military vehicles, the extinguishing system in crew compartments is required to extinguish an explosion in an occupied space very rapidly (<150 milliseconds). If the extinguishment takes any longer than this there is a risk of burns to the vehicle occupants. The extinguishing agent must be safe to use at its design concentration, must generate acceptable levels of decomposition products, and also provide protection against reignition. In addition, the extinguishing agent is required to provide protection across a wide temperature range. Currently only HFC agents (HFC-227ea and HFC-236fa) can meet these exacting criteria. Both of these are classified as PFAS.

Considering the alternatives to HFCs: Water freezes, so it does not meet the temperature specifications and is therefore not an option. Whilst the addition of antifreezes can prevent freezing, the nature of the fire means that a gaseous agent is required to prevent the fire re-igniting. Water has been extensively tested and it has been shown that fire can reignite, which means that water-based fire extinguishing agents are not appropriate for military vehicle fire threats. Inert gases require too much space and weight and are therefore also not appropriate for military vehicle fire threats.

The only other current alternatives are Halons 1301 and 1211. However, these have high ozone depletion potentials as well as high global warming potentials. Reverting to halons would be considered as a “backward step” as well as being in contradiction to EC Regulation 1005/2009 as amended by (EU) 744/2010.

2.2 Hydraulic fluid

Commercial airplane hydraulic power systems are used for actuation of primary and secondary flight control surfaces, extension and retraction, steering, and brakes for landing gear systems, cargo doors, engine thrust reversers, and other services requiring precise control of large operating loads. Military airplane hydraulic systems share commonality with commercial type services where applicable, but include many others such as: weapon bay doors, drives for guns and the delivery of missiles and other ordnance material, aerial refueling equipment, auxiliary power unit (APU) start systems, catapult and arresting hooks, radar antenna, and emergency generator drives. Missile, rocket booster, and space vehicle hydraulic systems are used primarily for controlling vehicle flight path by vectoring engine thrust and controlling aerodynamic surfaces. Helicopter hydraulic systems are used for controlling the rotor swashplates in both the cyclic and collective pitch modes, for stability augmentation servos, tail rotor blade pitch control, hoist winches and cargo hooks, landing gear retraction, brakes, steering, and APU and engine starting.

2.2.1 Key Functionalities

The control of streaming potential (movement of ions in hydraulic fluids that cause electrochemical corrosion) is done by the use of polyfluorinated surfactants. These surfactants also increase the lubricity (lowering friction) of the hydraulic fluid that limit wear on safety critical components of the hydraulic systems in aircraft, space vehicles and submarines as well as all other hydraulic systems that use non-flammable hydraulic fluids.

One of the important factors in designing any hydraulic system for aerospace applications is its weight contribution to aircraft. Lower weight of the hydraulic system provides higher fuel efficiency and less global warming gasses are released during flight of aircraft and space vehicles. To lower the overall mass of the hydraulic system, smaller, lighter tubes and components are used, but this requires the hydraulic fluid to be pumped at higher pressures. In so doing the overall volume of hydraulic fluid in the system is also reduced. In order to smoothly control the aircraft or space vehicle, the pressure must be reduced at the electrohydraulic servo valve (EHSV). While reducing pressure, streaming potential becomes a larger and larger problem as the pressure of the hydraulic system increases. In order to solve problems associated with the operation of the EHSVs at higher and higher pressures, more polyfluorinated surfactant has been needed. The unique characteristics of the carbon-fluoride bonds in these surfactants, accounts for their ability to both provide the lubricity needed under the extreme conditions in the hydraulic pump, and in their ability to quell streaming potential. The combined low acid production along with these other attributes make this surfactant irreplaceable in high pressure hydraulic fluids today.

Please also refer to the comment submitted by ExxonMobil which provides a thorough description of the erosion mechanism.

Required functionality generally includes the following.

- Must be able to operate at high pressure (e.g. 3,000 -5,000 psi)
- Minimize streaming potential that leads to electrochemical corrosion
- Low corrosion / erosion rate

2.2.2 Alternatives and Conclusion

One supplier of aerospace hydraulic fluids reports that non-fluorinated erosion inhibitors have been tested in past decades with less severe system designs, but that no potential replacement chemistry has been identified with adequate stability to survive in hydraulic fluid in aircraft service. Considering that decades of testing have not yet yielded any promising non-PFAS results, we are not confident that a promising candidate will be identified soon. However, any future promising candidate that is identified must successfully progress through the entire change process described in Section 1.7. Because of the importance of hydraulic fluid systems for flight control, functional testing necessary for validation and certification is expected to be extensive and affect the overall timeline for substitution significantly.

The proposed restriction includes a derogation for "additives to hydraulic fluids for anti-erosion/anti-corrosion in hydraulic systems (incl. control valves) in aircraft and aerospace industry until 13.5 years after EiF". Considering the discussion above, we lack certainty if this derogation is long enough, and a derogation with periodic evaluation of the availability of current technology is requested.

2.3 Coatings – Organic finishes

Organic finishes are an important category of uses for the aerospace and defense sectors. As in other sectors, coatings impart important functionality to the parts to which they are applied. Due to their strong influence on safety and reliability of the product, organic finishes are closely controlled by Government/military standards, Federal regulations, and OEM material and process specifications. Organic finishes are used on materials for environmental protection and for aesthetic appearance. They include primers, topcoats, and certain specialty coatings. The selection of finishes is usually predetermined or limited by contractual or product model finish specifications. Selection of finishes begins with the identification of finish requirements as determined by the following:

- Function of the coating
- Contractual or product requirements
- Required operating environments
- Manufacturing and handling environments

Fluorinated compounds may be used in coatings as wetting, leveling, and dispersing agents, and have been used to improve gloss and antistatic properties. They can also be used as process aids when producing individual ingredients that make up the paint, such as when grinding pigments or to improve pigment miscibility. It only been recently reported that fluorine components could be used in a paint formulation as a proprietary ingredient, so if present they may not be documented in the Safety Data Sheet. Both polymeric as non-polymeric PFAS may be used in organic coatings and finishes.

2.3.1 Non-polymeric PFAS in organic finishes

Non-polymeric PFAS use identified in organic finishes is primarily used as a solvent. The primary constituents are Benzene, 1-chloro-4-(trifluoromethyl)- (CAS 98-56-6) and 1,1,1,2-Tetrafluoroethane (CAS 811-97-2).

The purpose of organic solvents in a coating formulation is to dissolve the polymeric chains of the resin and other ingredients and produce a homogeneous liquid to allow acceptable application of the coating to the base material. The organic solvent will diffuse through and evaporate from the applied coating film after application and will not contribute to the film polymerization. In essence, solvents or thinners are added to the paint formulation to dissolve the solid ingredients of the paint formulation so they can be applied as a uniform aesthetically pleasing film that meets desired performance.

The key functionalities of solvents in any coating or organic finish are to:

- Reduce and control coating viscosity so that the coating can be applied to the base material
- Control evaporation and diffusion rate to allow uniform and continuous film formation, free of film defects when the coating cures
- Contributes to wetting of the applied paint to the base material. Improved wetting means better adhesion.

2.3.2 Polymeric PFAS in organic finishes

Polymeric PFAS additives are incorporated into coating formulations that typically comprise significant amounts of components that do not contain fluorine. The purpose is to add or enhance properties imparted by fluoropolymers that are not necessarily present in these coatings.

Additives may be in the form of an aqueous dispersion or by addition of polymeric PFAS particles to the coating matrix.

Key properties given (or improved) by addition of polymeric PFAS to coatings generally include

- Reduction in wear, mar, and scratching
- Reduction in friction
- Improved release properties
- Water and oil repellency

Specific coatings may be optimized for one or more of these or other properties.

2.3.3 Sub-uses and Key functionalities

Organic finish coating formulation usually contains solvent, resin (binder), pigment, filler, and additives. When applied to the underlying substrate, they provide a continuous coating that prevents cracking and structure breakdown during the service due to exposure to various environmental conditions.

Organic finishes are applied to various substrates including metals, plastics and composites. The first coating is typically the primer which can provide corrosion resistance to substrates, and to effect adhesion of subsequent finish coats where finish coating is required. Primers are usually selected as one of the elements of a finish system that can entail metal surface finishing (e.g. anodizing, conversion coating, plating, etc.), priming and application of a topcoat. The elements of a finish system vary based on the specific requirements and service environment of a part or component within an aerospace end product. Both polymeric and non-polymeric PFAS are present in organic coatings used in the A&D sector.

In cooperation with IAEG, AIA has identified a number of sub-uses for this category. These are listed in Table 2 along with an indication of what type of PFAS they contain.

Table 2 Uses of PFAS in coatings

Organic finish /coating	**Non-polymeric PFAS**	**Polymeric PFAS**
Primer	x	
Topcoat	x	x
Abrasion resistant coating		x
Aluminized coating		x
Conductive/RF coating	x	

Erosion resistant coating	x	x
High temperature resistant coating	x	
Temporary protective coating	x	
Conformal coating	x	
Fluorocarbon bonding preventative		x
Adhesion promoter for polysulfide and polythioether sealants	x	
Hydrophobic coating	x	

Primers. Primers are applied to various substrates including metals, plastics and composites. On metallic substrates they are formulated to provide corrosion resistance to substrates, and to effect adhesion of subsequent finish coats where finish coating is required. Primers are usually selected as one of the elements of a finish system, which generally includes metal surface finishing (e.g. anodizing, conversion coating, plating, etc.), priming and application of a topcoat. The elements of a finish system vary based on the specific requirements and service environment of a part or component within an aerospace end product.

Key functionalities

- Corrosion resistance
- Adhesion
- Hardness
- Resistance to chemicals, fluids, humidity, impact, temperature
- Compatibility with other layers

Topcoats. Topcoats are applied as the final finish process to complete the required environmental protection, and/or to provide the required visual characteristics, and/or provide other required special surface characteristics. Topcoating is not always required on permanently installed hidden or obscured items provided that the base material or primers are capable of furnishing the required environmental protection or special surface characteristics. Topcoats are usually selected in conjunction with the proper primer(s) to comprise a finish system.

Key functionalities

- Adhesion
- Hardness
- Resistance to chemicals, fluids, humidity, temperature, UV light or other end-use environment
- Compatible with other layers
- Camouflage
- Chemical agent resistance
- Abrasion resistance

Abrasion Resistant Coating. This coating produces a very smooth surface with high flexibility, impact resistance and lubricity. In situations where the bearing loads are light, it is effective in minimizing the effects of rubbing. These coatings are applied only in the localized area where rubbing will occur in service, such as surfaces that mate against seals.

Key functionalities

- Adhesion
- Abrasion resistance

Aluminum Pigmented Coatings. Aluminum pigmented coatings are used on metallic fasteners. They are formulated to prevent galvanic corrosion and provide aerospace fasteners with lubrication properties.

Key functionalities

- Corrosion resistance
- Appearance

Conductive/RF Coating. Conductive coating consists of a base resin with conductive pigment and a curing agent. Also known as anti-static coatings, they are applied to nonconductive (for example, fiberglass and other plastics) surfaces. They are intended to facilitate the discharging and positive grounding of static electrical charges to the primary structure.

Key functionalities

- Electrical conductivity/resistivity
- EMI/RF performance
- Flexibility
- Adhesion
- Compatibility with other layers

Erosion Resistant Coating. A specialty coating or coating system used to protect surfaces of parts susceptible to rain and sand erosion or damage. Erosion resistant coatings are applied to leading edges of aircraft components flaps, stabilizers, radomes, and engine inlet nacelles, as well as surfaces like helicopter blades and wind turbine blades. Resin formulations of both polyurethane and fluoropolymers are commonly used to meet rain erosion performance criteria.

Key functionalities

- Resistance to erosion by rain and sand
- Flexibility
- Impact resistance
- Weathering and moisture resistance
- Adhesion

High Temperature Coating. Used in higher temperature environments without damage to the coating or underlying structure.

Key functionalities

- High temperature resistance
- Adhesion

Temporary Protective Coating. Used to temporarily protect parts, components, structures etc. from environmental damage during manufacturing or maintenance. The coating is applied when the following step is not performed immediately and protection is required.

Key functionalities

- Corrosion resistance
- Removability

Conformal coating. Conformal coatings are insulating protective coatings, which conform to the configuration of the object coated. Used as a protective layer and encapsulant on in electronics on printed–wiring assemblies (PWAs). It is generally accomplished with an organic resin applied by dipping, brushing or spraying and is generally 0.003 to 0.01 inches thick.

Key functionalities

- Abrasion resistance,
- Electrical insulation
- Environmental isolation.

Fluorocarbon bonding preventatives.

Used to reduce friction and increase slippage between silicone rubber filler compounds and rotating aircraft engine components.

Key functionalities

- Adhesion
- Compatibility to substrates

Adhesion promoter for polysulfide sealants and polythioether sealants. The use of an adhesion promoter can significantly enhance the adhesion and bonding characteristics of polysulfide and polythioether aircraft sealant to a desired substrate. In addition, the use of adhesion promoter can sometimes compensate for surfaces that are difficult to access and may not have been adequately cleaned and prepared. This is especially applicable to repair purposes or when bonding to surfaces that are aged and have already been exposed to fuel and other fluids.

Key functionalities

- Adhesion of sealants to substrates

Aerospace Industries Association of America, Inc.
1000 Wilson Boulevard, Suite 1700 | Arlington, VA 22209-3928 | 703.358.1000 | www.aia-aerospace.org

Hydrophobic coating. Hydrophobic coatings are carbon-based coatings that utilize a high surface tension pigment, such as Teflon, to repel water from the surface. Fluorinated coatings also perform as hydrophobic coatings. The purpose of hydrophobic coatings is to cause water droplets that form on the surface to bead up and roll off similar to a freshly waxed car. Hydrophobic coatings are predominantly used as radome coatings, windshield coatings, or other surfaces where it is not desirable for water to easily wet.

Key functionalities

- Hydrophobicity
- Adhesion

2.3.4 Status of R&D where alternatives not available

We are not aware of active research and development activities to reformulate coatings using polymeric and non-polymeric PFAS. While AIA is not aware of active efforts to replace PFAS as solvent in existing already approved coatings, we are aware of efforts to proactively reformulate candidate coatings being developed for other aerospace projects and thus avoid the future use of PFAS solvents in these cases. It is still too early report on the success of these efforts. The specific substances being evaluated are proprietary to the formulators and cannot be disclosed at this stage.

For the replacement of polymeric and non-polymeric PFAS, a coating must be fully evaluated through all maturity stages (e.g. development, qualification, validation, certification, industrialization) described in Section 1.7. OEMs will rely on formulators to propose PFAS-free candidates for testing. We question whether formulators would be able to efficiently develop and propose alternatives for all affected materials to be tested by OEMs, and whether OEMs would have the capacity to test many candidates. Under current circumstances, full evaluation and substitution of reformulated coatings may take a couple years in the best cases or much longer where multiple iterations are required. However, if the PFAS restriction becomes final, the number of reformulations that need to be evaluated concurrently will increase significantly, use up available testing capacity and result in increased backlogs and timelines.

2.3.5 Conclusion

Non-polymeric PFAS used as a solvent would be expected to flash off during curing leaving an applied coating without PFAS. We do not have information on whether the applied coating would meet the proposed 25 part per billion concentration limit. If it did meet this limit, one option could be to apply coatings outside of the EU. In this scenario, production, maintenance and overhaul work would have to be done outside of the EU. The resulting non-use scenario would be similar to non-use scenarios described in aerospace and defense Authorisation review reports for chromate uses recently submitted by the Aerospace and Defence Reauthorisation consortium (ADCR).

The use of non-polymeric PFAS in coatings is not addressed by any proposed or potential derogation in the restriction proposal. As such, the transition period would be 18 months after entry into force as currently proposed. This short transition period would not allow sufficient time to fully substitute these coatings.

The use polymeric PFAS in coatings in A&D applications are potentially covered in the restriction proposal under: 6.o [applications affecting the proper functioning related to the safety of transport vehicles, and affecting the safety of operators, passengers or goods until 13.5 years after EiF]

Aerospace Industries Association of America, Inc.
1000 Wilson Boulevard, Suite 1700 | Arlington, VA 22209-3928 | 703.358.1000 | www.aia-aerospace.org

2.4 Seals

Several high-performance fluoropolymers and fluoroelastomers such as FKM, FVMQ, FFKM and PTFE are used as material for O-rings, seals for valves and gaskets, face seals, hose liners, bearing seals, seals for electronic devices and nut seals etc. A large majority of these are used in the oil, fuel and air systems of aircraft engines. These materials have a long history of successful and safe use in commercial and military aircrafts. The use of these materials is governed by requirements set by industry specifications as well as airworthiness regulations. Fluoroelastomers, such as those meeting the requirements of SAE Aerospace specifications AMS7287 and AMS7257, are used to provide sealing of aircraft fluid systems such as aircraft engine oil and aircraft jet fuel. Fluoroplastics, such as those meeting the requirements of SAE Aerospace specification AMS3678, are used to support fluoroelastomer seals and to function as bearings in aircraft engine oil and aircraft jet fuel systems. These fluoroelastomers and fluoroplastics provide a combination of long-term compression set resistance at elevated temperatures and resistance to aircraft engine oils and aircraft jet fuels that are not available with other polymers. The temperatures experienced in some sealing locations in aircraft engines are well above 200°C and sealing materials other than fluoroelastomers are inadequate under these conditions.

2.4.1 Key functionalities:

Fluoropolymer based materials are vital in providing the following key functionalities to seals, O-rings and gaskets

- Friction and wear properties
- Mechanical strength
- Resistance to aircraft engine oils, jet fuels at elevated temperatures
- Resistance to other chemically aggressive fluids such as hydraulic fluids, de-icing agents, cleaners
- Electrical insulation
- Heat and flame resistance

2.4.2 Alternatives

We are not aware of active research and development activities on non-fluoropolymer-based materials for A&D seal applications. Replacement materials, once developed by formulators must be fully evaluated through all maturity stages (e.g. development, qualification, validation, certification, industrialization) described in Section 1.7. They will require varying levels of component tests and engine tests to establish functionality & durability. These include, but are not limited to required component/system testing to show equivalent levels of performance for various parameters including:

- Thermal resistance
- Pressure resistance
- Geometry (stretch, squeeze, gland depth, seal profile, etc.)
- Material properties (hardness, set etc.)
- Material compatibility (fluids, metals, electrical resistance, etc.)

Current designs use seal/hose geometries established based on operational experience with fluoropolymers and new/alternative materials may also require updated or new geometric design standards.

Potential alternatives to aerospace seal materials made of perfluoroelastomers have been presented in a report compiled by Dupont (EPPA, *'Submission document for public consultation of potential restriction of the per- and polyfluoroalkyl substances (PFAS) related to precision polymeric parts and shapes used in high performance industrial operating environments'*). Data presented in the report show that non-fluoropolymer-based materials such as Hydrogenated Nitrile Butadiene Rubber (HNBR) and Silicone (VMQ), while comparable in some properties, are not able to offer the complete set of characteristics provided by fluoropolymers. Similarly, for wear strips, molded shapes and seals made of fluoropolymers a number of alternatives including bronze, steel, polypropylene, polyvinyl chloride (PVC), polyether sulfone and others are shown to fall short in their ability to meet all requirements.

Other polymers which have been used in aircraft fuel systems in the distant past, such as nitrile polymers, do not have the long-term, high temperature compression set resistance required by today's high efficiency aircraft engines. Substitution of fluoroelastomers with these inferior polymers would result in inefficient aircraft engines with poor durability and increased maintenance.

2.4.3 Conclusions and Adequacy of proposed derogation

The use of fluoropolymers as material for seals in A&D applications are potentially covered in the restriction proposal under: 6.o [applications affecting the proper functioning related to the safety of transport vehicles, and affecting the safety of operators, passengers or goods until 13.5 years after EiF].

In addition to the unmatched properties of the fluoropolymers, the number and variety of applications that employ fluoropolymers will make the identification and qualification of alternatives an immense task, making an extended duration derogation absolutely essential. As mentioned above, there are no alternatives currently available and the testing required for any new material will be extensive.

2.5 Wires, Cables and Optical Fibers

Wires, cables and optical fibers are extensively used in aircrafts, satellites, radars and other A&D systems. They serve to provide a network of reliable electricity and signal transmission to control communications; safety and mission critical systems including flight controls. A single aircraft, satellite, or vehicle will have numerous cables and cable assemblies, each with unique performance requirements based on its specific use in a complex system. Cables and Cable Assemblies used in A&D applications must operate reliably over a long product life cycle that can reach beyond 30 years.

Different types of polymeric PFAS such as PTFE, FEP and PFA are used in aerospace wire insulation applications. In most cases their use is required by standards due to their superior performance for mechanical strength, electrical insulation, heat and flame resistance and chemical resistance.

Fluoroplastics, such as those meeting the requirements of SAE Aerospace specifications AS23053/11, AS23053/12 and AS23053/13, are used as heat-shrinkable tubing to provide mechanical protection and electrical insulation for electrical wiring in aircraft electrical systems. These fluoroplastics provide a combination of mechanical strength, electrical insulation, heat and flame resistance, and resistance to aggressive aircraft fluids that are not available with other polymers. Fluoroplastic electrical insulation, such as that used to meet the requirements of SAE Aerospace specification AS22759/11, is used to coat electrical wiring to provide electrical insulation in aircraft electrical systems.

2.5.1 Key functionalities

Key performance requirements for wires, cables and optical fibers in A&D include:

- Thermal resistance over a wide range of operating temperatures

Cables experience a wide range of operating temperatures from extreme conditions in varied climates, to low temperature at high elevation during flight and the extremes of space. This may range from temperatures below -100 °C for some space applications to greater than 150 °C.

- Dielectric constant (εr)

Dielectric constant is an important material characteristic which relates to the ability of the material to store electrical energy in an electrical field. Low dielectric constant values are necessary for high frequency or power applications to minimize electric power loss, enabling precise, consistent, and efficient signal transmission.

- Chemical resistance

The material must perform its function in harsh conditions and provide chemical resistance to oils, aircraft fluids, fuels, and other chemical substances.

- Mechanical strength and flexibility

The wires and cable materials must be highly durable and withstand frequent/rapid flexing, torsion, and pulling without compromising electrical performance under demanding environments (e.g., extreme temperatures).

- Low coefficient of friction

The cable insulation and jacket layers must have a low coefficient of friction in order to decrease abrasion under continuous flexure and movement and during installation in aircraft and other systems.

2.5.2 Alternatives

To operate in harsh and extreme conditions, cable applications need critical properties that only a small subset of potential materials can provide. Submissions to this consultation by various entities including W.L. Gore (# 6301), Dupont (# 4530), Amo Special cables (# 4479) present thorough analyses of the state of alternatives.

Some of the alternative polymers and their shortcomings for A&D applications are outlined below:

- *Polyimides* – lack of flexibility, high dielectric constant and stiffening under humidity
- *Polyesters, Polyethylene, Polyurethanes* - limited by maximum use temperatures and drop in performance over 80 °C. Further they would require the addition of flame retardants most of which are of regulatory concern
- *Silicones* – limited due to their high dielectric constant which leads to poor performance in signal transmission cables
- *Polyvinyl chloride (PVC)* – lack of chemical resistance and low abrasion resistance

2.5.3 Conclusions and adequacy of proposed derogations

From numerous comments made in response to the current consultation from electronics and semiconductor suppliers (and their representative trade associations), it is apparent how critical fluoroplastics are in developing and supporting A&D products, including aircraft, ground and test equipment and many other A&D products that depend on electricity for their proper functioning. As such, the US A&D industry is greatly concerned about the continued supply and cost of electronics products impacted by the final restriction.

Aerospace Industries Association of America, Inc.
1000 Wilson Boulevard, Suite 1700 | Arlington, VA 22209-3928 | 703.358.1000 | www.aia-aerospace.org

2.6 Refrigerants

Refrigerants are used in refrigerators, chillers and freezers in aircraft galleys and in liquid cooling refrigeration units for cabin and cargo air conditioning. In defense applications, refrigerants are used in radars, operator shelters and defense vehicles.

Fluorocarbon based refrigerant gasses have been in use in Aerospace and Defense equipment for over 10 years, principally as a replacement for Freon (HCFC-22 and R-22, typically) as a result of the ban on such substances more than a decade ago. These fluorocarbon-based refrigerants (HFC-134A, HFC-125) have proven to be functional in providing reliable and safe alternatives. In order to optimize the necessary thermal cycle however the integration of the fluorocarbon-based refrigerants involved significant redesign of the hardware. Further the Aerospace Industry has not yet identified a substitute for HFC134a that would satisfy the FAA and DoD certification criteria, and in particular a substitute with the low flammability properties of HFC-134a.

Since 2010, our new products have been specifically designed and sized for HFC-134a and HFC-125 fluorocarbon based refrigerants being utilized. As weight/volume is critical within aircraft/spacecraft, this optimization is required to meet both size and purpose of use.

2.6.1 Key functionalities and Alternatives

Fluorocarbon based refrigerants are critical to Aerospace and defense application:

- They must operate at Flying at 35,000 feet which exposes aircraft to -55C
- They must have low flammability properties
- Due to the closed environment of the applications, in the unlikely event of a leakage, the refrigerants must be non-toxic
- They must be thermally efficient to minimize system size and weight

Most alternatives to Freon refrigerants currently available are materials developed to have lower global warming potential than the incumbents. However, these are still based on fluorinated chemicals (HFCs, HFOs or HFC/PFAS). Many of them have issues such as flammability even if they meet some performance requirements. For example, the thermal performance of R1234yf (hydrofluoroolefin; HFO) is similar to R134a, however, R1234yf's mildly flammable property makes it unsuited for use in aircraft environments. Another HFO based refrigerant, R513a is considered a “drop in” replacement (equivalent performance in terms of refrigeration capacity, pressures and temperatures) to R134a, however it has higher global warming potential.

2.6.2 Conclusions and adequacy of potential derogations

Under the current restriction proposal, the use of refrigerants in A&D has potential derogations under the following: 5.q refrigerants in transport refrigeration other than in marine applications until 6.5 years after EiF; and 5.dd [use as refrigerants and for mobile air conditioning in vehicles in military applications until 13.5 years after EiF]. In view of the discussion presented above, it is unlikely that these time periods will be sufficient to substitute PFAS containing refrigerants in A&D use and further technical readiness review with a scope for extension is requested.

2.7 Solvents, Cleaners

The Aerospace and Defense industry depends on PFAS as solvents for many different uses, including as a general solvent in other chemical products (coatings, lubricants, cleaners, adhesives, water proofing agents), as well as direct use in specialized applications such as oxygen system cleaning and electronics precision cleaning.

PFAS-containing cleaners have low surface tension enabling rapid penetration coupled with high solvency (Kb values >100) to remove oils, greases, silicone residues, polar materials and soils, dust, particulate and flux agents. They evaporate quickly and leave low to no residue. They contain low water content (hydrophobic) which is critical to aircraft and space components. They are non-flammable and can be used safely on heated surfaces. Further, PFAS-containing cleaners are safe to use on metals, ceramics, composites, and various plastics including but not limited to PVC, polycarbonates, nylons, phenolics and fluoropolymers such as PTFE and ETFE.

PFAS solvents are used for cleaning equipment intended for use with either liquid or gaseous oxygen. Contaminants in oxygen-rich systems pose serious risks. Where used in industrial settings, oxygen cleaning eliminates fire or explosion danger due to flammable contaminants. They are often specified for use in space systems where low non-volatile residue requirements are mandated, along with oxygen compatibility and non-flammability. Hydrofluoroether-based oxygen system cleaners replace ozone-depleting substances (ODSs) and compounds with high global warming potential (GWP) previously used for that purpose.

A & D. products with precision cleaning requirements include electronic equipment, including PWBs, switches, relays, etc.; Sensors; Actuators; fiber optic termini and fiber optic insert alignment sleeve holders.

2.7.1 Key functionalities and Alternatives

In those uses, PFAS provides numerous beneficial properties, including

- low flammability/ acute toxicity (vs. some other potential alternatives),
- rapid and complete evaporation,
- non-reactivity/ compatibility with other materials,
- low moisture absorbancy,
- excellent solvation/ surfactant properties such as low surface tension
  thermal stability.

Specific uses include uses in coatings, desmutting, degreasing, glass surface treatments for aircraft cockpits and in 3D printing release agents and in primary lithium batteries. PFAS solvents are also essential for the performance of critical fluoropolymer resins.

Expanding on the dependence of our industry to critical uses in the A&D value chain, it is apparent that many parts and assemblies that the industry relies on for consistently producing effective, safe, reliable and supportable products will be severely (if not completely) impacted by a restriction on PFAS solvents.

Solvents historically used for oxygen tube cleaning have been phased out and are no longer available. Trichloroethylene based vapor degreasing was prominent among these. TCE is now listed on Annex XIV and subject to Authorisation. Efforts to qualify aqueous cleaners met with limited success. Ultimately PFAS based cleaners using constituents such as Pentane, 1,1,1,2,2,3,4,5,5,5-decafluoro- (CAS # 138495-42-8), Butane, 1,1,1,2,2,3,3,4,4-nonafluoro-4-methoxy- (CAS # 163702-07-6), 2-[Difluoro(methoxy)methyl]-1,1,1,2,3,3,3-heptafluoropropane - (CAS # 163702-08-7) have been the most successful replacements.

2.7.2 Conclusions

AIA member companies and companies in their supply chains operating the EU as well as their customers, including commercial operators and ministries of defense (MODs), will all require the use of continued use of PFAS-based solvent cleaners until alternatives are developed and qualified that meet all performance requirements. At this time, we cannot say with certainty what alternatives would be pursued nor how long this endeavor would take from start to finish. Nor can we say with certainty that two of the proposed derogations (5.k: industrial precision cleaning fluids until 13.5 years after EiF; and 5.l: cleaning fluids for use in oxygen-enriched environments until 13.5 years after EiF) in the restriction report would allow enough time to develop, qualify, validate, certify and industrialize replacements for all applications. Both of these derogations are clearly applicable to A&D, but is also unclear that these two derogations would cover all of our required uses.

2.8 Composite Processing Applications

Composites in A&D applications usually refers to layered combinations of carbon fiber or fiberglass in a plastic resin, combining properties of each material. They are broadly used aerospace applications because of their ability to be formed into complex shapes, lighter weight, exceptional strength, durability, fatigue properties and reduced corrosion potential. In aircraft applications composites are used for fuselage, radomes, landing gear doors, strut-forward and aft fairing, outboard flap, trailing edge panels, fin torque box, rudder, elevator, floor beams, flaps, ailerons, inboard and outboard spoilers, engine cowling, central torsion box, tail cone, vertical and horizontal stabilizers, and more.

In aerospace composite applications fluoropolymers are important both in processing and sometimes as a functional layer incorporated into composites. In order for composite materials to maintain repeatable processes, careful evaluation and consideration of material types are used. Fluoropolymer based composite release films (or parting films) allow for removal of composite parts from other media used in the curing process. The films also have heat resistance, good elongation and strength and provide a low friction surface. Fluoropolymer films are also used extensively for production of composite parts prior to cure. The lubricity of the film surface is critical in the ability to manufacture said complex shapes with extremely tight tolerances that enable the high level of performance for A&D advanced composite structures. Fluoropolymers are also used extensively in automated equipment used for composite part production. With high speed processing and heated operations, it is critical to the functionality of these machines that the extremely sticky resins typical of uncured composite materials do not stick to contact surfaces within the equipment. Fluoropolymers are ideal for this type of equipment and is used extensively throughout the industry in this way.

Example uses are:

- Location and positioning of materials during the layup of uncured parts. These are commonly referred to as shop aids.
- Teflon backed tapes for maintaining placement of composite part constituents like honeycomb core
- Protective film on table surfaces (for example) for manual manipulation of uncured material
- Rollers, tension bars, guide rails and other components for automated equipment such as Automated Fiber Placement (AFP) and Contoured Tape Laying Machine (CTLM)
- Protective film for material after kitting, moving between work stations
- Utilization as a slip plane for complex part assembly
- Part quality aid during cure such as breather

2.8.1 Key functionalities:

Composite parts must be carefully manufactured, evaluated, & tested to ascertain that the materials repeatably demonstrate critical performance properties as designed. These designs are a key aspect of how composite material achieve the benefits for lighter weight, higher performing structure. Not only does this result in more cost-efficient structure but also A&D platforms with lower environmental impacts due to reduced fuel burn, greater payload capability per trip. Fluoropolymers like PTFE and FEP are used extensively in these highly controlled and detailed manufacturing processes. These materials are chosen for many reasons including:

- Low adhesion for maximum releasability (lubricity) -resin must not stick to these shop aids as loss of resin can result in degradation of material properties. Modern A&D composite material system are typically net resin systems
- Minimum transfer of residue that can result in unacceptable adhesion, mechanical strength or fatigue performance of subsequent layers (e.g. composite, primer/paint, etc.)
- Ease of handling and ability to resist wrinkles, tears or other discrepancies such as delamination, distortion, inclusions etc. that can degrade part quality.
- Strength and durability of the film or machine components to maintain shop operations.

2.8.2 Alternatives

For the use of fluorinated systems as shop aids, one AIA member company has undergone an extensive survey of usage and potential alternative materials as the result of a contamination investigation. Through that investigation, implementation of alternatives like polyethylene (PE) was investigated for placement of preforms, use as a slip plain material, etc. While some applications could make the switch, it was found that there were other instances where the engineering tolerances were such that only the higher lubricity and strength to thickness offered by PTFE was capable of manufacturing the part in question without inducing quality defects.

Other shop aids such as the tapes and breathers have also been difficult to find replacements as many of the alternatives present on the market pose significant risk to part contamination (silicone coated breathers for example or acrylic backed tapes). All contact materials that are used in the production of composite parts go through an extensive testing program to ensure that they do not pose a risk to the resulting structural laminate. If they are used with multiple composite types (e.g. epoxy, bismaleimide (BMI), cyanate ester), they must be screened against each unique resin chemistry and process type to ensure compatibility. This often results in an iterative effort to find a specific shop aid that functions with the material system and part configuration.

For application of fluorinated components in automated equipment, the industry offers some alternatives such as silicone rubber. However, this material does not offer the same wear resistance as its fluorinated counterparts. This material has a much higher risk of contamination to the composite laminate, especially as the components wear over time and usage. Processes and safeguards must be in place to ensure that this does not occur as it can cause structural failure due to silicone transfer to the composite material. This transfer is not detectible with standard NDI techniques or other quality inspection processes. The fluorinated components not only have significantly less contamination risk but also have better wear life typically. Metallic or ceramic components are also sometimes utilized. However, the most common version of these are actually ones that are embedded with PTFE coatings to help with resin release and cleanliness.

The ability to find a substitute or alternative approach around PFAS impacted composite production is very dependent on the structure in question as well as the production environment. The use of PVF as a barrier film on critical structure such as engines helps to protect critical components from water ingress during flight. Multiple efforts over the last 20 years have been undertaken to find an alternative to this material due to cost and sourcing concerns. However, other polymeric systems that could be co-cured with the underlying epoxy substrate did not prove to have either the environmental resistance (was not a good barrier film) or was not resistant enough to the chemical environment found around propulsion systems for life of the airplane usage.

2.8.3 Conclusions

As described above, fluoropolymers provide essential characteristics and functionality in the production of composites in the A&D sector and cannot be easily substituted. A&D companies are not aware of materials with similar properties to fluoropolymers that could fill the roles described here. If potential candidate materials were identified they would need to be fully tested and qualified before being put into use. In fact, since such a change in production method could potentially affect the quality of parts produced and hence the overall design certification of the aircraft, the effort needed to substitute them would need to follow the same process as is used to substitute as described in section 1.7. The clock on the substitution timeline could start only after such materials are identified.

Companies in the A&D sector are confident that the potential derogation 6.o (which allows for applications of fluoropolymers affecting the proper functioning related to the safety of transport vehicles) would be applicable in this situation, as the required composite parts could not be produced without them. However, this potential derogation would expire after 13.5 years, which, given the current state of unknown potential alternatives, would require some (perhaps all) EU composite processing applications to cease (and likely be moved out of the EU).

Appendix A: GCCA White Paper

AIA understands that the link to the AIA white paper on the GCCA website is currently not functioning. The text of the white paper titled "Aerospace & Defence Qualification Process Impacts on Ability to Substitute Cr(VI) Substances" is reproduced here for reference.

Aerospace & Defence Qualification Process Impacts on Ability to Substitute Cr(VI) Substances

Aerospace and Defence (A&D) products operate and carry people in extreme environments over extended timeframes, while having to fulfil extremely challenging technical, reliability, and safety requirements. To ensure the safety and reliability of aerospace products, comprehensive airworthiness regulations have been in place globally for decades. **These regulations require a systematic and rigorous framework to be in place to qualify all materials and processes to meet stringent safety requirements that are subject to independent certification and approval through, EASA and other agencies requirements.** Air, ground and sea-based defence systems, and also space systems, are subject to similar rigorous qualification requirements. Changes to A&D hardware offer unique challenges that are not seen in other industries.

The A&D companies that design and integrate the products (e.g. aircraft, engines, radar systems, missiles), are each responsible for their own product qualification, validation and certification, according to airworthiness regulations or defence/space customer requirements. Within a single A&D company, even seemingly 'similar' components or hardware used in different systems/models have unique design parameters and performance requirements, driven by the system-level requirements of the final delivered product. **<u>A&D products cannot be placed on the market without going through this demanding process irrespective of any REACH legislation.</u>** The same rigorous process is in place to approve materials used for the repair and maintenance of these products. Figure 1 illustrates the process required in the A&D industry when substituting a material.

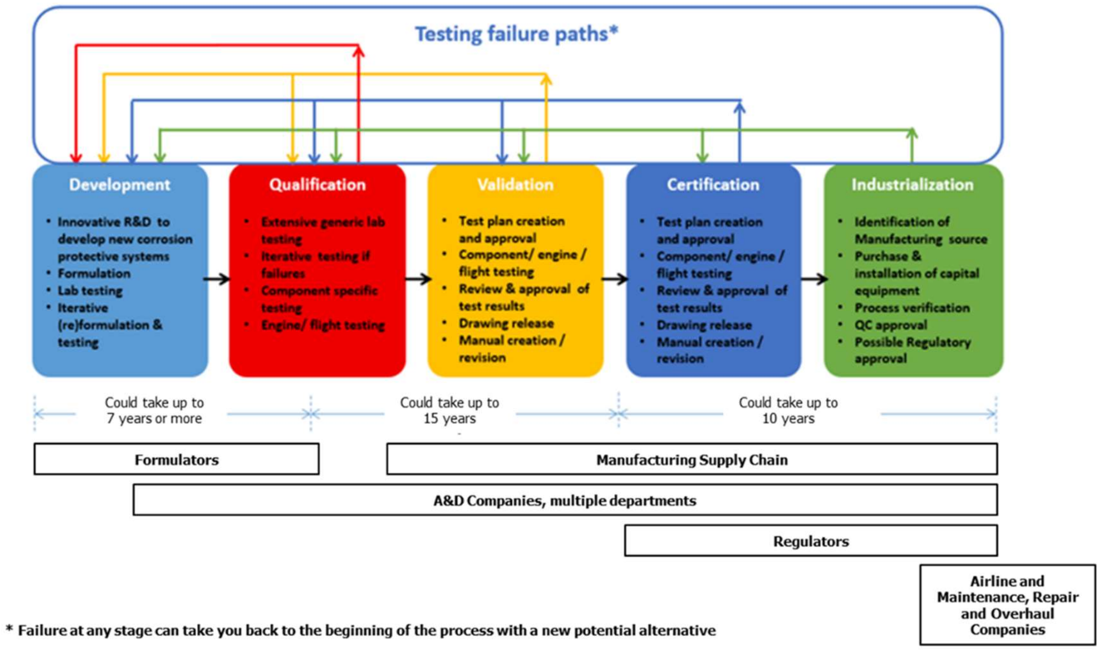

Figure 1: Illustration of the development, qualification, validation, certification and industrialisation process required in the aerospace industry

Whilst a formulator may introduce an alternative into their products, there are many discrete activities required to introduce an alternative candidate into A&D hardware. The testing and qualification criteria is dictated with due regard to the design and performance requirements of each component and system. An example suite of tests for primers may include enhanced corrosion, fatigue, chemical resistance, erosion, repair and manufacturing trials, engine and/or flight tests. Once a candidate technology has reached a sufficient level of maturity, then integration into products is permitted. Industrialisation is an extensive step-by-step methodology followed in order to implement a qualified material or process throughout the manufacturing, supply chain and maintenance operations, leading to the final certification of the A&D product. This includes re-negotiation with suppliers, investment in process implementation and final audit in order to qualify the processor to the qualified process. An individual component may become part of multiple subsystems and systems, each imposing its own design requirements and challenges**. Thus, successful substitution for one component in a given subsystem does not imply that it is suitable for use in a different subsystem. Each individual subsystem and system must be assessed and validated independently.**

Formulators are responsible for developing and performing the preliminary assessment of any candidate alternative's viability. However, **only the original design owner can determine when a candidate alternative is fully qualified and/or validated and therefore meets both airworthiness and comparable performance requirements for each of their A&D applications independently.**

The A&D industry has long recognized the risks associated with Cr(VI) and the necessity of implementing the use of alternatives. Significant efforts have been expended by the A&D industry over several decades to develop and implement alternatives. A&D companies have rigorous processes in place requiring extensive documentation, reviews, and approvals to justify use of Cr(VI) in new designs or changes to existing designs. Once a new validated, certified and approved alternative is incorporated into a design, adherence to the new design becomes a contractual and regulatory requirement.

Despite these efforts, there remain many applications for which no suitable alternative can be implemented. Recognizing that there are many different uses of Cr (VI) and that each must be assessed individually, to date there is no universal replacement for any of these coatings and surface treatments for A&D uses. For many A&D products it may not be feasible to make certain changes due to the complexity of ensuring that no negative impacts are introduced into proven designs. The complex relationship between each component and its performance requirements within its own unique design parameters requires certification of each substitution individually (see Figure 2). Qualification in one particular application does not guarantee that use in another application is qualified. Every application must be individually assessed to determine that requirements are met. This process must be independently replicated across all A&D products by each A&D company. A&D products (e.g. a specific aircraft model) may be in service for 30-50 years (even longer in defense uses), requiring maintenance, repair and spare parts over their entire service lives. Any changes to these parts or processes must be fully validated and certified to ensure safety and performance are not compromised.

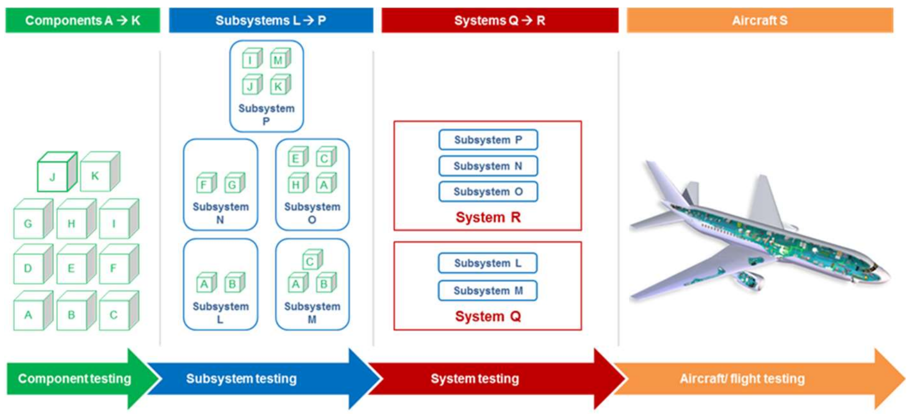

Figure 2: Systems assessment and validation overview

The industry was diligently pursuing alternatives prior the passage of the REACH regulation, and will continue to do so regardless of the details of any particular Authorisation decisions.

KLÜBER LUBRICATION

February 28, 2024
Katrina Kessler
Commissioner, Minnesota Pollution Control Agency
520 Lafayette Road N
St. Paul, MN 55155-4194

Submitted via the Minnesota Office of Administrative Hearings eComments Website

Re: Klüber Comments on MPCA's Planned PFAS in Products Currently Unavoidable Use Rule

Dear Commissioner Kessler:

Klüber Lubrication NA LP (Klüber) respectfully submits these comments on the Minnesota Pollution Control Agency (MPCA) planned rule regarding currently unavoidable use (CUU) determinations for intentionally added PFAS in products (the CUU Rule) to implement Minn. St. § 116.943, subdivision 5(c). Specifically, the statute exempts from its 2032 material restriction uses of PFAS that the MPCA has determined are CUUs because they are "essential for health, safety or the functioning of society and for which alternatives are not reasonably available."

The MPCA's request for comments in part solicited input on whether the agency should make initial CUU determinations through this CUU rulemaking, and for what products and uses. We support the agency making CUU determinations now, since this will help give manufacturers sufficient time to plan for the material restriction that will go into effect in 2032. In addition, we request that the MPCA grant a CUU determination as part of this rulemaking for the use of polymeric PFAS in lubricants and greases (hereinafter "fluoropolymer-containing lubricants and greases").

Klüber offers expert tribological solutions by supplying high-performance specialty lubricants, including fluoropolymer-containing lubricants and greases, to professional and industrial customers in almost all branches of industry and regional markets. Fluoropolymer-containing lubricants and greases in particular represent CUUs of PFAS because they are essential for health, safety, and the functioning of society. These products are crucial in reducing friction and wear, protecting components, and preventing overheating in products and applications that make modern life possible. As such, fluoropolymer-containing lubricants and greases are widely used across many different industries in the most critical and demanding applications such as in transport, nuclear and wind power generation, and medical and other manufacturing.

Likewise, there are no reasonably available alternatives to polymers that fall under the state's PFAS definition for many high-performance applications of lubricants and greases. Switching to non-fluoropolymer lubricants and greases would have many negative consequences including decreased energy efficiency (and therefore higher greenhouse gas (GHG) emissions), decreased product safety, shorter product life (and therefore higher resource consumption), and more intensive maintenance requirements.

Our requested CUU determination is further supported by the fact that the hazards posed by these fluoropolymers are minimal. Most are used in closed systems in small amounts with limited opportunity for exposure to humans or the environment. Furthermore, among PFAS, polymers are expected to present the lowest concern to humans and the environment.

I. Fluoropolymer-containing lubricants and greases are essential for health, safety, and the functioning of society because they are widely used across critical industries.

Fluoropolymer-containing lubricants and greases are used in several critical industries and are found in many industrial, commercial, and consumer products essential for health, safety, and the functioning of society. Negative consequences of switching to an improper alternative might include transportation accidents, nuclear power plant accidents, increased GHG emissions across a variety of products, and increased resource consumption due to shorter product life. Due to their cost, fluoropolymer-containing lubricants and greases are typically used only when non-fluoropolymer lubricants and greases are not practicable choices, for the reasons described in these comments.

Fluoropolymer-containing lubricants and greases are widely used across many different industries in the most critical and demanding applications. Affected industries include, for example:

• Transport (aerospace, automotive, buses, and passenger trains). Fluoropolymer-containing lubricants and greases are used for bearings, small gears, and actuators. For instance, to lubricate plastic gears and actuators in automobiles, a grease or lubricant must last the full lifetime of the automobile. If fluoropolymer-containing lubricants were not used, automobile manufacturers would need to switch to much heavier parts. This could have costly impacts to Minnesota's transportation sector, which supports over 32,000 jobs in freight-focused transportation alone and underpins the many companies that are headquartered in Minnesota due to its robust transportation network.

• Nuclear power generation. In nuclear power plants, fluoropolymer-containing lubricants are used in pumps for radiation-exposed areas. Non-fluoropolymer lubricants would break down under these conditions, leading to pump failure and potential catastrophic consequences. There are two nuclear power generating facilities in Minnesota – the Prairie Island and Monticello Nuclear Generating Plants. The MPCA must ensure the safety and effectiveness of these plants, and granting our requested CUU determination will support this effort.

- Wind power generation. Fluoropolymer-containing lubricants are used in wind turbine applications where friction could lead to critical loss of power generation efficiency. As described by the Minnesota Department of Commerce, "[w]ind is an increasingly significant source of energy in Minnesota . . . As a major producer of wind energy, Minnesota ranks in the top 10 in the nation for generating energy from wind." Without our requested CUU determination, this progress could be undermined.

- Medical and other manufacturing. In industrial manufacturing facilities, including for medical products and other industries with the most exacting specifications, fluoropolymer-containing lubricants and greases are used to lubricate bearings, valves, fittings, and electrical contacts. Minnesota is known as "Medical Alley" because of its robust health tech industry, and the state is home to over 1,100 pharmaceutical and biotech R&D companies that employ nearly 14,265 people. This burgeoning sector in Minnesota's economy could be negatively impacted by Minn. St. § 116.943 if our requested CUU determination is not granted.

Fluoropolymer-containing lubricants and greases serve essential roles within these industries. For example, properly lubricated products and parts are critical for resource efficiency. A study has concluded that 23% of global energy consumption originates from tribological contacts (i.e., friction and wear). If advanced technologies – including fluoropolymer-containing lubricants and greases – are used to reduce friction and prevent wear, that energy loss would be reduced by 18% within the next eight years and 40% within the next 15 years. This would lead to a reduction of 1.460 million tons CO2 emissions within the next eight years and a reduction of 3.140 million tons of CO2 emissions within the next 15 years. Other negative outcomes of a switch to non-fluoropolymer lubricants and greases might include:

- Failure to meet GHG reduction targets. Lubricants are critical for the safe operation of nuclear power generating facilities and the efficient operation of wind turbines. Automobiles would need to switch some plastic components for metal, which would lead to an estimated 100-kilogram increase in weight.

- Availability of consumer products in Minnesota. Certain consumer products, for example automobiles and electronics, contain fluoropolymer-containing lubricants and greases that are necessary to last the lifetime of the product without maintenance. Rather than switch to an inferior alternative, product manufacturers may simply choose to make their products unavailable for sale in Minnesota.

- Transportation accidents. Prematurely worn or improperly lubricated parts could lead to sudden failure of transport systems (e.g., aerospace, automotive, bus, train).

- Tunnel accidents. Fluoropolymer-containing lubricants and greases are used in flue gas ventilation systems necessary to provide life-saving ventilation of tunnels and other enclosed areas in case of fires.

- In-home accidents. Gas fittings in households typically use fluoropolymer-containing lubricants and valves would need to be redesigned to avoid the risk of gas explosions.

- Dangerous maintenance. Some industrial products or systems can be inherently difficult or hazardous to maintain, for example, because of their location. Using non-fluoropolymer lubricants would increase the required frequency of maintenance (e.g., re-applying non-fluoropolymer lubricants or greases or changing worn parts).

- Increased resource consumption. Switching to non-fluoropolymer lubricants and greases for improper uses would lead to premature obsolescence of products. This would cause increased resource consumption as these products were replaced.

II. Fluoropolymer-containing lubricants and greases are also essential because specialized applications often require use of fluoropolymers for their unique performance characteristics.

Some specialized applications of lubricants and greases require the use of fluoropolymers, such as perfluoropolyether (PFPE) and polytetrafluoroethylene (PTFE). Fluoropolymers contain carbon-fluorine bonds, which are the strongest carbon bonds and resist breaking down even in extreme conditions and long lifetimes. The use of these specialized lubricants and greases is required in the following conditions:

- Extreme temperatures. Some equipment must operate efficiently and reliably even at very high or low temperatures. Non-fluoropolymer lubricants and greases are prone to rapidly breaking down or igniting at high temperatures and losing critical functionalities at low temperatures.

- Reactive environments. Some lubricants and greases must be used in corrosive or other reactive environments. Non-fluoropolymer lubricants and greases may break down under these conditions.

- Exposure to radiation. In nuclear power plants, perfluoropolyether (PFPE) is used as a bearing lubricant for pumps operating in radiation-exposed areas. Radiation rapidly decomposes ordinary petroleum lubricants, while PFPE-containing lubricants are able to operate for long periods of time under these conditions without appreciable decomposition.

- Long lifetime specifications. Fluoropolymer-containing polymers have long service lives, in part because they resist oxidation in the presence of oxygen. Certain applications of lubricants and greases must last the full lifetime of products due, for example, to inaccessibility of the components being lubricated or to the inherent danger of maintenance activities for certain products. Use of non-fluoropolymer lubricants and greases for certain applications could shorten the lifetime of the product.

- Low-outgassing specifications. Some specialized equipment – such as optical equipment and light housing – requires the use of lubricants and greases that do not form condensates. For these applications, PFPE or another fluoropolymer-containing lubricant or grease must be used.

- Applications with low failure tolerance. The use of fluoropolymer-containing lubricants and greases is critical for applications with the lowest tolerance for failure, including aerospace and other transport, oxygen supply, medical manufacture, nuclear power generation, and flue gas ventilation.

III. Alternatives to the use of fluoropolymers in lubricants and greases are not reasonably available since none meet the performance capabilities of fluoropolymers.

There are no reasonably available non-fluoropolymer lubricants or greases that meet the performance capabilities of fluoropolymers. Fluoropolymer-containing lubricants and greases have unmatched friction-limiting properties, chemical and radiological inertness, stability, non-flammability, and low vapor pressure. Based on Klüber's technical expertise in this field, if such an alternative existed, we would be aware of it and would make it available to our customers.

Even if there were alternatives, it is foreseeable that these alternatives would not be reasonably available because of the risks they may pose to human health and the environment when compared to fluoropolymers. PFAS are a large and diverse group of chemicals and should not be assumed to all present similar hazards. Fluoropolymers fulfill Organisation for Economic Co-operation and Development (OECD) criteria as polymers of low concern (PLC) and are not considered a hazard for public health or the environment. Fluoropolymers used in lubricants and oils are high molecular weight polymers (more than 10,000 Da) and are not soluble in water, which limits their bioavailability and toxicity.

Additionally, fluoropolymer-containing lubricants and greases are used within closed systems (except in rare cases where this is technically infeasible) and are often used in vary small amounts, both of which limit exposure to humans and the environment. The requested CUU determination would help avoid a situation of regrettable substitution where an alternative with heightened risks to human health and the environment must be used, or in the alternate the lubricants and greases must be pulled from the Minnesota market entirely.

We appreciate the MPCA's consideration of our comments. If you have any questions, please feel free to reach out to us.

Appendix A: Non-Exclusive List of Current Critical Applications and Impacted Industries for
Fluoropolymer-Containing Lubricants and Greases

Product-Level Applications

- Hydraulic systems
- Pneumatic systems
- Valves
- Seals
- Bearings
- Electric and electronic products
- Tools, machines, installations
- Compressors
- Connection systems
- Low-outgassing applications (e.g., optical instruments)
- High and low temperature applications
- Vacuum applications
- Applications in caustic and radiation-exposed environments
- Water taps
- Applications that require precise compatibility with other media
- Oxygen supplies

Impacted Industries

- Automotive (e.g., cars, buses, motorbikes, public transport)
- Shipping
- Aerospace
- Railroad
- Power (e.g., nuclear power generation, wind turbines and other renewable sources, transmission)
- Plumbing
- Medical and other manufacturing
- Information and communication technology

Re: Request for Comments – PFAS in Products Currently Unavoidable Use Rule

The Truck and Engine Manufacturers Association (EMA) hereby submits comments on the planned new rules for the Minnesota Pollution Control Agency's (MPCA) determination of Currently Unavoidable Uses of Per-and polyfluoroalkyl substances (PFAS) in products. The rulemaking is referred to as the PFAS in Products Currently Unavoidable Use Rule (the Rule).

The Minnesota Pollution Control Agency (MPCA) has issued a Request for Comments, giving notice of its intent to begin rulemaking. The purpose of the Rule is to establish criteria and processes through which the MPCA will make decisions on what if any uses of intentionally added PFAS will qualify as currently unavoidable uses (CUU) in products sold, offered for sale, or distributed in Minnesota.

Introduction

EMA represents worldwide manufacturers of internal combustion engines and on-highway medium and heavy-duty vehicles (greater than 10,000 pounds gross vehicle weight rating). EMA member companies design and manufacture internal combustion engines that are used in a wide variety of applications, including: trucks and buses (including school buses); farm, construction, and industrial equipment; marine vessels; locomotives; lawn, garden and utility equipment, and electric generators and other stationary applications. PFAS is widely used in a variety of applications to provide products with strength, durability, stability, and resilience. It is also known to be used for its flame retardant properties. Consequently, EMA's members are significantly and directly impacted by the Rule.

EMA also submitted comments on November 21, 2023, on the MPCA PFAS in Products Reporting Rule. (EMA Comments, 2023). Those previously submitted comments are incorporated herein by reference. Complex products, like heavy-duty engines, vehicles and equipment are composed of hundreds of components and thousands of parts. Additionally, there is a high level of customization with heavy-duty vehicles and equipment, with a variety of options and therefore differing components.

The proposed PFAS definition is extremely broad and could encompass over 12,000 PFAS chemistries. EMA has requested that MPCA establish de minimus reporting thresholds and provide a defined list of CAS identified PFAS chemistries that are subject to the requirements. Without reasonable limits on the scope of the requirements, manufacturers face an unworkable task of investigating thousands of parts in a global supply chain consisting of hundreds of suppliers. Extensive effort will be required to investigate and identify the presence of PFAS in the complex products produced by EMA's members. Hundreds of suppliers in global supply chains, some of whom are 8 to 10 layers deep in the supply chain, hold chemical composition information for parts and components. Chemical composition information is often considered proprietary, and disclosure is not easily obtained. Manufacturers may need to investigate thousands of components and that process could take at least 2 years to complete for complex products. (See EMA Comments, 2023). Although the compliance obligations are directed at the manufacturers of products, PFAS use is fundamentally controlled at the supplier level. Disclosure of PFAS use is also fundamentally controlled at the supplier level.

EMA members and their supply chain are actively engaged in gathering information on the uses of PFAS within their products, as yet not all have been identified. In part this is due to the challenges in their identification as many PFAS used in mixtures have not been classified as hazardous per the Globally Harmonised System for classification and labelling. In addition, many PFAS are not shown on material data sheets even though the substance is present. Moreover, when PFAS are used as articles or articles in complex objects, the complex objects, the parts suppliers are currently under no regulatory obligation to highlight the presence of PFAS.

<u>MPCA Questions for Comment</u>

1. *Should criteria be defined for "essential for health, safety and or functioning of society"? If so, what should those criteria be?*

It is critically important that the MPCA consider the potential impacts, restrictions and bans on the use of PFAS. PFAS plays an important role in the functionality, durability, and safety of many products. Alternatives have not been identified for many critical PFAS uses in engines, vehicles and equipment and as such, the use of PFAS in these applications should be considered "Currently unavoidable use".

If criteria are identified, they should include uses that are necessary to achieve compliance with other regulatory requirements related to safety, durability, emissions requirements, flammability requirements, etc. In the case of engines, vehicles and equipment, EMA member companies are downstream users of PFAS substances, and PFAS may be present in components generally not accessible to users of the products. However, the presence of PFAS is vital to imbue safety, durability and quality attributes to components and finished products.

Criteria should include engines, vehicles and equipment that power construction, industrial and agricultural equipment vital for everyday life; heavy-duty engines that power vehicles used to transport goods and products including food, medicine and almost every consumer product that you can name, and stationary engines that support critical functions in hospitals and other settings. Engines, vehicles and equipment support every aspect of life as we know it, including the functioning of hospitals, data centers, power plants, public transport, emergency and military equipment, just to name a few, and PFAS is present in extremely small quantities (often de minimus levels), to ensure the functionality and safety of these products.

Substitutes for PFAS chemicals will not be easily identified and may not be available in any event. In many instances, their use is necessary to achieve compliance with other regulatory requirements related to flame resistance (i.e., the Federal Motor Vehicle Safety Standard No. 302, Flammability of Interior Materials) and durability requirements to ensure the long-term durability of components, including emissions components. PFAS, as broadly defined in the proposed rule, may also include some refrigerants, like HFC-134a, and HFO-1234yf, which are widely used because of their extremely low global warming potential. In fact, the transition to HFO-1234yf has been spurred by Federal rulemaking activity related to reducing HFCs. MPCA should also consider that PFAS is used in alternative power technologies, including batteries and hydrogen fuel cells to imbue vital functional properties. Many PFAS compounds are very expensive and these compounds are used because they are effective and no suitable alternatives have been identified. (See EMA Comments, 2023).

Where PFAS is used in components subject to other federal requirements (like engines and vehicles), any substitution or change in the components may require significant and time-consuming, testing, verification and certification of any redesign or substitute. Where durability requirements are applicable, testing burdens can be significant. Resources for such testing are finite and are already overburdened with demands related to design and certification of new products. Introducing the additional project of identifying chemical substitutes and proving them out for durability, safety and emissions verification purposes will certainly create timing and resource management challenges that may lead to supply shortages for critical components and products. (See EMA Comments, 2023).

2. *Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?*
4. *What criteria should be used to determine the safety of potential PFAS alternatives?*

Where PFAS is used in components subject to other federal requirements (like engines and vehicles), any substitution or change in the components may require significant and time-consuming, testing, verification and certification of any redesign or substitute. Where durability requirements are applicable, testing burdens can be significant. Resources for such testing are finite and are already overburdened with demands related to design and certification of new products. Introducing the additional project of identifying chemical substitutes and proving them out for durability, safety and emissions verification purposes will certainly create timing and resource management challenges that may lead to supply shortages for critical components and products. (See EMA Comments, 2023). Costs associated with redesign, testing and verification for safety, durability and compliance reasons should be considered in the costs and in determination of what is "reasonable".

MPCA must consider the nature of the products impacted. Heavy duty engines, vehicles and equipment are not the same as a mattresses, frying pans, carpets, and other disposable consumer products, and they should not be treated the same under the proposed rule. Commercial vehicles, engines and equipment are long-lasting, durable by design and regulatory mandate, and utilize end-of-life design provisions to ensure that potentially problematic substances are captured and recycled. Remanufacturing processes are an integral part of the heavy-duty industry and support the development of a circular economy while promoting robust waste management to prevent releases of pollutants to the environment. Aftermarket parts and components must also be considered to ensure that in-service equipment is not impacted by restrictions on legacy parts. Transition to substitutes for PFAS will be extremely challenging for new products moving forward. Expectations that legacy parts and components will also transition to substitutes are simply unrealistic. Failure to recognize this fundamental obstacle will lead to critical shortages of parts and will lead to in-service equipment being rendered obsolete, short of their expected full useful life. Regulatory efforts should focus on high risk PFAS chemicals and high-risk end-use applications. (See EMA Comments, 2023). It is not "reasonable" to impose replacement costs in the absence of consideration of relative risk and the potential for unintended consequences of replacement, like those described in our comments.

In the case of many PFAS uses, there is no suitable alternative and the impacts of the removal of PFAS could be the inability to comply with important regulatory requirements related to safety, durability, emissions compliance and flammability, and could ultimately impact the availability of product. In these instances, cost considerations should take into account the costs associated with increased risks related less effective substitutes, like noncompliance with other important regulatory mandates, the potential impacts of "regrettable substitution", and the consequences of limits on product availability, including consideration of the air quality impacts of slowed fleet turnover to newer, lower emitting engines, vehicles and equipment.

Consideration of alternatives must include time for study of potential long term health and environmental impacts, along with extended durability and reliability studies to understand the effectiveness of options. It would be irresponsible to force a shift to less effective, less suitable, less understood, substances.

5. *How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently avoidable use determination be decided? Should significant changes in available information about alternatives trigger re-evaluation?*

Currently unavoidable use (CUU) determinations should be indefinite for uses where safety, durability and compliance with other regulatory requirements necessitates the use of PFAS and the use of PFAS in the application has not been demonstrated (with unbiased, widely recognized and accepted data) to pose a health risk that cannot be mitigated with safety precautions, like the use of personal protective equipment. The uses of PFAS in engine, vehicle and equipment components in small (often de minimus) quantities, would fall under this description.

As described above, the process for identifying alternatives, conducting appropriate health and safety testing, demonstrating the viability of a substitute in thousands of components, conducting durability testing and complying with re-certification requirements for components with regulatory impacts would be a lengthy process, assuming viable substitutes exist. However, they currently do not and are not anticipated to be readily identifiable.

There is no single time line that can define CUU determinations and the need for CUU determinations could span decades, not years, depending on the scope of the proposed restrictions, the nature of the "substitute", and the specific use. The potential scope of the proposed approach is too wide-reaching to allow for speculation about the length of CUU determinations.

6. *How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?*

CUU determinations should be made by the agency imposing the restrictions. Presumably they should be qualified to evaluate the validity of the request for a CUU determination. Opening the door to requests to prevent or "block" CUU determinations undermines the authority of the regulating agency and will encourage preemptive activity by parties lacking the requisite understanding of the basis for the CUU determination request. Moreover, the CUU determination requests may include proprietary information that cannot be shared. If state regulatory agencies are responsible for the restriction and control of a substance, they should be entrusted with the process of evaluation of the information to make CUU determinations without outside influence. Providing a process to "block" such determinations is ill-conceived at best and will lead to increased demands on MPCA staff to evaluate such "requests".

7. *Please share what uses and products you may submit a request for in the future and briefly why.*

Requests for the entire class of engines, vehicles and equipment may be submitted.

EMA member companies manufacturer internal combustion engines and on-highway medium and heavy-duty vehicles (greater than 10,000 pounds gross vehicle weight rating). EMA member companies design and manufacture internal combustion engines that are used in a wide variety of applications, including: trucks and buses (including school buses); farm, construction, and industrial equipment; marine vessels; locomotives; lawn, garden and utility equipment, and electric generators and other stationary applications. PFAS is widely used in a variety of applications to provide products with strength, durability, stability, and resilience.

Engines, vehicles and equipment support every aspect of life as we know it, including the functioning of hospitals, data centers, power plants, public transport, emergency and military equipment, food production, infrastructure development and transportation and delivery of goods (including food and medicine), just to name the most obvious. These products are "essential for health, safety, or the functioning of society" as described in the definition of "Currently unavoidable use" (Minnesota Statutes 116.943). PFAS is present at the component level, in extremely small quantities, (often de minimus levels), to ensure the functionality and safety of these products.

8. *Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?*

MPCA should exempt engines, vehicles and equipment from the rule. In the alternative, permanent CUU determinations should be established to include engine, vehicles and equipment.

Conclusion

EPA should lead efforts on PFAS reporting and restrictions. If the MPCA engages in PFAS rulemaking, the definition of PFAS must be narrowed and a de minimus threshold must be identified. Engines, vehicles, and equipment should be exempt from the rule or permanent CUU designations should apply to the entire class of engines, vehicles, and equipment.

We appreciate the opportunity to provide these comments. Please do not hesitate to contact Dawn Friest at (519) 999-4480 (or at dfriest@emamail.org) if you have any questions.

Respectfully submitted,

Office of Administrative Hearings
Mr. William Moore
600 North Robert Street
P.O. Box 64620
Saint Paul, Minnesota 55164-0620

Re: **In the Matter of the Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS); OAH Docket No. 71-9003-39667; Governor's Revisor's ID Number: R-4837**

Dear Mr. Moore,

The Minnesota Pollution Control Agency requested that the Office of Administrative Hearings review comments on its proposed rules governing PFAS in Products under the statutory authority of Minnesota Statutes Section 116.943, subdivisions 5(c), 9, for the following item:

i. **Definitions, Prohibitions, and Rulemaking Authority**; Minnesota Statutes Section 116.943, subdivisions 1, 5(c), & 9, respectively.

The request for comments was published in the State Register OAH Docket No. 71-9003-39667, on December 8, 2023. Enclosed for your review are the requested comments submitted by Honeywell.

Should you have any questions or concerns with our submission please don't hesitate to get in touch with us.

Sincerely,

Atashi Bell, PhD
Senior Director, Global Government Relations
Atashi.Bell@honeywell.com

Honeywell appreciates the opportunity to comment on the above-referenced Planned Rules ("Planned Rules") on unavoidable use determinations for Per- and Polyfluoroalkyl Substances ("PFAS") ("Unavoidable Use Determination Rule") pursuant to Minn. Stat. § 116.943, subdivision 5(c) issued by the Minnesota Pollution Control Agency ("MPCA" or the "Agency").

Honeywell is an integrated operating company serving a broad range of industries and geographies globally. Our business is aligned with three powerful megatrends - automation, the future of aviation, and energy transition - underpinned by our Honeywell Accelerator operating system and Honeywell Connected Enterprise integrated software platform. As a trusted partner, we help organizations solve the world's toughest, most complex challenges, providing actionable solutions and innovations that help make the world smarter, safer, and more sustainable. The company traces its roots in Minnesota back to 1927 when the Honeywell Heating Specialty Company merged with the Minneapolis Heat Regulator Company to form the Minneapolis-Honeywell Regulator Company.

Today, Honeywell's workforce in Minnesota includes approximately 1,870 employees at five facilities across the State. Three of these sites develop and manufacture various equipment and materials for the aviation, space, and defense sectors ("Aerospace & Defense" or "A&D").[1] Within the A&D sector, fluorinated substances comprise critical components of aircrafts, vessels, satellites, rockets, and missile actuation systems, and enable critical functions including thermal management, life support, avionics, fuel supply, engine operation, auxiliary power, navigation, communication, microelectronics, sensors, radars, insulation, and hydraulics. Of these materials listed, it is worth noting that Honeywell safety systems are included in 90% of all global aircrafts and 80% of all commercial satellites in orbit. Honeywell materials have been instrumental for every NASA human space mission and have demonstrated our ability as an industry leader to provide mission critical, safe, space-based optical and science equipment for nearly 60 years.

In addition to A&D, Honeywell operates two additional sites in Minnesota that produce a variety of switches; safety shut-off valves; flow meters; flame detectors; pressure regulators; residential heat, water, and gas meters; and other materials in the smart energy and thermal solutions sectors which are instrumental in safeguarding against hazards of those working within chemical and other manufacturing plants. These components are designed to meet extensive industry manufacturing standards, responsible manufacturing commitments from industry, and ensure negligible leakage during the use phase for all industrial production in semiconductors, automotive, medical, petrochemical, and crude oil sectors. Fluorinated polymeric materials make these critical components possible.

Honeywell is also a manufacturer of various fluorinated gases, including hydrofluorocarbons ("HFC"), hydrochlorofluoro-olefins ("HCFO"), hydrofluoroolefins ("HFO") refrigerants and their mixtures ("Blends"). Such products are used in refrigeration, heating, ventilation and air conditioning ("RHVAC"), mobile air conditioning ("MAC"), thermal management systems ("TMS") in electric vehicles ("EV"), propellants in medical dose inhalers ("MDI"), and foam blowing agents in insulation applications. Honeywell also manufactures a high-performance fluoropolymer - polychlorotrifluoroethylene ("PCTFE") - used in the primary and secondary packaging of medicinal products, medical devices, and over-the-counter ("OTC") medications globally.

Introduction

On May 24, 2023, Minnesota Governor Tim Walz signed into law Minnesota Session Law – 2023, chapter 60, article 3, section 21, (Minn. Stat. § 116.943). Specifically, subdivision 5(c) prohibits the sale or distribution of "any product that contains intentionally added PFAS, unless the commissioner had determined by rule that

[1] Across the United States, the Aerospace and Defense industry supported 2.1 million jobs in 2022. See https://www.aia-aerospace.org/industry-impact/.

the use of PFAS in the product is a currently unavoidable use," in the state of Minnesota beginning January 1, 2032. The term "currently unavoidable use" is defined in Minn. Stat. § 116.943, subdivision 1(j), as "a use of PFAS that the commissioner has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available." Subdivision 9 of Minn. Stat. § 116.943 allows the MPCA to adopt "rules necessary to implement this section." Accordingly, the MPCA issued a request for comments regarding the Planned Rules on December 8, 2023. These comments address the specific questions posed by MPCA as well as other possible aspects of the Planned Rules that may assist MPCA in its rulemaking.

Honeywell fully supports MPCA's authority to mitigate unreasonable risks with sensible regulations when such risks are presented by specific chemical substances. However, Honeywell is concerned the Unavoidable Use Determination Rule will impose considerable burdens on the regulated community without achieving commensurate benefit to human health or the environment. It may also be duplicative of new federal and global classification efforts. Several federal agencies have already created robust review programs around PFAS unavoidable use determinations and viable alternatives (i.e. SNAP, TSCA). MPCA has both the authority and the obligation to create the most cost-effective and efficient regulatory program by incorporating use determinations that have already undergone review by a regulatory agency into the initial rulemaking process. Accordingly, Honeywell offers comments on opportunities to improve the effectiveness of unavoidable use determinations, which will be critical to MPCA's mission of assessing and mitigating potential risks to human health and the environment.

Question 1: Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Essential Use Criteria Considerations and Examples

Honeywell recommends the rulemaking establish a clear-cut process under specified timelines for determination and criteria whereby any PFAS-containing product manufacturer may seek a "currently unavoidable use" determination. When making a "currently unavoidable use" determination, MPCA should consider the following factors:

- benefits to public health, the environment, community safety, national security, critical infrastructure, or other critical function of society;
- the known effects of the PFAS or PFAS-containing product on human health and the environment including the specific substance's physical-chemical characteristics, its environmental fate, as well as its toxicity, including how such characteristics compare to other substances which provide the similar performance characteristics;
- the availability of technically and economically feasible chemical alternatives that can be used for the same purpose and which can be demonstrated to be environmentally preferable to the PFAS under consideration;
- whether the use of the PFAS or PFAS-containing product contributes to achieving environmental objectives, including the mitigation of climate change;
- whether the use of the PFAS or PFAS-containing product is of value to society because it contributes to the safety, efficacy, or accuracy of useful activities and products including those used in scientific research, medical equipment or treatments, pharmaceuticals and their packaging, medical devices, and in the manufacture of components in critical goods; and
- whether the use is beneficial in other applications or commercial uses in important sectors of

the economy (such as aerospace, defense, industrial and commercial equipment, and automotive sectors.

- the product or substance has been approved, governed or authorized by a federal or state agency

Possible tools for the agency to adopt in its decision-making process may include a decision tree (Fig. 1) or a risk matrix (Fig. 2) where chemical risks factors like persistence, bioavailability, and toxicity (PBT) characteristics can be ranked in alignment with emissions or production volumes of the chemical in question.

Figure 1: Essentiality Decision tree

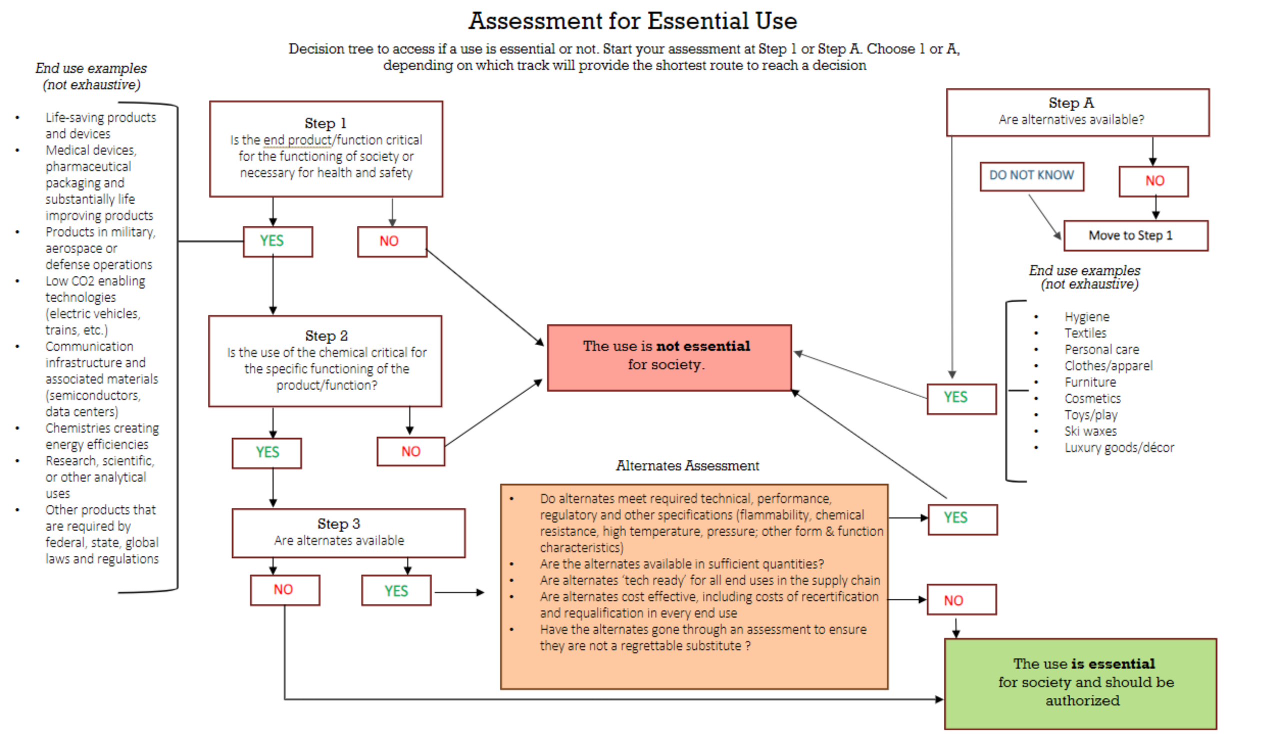

Figure 2: Risk Matrix

	Known Low Production/Emissions	Unknown Production/Emissions	Known High Production/Emissions	
Known High PBT Risk				High priority regulatory targets; decreasing priority to the left
Unknown Risk				High priority for risk studies to identify or eliminate additional substances of concern; decreasing priority to the left
Known Low PBT Risk				Lower priority for both regulations and additional research
	Candidates to monitor for change in production/emissions volume; increasing priority toward the top	Candidates for more research on production/emissions; increasing priority toward the top	Candidates for research on emissions profiles & environmental fate; increasing priority toward the top	

Essential Use Product Example: Honeywell's Solstice® Hydrofluoroolefin ("HFO") Technology

HFO technology is an example of a fluorotechnology that safely meets important societal needs while providing significant environmental benefits. To date, the use of Honeywell HFO technology has helped avoid the potential release of the equivalent of more than 326 million metric tons of carbon dioxide into the atmosphere. This is equal to removing the carbon emissions from nearly 70 million gasoline-powered passenger vehicles annually.[2]

<u>Mobile Air Conditioning (MAC) and Electric Vehicle Thermal Management Systems (EV TMS)</u>

HFO-1234yf (or refrigerant R-1234yf, trademark Solstice® yf) is widely used as a refrigerant in MAC, vehicle HVAC and TMS in EV systems.

HFO-1234yf is a refrigerant that was specifically designed to minimize persistence and overall environmental impact. As of today, **<u>every vehicle manufacturer</u> producing vehicles for sale in Europe, Turkey, the United Kingdom, South Korea, Canada and the US is using HFO-1234yf successfully.** HFO-1234yf is the low-GWP refrigerant of choice for carmakers, consumers and the environment. The shift from R-134a, an older generation automotive refrigerant, to HFO-1234yf, which took 10 years to transition, has had a dramatic positive impact on the environment. The most recent assessment of the Intergovernmental Panel on Climate Change (IPCC AR6 of 2021) shows HFC-134a with a GWP (100) figure of 1530 while the GWP (100) of HFO-1234yf to be 0.501.[3] Assuming 200 million vehicles on the road with R-1234yf and an average charge of 0.6Kg per vehicle, the refrigerant change from R-134a to R-1234yf equals more than 183 metric tons of CO_2e reduction.

HFO-1234yf is a low hazard, non-bioaccumulative, very low persistent (atmospheric lifetime 10 days), mildly flammable gas with very low-GWP, no-ODP and with well-established DNEL/PNEC levels as well as no noticeable health or environmental hazards or PBT/vPvB equivalent concerns.

Oak Ridge National Laboratory on HFOs

Further, as confirmed in recent analyses from Oak Ridge National Laboratory, HFOs represent greater energy efficiencies across important commercial applications, including in appliances, residential air conditioners, supermarket refrigeration systems, and spray foam insulation.[4] In commercial refrigeration applications, HFO solutions will consume 5% to 21% less energy as compared to propane systems over the lifetime of the system (15 years), and 8% to 50% less energy as compared to CO_2 systems over the lifetime of the system (15 years).[5] When evaluating the performance attributes of HFO blowing agents to evaluate energy efficiency, as well as safety attributes to identify HFOs' flammability characteristics, Oak Ridge National Laboratory researchers concluded that "HFOs can effectively replace higher GWP solutions, such as HFCs, to

[2] Calculations are based on actual sales of Solstice products (in lbs.) from Jan 2010 through Jan 2022, and utilize the EPA GHG equivalency calculator for conversion.

[4] Minnesota's Building Code permits the use of HFO as insulation for residential dwellings. *See* Minn. R. 1322.0402, 1346.0604. Restrictions on the use of HFO under the pending rule would be inconsistent with other agencies that have approved HFO as a safe and appropriate product for residential use.
[5] Oak Ridge National Laboratory Study "Technology Options for Low Environmental Impact Air-Conditioning and Refrigeration Systems"

reduce emissions and mitigate the use of flammable and explosive materials in high-density, urban areas."[6]

Department of Defense on HFOs

The Department of Defense recently identified refrigeration, air conditioning, cooling and electronics thermal control as a ***mission critical application*** in their recent report on the Critical Uses of PFAS report[7] stating that,

> *"Most refrigerants used in civil and military cooling and refrigeration applications can be classified as PFAS. Many next-generation refrigerant alternatives adopted by U.S. industry (and U.S. households) between now and the end of 2025 are also PFAS. Under the AIM Act and EPA technology transition regulations, the U.S. economy is in the process of switching from one set of PFAS-classified refrigerants (e.g., HFCs) to a new generation of refrigerants (e.g., HFOs), which are also, in the broadest definitions, considered to be PFAS. Known non-PFAS alternatives (e.g., hydrocarbon or ammonia alternatives) pose flammability, toxicity, or high-pressure concerns. The same PFAS that are used in quantities of several hundred million pounds per year throughout the U.S. economy for cooling applications are used in much smaller quantities (i.e., a fraction of one percent) for military cooling and military thermal control of all kinds."*

Unavoidable Use Criteria Should Acknowledge Past Precedents and Incorporate Federal Authorizations

The concept of essential use has witnessed both successes and failures in its historical implementation. The following section will aim to summarize examples and concepts from both ends of this spectrum, highlighting the complexities and challenges inherent in balancing policy with the practical needs of society.

A Successful Model: the Montreal Protocol

The "essential-use" concept was first introduced in 1987 in the Montreal Protocol to phase out ozone-depleting chlorofluorocarbons, except for certain "essential" uses. The concept of "essential use" was developed to address situations where the complete elimination of ODSs would cause significant societal or economic harm, or where there were no technically or economically feasible alternatives available at the time. It acknowledges that in some specific applications, alternatives to ODSs may not yet exist, or their adoption might have serious adverse effects on health, safety, or the environment. The Montreal Protocol framework sets rigorous criteria and procedures for determining essential use exemptions, recognizing that the designation of essential use should not be taken lightly. It was agreed that a "controlled substance should qualify as 'essential' only if:

> (1) it is necessary for the health, safety, or is critical for the functioning of society (encompassing cultural and intellectual aspects); and
>
> (2) there are no available technically and economically feasible alternatives or substitutes that are acceptable from the standpoint of environment and health. It is also mentioned that essential uses should be permitted if all economically feasible steps have been taken to minimize the emissions of the controlled substance.[8]

[7] Department of Defense "Report on Critical Per- and Polyfluoroalkyl Substance (PFAS) Uses" https://www.acq.osd.mil/eie/eer/ecc/pfas/docs/reports/Report-on-Critical-PFAS-Substance-Uses.pdf, p.14

[8] Decision IV/25, 'Essential Uses', 4th Meeting of the Parties to the Montreal Protocol on Substances that Deplete the Ozone Layer,

Under the Montreal Protocol, substances deemed "essential" for specific applications are granted exemptions from phase-out schedules. This means that despite the overall goal of phasing out ozone-depleting substances (ODSs), certain uses are considered necessary and are permitted to continue for a limited time until suitable alternatives become available.

One significant aspect of the essential use concept is the allowance for the use of these substances as feedstocks. Feedstocks are raw materials that are used to manufacture other products. In some cases, ODSs serve as crucial feedstock in various industrial processes, such as the production of pharmaceuticals, electronics, or specialty chemicals. Recognizing the importance of these substances as feedstocks, the Montreal Protocol provides exemptions for their use in specific applications.

Critically, Montreal Protocol focuses on a very limited number of essential substances keeping the scope narrow, well-defined, and reviewed on a regular cadence; publishing its decisions relating to essential uses with the most recent released in 2020.[9]

An Unsuccessful Model: European Union (EU) Chemicals Strategy for Sustainability (CSS)

Recently in 2020, the European Union (EU) released its Chemicals Strategy for Sustainability (CSS), calling for the phase out of the most harmful uses of chemicals, except for those uses that are determined to be essential for society.[10] This strategy was developed with neither prior public consultation nor a proper impact assessment. As such, CSS has been unsuccessful in that it neither defined which harmful chemicals would justify use of this concept, what criteria should be applied, nor did it provide a process to help identify or select chemicals of concern. At present, there does not exist agreement or a formal process to incorporate the essential use concept into existing European frameworks like the Registration, Evaluation, Authorization and Restriction of Chemicals (REACH) or the classification, labelling and packaging of substances (CLP). Attempts to bring them into alignment over the last few years have been met with significant debate and concern from various stakeholders. As seen from the notes of the competent authorities for REACH and CLP, many proponents caution that "banning or restricting uses of substances on the basis of their essentiality, without sufficient assessment of the impacts may lead to regrettable substitution or impaired competitiveness and innovation."[11]

Secondly, many of these existing frameworks already have infrastructure built-in for chemicals of concern to request authorizations or "use-specific" exemptions if the requestor can demonstrate that under normal conditions of use, the risks are adequately controlled. Lastly, a broader concern with this concept, cautions that assessments around essential use can vary widely depending on who and how they are determined. Placing diligence around best practices should be exercised where some chemicals deemed "non-essential" today, could be "essential" in the future, thus allowing space for science and technology to evolve, be it for

global emergencies, or other unforeseen future needs where flexibility in these areas will be needed to eliminate supply chain vulnerabilities or barriers to innovation, trade, or commerce.

Minnesota-Specific Essential Use Examples

Minnesota has many examples of both successful and unsuccessful regulatory schemes from which to learn in its development of unavoidable use criteria. MPCA should look to the successes and challenges of its past phaseouts when developing unavoidable use criteria. Such learnings may be found in the regulation of Trichloroethylene (TCE), Formaldehyde, Heavy Metals, and PCBs.

For example, in the case of Formaldehyde, Minn. Stat. 325F.174 et seq., the Minnesota legislature recognized the extensive, existing regulatory structures around specific product categories and thus exempted many FDA-regulated products and products in conformance with ASTM International Standard F963. In doing so, the state reduced MPCA's administrative burden, reduced the regulatory burden on industry by minimizing duplicative or inconsistent regulation, and effectuated the goal of reducing this potentially hazardous chemical in Minnesota. A similar approach was taken with Heavy Metals in consumer products, Minn. Stat. 325E.3891 et seq. Further, in the case of TCE, a successful phaseout was tied to an existing permitting program, thereby focusing MPCA's efforts on some of the state's largest users, Minn. Stat. 116.385 et seq. While the Minnesota Legislature did not specifically dictate these exemptions or structures in the case of PFAS regulation, it did give MPCA wide latitude to define and implement unavoidable use criteria.

<u>Recognizing Existing Essential Use Determinations and Criteria</u>

As the MPCA promulgates its own essential use rules, it must ensure that they align with the detailed criteria developed under other domestic and international programs. Harmonization with existing criteria is crucial to maintain consistency in regulations, promote efficiency, and avoid conflicting requirements that could hinder effective environmental protection efforts such as ozone layer protection.

For instance, our strong recommendation would be that the MPCA consider the criteria outlined by the Montreal Protocol and any guidance provided by relevant international bodies, such as the United Nations Environment Programme (UNEP) and its Ozone Secretariat. These criteria typically include considerations such as technical feasibility of alternatives, economic impact assessments, and environmental considerations.

Furthermore, coordination with other domestic programs, such as those established by federal agencies like the Environmental Protection Agency (EPA), is essential to ensure coherence in regulatory frameworks and prevent duplication of efforts. Other PFAS essential use determinations that can be relied on by MPCA include the SNAP program under the Clean Air Act, the EPA's new chemical review program under Section 5 of the Toxic Substances Control Act (TSCA) , the Federal Food, Drug, and Cosmetic Act (FFDCA), and other federal programs whereby either the PFAS, or products containing them, have been deemed acceptable for their intended use through risk assessments by federal agencies. PFAS-containing products that are subject to, or necessary for, meeting federal specifications (e.g., military specifications, United States Federal Aviation Administration (FAA) standards, or NASA requirements) also should be considered currently unavoidable use. Such an approach will help MPCA concentrate its efforts on non-essential uses within consumer products. This approach also provides fairness and market stability for businesses that have successfully completed federal reviews for their PFAS-containing products under these federal programs. The approach will also ensure the continued availability of products that must meet military, technical, or similar government specifications.

Question 2: Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Costs of PFAS Alternatives Should be Taken into Consideration When Determining Their Availability

High costs can create barriers to adoption for industries or applications and may have severe impacts on end users and consumers with limited financial resources. Evaluating costs will allow regulators to assess the economic feasibility, or reasonableness, of transitioning to alternative substances and will ensure that feasible alternatives are identified where needed.

Sector Example: Aircraft Manufacturing in the Aerospace and Defense Industry

In the most recent 'Minnesota by the Numbers' Aerospace and Defense was listed as a top industry in Minnesota[12]. It is important for the agency to perform a sector-by-sector risk assessment within the State that accounts for impacts to Minnesota's top revenue-generating industries. In light of some of these complex supply chains there could also be global repercussions with crippling costs or critical equipment obsolescence that might occur if a key use is missed. When the US Chamber of Commerce recently reviewed trade implications between the US and Europe that could be impacted under PFAS restrictions in Europe[13], the market sector with the largest estimated trade value at risk was Aerospace and Defense at $48 billion. Figures taken from that report also considered US GDP and distribution of total impacts. The figures showed that aircraft manufacturing would suffer the most significant impact to jobs by sector (Fig. 3). Further, the State of Minnesota (fig 4) would have over 8000 jobs that could be impacted by PFAS restrictions if exemptions were not provided for this sector. For Honeywell's A & D facilities alone, an initial assessment has revealed more than 2,000 distinct part numbers stand to be affected should the sector not be classified as essential. This has the potential for significant supply chain disruptions as well as significant financial considerations. As a company with deep ties to the state of Minnesota, and a thriving Aerospace and Defense business, these numbers are deeply concerning to us as an employer within the state in this industry.

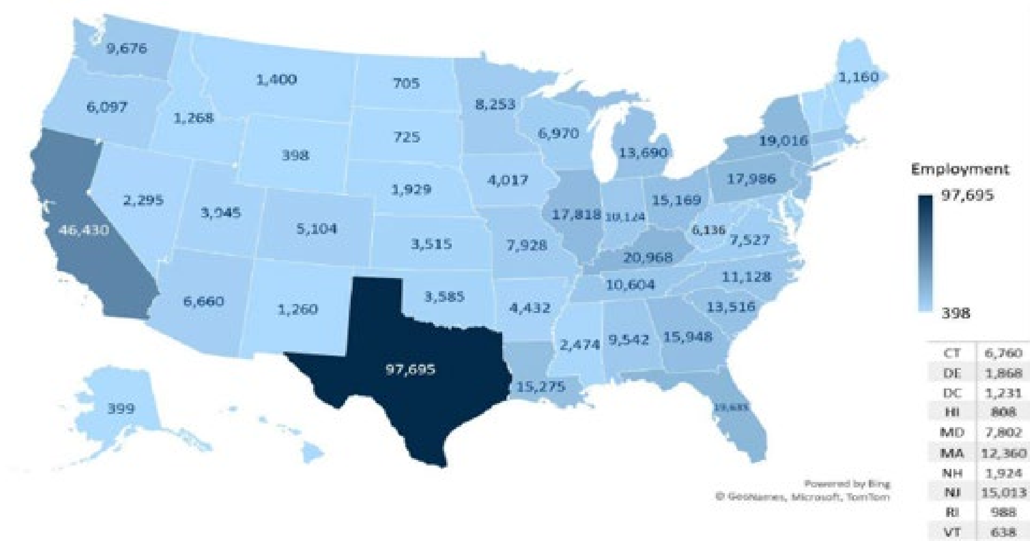
Figure 4: Job Impacts by State



Source: https://www.uschamber.com/international/impacts-of-the-pfas-restriction-on-trade-between-the-u-s-and-the-european-union

Product Example: PCTFE in Medical Packaging

In the pharmaceutical sector, Honeywell provides the fluoropolymer, PCTFE, for use in medicinal packaging for both humans and animals. If new alternatives must be identified, for every change to an approved packaging, this could require additional stability testing and approval of changes/variations by the US FDA and other international medicine authorities for each existing active substance and dosage of the final medicinal product. This will not only require substantial development time (i.e., tests normally performed for long time periods with regular intermediate controls) but also considerable human resources from the industry and authorizations by authorities. According to available information, the costs of stability testing for each medicinal product could reach $100,000-500,000 USD, for the approval of potential variations. There are currently over 600 products which may be impacted.

In cases where alternative packaging would not provide satisfactory stability characteristics to active substances or final medicinal products, changes to medicinal formulations could be required. Formulation changes will demand considerable costs and time for developing new medicinal products and obtaining marketing authorizations. This will also trigger additional costs for processors/producers of packaging materials to retool and retrofit their machinery for other barrier materials. According to Honeywell's estimates, new packaging changes alone could potentially add over $3 million of additional costs for one drug and close to $2B for the entire PCTFE product portfolio. All of these costs would likely be passed on to final consumers and public budgets.

Understanding the revenue impacts at the state level will help keep regulations from becoming overly burdensome on all sizes of business owners, continue to drive innovation, foster competition, and keep jobs and tax revenue within the State of Minnesota. Regulatory perception amongst investors and entrepreneurs can also impact future business for investment and economic growth, thus making it critical for policymakers to strike a balance between necessary regulations to protect citizens while simultaneously supporting an environment of growth and sustainability of its key industries.

Honeywell further requests that the MPCA make the information used in conducting an assessment or evaluation of alternatives including their socioeconomic impacts on both costs and jobs by sector publicly available for review and comment.

Need to Consider Small Businesses and Municipalities

Finally, Minnesota Statutes Section 14.127, specifically requires MPCA to determine the financial impact of this rule on small businesses and municipalities—if MPCA determines that the rule will cost these entities more than $25,000 in the first year after the rule takes effect, affected entities may apply for an exemption that can only be overridden by subsequent legislative action. A failure on the part of MPCA to consider these entities results in a deviation from proper rulemaking procedures under Minnesota's Administrative Procedures Act. While Honeywell is not a small business under this statute, many of its supply-chain partners in Minnesota fall into this category. Therefore, Honeywell will be working closely with our small business partners to assist MPCA's evaluation of how PFAS regulation will impact these entities pursuant to Minn. Stat. § 14.127. For example, most of the foam blowing contractors reliant on Honeywell's HFOs are characterized as small businesses. These enterprises often operate on a local or regional scale, providing insulation services to residential, commercial, and industrial clients. Due to the specialized nature of their work, these contractors typically have limited resources and may face challenges in transitioning to alternative, blowing agents.

The Reasonable Availability of Alternatives Should Take into Account Multiple Factors Beyond Cost

How the MPCA will determine when alternatives are not reasonably available should also be explained in the regulation and should include the concepts of performance, safety, cost, and supply chain considerations. A long-term perspective is crucial when evaluating unavoidable use, especially considering the potential for future regulations, liabilities, and societal expectations regarding environmental stewardship.

In many essential A&D applications, only fluorinated substances can fulfill all required technical (AMS3255, AMS3678, ASM3659, ASTM D1710, AMS7276, AMS7287, AMS365 AMS3667) and military specifications (MIL-S-46163, MIL-PRF-276717)[14]. A&D production also needs to adhere to strict quality standards like ISO AS9100 and Nadcap. Due to the nature of critical A&D uses, known alternative materials are not available to simultaneously satisfy all required properties, such as low flammability, high service temperature (above~200 °C), low dielectric constant, electric arc tracking resistance, mechanical strength and elasticity, and chemical resistance/inertness to even the most aggressive chemicals.

Moreover, the combination of properties required in most A&D applications will be difficult to achieve in a new material. Even after a material with the suitable combination of properties would be discovered or invented, it will take decades to approve its use by the overall A&D industry (e.g., all major aircraft producers should test and approve) and to certify it under all applicable standards worldwide. It is estimated that, in practice, this process would require approximately 30 years (on average) for many critical aircraft components.

Industry Example: Halons-Based Applications

Although Halons are not part of our chemistry, they are an industry application example of ozone-depleting substances with an essential use exemption under the Montreal Protocol. Despite decades of innovation efforts to replace them, the only result has been a ‘regrettable substitution’. Recently the A&D industry successfully substituted Halon 1211 in portable (handheld) and lavatory receptacle extinguishers used in commercial aircrafts and is working to substitute halons in commercial aircraft fire suppression systems. The new Halon 1211 substitutes constitute a “regrettable substitution,” because they are still technically deemed a PFAS substance under Minnesota’s definition of PFAS, thus making the ‘new’ solutions non-viable.

In addition, the industry has been working for many years to substitute Halon 1301 in cargo & auxiliary power unit (APU) compartment and engines nacelles commercial aircraft fire suppression systems. Despite these efforts, viable halon alternatives have not been found. Many potential alternatives turned out to be technically not feasible, because they do not meet specific performance requirements. Moreover, fire suppression is a critical safety item and specific airworthiness requirements apply to fire suppression, which must be met in the aircraft certification process. Many of the remaining potential Halon 1301 substitutes the industry is currently investigating are PFAS. Therefore, additional restrictions of PFAS potentially used in fire suppression systems would put the industry's achievements at risk and potentially require a restart of the research by focusing on non-PFAS agents, should they even be available.

[14] For example, technical specifications for PTFE/ETFE insulated wire under M22759 (SAE AS22759) standards or requirements for heat transfer fluids, solvent resistance O-rings, etc.

A Transparent and Well-Defined Framework for Reasonableness Determinations

The Agency should consider establishing a transparent and well-defined framework in determining the reasonable availability of alternatives, considering cost and additional factors. Subsection (i) of the American Innovation and Manufacturing Act of 2020 (AIM Act), entitled “Technology Transitions,” may serve as a useful example of criteria that a substitute, or alternative, must meet prior to EPA establishing restrictions on the use of a substance being substituted. Specifically, when determining whether to restrict the use of a substance, EPA, under this provision, is required to consider “the availability of substitutes for use taking into account technological achievability, commercial demands, affordability for residential and small business consumers, safety, consumer costs, building codes, appliance efficiency standards, contractor training costs, and other relevant factors…”[15] Honeywell urges the MPCA to consider adopting a similar approach in assessing substitutes to PFAS, and to identify the criteria that the MPCA intends to use in ascertaining the reasonable availability of alternatives.

Question 4: What criteria should be used to determine the safety of potential PFAS alternatives?

The Definition of “Alternatives” Should Include Concepts of Functional Equivalency and Reduction of Potential Risk

Honeywell requests that MPCA provide a detailed definition of “alternatives” as that term is used within the definition of “currently unavoidable use.” The definition should include concepts of functional equivalency and reducing potential risk to human health or the environment. The basis for those concepts must be consistent, fair, transparent, and well-defined.

For example, in the Montreal Protocol on Substances that Deplete the Ozone Layer, an international treaty designed to protect the ozone layer by phasing out the production and consumption of ozone-depleting substances (ODS), defines “alternatives” as substances or technologies that:

- Do not deplete the ozone layer: Alternatives must not have ozone-depleting potential or, at the very least, have significantly lower potential compared to the substances they are intended to replace.
- Are more environmentally friendly: Alternatives should have a reduced impact on the environment, including lower global warming potential and lower potential for other environmental impacts.
- Are technically and economically feasible: Alternatives should be practical and viable from both a technical and economic standpoint to ensure that industries can transition smoothly away from ozone-depleting substances.

The definition of alternatives is crucial to the success of the Montreal Protocol, as it guides the efforts to find and adopt substitutes for ODS in various industrial processes and applications. The protocol encourages the development and use of alternatives to accelerate the phase-out of substances like chlorofluorocarbons (CFCs), halons, and other ozone-depleting chemicals.

Another example is the definition of “substitute or alternative” under EPA’s SNAP program, which defines the term as “any chemical, product substitute, or alternative manufacturing process, existing or new, that

[15] https://www.govinfo.gov/content/pkg/USCODE-2020-title42/html/USCODE-2020-title42-chap85-subchapVII.htm

could replace a class I or II substance."[16] EPA also takes into account an alternative that "(1) reduces overall risk to human health and the environment, and (2) is currently or potentially available.

In August of 2023, the Department of Defense (DoD) released their "Report on Critical Per- and Polyfluoroalkyl Substance (PFAS) Uses" which speaks to the challenges and costs relating to finding, and qualifying equally performing alternatives to existing materials in key sectors of strategic importance to our national security. When asked if alternatives[17] existed in most of these end uses, there were very few, with most citing complex, multi-leveled supply chains which would require 10–30-year recertification processes, and incompatibilities with other 'like' materials due to the strict performance, regulatory, and safety parameters these materials must meet. Trying to phase out chemistries in these applications could cost program offices millions of dollars, not to mention the countless hours that will need to be spent identifying and qualifying any new materials, thereby creating ripple effects in the economy that would be passed on to consumers, taxpayers, and cause supply issues with mission critical components leaving our country at risk or vulnerable in our defense of national security.

Defining alternatives with respect to Aerospace and Defense (A&D) companies will be challenging. As previously mentioned, these alternatives must be qualified (i.e., evaluated and tested) in the context of the aircraft system or sub-systems. These processes must be repeated where the alternatives are found to be unsuitable. Once qualified, the system must be revalidated to maintain certification of the product (e.g., aircraft, vessel, vehicle, etc.). Certification is strictly controlled by regulatory bodies in both the United States and other jurisdictions, in both the civil aerospace and military domains. Examples include the EASA, the FAA, and their military counterparts.

As A&D products are subjected to some of the most austere environments around the world. They must operate successfully in extremes, including altitude, temperature, pressure, and precipitation, while having to fulfill the highest technical reliability and safety requirements. To ensure aircraft safety, comprehensive airworthiness regulations have been in place around the world for decades. These regulations require qualification of all materials and processes according to a systematic and rigorous process to meet stringent safety requirements subject to independent certification and approval. Such rigorous testing and qualification processes are required to assure that any changes do not compromise the integrity of the affected components or the safety of the product as a whole.

The DoD concluded in their paper that, "it is critical that future laws and regulations consider and balance the range of environmental and health risks associated with different individual PFAS, their essentiality to the U.S. economy and society, and the availability of viable alternatives."

It is critical that Minnesota give credence to federal authorizations for the use of PFAS in the state's development of unavoidable use criteria because failure to do so will jeopardize some of the nation's most critical industries and applications.

Question 5: How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger re-evaluation?

---

[16] 40 CFR § 82.172 "Substitute or alternative"

[17] Report on Critical Per- and Polyfluoroalkyl Substance (PFAS) Uses, Appendix A-1 Alternatives Assessment pg 21-27 https://www.acq.osd.mil/eie/eer/ecc/pfas/docs/reports/Report-on-Critical-PFAS-Substance-Uses.pdf

Unavoidable Use Determinations Should Be Good for Unlimited Time

As stated in previous questions, the agency will need to look at each sector's specific use of PFAS and prioritize its actions accordingly. MPCA should identify critical PFAS and align with certain uses that have already undergone federal authorizations within existing regulatory frameworks within the United States for specific uses pursuant to programs such as, but not limited to, the SNAP program under the Clean Air Act, the EPA's new chemical review program under Section 5 of the Toxic Substances Control Act (TSCA) , the Federal Food, Drug, and Cosmetic Act (FFDCA), and other federal programs whereby either the PFAS, or products containing them, have been deemed acceptable for their intended use by federal government agencies. PFAS-containing products that are subject to, or necessary for, meeting federal specifications (e.g., military specifications, United States Federal Aviation Administration (FAA)-issued standards, NASA requirements) also should be considered currently unavoidable use. Such an approach will help MPCA concentrate its efforts on non-essential products. Fairness and market stability should be assured to businesses that have successfully completed federal reviews for their PFAS-containing products under these statutes. Likewise, the longest essential use determinations should be granted to companies that manufacture or provide products that must meet military or similar government specifications, taking into consideration supply chain complexity and length of qualification times for an alternative to be assessed, tested, and demonstrated safe at requisite scale and scrutiny.

Question 6: How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Role of a Technical Advisory Committee

Honeywell suggests the agency establish a Technical Advisory Committee (TAC) comprised of various stakeholders including but not limited to agency staff, scientists, health professionals, industry experts, small business owners, and those from civil sectors or those most similar representatives from industries within the State of Minnesota. Furthermore, MPCA should open these for public review, much like how the Montreal Protocol does, publishing its decisions relating to essential uses.[18] The agency should seek to find committee members who support the adoption of essential use criteria and help guide the Agency with the principles of understanding changing societal needs and a mindset for future innovations The technical committee must understand that a static view of essentiality could lead to a static society. Many concepts 30 years ago for instance like mobile phones were not considered essential, where now such devices are essential to societal function and progress. Having a process combining public review and proper membership should help guide the agency in its assessment of critical societal needs vetted by necessary expertise, sound science, and data. The technical committee should also help the agency identify representation of vulnerable and at-risk populations impacted by the Rule.

MPCA may model its Technical Advisory Committee after U.S. EPA's Science Advisory Committee on Chemicals ("SACC"). The SACC provides independent advice to EPA to assist the agency in implementing the Toxic Substances Control Act. Members are identified through a public call for nominations and are appointed by the Administrator of the EPA. Members have diverse backgrounds in policy, science, government, and industry, which inform their recommendations to the agency.

[18] UNEP Ozone Secretariat, Handbook for the Montreal Protocol, Section 3.2 "Essential Use Exemptions" pg 752-767 https://ozone.unep.org/sites/default/files/Handbooks/MP-Handbook-2020-English.pdf

Deferring to Environmental Protection Agency's (EPA) Significant New Alternatives Policy (SNAP) program Decisions

Another option that the MPCA should consider modelling their approach to is the EPA's SNAP program which operates as a regulatory framework aimed at identifying and promoting the use of environmentally preferable alternatives to ODS and high- GWP substances in various sectors. Here's how SNAP works to ensure the adoption of the best refrigerants across viable sectors:

1. **Identification of Alternatives:** SNAP assesses potential substitutes for ODS and high-GWP substances used in refrigeration, air conditioning, and other applications. It evaluates the environmental impact, safety, and efficacy of these alternatives to determine their suitability for specific sectors.

2. **Regulatory Determination:** Based on its evaluation, SNAP issues regulatory determinations that categorize alternatives as acceptable, unacceptable, or acceptable subject to use conditions. Acceptable alternatives are those deemed environmentally preferable and safe for use, while unacceptable alternatives are prohibited.

3. **Sector-Specific Guidelines:** SNAP develops sector-specific guidelines and regulations to guide the use of acceptable alternatives in various applications. These guidelines may include usage restrictions, performance standards, and reporting requirements to ensure proper implementation and monitoring.

4. **Stakeholder Engagement:** The SNAP program engages stakeholders, including industry representatives, environmental advocates, and scientific experts, throughout the decision-making process. This collaboration helps to gather input, address concerns, and foster consensus on the adoption of alternative refrigerants.

5. **Technology Assessment and Innovation:** SNAP encourages ongoing research and development of new refrigeration technologies and alternative substances with lower environmental impact. By promoting innovation, the program seeks to continually improve the availability and performance of environmentally friendly refrigerants across different sectors.

6. **Compliance Monitoring and Enforcement:** SNAP monitors compliance with its regulations and guidelines through inspections, data reporting requirements, and enforcement actions against violators. This helps to ensure that the best refrigerants are used in every viable sector while deterring the illegal use of prohibited substances.

Question 7: In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Uses and Products for Which Honeywell May Submit an Unavoidable Use Request

The following are a categorical list of uses and products for which Honeywell anticipates it will submit an unavoidable use request:

(1) A product used in a manner that has been approved or authorized by a federal or state agency.
(2) Items that are required by Federal or State laws and regulations.

(3) Drugs, medical devices, biologics or diagnostics regulated by the Federal Food and Drug Administration or the US Department of Agriculture or otherwise subject to regulation under the Federal Food, Drug, and Cosmetic Act, as amended, 21 U.S.C. § 301 et seq;
(4) Packaging for drugs, medical devices, biologics, diagnostics or [non-pulp based] food regulated by the Federal Food and Drug Administration or the US Department of Agriculture or otherwise in scope of the Federal Food, Drug, and Cosmetic Act, as amended, 21 U.S.C. § 301 et seq
(5) Products registered for use under the Federal Insecticide, Fungicide, and Rodenticide Act, as amended, 7 U.S.C. § 136 et seq.
(6) Substances designated by rulemaking or otherwise as acceptable substitutes in specific uses under U.S. EPA's Significant New Alternatives Policy (SNAP) program, or substitutes needed to execute the American Innovation and Manufacturing (AIM) Act.
(7) Polymeric substances for which the main chain (backbone) of the polymer is either a per- or polyfluorinated carbon-only backbone or a perfluorinated polyether backbone.
(8) A used product offered for sale or resale.
(9) Finished products certified or regulated by the FAA or the DOD, or both, when used in a manner that was certified or regulated by such agencies, including parts, materials, and processes used to manufacture or maintain such regulated or certified finished products;
(10) Motorized vehicles, including on and off-highway vehicles, such as all-terrain vehicles, motorcycles, side-by-side vehicles, farm equipment, and personal assistive mobility devices;
(11) Inaccessible electronic components of an electronic product, and
(12) Cooling, heating, ventilation, air conditioning and refrigeration equipment, components and servicing needs.
(13) Apparel that would be deemed personal protective equipment or clothing items for exclusive use by the United States military, defense sector, space sector, or another agency or organization fitting these descriptions.

Question 8: Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

<u>MPCA Should Make Initial Currently Unavoidable Use Determinations</u>

Honeywell recommends MPCA make initial unavoidable use determinations by incorporating parallel federal agency determinations into the final rule, much like the suggested list from question 7; MPCA has both the authority and obligation to promulgate initial determinations in this rulemaking for several reasons. First, Minnesota's Administrative Procedure Act (MAPA) specifically directs agencies to avoid unnecessarily costly and ineffective regulatory programs by developing programs that meet the regulatory objectives and provide the "maximum flexibility" for the regulated party. Minn. Stat. § 14.002. MAPA also requires each agency to submit a list of rules that are "duplicative of other state or federal statutes or rules" and act to repeal the duplicative rules. Minn. Stat. § 14.05, subd. 5. These statutes demonstrate the Minnesota legislature's strong preference to create efficient and complementary regulatory programs. Second, MAPA explicitly authorizes an agency to incorporate by reference the text from federal legislation and the Code of Federal Regulations. Minn. Stat. § 14.07, subd. 4. Third, the statutes governing MPCA specifically direct the commissioner to "coordinate the agency's activities where appropriate with the activities of other governmental agencies." Minn. Stat. § 16.03, subd. 2(a)(3). Fourth, Minn. Stat. § 16.943, subd. 3(c) authorizes the commissioner to enter into an agreement with other political subdivisions and accept information to a shared system.

In sum, several federal agencies have already created robust review programs around PFAS unavoidable use determinations and viable alternatives (i.e. SNAP, TSCA). MPCA has both the authority and the obligation to create the most cost-effective and efficient regulatory program by incorporating use determinations that have already undergone review by a regulatory agency into the initial rulemaking process. Failure to align the MPCA's product review process with those federal review processes already in existence would result in a duplicative, inefficient regulatory process that MPCA seeks to avoid. Therefore, Honeywell recommends that MPCA incorporate products that have already completed the federal regulatory review process as final determinations on unavoidable use.

Question 9: Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

<u>Other Issues Related to Defining Currently Unavoidable Use</u>

Speed of Innovation

An additional aspect the agency needs to understand is also the speed of innovation and development and how that process relates to the protection of intellectual property and confidential business information. There are times where inventors, innovators, entrepreneurs cannot discuss or publicize ideas or products prematurely, which could lead to difficulty in:

1. Sharing the idea, concept, or use publicly in a non-essential use/essential use forum.
2. Demonstrating the essential use to a TAC or others due to the 'newness or fluidity of the innovation process'.
3. Create an environment where truly innovative products could be produced outside of the State or the country where the State or United States could never recover to non-US competition.

Confidential Business Information

Much of the data needed to be analyzed to determine unavoidable use will be trade secret and otherwise business confidential. Under existing Minnesota law, this information should not be made publicly available. Minn. Stat. § 13.37, Subd. 2 identifies "trade secret information" as not available to the public pursuant to the Minnesota Data Practices Act. "Trade secret information" is defined under Minnesota law as "government data, including a formula, pattern, compilation, program, device, method, technique or process (1) that was supplied by the affected individual or organization, (2) that is the subject of efforts by the individual or organization that are reasonable under the circumstances to maintain its secrecy, and (3) that derives independent economic value, actual or potential, from not being generally known to, and not being readily ascertainable by proper means by, other persons who can obtain economic value from its disclosure or use." Minn. Stat. § 13.37, Subd. 1(b).

MPCA should apply this standard and pre-identify categories of information provided under the Minnesota Statute as trade secret and not publicly available pursuant to the Minnesota Data Practices Act. Such required information.

Honeywell recognizes the difficulty MPCA faces in its effort to develop and implement unavoidable use criteria. The agency must find a balance between protection of the environment and burden to industry. Honeywell appreciates the opportunity to provide comments to MPCA in the hope that the Unavoidable Use criteria are sufficiently protective while not suppressing innovation or stifling economic opportunity in the state.

Honeywell

Conclusion

Honeywell appreciates your consideration of these suggestions and would be glad to participate in further discussions about these comments. We look forward to reviewing and commenting on the Planned Rule.

Sincerely,

Atashi Bell, PhD
Senior Director, Global Government Relations
Atashi.Bell@Honeywell.com

Submitted via the Minnesota Office of Administrative Hearings eComments Website

Katrina Kessler
Commissioner
Minnesota Pollution Control Agency
520 Lafayette Road N
St. Paul, MN 55155-4194

Re: Intel Corporation's Comments on the MPCA's Request for Comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per- and Polyfluoroalkyl Substances (PFAS); OAH Docket No.71-9003-39667; Governor's Revisor's ID Number: R-4837

Intel Corporation (Intel) appreciates the opportunity to provide our comments on the Planned New Rules Governing Currently Unavoidable Use ("CUU") Determinations about Products Containing per- and polyfluoroalkyl substances (PFAS) being developed by the Minnesota Pollution Control Agency (MPCA or the Agency), as authorized in Minn. St. § 116.943 (Section 116.943). These comments discuss the MPCA's planned rules governing currently unavoidable use determinations about products containing PFAS.

Intel is a leading developer of microchip processor technologies, operates semiconductor manufacturing facilities in the United States, and sells semiconductor products into the State of Minnesota. Intel also has participated in providing information to MPCA as a contributor to the more detailed comments provided by the Semiconductor Industry Association (SIA) and SEMI; Intel endorses and adopts the SIA and SEMI comments that will be submitted prior to the comment deadline.

The use of per- and polyfluoroalkyl substances (PFAS) materials in the semiconductor manufacturing process is critical. PFAS' unique chemical properties, including stability and non-reactivity are invaluable to their use as process chemistries in the discrete semiconductor manufacturing steps but also to the use of fluoropolymers in the wider semiconductor manufacturing process ecosystem.

Additionally, a peer-reviewed journal article published by Professor Chris Ober and colleagues at Cornell University summarizes the uses of fluorinated materials in the lithography process and concludes: "The addition of small quantities of fluorinated materials enables patterning capabilities that are otherwise not possible to achieve, and this leads to superior device performance. The compact size of the fluorine atom and its strong electron withdrawing characteristics make it stand out in the periodic table and gives fluorocarbon materials unique properties, unmatched by other chemical compounds."1

As a company committed to environmental sustainability, corporate responsibility, and the safety of our workers and communities, Intel strives to minimize our use of substances that pose risks to the environment or human health. Since 2002, we have migrated from long-chain PFAS (PFOS and PFOA) to short chain PFAS; and it is Intel's policy to no longer use, buy, or conduct research with long-chain PFAS materials. Our focus on eliminating long

[1] Christopher K. Ober, Florian Käfer, Jingyuan Deng, "The essential use of fluorochemicals in lithographic patterning and semiconductor processing," J. Micro/Nanopattern. Mater. Metrol. 21(1), 010901 (2022), doi: 10.1117/1.JMM.21.1.010901, available at http://dx.doi.org/10.1117/1.JMM.21.1.010901

chain PFAS varieties was consistent with the US and EPA regulatory focus and the scientific consensus that longer-chain PFAS are of greater health and environmental concern than shorter-chain varieties. However, today the industry remains dependent on short-chain PFAS, with no non-fluorinated alternatives on the horizon for most existing uses.

The MPCA, in the Request for Comments, is seeking comments on specific questions: The following are Intel's responses to those specific questions on which the MPCA requested input.

1. Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Intel endorses and adopts the SIA and SEMI comments that will be submitted prior to the comment deadline.

2. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Intel endorses and adopts the SIA and SEMI comments that will be submitted prior to the comment deadline.

3. Should unique considerations be made for small businesses with regards to economic feasibility?

Not applicable, as Intel does not operate as a small business.

4. What criteria should be used to determine the safety of potential PFAS alternatives?

Intel endorses and adopts the SIA and SEMI comments that will be submitted prior to the comment deadline.

5. How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

Intel endorses and adopts the SIA and SEMI comments that will be submitted prior to the comment deadline.

6. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Intel endorses and adopts the SIA and SEMI comments that will be submitted prior to the comment deadline.

7. In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Intel intends to seek a CUU determination for:

- Uses of PFAS in the semiconductor industry as a general category of usage
- Uses of PFAS in cables, connectors, and capacitors

Copyright © Intel Corporation. All rights reserved. Intel and the Intel logo are trademarks of Intel Corporation.

- Use of hydrofluoroolefin (HFO) refrigerants for Electronics Cooling in Data Centers

Intel requests that a Currently Unavoidable Use (CUU) be provided as a general category for the semiconductor industry that includes all currently unavoidable uses throughout the semiconductor supply chain, including the upstream semiconductor supply chain industries, the semiconductor manufacturing process, and the final packaged semiconductor devices that are produced. Examples of CUU PFAS uses in each of these three subcategories are as partially listed below and including:

- Uses in upstream semiconductor supply chain industries, including but not limited to uses of fluoropolymers and other PFAS used in high purity chemical production and packaging, and fluoropolymers and other PFAS integrated into semiconductor manufacturing equipment, and
- Uses within the semiconductor manufacturing process, including but not limited to PFAS ingredients within specialty chemicals and fluids, fluoropolymers and other PFAS used in production of high purity water and in containment and transport of high purity water and chemicals, and uses of fluoropolymers and other PFAS in facility systems, and
- Uses within the final packaged semiconductor devices, including but not limited to finished semiconductor devices and component parts such as encapsulants, thermal interface materials, adhesives, coatings, and substrates.

Semiconductors form the essential building blocks of modern technology, enabling critical technologies and industries that form the foundation of the U.S. economy and the functioning of society, including the automotive industry, defense, electronics, communications, data storage and analysis, legal and regulatory infrastructure, scientific (including materials) research, medicine and medical devices, the green energy transition, transportation (including aviation), and much more. With up to tens of billions of transistors on a single piece of silicon, producing these complex devices requires highly advanced processes and equipment, as well as the use of chemicals, gases, and other materials with specific performance and functional attributes. Today, the smallest transistor is just 3 nanometers in size – 5 atoms thick and 30,000x thinner than a human hair. The fabrication process can include up to 1,400 process steps, with each process step typically involving the use of a variety of unique, highly sophisticated machines and materials. The supply chain for semiconductor manufacturing is extremely complex, as noted by numerous U.S. government publications.[2]

PFAS are among the inputs essential to chip manufacturing, used in a wide range of industrial processes and consumer products. Although the semiconductor industry accounts for only a small fraction of the world's total PFAS usage[3], many uses of specific PFAS are essential to semiconductor manufacturing. PFAS have essential uses in a wide variety of applications because they possess certain critical performance and functional attributes needed to manufacture semiconductors and the sophisticated equipment and infrastructure needed in the process. The carbon-fluorine bonds and structure of PFAS give them unique physical and chemical properties, such as strong electronegativity, low refractive index, good thermal stability, good barrier properties, hydrophobicity, low dielectric current, uniformity in coating with minimal effect on properties provided by other chemicals, thermal resistance, chemical resistance, low surface adherence, resistance to grease and stain, anisotropic etching capability, selective metal oxide removal, reduced shedding, high-temperature thermal stability, low adhesion strength,

chemical inertness, low volatility, UV resistance, flame resistance, low coefficient of friction, and many others. This range of properties across the many different types of PFAS and applications, are useful in many industrial and consumer applications, including semiconductor manufacturing. Given the complexity of semiconductors and related systems, MPCA must recognize that even just one use of PFAS deemed not to be a CUU could inadvertently prohibit the import of semiconductors into the state and cause all semiconductor manufacturing in Minnesota to cease operations.

The Semiconductor PFAS Consortium[4] has identified over 1000 uses of PFAS in the semiconductor manufacturing process and associated supply chain. Each use is essential to producing the final chip. There are currently no known substitutes for most of these applications. Identifying, developing, and qualifying suitable substitutes will require new inventions, and if found, the process of introducing substitutes into high volume manufacturing is complex; the process can take anywhere from 5 to 25 years, and in many cases may never be possible.

The reason why Intel intends to seek a CUU for use of PFAS in cables, connectors and capacitors is because the PFAS fluoropolymers that are used in these applications provide combinations of essential properties that alternative non-PFAS materials do not.

The reason why Intel intends to seek a CUU for use of HFO refrigerants for electronics cooling in data centers is because of the need to provide adequate cooling for high performance server computing products, such as those that support artificial intelligence (AI), in applications where alternative non-PFAS based cooling technologies are not capable of providing adequate cooling.

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Intel endorses and adopts the SIA and SEMI comments that will be submitted prior to the comment deadline.

9. Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

Intel endorses and adopts the SIA and SEMI comments that will be submitted prior to the comment deadline.

Conclusion

Intel is grateful for the opportunity to engage on MPCA's planned rulemakings and is available to meet at your convenience to further elaborate on the issues discussed in these comments. If you have any questions or would like to discuss our positions, please do not hesitate to contact Kevin Wolfe (kevin.w.wolfe@intel.com).

[4] In January 2021, SIA facilitated the establishment of the Semiconductor PFAS Consortium, an international group formed to collect the technical data needed to formulate an industry-wide approach and better inform public policy and legislation regarding the semiconductor industry's use of PFAS. The consortium membership is comprised of semiconductor manufacturers and members of the supply chain including chemical, material, and equipment suppliers. To date, the Consortium has published a series of nine technical papers summarizing the uses of PFAS in the semiconductor industry and significant technical challenges to replace these substances in the range of uses in the fabrication process and fab equipment. Additional information is available at www.semiconductors.org/pfas/ Semiconductor PFAS Consortium, Background on Semiconductor Manufacturing and PFAS, May 17, 2023.

JBMIA's Proposals on Currently Unavoidable Uses (CUUs) under Maine PFAS Law - 38 M.R.S. §1614

JBMIA Chemical Products Technical Committee

Japan Business Machine and Information System Industries Association (JBMIA) represents the global leading companies of business machines industry, and our main products are printers, copying machines, multifunction devices (MFDs), and their consumables, including toner.

JBMIA appreciates the opportunity to give our proposals on Currently Unavoidable Uses (CUUs)under Maine PFAS Law - 38 M.R.S. §1614.

1.Provide a brief description of the type of product including, if applicable, the Global Product Classification (GPC) brick category and code, or if GPC is not applicable than the Harmonized Tariff System (HTS) code.

Global Product Classification (GPC)
10001156 Printer Consumables
10001251 Photocopier Consumables

These are consumables for office machines, multifunctional devices(10005229), photocopiers(10001252) and printers(10001158).

2.Describe the intended use of the product and explain how it is essential for health, safety or the functioning of society.

Multifunction devices, copiers, and printers are devices for printing documents and images in offices and homes. Multifunction printers usually combine multiple functions into one device. Basic functions include printing, copying, and scanning. Some models may also include fax functionality. A printer is a device that is primarily used for printing, and is generally capable of only printing. All of these devices are used to meet a variety of printing needs for work, study, and personal use, and are essential infrastructure for society.

JBMIA

3.Describe how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, provide citations to that requirement.

Copiers and printers can print on paper by using consumables such as toner, ink, and developer (a mixture of toner and carrier). For example, the toner is composed of resin, wax, pigment, and other additives, and as part of these additives, PFAS (fluoropolymers, fluoroalkyl compounds with functional groups, etc.) are used for the reason that they can simultaneously provide various functions such as low dielectric constant, low dielectric tangent, low surface tension, water repellency, heat resistance, chemical resistance, and high negative charge. Under the copiers and printers of two-component development system, carrier is used for attaching the toner onto the photoconductor by electrostatic effect. PFAS (Fluoropolymers, polymers with fluoroalkyl groups in their side chains, etc.) are used as a component of some carriers to provide high negative charging and wear resistance. (See Attachment 1)

In the case of ink, it is necessary to add a dispersant having a surface-active function in order to disperse the pigment uniformly.

Especially for high-speed printing system of plain paper, PFAS is an essential ink component not only because of its surface-active function but also because of the uniformity of ink droplets and rapid fixing and drying. (See Attachment 2)

If the use of PFAS is effectively banned, they will not be able to produce consumables that use PFAS, and copiers and printers operating in the market which use consumables that use PFAS will not be able to use them.

Printers have already become an essential social infrastructure, and if PFAS is banned, a certain percentage of copiers and printers will immediately become unusable, affecting companies/government agencies/individuals.

4.Describe whether there are alternatives for this specific use of PFAS which are reasonably available.

PFAS replacement requires a review of the entire system configuration of copiers and printers, and it is necessary to develop both the main unit and consumables. At present, the outlook for the time frame and cost required for the current development is uncertain. In addition, if consumables for copiers and printers in the market use PFAS, it is not possible to replace only the consumables with alternatives that do not use PFAS. (See Attachment 3)

If PFAS is completely banned, a certain percentage of consumables for products cannot be supplied, and copiers and printers that can normally operate will quickly become waste before reaching the end of their lifespan, resulting in an increase in waste. Please exempt printer consumables and copier consumables from the sales ban as unavoidable uses.

5.Provide contact information for the submission.

About JBMIA

Japan Business Machine and Information System Industries Association (JBMIA) is the industry organization which aims to contribute the development of the Japanese economy and the improvement of the office environment through the comprehensive development of the Japanese business machine and information system industries and rationalization thereof. The advancement of information technology has brought about sophistication of the age of digitalization and networking and resulted in significant changes in the office environment accordingly. In response to the shift of business emphasis from the hardware to total business solutions including products, JBMIA carries out active committee/group activities regarding important issues that the industries are confronting in and outside Japan by conducting investigations and researches regarding the policy proposals, international cooperation, prevention of warming, environment preservation, standardization, product safety, etc., by deepening the association with the sales and software-related companies, as well as the manufacturers.

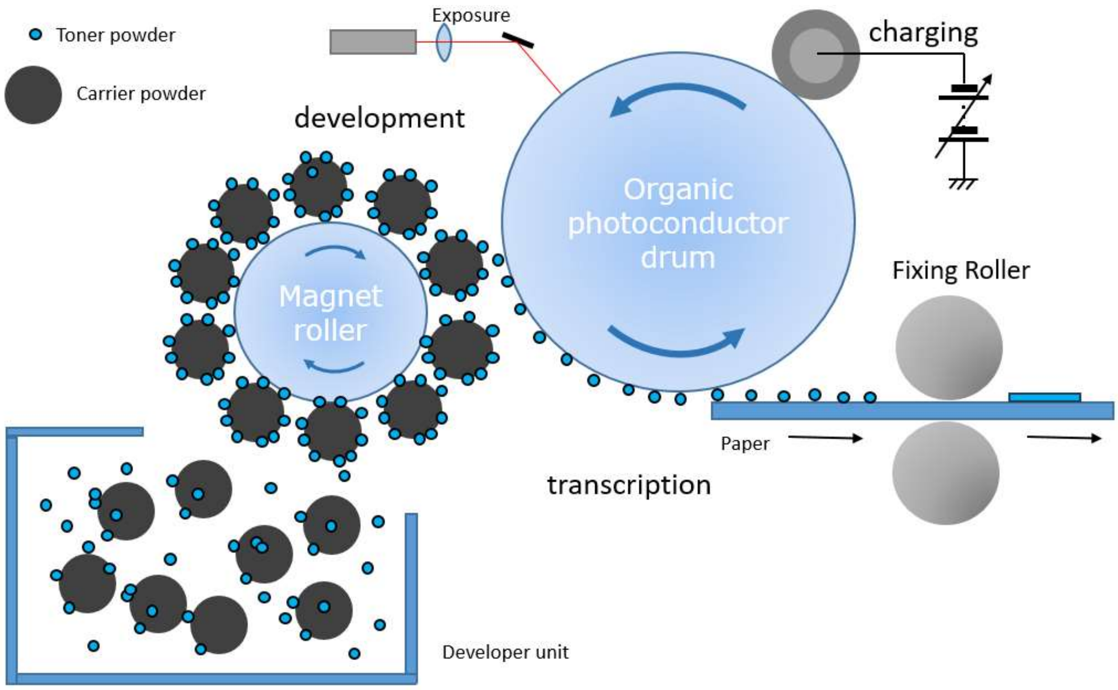
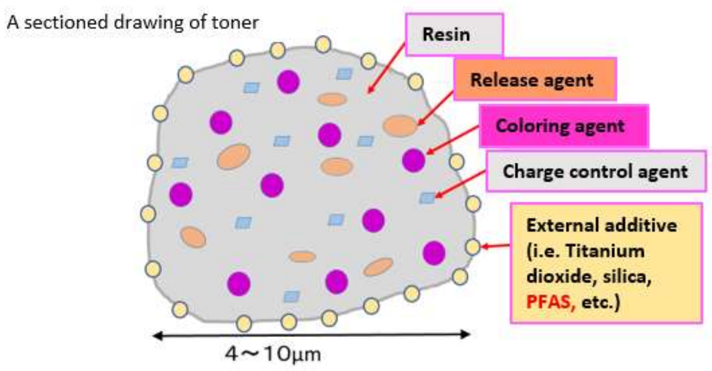
Description about Toner and Carrier

The electro photographic development system is a complex technology that works when there is a perfect balance with the carrier that feeds the toner to the photoconductor.

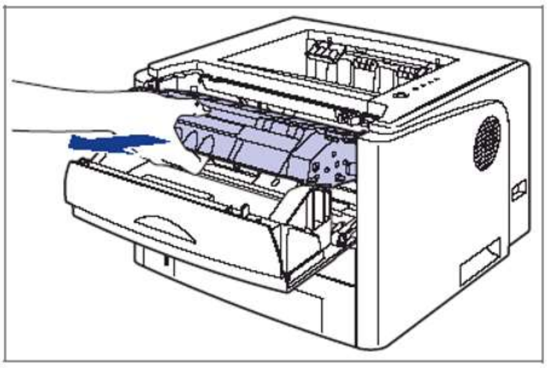
The toner and carrier are mixed and permanently agitated in the developer station to keep the toner particles with the precise electrical charge needed for their development process. This toner and carrier blend is named developer.



The toner is composed by a thermoplastic polymer of 5-10μm particle size, usually a polyester or a styrene-acrylic resin. About 10-20% of its composition are pigments, waxes, silica and other minor additives such as fluoropolymers.



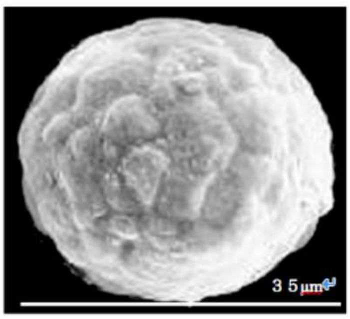
The toner is delivered to the consumer in a sealed condition in a toner cartridge. Plural kinds of toners of various combinations of constituent materials are used according to the equipment, and the capacity is also different according to the specifications of the equipment, and the shape is also different according to the mechanism of the equipment.
The warranty period of the product is usually around 10 years.
Therefore, we must continue supplying the toner cartridges as consumables to customers who have purchased copiers and printers for at least 10 years.



Toner cartridge

Toner bottle

The carrier are bigger particles, usually 40-100μm in average particle diameter, composed by an iron or a ferrite core, and a coating. The coating is usually a fluoropolymer, silicone, or styrene acrylate. Due to the mixing, there is friction between toner and carrier particles which give electrical charge to the toner particles.
we must continue supplying the carrier(developer) as a spare parts to customers who have purchased copiers and printers for at least 10 years.



Toner

Quoted from a certain carrier manufacturer

Description about roles, functions, and necessity of PFAS

By applying PFAS as either of a coating on the carrier particles or a toner surface additive, or by applying PFAS as both of them, friction between the toner and the carrier is reduced, and the toner is protected from degradation and the carrier particles are protected from contamination. As a result, a staggering number of the developer life were established, which could not have been achieved without the use of PFAS.

In addition, its electrical charging properties can contribute to such effects as improving initial charge rising property and ensuring the stable frictional charging to the toner particles during all the developer life.

Relation and Influence with the equipment

Toners including PFAS achieve an increased durability meanwhile printing.

This means that any part or component where there is friction between toner or printed paper and metal such as printer rollers, drums, blades, etc in the printer or in the post-processing equipment will be protected and achieve a longer life thanks to the use of PFAS.

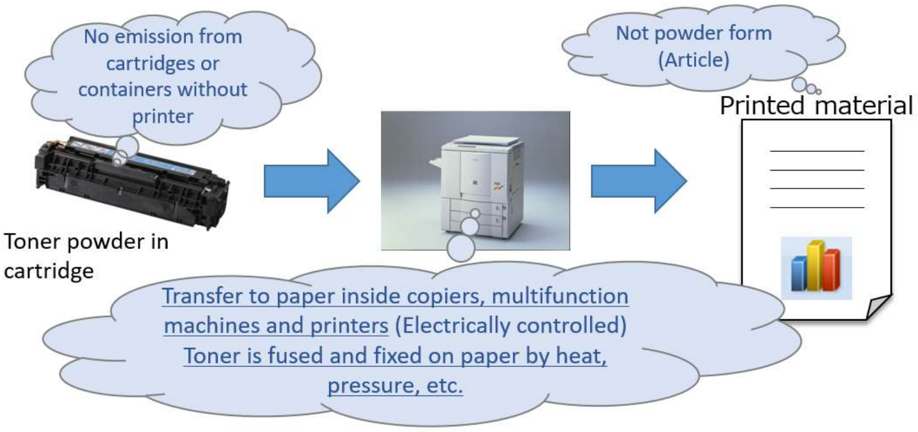
In small and medium size printers for home and office, the damage of unreplaceable components, means a shorter life-time of the printer and an increase of electronic waste generation. In case of large size and production printers, without the aid of PFAS, parts and components of rollers and post-processing units will need to be fixed or replaced earlier with the consequent effect of maintenance cost increase and productivity loss.

Further, the toner containing the PFAS improves initial charge rising property and charging stability. Due to that, effects such as making generation of the toner scattering not easily and making fogging generation not easily, can be obtained, thereby contributing to prevention of contamination in an equipment by scattering toner and stabilization of image quality.

If there is no aid of PFAS, it may have negative effects, such as deterioration of the contamination in an equipment and destabilization of image quality, and it can be considered that the maintenance cost to cope with them will be increased and productivity will be decreased.

Possibility of exposure during use

- Machine design: Extremely low risk of exposure to toner under normal use condition



- Toner powder is melted and fixed into the paper during fixing process.
- The printed material is recognized as an "Article".

Attachment 2

Ink used in inkjet printing system

The inkjet printing system has inkjet head devices to change ink into fine particles by applying pressure and heat, and ejecting these particles allows printing directly onto print media.

There are various types of ink (pigment ink, dye ink, solvent ink, and water-based ink etc.). The common requirements for these inks are same droplet size, high print density, quick fixing & drying, hard to fade, and hard to clog the inkjet head etc. The ink type is selected according to the application, but water-based pigment ink is preferred to make image less prone to fading and to reduce volatile organic solvents.

Usually, pigment never mix with water, therefore it is needed to add surfactant function. Besides, to achieve above requirements, the ink is mainly composed of pigment, water, dispersant (including surfactant function), resin for fixing, penetrant and organic solvent called wetting agent etc.

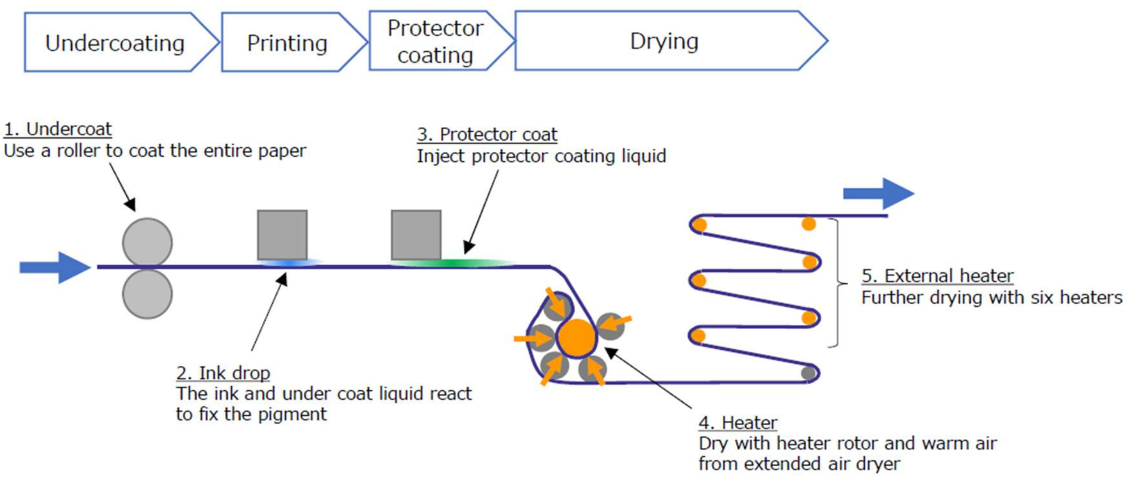

Fig.1 Inkjet system (PFAS contributes to quick fixing and drying.)

PFAS roles, functions, necessity etc.

As mentioned above, it is important to maintain a balance between hydrophobic and hydrophilic substances in the ink. If the balance is lost even a little, ink loses its function. PFAS does not have only surfactant function, excellent chemical resistance, heat resistance, but also maintains its balance for a very long time in usage and transportation environments. Moreover, due to its low surface tension properties compared to other surfactants, PFAS is particularly good at ejecting uniformly sized droplets at high speed, especially on plain paper. Also, PFAS is superior in fixing and drying due to its fast penetration into the print media, so high speed printing (150m/min) could not be realized without PFAS.

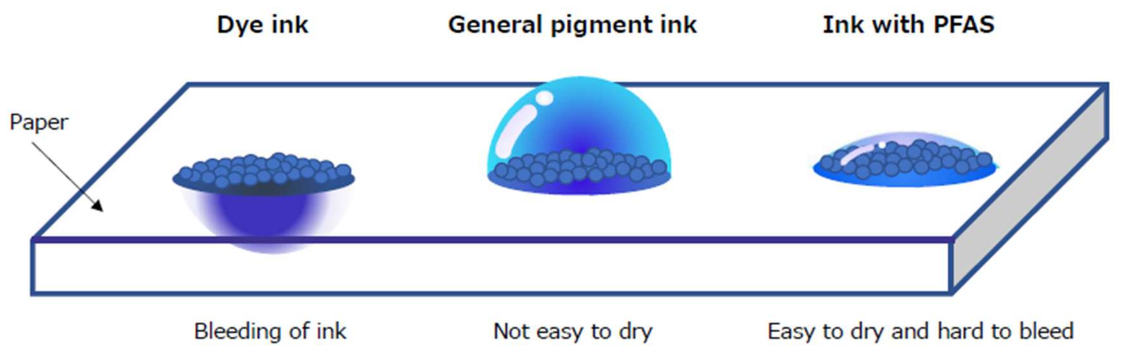

Fig.2 High quality ink droplets

(PFAS achieves both droplets uniformity and high-speed fixing & drying.)

Influence on the printer

PFAS prevents ink from adhering near inkjet head nozzles, so the maintenance period and the inkjet head life can be extended. It means less downtime and increased productivity. Without PFAS, parts need to be replaced soon and it leads increased maintenance cost and decreased productivity.

Attachment 3

Need a huge time to phase-out PFAS used for printers EVEN IF the substitute material of PFAS is available in the future

The substitute materials instead of PFAS to fulfil for many of necessary functions required in printing process is not available yet.

Challenging issues to be addressed for substitution of PFAS

We expect that it will take a huge time to explore alternative materials to fulfil the superior properties of PFAS, even if we focus only on PFAS containing in toner itself.

Since toner closely interacts with various components and units in the whole printing processes, a change of toner materials will have a large influence on various mechanical components, electrical setting, sequential process and software and so on, which are mutually influence each other. As a result, all of them will need to be changed, so a long period will be necessary for research and development for alternative materials.

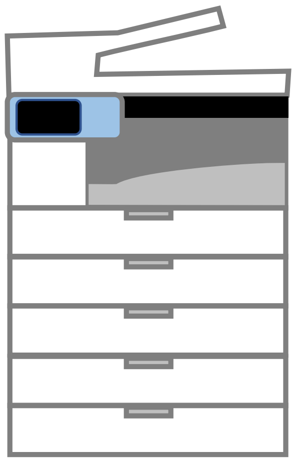
Please note that the above situation is the same as ink other than toner.

Material

Toner and carrier materials affect various behaviors.
In case of changing a material of toner or carrier, a various properties such as charging properties, fluidity and adhesion, etc. will be changed, but only certain property cannot be changed. It is quite possible that extending one property degrades another. In particular, since PFAS is a material that satisfies many excellent properties simultaneously, it is impracticable to substitute materials for the toner and carrier while maintaining the same properties.
In addition, when the material of the toner and the carrier is changed, the mechanical device, the electrical device, the sequence, etc. must be changed.

Mechanical devices

In case of the toner material changes, the behaviors between the toner and the various mechanical components are also changed. (For example, a change in sliding behavior, torque of a motor, etc.)
In addition, the size, angle, thickness, strength, and material of the component may have to be changed to satisfy the physical behavior.
Changing the toner requires adjusting them. Because they interact in complex ways, they cannot be changed independently, and a lot of time is needed to satisfy all conditions.



Software

The printer and copy processes and operations requires precise movement of various parts, components and units in conjunction with each other.
Each timing, elapsed time, voltage magnitude and application time, heater temperature and operation time, motor driving speed and time, etc. must be precisely controlled.
In case of changing a certain material in the toner, it is absolutely necessary to change all of these timings, operation times, intensities, and sequences.
They also affect each other, so it takes a lot of time to find a configuration change that meets all requirements.

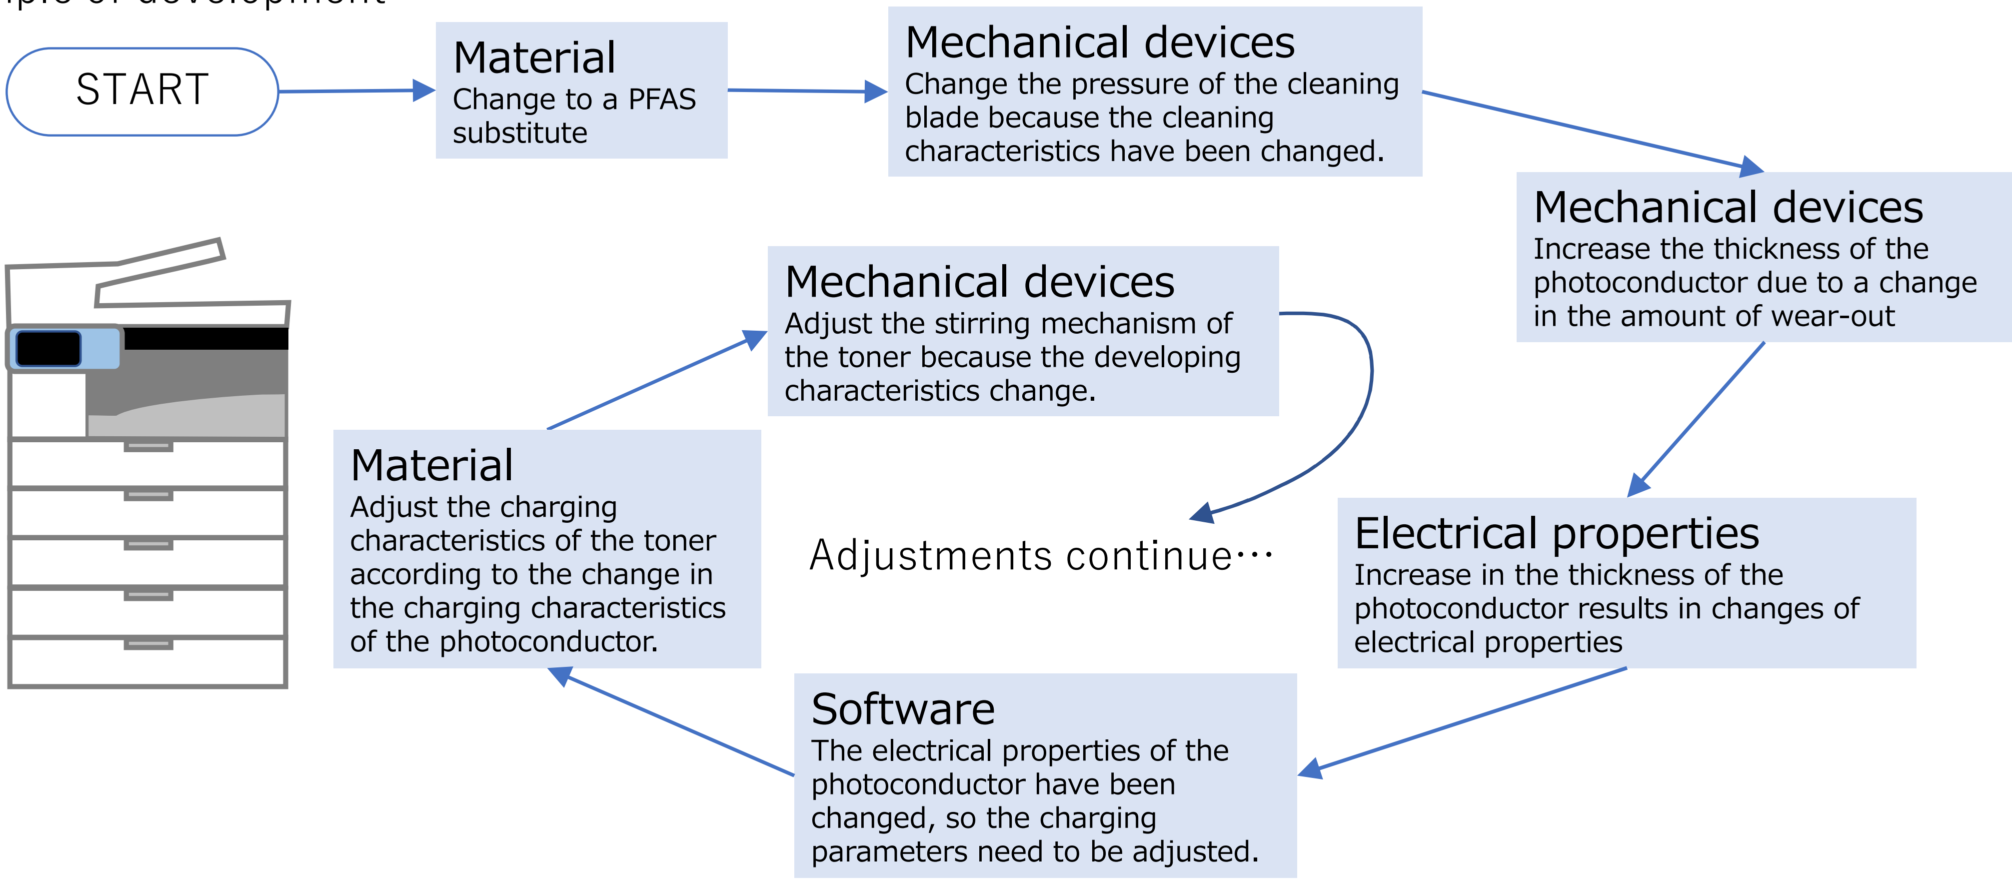
Electrical properties

In the printing and copying operations, the toner must adjust its electrical characteristics with a photoconductive drum or an intermediate transfer belt.
When the toner material is changed, the electrical settings must be changed too, but because various variables affect each other, it takes a lot of time to find an optimized setting change that meets all the performance requirements.

Challenging issues to be addressed for substitution of PFAS

The material change of a certain part will have an influence on many of various components and properties, which are mutually influence each other. As a result, all of them will need to be changed, so a long period will be necessary for research and development for alternative materials.

Example of development



Can the development period of copiers and printers be shortened?

=> We believe that it will be Impracticable

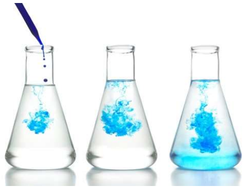
Performance requirements for copiers and printers, quality requirements for printed and copied images, and durability vary by model.
Since there are few common development items in these developments, it is not easy to shorten the development period.
For substituting materials, it will take at least two or three years for equipment development, matching with toner and ink, and production preparation respectively, and multiplied by the number of models.

	Consumer model	Office model	High-performance/production model
Examples of performance required	・Maintenance Free ・Space-saving	・High productivity (speed) ・energy-saving property	・Printed image quality ・low running cost
Examples of Output	・Documents used at home	・Office documents	・Catalogs, publications, posters, etc.
Examples of print volume	・10～100 sheets/month	・500～5000 sheets/month	・more than 10000 sheets/month

Need a huge time to phase-out PFAS used for printers EVEN IF the substitute material of PFAS is available in the future,

The substitute materials instead of PFAS to fulfil for many of necessary functions required in printing process is not available yet.

*This page refers to toner as an example of consumables, but also ink.



exploration and development of materials

The substitute material for PFAS is currently not available for toner, so the joint research and development with materials manufacturers will be required.

・confidentiality agreement
・joint development agreement
・Testing of chemical substances and registration
・Screening test for basic characteristics
・Performance tests for material selection
・Adjustment work for improving characteristics
(Material shape, size, mixing ratio, etc.)

toner development

Development of toner & carrier takes time even after material determination

・Matching of new raw materials with other materials
・Adjustment of properties such as friction coefficient, dielectric constant, electrical resistance, fluidity, and thermoplastic properties
・Adjustment of charging characteristics in developing device
・Durability to maintain performance over long periods of time
・Maintaining characteristics under various environments such as high temperature and humidity

development of equipment & Matching

After the development of the toner & carrier, it is necessary to verify whether the functions are appropriately work in the copying and printing processes.

・Is it properly discharged from the container? Is it necessary to adjust the discharge mechanism?
・Is image development is appropriate? Is it necessary to change the agitation?
Is it necessary to adjust the nip width between the developer and the photoconductor?
・Is the toner remaining in the photoconductor properly cleaned? Is cleaner adjustment needed?

production preparation

It is necessary to verify that the quality of the product meets a various requirements as final product prior to production processes.
(For example, it is necessary to measure VOCs emitted from machines and inspect that they fall below the permissible value specified by environmental labels, etc.)

・If production processes and / or facilities need to be changed, it is necessary to develop an investment plan and to carry out modification of facility or construction.
・It is necessary to carry out equipment tests, etc. depending on modification of facility or construction. In some cases, it is necessary to undergo statutory inspections and occupational safety audits.

delivery

Some countries require customs clearance procedures, so it is necessary to do so in advance.

It may take several months to ship products by sea.

For a stable delivery of products, it is necessary to establich a supply system by multiple raw material manufacturers. It is quite important from the view point of the Business Continuous Plan.

3-4 years → 2-3years x models → 2-3years x models → Few months

The warranty period of the product is usually around 10 years. This means that after selling, the company must continue to provide spare parts for another 10 years.
In other words, **the development period of equipment and parts (7 to 10 years or more) plus the provision period of spare parts (10 years) is required** to complete the PFAS-free process.

Comments on the *PFAS in Products Currently Unavoidable Use Rule*

February 2024

We welcome the opportunity to contribute public comments on the Minnesota Pollution Control Agency's (MPCA) rulemaking for the *PFAS in Products Currently Unavoidable Use Rule*, which will implement Minnesota Statute 116.943. We have prepared and organized our comments below based on the nine questions provided in MPCA's Request for Comments.[1]

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Criteria should be defined. Doing so will promote transparency in currently unavoidable use (CUU) determinations. In addition, it will allow parties seeking such determinations to better understand the bases for such determinations and to provide information that will best inform the MPCA's determinations.

Defining the criteria for CUU determinations presents an opportunity to best protect the health, safety, and economic interests of Minnesota citizens. The statute at issue defines PFAS broadly (Minn. Stat. § 116.943(1)(p)), but not all of the PFAS included in that definition present the same risks to human health and the environment or provide the same irreplaceable value to society. As explained below, to reduce the risk that the statute's broad definition of PFAS will deprive Minnesotans of essential PFAS uses and the associated economic, health, and safety benefits those uses provide, the criteria should promote determinations based on the relative risks and benefits of the particular PFAS compound and use at issue.

The relative risks posed by different PFAS should be accounted for in the criteria. The Minnesota statute's broad definition of PFAS includes a wide variety of PFAS that present different risks to human health and the environment. As a result, the idea of a one-size-fits-all approach for all PFAS and all uses of PFAS is not appropriate. Risks should be quantitatively assessed on a substance-by-substance basis as well as a use-by-use basis.

The risk posed by the particular PFAS, and the particular use of the PFAS, at issue should inform the showing needed to demonstrate that a use is essential. Although PFAS

---

[1] *See* https://www.pca.state.mn.us/sites/default/files/c-pfas-rule3-01.pdf (lasted accessed on Feb. 21, 2024).

presenting significant risks may require greater scrutiny in determining whether they are essential, PFAS presenting less risk should receive less scrutiny. Importantly, some of the PFAS included under the Minnesota statute's broad definition are also uniquely suited for uses important to the health, safety, or functioning of society. Such uses include those related to climate goals and green energy, critical infrastructure such as buildings and roads, public transportation, construction, healthcare, critical industry and economic drivers, and cultural traditions. Balancing the risks and benefits of a particular PFAS and its use – such that those posing less risk are more likely to be found essential – would allow Minnesota to best capture the benefits from PFAS uses important to the health, safety, or functioning of society while minimizing risk to Minnesota citizens.

For example, criteria should be adopted that ensure that fluoropolymers, and especially PVDF, are determined to be CUU. Of the thousands of different types of PFAS, there are only about 40 fluoropolymers, and fluoropolymers have fundamentally different physical properties from low molecular weight PFAS such as PFOS and PFOA. Unlike low molecular weight PFAS like PFOS and PFOA, fluoropolymers do not enter the metabolic system of the human body or bioaccumulate and, because they are insoluble in water and non-mobile, they do not leach into soil or water systems when landfilled. Scientific literature indicates that fluoropolymers have minimal impact to human health and the environment, and that 96% of the global fluoropolymer market meet the criteria for Polymers of Low Concern (PLC).[2]

In addition, fluoropolymers have numerous uses critical to health, safety, and the functioning of society. For example, the unique properties of PVDF have led to its essential use in binders and adhesive tapes for lithium-ion batteries, including those for EVs (electric vehicles), various components in the semiconductor industry (pure water piping, chemical piping, etc.), medical applications (pure water piping, chemical pump components, cleaning tank lining, etc.), piezoelectric and pressure sensors (bridges, roads, etc.), piezoelectric speakers, ultrasonic probes, touch panels for smartphones and tablets, coating films (walls, floors, vehicles, etc.), fishing line, and musical instrument strings. These uses of PVDF play an essential, and irreplaceable, role in society. Further, all of these uses take advantage of

---

[2] B J Henry et al, 'A Critical Review of the Application of Polymer of Low Concern and Regulatory Criteria to Fluoropolymers.' *Integrated Environmental Assessment and Management* **2018**, 14 3, 316–334; S H Korzeniowski et al, 'Critical Review of the Application of Polymer of Low Concern Regulatory Criteria to Fluoropolymers II: Fluoroplastics and Fluoroelastomers.' *Integrated Environmental Assessment and Management* ***2022***, 326-354.

the unique properties of PVDF, and there is no alternative material that combines all of these properties.

As such, these uses of PVDF fall squarely within the definition of CUU in the Minnesota statute, as "essential for health, safety, or the functioning of society and for which alternatives are not reasonably available" (Minn. Stat. § 116.943(1)(j)). At the very least, clear criteria should be adopted to ensure the uses of PVDF outlined above are determined to be CUU.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

The costs of potential PFAS alternatives should be considered in any definition of "reasonably available." A cost-prohibitive alternative may have the practical effect of depriving society of a PFAS use that would otherwise be found essential for health, safety, or the functioning of society.

Costs for alternatives would include the economic cost of production – such as the cost of raw materials, and the time and cost to transition manufacturing processes and to market the alternative – as well as the potential resulting social costs. For example, cost-prohibitive alternatives may lead companies to stop manufacturing certain essential products, to raise the prices of those essential products, or to replace products with poorly functioning alternative products.

The cost threshold for determining whether a particular alternative is "reasonably available" will depend on a number of considerations. In addition to accounting for the relative risks and benefits of the particular PFAS and use at issue, the economic incentives created by and socio-economic impacts of a particular alternative should be considered.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

Economic feasibility for Small and Midsized Enterprises (SMEs) should be considered. In comparison to larger businesses, SMEs often have fewer financial and human resources. As such, economic feasibility for SMEs may have a significant impact on the availability of certain essential products. For example, if SMEs can no longer afford to manufacture an essential product, that product may no longer be available or that product's price may rise due to reduced price competition in the market for that product. In addition to considering these SME-specific economic issues, MPCA should examine options to ameliorate SME-specific economic impacts, such as establishing a grace period for compliance by SMEs.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

Criteria should be developed for determining the safety of PFAS alternatives. Such criteria should account for the relative risks and benefits of the particular PFAS compounds being replaced in comparison to the risk posed to human health and the environment over the alternative compound's life cycle.

For example, as explained in the response to Question 1, scientific literature indicates that fluoropolymers (such as PVDF) have minimal impact to human health and the environment and that the vast majority of fluoropolymers meet the criteria for PLC; and fluoropolymers have numerous uses critical to health, safety, and the functioning of society. In addition, fluoropolymers are chemically stable, insoluble in water, and have a long useful life. Indeed, based on recent studies evaluating available data from 2020, it is anticipated that less than 0.01% by weight of fluoropolymers entered relevant waste streams in Europe, which is significantly lower than the 4.8% estimated for other plastics.[3]. Replacing fluoropolymers with other plastics would thus likely result in increased plastic waste.

Accordingly, criteria should be adopted to analyze the safety risks and benefits to human health and the environment of PFAS alternatives, and such criteria should ensure that uses such as those identified for PVDF in response to Question 1 are determined to be CUU.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

The duration of a CUU determination should not be set uniformly. Each CUU determination should be different, as it should be based upon the relative risks and benefits of the particular PFAS and the particular use at issue, as well as the economic and social costs of any reasonably available alternatives. In addition, the time and cost required to

[3] J Sales et al, 'Fluoropolymers: The Safe Science That Society Needs.' International Chemical Regulatory and Law Review 2022, 5 (1), 13-23.

develop and market alternative products will differ. The duration of a CUU determination should account for such time periods, so as not incentivize companies to rush inadequate alternatives to market before a CUU determination expires.

Although a significant change in the available information about reasonably available alternatives may warrant re-evaluation of a CUU, standards should be set for what qualifies as a significant change. Otherwise, there is a risk that the burdens and costs imposed by the regulatory process itself will make production and sale of products recognized as CUU – namely, products recognized as essential and without reasonably available alternatives – economically infeasible. For example, for the reasons provided above, the uses of PVDF described in response to Question 1 should be determined to be CUU, and the burden of the regulatory process should not deprive Minnesotans of those critical uses.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

If there are PFAS uses that stakeholders believe should or should not be determined a CUU, they should be given the opportunity to provide reliable evidence supporting their position. Quantitative evidence of the relative risks and benefits of the particular PFAS and use at issue, as well as the economic and social costs of any reasonably available alternatives, should be required. Any evidence should be subject to rigorous scrutiny to determine its reliability.

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

For the reasons provided above, the uses of PVDF described in response to Question 1 should be determined to be CUU. The author currently intends to submit requests that certain uses of PVDF be determined CUU.

8) Should MPCA make some initial currently unavoidable use determinations as part of this

rulemaking using the proposed criteria?

For the reasons provided above, the uses of PVDF described in response to Question 1 should be determined to be CUU.

9) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

The statute at issue defines PFAS broadly (Minn. Stat. § 116.943(1)(p)), but not all of the PFAS compounds included in that definition present the same risks to human health and the environment or provide the same irreplaceable value to society. In defining the criteria for CUU determinations, the MPCA has an opportunity to reduce the risk that the statute's broad definition of PFAS will deprive Minnesotans of essential PFAS uses and the associated economic, health, and safety benefits those uses provide.

 Masatoshi Tsuruoka Attachment 1

The comment to PFAS in Products: Currently Unavoidable Uses (CUUs)

February 29, 2024

We, NIPPON ELECTRIC CONTROL EQUIPMENT INDUSTRIES ASSOCIATION (NECA), would like to express the gratitude of having the opportunity of stating our opinion to PFAS in Products: Currently Unavoidable Uses (CUUs)

Submission Requirements

1. *Provide a brief description of the type of product including, if applicable, the Global Product Classification (GPC) brick category and code, or if GPC is not applicable than the Harmonized Tariff System (HTS) code.*

0.1.1 About NECA

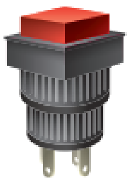
NIPPON ELECTRIC CONTROL EQUIPMENT INDUSTRIES ASSOCIATION (NECA) was established in 1964 and promoting the growth of the electric control equipment fields such as Relays, Switches, Sensors, PLC/FA System Equipment and others, Safety Control Equipment. Our website provides further information on our recent news and activities: https://www.neca.or.jp/en/

0.1.2 Product of NECA

<Relays>

Relays use electrical signals to open or close contacts, and consist of electric coils and contacts.
Variations include solid-state non-contact relays and relays incorporating timers and counters that provide measurement functionalities.

<Switches>



Switches allow users to directly power on and off system and equipment by hand, finger or foot by opening and closing the contacts to toggle electrical signals. These switches act as an interface between human and machine, allowing the user to take control such as starting up an operation.

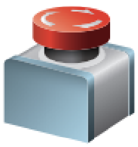
<Sensors>

Sensors that toggle electrical signals or generate an output, by physical contact or non-physical contact based on changes in light or magnetism to detect the presence of an object, its location, color, temperature, or rotational angle.

<PLC/FA System Equipment>

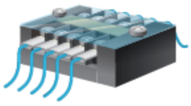
Programmable logic controllers, programmable display equipment, and FA (Factory Automation) system equipment such as ID systems, image processing systems, and temperature control devices that perform control and monitoring functions based on pre-programmed settings.

<Safety Control Equipment>



Emergency stop device, safety light curtains, safety relay, safety PLC, are control devices and I/O devices that conform to safety standards, designed for use in control circuits that ensure compliance with safety regulations for equipment and facilities.

<Other Control Equipment>



Equipment for transmitting electrical signals such as connectors and terminal, display and monitoring equipment such as revolving beacon and panel meters, and other control equipment such as power supply and solenoids for control functions.

<Parts and products in NECA are assembled into other products or system in variety types of business field such as shown below>

Classification	Example
Social infrastructure	Traffic monitoring and control including train and high speed motorway, automated teller machine, automated distribution system, automated ticket gate, analytical instrument, measurement instrument, tele communication, building management system, etc
Industry automation,	Robot for the automation, automated inspection

Process automation, Factory automation	instrument for something such as PCB, (Printed Circuit Board), equipment and protective system intended for use in potentially explosive atmosphere, monitoring and control instrument for the automation etc
Semiconductor manufacturing	To be made input from the business sectors The impact of potential PFAS restriction on the semiconductor section by SIA PFAS consortium is better to understand the examples. (*1)
Automotive vehicle	To be made input from the business sectors
Medical equipment	To be made input from the business sectors

(*1) https://www.semiconductors.org/wp-content/uploads/2023/04/Impact-of-a-Potential-PFAS-Restriction-on-the-Semiconductor-Sector-04_14_2023.pdf

Please see an attached file for HTS codes.

2. *Describe the intended use of the product and explain how it is essential for health, safety or the functioning of society.*

2.1. Features of our products

Our parts and products are assembled into highly specialized instruments used in laboratories, specialized institutions, and industrial sites. Therefore, the user must undergo special training and education in order to use it safely and correctly. In this opinion we will refer to our product as "EEE specialist equipment" to distinguish it from general consumer products.

2.2. Critical for social infrastructure

We would like to emphasize strongly that EEE specialist equipment we manufacture plays a very important role in the social infrastructure. Below are some examples. We believe that you can understand that the nature is different from the product of "nice to have".

<Case-1: Measuring and Control Instruments for Factory and Process Automation >

Measuring and Control Instruments for Factory and Process Automation are a product group for automating the operation of facilities and equipment in factories and infrastructure.

These products are indispensable for the production of all kinds of products that support people's lives and the economy, from raw materials industries such as petroleum and petrochemical products, iron and steel, and paper, to processing and assembling industries such as automobiles, electrical and electronic equipment, to food manufacturing industries such as beverages, and to pharmaceutical and medical equipment manufacturing industries.

It is also widely used as an important facility for the safe and uninterrupted supply of infrastructure such as electricity, gas, water and sewage.

In today's factories and infrastructure, these devices enable efficient and environmentally friendly facility operations and risk management measures, and provide safe and stable living environments for people.

However, parts containing PFAS are used in many Measuring and Control Instruments for Factory and Process Automation.

With the exception of electronic components, these devices have many parts that come into contact with products such as gas, water, and petroleum products and materials necessary for their production (including harmful chemical substances). They are used in a variety of environments, and therefore require high performance, such as, heat resistance, weatherability, chemical resistance, repellency from water and oils, electric insulation, and low friction.

PFAS is the only chemical substance that satisfies all of these requirements, and it is an indispensable material for long-term stable operation of factories and infrastructure.

If the use of PFAS is prohibited, Measuring and Control Instruments for Factory and Process Automation cannot be used within the US and the Maine state, and infrastructure and economically important products will not be supplied.

This will have a major impact on society and the economy.

2.3. Low volume of production, long-life, long supply chain

Our parts and products are assembled into the EEE specialist equipment. It is made in small numbers, is produced for long periods without modification or changes, and is a long-life product. The instruments would have been replaced typically after 7-10 years or more from the release of the products.[1] The supply chains are very long and take time to eliminate restricted substances from the supply chain. The data sources are

[1] Dr Paul Goodman, *Review of Directive 2002/95/EC (RoHS) Categories 8 and 9 – Final Report*, ERA Technology, 2006 Page 27-34
https://ec.europa.eu/environment/pdf/waste/weee/era_study_final_report.pdf

from the European Union; however, EEE used for social infrastructure accounts for small percentage. We believe that the other area around the world , more or less, the status is similar with this.

Characteristic	Test equipment	Mobile phone
Typical numbers sold	350	5.5 million
% of pre- 2003 products on market in 2006	>80%	<1%
Number of current distinct models per manufacturer	1600	300
Number of engineers available for each product	1.9	61.6
Time between launch of one product and its replacement	7 years on average	~ 6 months
Custom made parts	~25%	<5%
Time required for reliability testing (average per model)	4.3	0.7
Authorisations	Up to 2 years	< 6 months

Data from the Test and Measurement Coalition.

Table 1 Table comparison of industrial test equipment with mobile phones[2]

Table 5-4 Amount of EEE (tons) put on the EU market, per year and product category, “Support for the Evaluation of Directive 2011/65/EU on the restriction of the use of certain hazardous substances in electrical and electronic equipment Final Report” shows the percentage of category 8 and 9 products is only 3.5 of all amount of electric and electronic equipment(EEE) (tons) put on the EU market (see the below).[3] EEE used for social infrastructure accounts for small percentage. The statistics is from the European Union. We believe that the other area around the world, more or less, the status is similar with that of the EU.

---

The picture is produced from Table 5-4 Amount of EEE (tons) put on the EU market, per year and product category, Support for the Evaluation of Directive 2011/65/EU on the restriction of the use of certain hazardous substances in electrical and electronic equipment Final Report, p.147 https://op.europa.eu/en/publication-detail/-/publication/5b807311-9d93-11eb-b85c-01aa75ed71a1/language-en

2.4. Spare (Repair/Replacement) parts are necessary

Spare parts are necessary to guarantee the expected lifetime (more than 20 years) of EEE specialist equipment. Especially since EEE specialist equipment requires high performance and high reliability, we would like to emphasize that the same spare parts are required throughout the life of the product as when it was first evaluated. Without spare parts, waste minimization according to the principles of “Right to repair” and “Repair as produced” cannot be achieved.

2.5. Long development cycle

Our customers are required to be highly reliable because they are manufactured for a long period of time without modification. Along with this, long-term reliability tests are required. If there is a certification request, a longer period is required to obtain it. As a result, development cycles are longer compared to other consumer products.

An example of development process is below:

- Searching of parts and materials: 1-2 years
- Reliability test: performance test of the product: 1-2 years
- Device design: 0.5-1 year
- Develop the production line /buy new production equipment: 1-2 years
- Create Technical Documentation: 0.5 year
- Training at the production site: a few months
- Production management (information to customers): 0.5-1 year
- Third-party certification: 1 year without clinical trial

a few years or more with clinical trial or customer approvals

3. *Describe how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, provide citations to that requirement*.

   Please see an attached file.

   Hydrofluorocarbons (HFCs) phase down has been tackled by US EPA. The restriction should be aligned among Marine state and the rules of US EPA.
   Reference materials and substances used in scientific research and development are necessary for the analysis of PFAS. Without these, precise analysis is not possible. Therefore, reference materials for its analysis should be excluded from the scope.

4. *Describe whether there are alternatives for this specific use of PFAS which are reasonably available.*

   Please see an attached file.

5. Provide contact information for the submission.

Currently Unavoidable Use

1. Safety switches

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors
Application/ HTS code	Emergency stop pushbutton switch / 8535.**, 8536.** (excluding .10), 8531.**, 8538.90. Safety switches / 8535.**, 8536.** (excluding .10), 8531.**, 8538.90. Safety limit switches / 8535.**, 8536.** (excluding .10)
CAS RN	9002-84-0, 69991-67-9, 60164-51-4, 1623-05-8, 25038-02-2 and more
Regulated candidate substance name	PTFE [Poly(tetrafluoroethylene)] PFPE [Perfluoropolyether]
Generic name for the final product	Same as above application
Common name for application parts	Plunger, Cam, Contact
Detailed application description	1. Sliding parts of internal switch 2. Contact coating Technical Description of Essential Uses	Switches require mechanical durability and high reliability, so the sliding parts are coated with a fluorine-based lubricant to reduce frictional resistance. And it is used in coatings to protect contacts from dirt, reduce frictional resistance, and maintain high reliability. The technically difficult points of substitution are as follows. ・ Abrasion powder is generated when resin/metal parts mechanically slide. Adhesion of abrasion powder to the contacts reduces the reliability of the contacts. ・ Decrease in stability of Switch operation due to increased friction of sliding parts.

2. Safety switches / Microswitch / Limit switch

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Push-button switch / 8535.**, 8536.** (excluding .10), 8531.**, 8538.90. Microswitch / 8535.**, 8536.** (excluding .10) Limit switch / 8535.**, 8536.** (excluding .10)
CAS RN	1-Propene, 1,1,2,3,3,3-hexafluoro-, oxidized, polymd. 69991-67-9
Regulated candidate substance name	PFPE (Perfluoropolyether)
Generic name for the final product	Same as above application
Common name for application parts	Plunger
Detailed application description	Sliding parts of internal switch Technical Description of Essential Uses	Switches require mechanical durability and high reliability, so the sliding parts are coated with a fluorine-based lubricant to reduce frictional resistance. The technically difficult points of substitution are as follows. ・ Abrasion powder is generated when resin/metal parts mechanically slide. Adhesion of abrasion powder to the contacts reduces the reliability of the contacts. ・ Decrease in stability of Switch operation due to increased friction of sliding parts.

3. Safety switches

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Emergency stop pushbutton switch / 8535.**, 8536.** (excluding .10) Safety switches / 8535.**, 8536.** (excluding .10) Safety limit switches / 8535.**, 8536.** (excluding .10)
Application	Safety switches
CAS RN	9011-17-0
Regulated candidate substance name	FKM [1,1-Difluorethylene-hexafluorpropene polymer]
Generic name for the final product	Same as above application
Common name for application parts	O-ring
Detailed application description	< Sliding / Seal parts of internal switches > Technical Description of Essential Uses	Switches use rubber parts such as O-rings to ensure a protective structure. The technically difficult points of substitution are as follows. ・ High oil resistance and chemical resistance are required. ・ Harmful outgassing must not occur at the contact.

4. Push-button switch / Microswitch / Limit switch

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Push-button switch / 8535.**, 8536.** (excluding .10) Microswitch / 8535.**, 8536.** (excluding .10) Limit switch / 8535.**, 8536.** (excluding .10)

Regulated candidate substance name	Fluorine grease / PAO grease / Fluororesin
Generic name for the final product	Same as above application
Common name for application parts	Fluorine grease / PAO grease / Fluororesin
Detailed application description	Used for the sliding part inside the switch Technical Description of Essential Uses	In order to ensure high durability, the switch applies grease to the sliding parts of the parts. Resin parts with excellent slidability are sometimes used. The technically difficult points of substitution are as follows. ・ If grease is not applied, parts will be seized and high durability cannot be achieved. ・ High heat resistance and chemical resistance are required depending on the usage environment of the customer. ・ Harmful outgas must not be generated at the contact.

5. Push-button switch / Microswitch / Limit switch

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Push-button switch / 8535.**, 8536.** (excluding .10) Microswitch / 8535.**, 8536.** (excluding .10) Limit switch / 8535.**, 8536.** (excluding .10)
CAS RN	<THV> 116-14-3 Ethene, tetrafluoro- 25067-11-2 Polymer of 1,1,2,3,3,3-hexafluoroprop-1-ene / 1,1,2,2-tetrafluoroethene 25190-89-0 1-Propene, 1,1,2,3,3,3-hexafluoro-, polymer with 1,1-difluoroethene and 1,1,2,2-tetrafluoroethene < O-ring > 9011-17-0 1,1-Difluorethylene-hexafluorpropene polymer
Regulated candidate substance name	[Cable] THV [O-ring] FKM fluorine rubber
Generic name for the final product	Same as above application
Common name for application parts	Cable / O-ring
Detailed application description	1. Used for the cable of Switch 2. Used for the O-ring of Seal parts << Schematic Cross-sectional View >> Cable  1) Cable Fluororesin, which is less likely to be deteriorated by either 7-insoluble or water-soluble cutting oils, is used for the cable sheath. This prevents penetration of cutting oils into the cable. 2) O-ring HNBR+ fluorine rubber kneading, which is less likely to be deteriorated by either water-insoluble or water-soluble cutting oils, is used for the O-ring. This prevents penetration of cutting oils into the connector. In addition, fluorine coating on the O-ring improves assembly and slidability.

7. Proximity switch

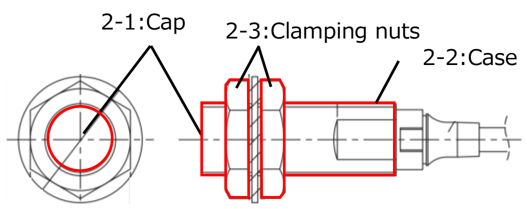
Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Proximity switch / 8536.50.70.00
CAS RN	Unidentified
Regulated candidate substance name	Fluororesin PFA Fluororesin coating
Generic name for the final product	Spatter-guarded proximity switch
Common name for application parts	Cap Housing
Detailed application description	Part of the housing of the spatter-guarded proximity switch used in a welding environment. Cap : Fluororesin PFA sensing surface Housing : Coated with fluororesin.  Spatter-guarded proximity switch
Technical Description of Essential Uses	The following features can be obtained by using Fluororesin. Cap : It can withstand the heat of welding spatter. By making spatter less likely to adhere, reducing malfunctions and improving maintainability Housing : It is difficult for spatter to stick.
Heat-resistant	Heat resistant temperature: about 260°C
No-adhesion	Prevention of adhesion of welding spatter
Required derogation period	13.5 years or more
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

8. Proximity switch

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Proximity sensor / 8536.50.70.00
CAS RN	9002-84-0, 26655-00-5, 25190-89-0, 116-14-3
Regulated candidate substance name	• Polymer of 1,1,2,2-tetrafluoroethene • Polymer of 1,1,1,2,2,3,3-heptafluoro-3 -[(1,2,2-trifluorovinyl)oxy]propane / 1,1,2,2-tetrafluoroethene • 1-Propene, 1,1,2,3,3,3-hexafluoro-, polymer with 1, difluoroethane and 1,1,2,2-tetrafluoroethene • Ethene, tetrafluoro-
Generic name for the final product	Same as above application
Common name for application parts	As its usage differs by product series of Proximity Sensors, categorized into 1 to 3. (1) Oil resistance 1-1 : Parts connecting cable, 1-2 : Cable sheath (2) Spatter resistance 2-1 : Cap, 2-2 : Case, 2-3 : Clamping nuts (3) Chemical resistance 3-1 : Case, 3-2 : Cable clamp, 3-3 : Clamping nuts
Detailed application description	<u>(1) Oil resistance Proximity Sensor</u>  The product is mainly used in the processes of cutting and polishing parts in automobile industry, and fluorine coating is used to prevent the joint of sensor cables and sensor from being degraded by cutting oil. 1-1 Parts connecting cable and sensor: Fluororesin parts which connects the cable and sensor 1-2 Cable sheath: Cable which sheath is made of fluororesin

<table>
<tr>
<td></td>
<td>

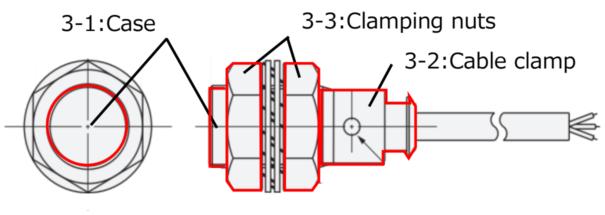
(2) Spatter-resistant Proximity Sensor



The product is mainly used in the welding process in the automobile industry, and fluorine coating is used for the outer parts to prevent spatters (molten iron) from adhering to the sensor.

2-1 Cap: Fluororesin parts
2-2 Case: Metal parts with fluororesin coating
2-3 Clamping nuts: Metal parts with fluororesin coating

(3) Chemical-resistant Proximity Sensor



Fluororesin coating is used for the outer parts to prevent applicable part from corroding by detergent for equipment cleaning in the production processes of food, pharmaceutical, and cosmetics industries.
3-1 Case: Fluororesin parts
3-2 Cable clamp: Fluororesin parts
3-3 Clamping nuts: Clamping nuts made of fluororesin

</td>
</tr>
<tr>
<td>Technical Description of Essential Uses</td>
<td>

(1) Oil-resistance Proximity Sensor

Proximity Sensors are usually installed inside of cutting and polishing machines and subject to spillage of cutting oil on a constant basis. PVC and PUR cables are not resistant enough under such environment. There is no material that can substitute fluorine which has excellent cutting oil resistance and flexibility.

</td>
</tr>
</table>

	(2) Spatter-resistant Proximity Sensor  Proximity Sensors are usually installed near welding machines and used in environment where spatters scatter and adheres to the Sensor. In such environment, there is coating such as silicone coating for outer case and clamping nuts; however, since spatter resistance is lower, the failure cycle of the Sensors becomes faster, and it decreases our customer's productivity. In terms of the cap, in addition to spatter resistance, special chemical surface finishing is performed to join the resin filled inside in the production process of the Sensors. There is no alternative material for fluorine including this processing. (3) Chemical-resistant Proximity Sensor  Equipment which Proximity Sensors are installed is cleaned using detergent for hygienic management. Since detergent is poured on the Proximity Sensors during equipment cleaning, resistant to such detergent is required. Fluorine used for outer parts is required to have corrosion resistance, chemical resistance and heat resistance. Additionally, special chemical surface finishing is performed to join the resin filled inside in the production process of the Sensors. There is no alternative material for fluorine including this processing.
Oil resistance	(1) Oil resistance which oil does not penetrate inside the Sensor in the internal acceleration test (Dipping in water-soluble cutting oil with 55 degrees C for 2000 hours) is required. For cables, penetration must be within about 0.3mm.
Flexibility	(1) As cable is bent to wire to equipment, flexibility which can be bent at 25mm of bend radius is required. Young's modulus of approximately 200 MPa
Spatter resistance	(2) Oil/water repellency that does not allow malfunction of the Sensors when spatters adhere to the Sensors due to degradation of the coating in the test using actual product which applies spatters is required. Continuous use temperature: Approximately 220°C or higher, and contact angle with water is approximately 100° to 110°
Chemical resistance	(3) Chemical resistance that corrosion and degradation do not occur even when exposed to detergent and chemical solutions is required. Typical evaluation conditions are as follows. ・ NaOH concentration 1.5% 70°C 240 hours ・ H_3PO_4 concentration 1.5% 70°C 240 hours ・ H_2O_2 concentration 6.5% 70°C 240 hours

9. Environment-resistant photoelectric switch with built-in amplifier

<table>
<tr><th colspan="2">Essential Application</th></tr>
<tr><td>Main use sector</td><td>Metal plating and manufacture of metal products
Electronics and semiconductors etc.</td></tr>
<tr><td>Application/
HTS code</td><td>Environment-resistant photoelectric switch with built-in amplifier / 8536.50.70.00</td></tr>
<tr><td>CAS RN</td><td>Unidentified</td></tr>
<tr><td>Regulated candidate substance name</td><td>Polymeric PFAS paint /
PTFE, FEP</td></tr>
<tr><td>Generic name for the final product</td><td>Environment-resistant photoelectric switch with built-in amplifier.</td></tr>
<tr><td>Common name for application parts</td><td>Housing made of zinc alloy coated with fluorocarbon resin.</td></tr>
<tr><td>Detailed application description</td><td>

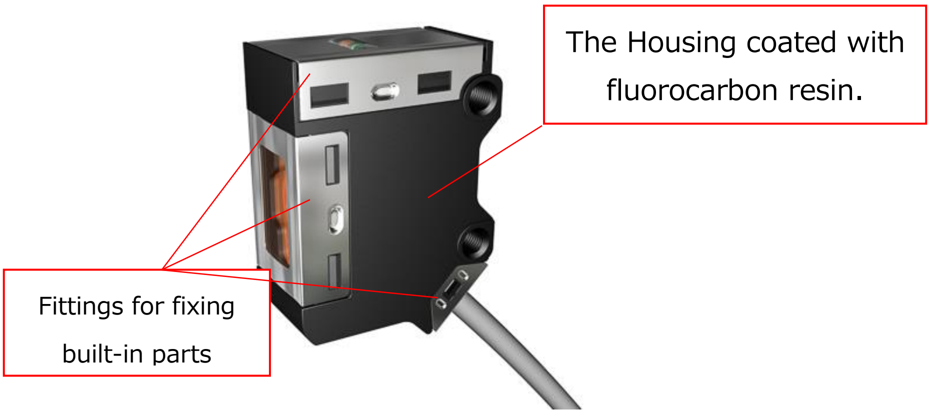


Fig.1 External view

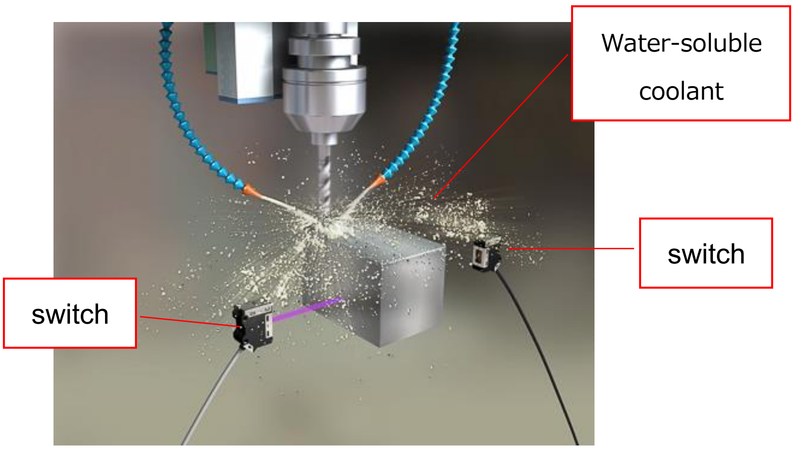

Fig. 2 Detection of workpiece seating in machine tool

The housing of the environment-resistant photoelectric switch is coated with fluorine paint (Fig. 1). There are two purposes of fluoride coating.

1. Improved corrosion resistance of housing

The housing of Environment-resistant photoelectric switch is made of zinc die-cast. Zinc

</td></tr>
</table>

	die-casting has advantages such as high fluidity, easy dimensional accuracy, low molding temperature, and long service life of metal mold, but it has low corrosion resistance. Therefore, it cannot be used in machine tools and automobile parts machining lines, which are users of this switch, unless corrosion resistance is improved by painting and plating. Water-soluble coolant (basic) is often used in machine tools and automobile parts machining lines, and zinc die-cast housing is highly likely to be corroded unless surface treatment such as painting is performed (Fig. 2).  Fig. 3 Confirmation of Existence of Tool in Machine Tool 2. Prevention of crevice corrosion and dissimilar metal contact corrosion The housing is assembled with a metal stopper (SUS plate (zinc plated)) (Fig. 1) and attached to an accessory SUS bracket or the mounting surface of the user side (metal, resin, etc., materials cannot be specified) (Fig. 3). Therefore, it is necessary that the metal surface of the housing is not exposed in order to prevent electrolytic corrosion due to gap corrosion and contact between different metals.
Technical Description of Essential Uses	The former model number of this switch had adopted acrylic coating, but it was changed to fluorine coating due to low resistance to water-soluble coolant. The surface of the housing must be free from exposed metal. Therefore, coating by coating is necessary instead of plating. For the same reason, coating is necessary even if the housing is changed to a highly corrosion resistant metal material such as SUS. There are concerns about the following impacts due to the unavailability of this technology

	・ Affects machining with machine tools that use water-soluble coolant and parts machining and production on automotive parts production lines. ・ There is no alternative technology. When a switch without fluorine coating is used, corrosion of the switch causes contamination of corrosion products (foreign matter) into parts, generation of rust in processed parts, and increase of stoppage period of machine tools and production lines due to increase of sensor replacement frequency. For the above-mentioned reasons, the prohibition of coatings with fluorine-based paints should be exempted indefinitely from this restriction because of the economic burden due to the increased frequency of replacement and the serious degradation to the finished product. In terms of disposal, restrictions should not be applied as coatings by fluorinated paints generally lead to a reduction in waste.
chemical resistance	Resistance to water-soluble coolants (basic) used in machine tools and automotive parts processing lines
Required derogation period	13.5 years or more Note: This application should have the same derogation period as petroleum and mining.
Socio-economic impact	Problem with the safety of the worker. Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

10. External protection of liquid leak sensor

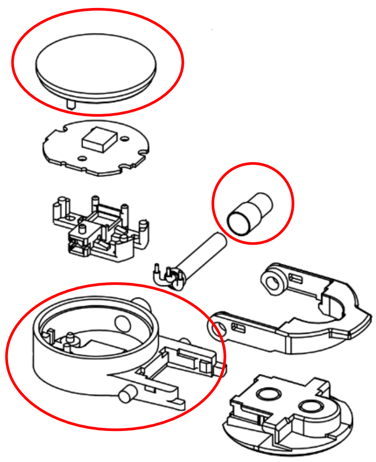
Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	External protection of liquid leak sensor / 8536.50.70 00, 8536.70.00.00
CAS RN	26655-00-5
Regulated candidate substance name	Polymeric PFAS / PFA
Generic name for the final product	Liquid leak sensor
Common name for application parts	housing
Detailed application description	• This leakage sensor is used for the following applications. - Liquid leakage detection in semiconductor wafer cleaning and developing processes - Detection of tank leakage

Liquid tank

Liquid leak sensor

The sensor housing is made of PFA resin.

Schematic diagram of sensor structure
The sensor housing cover, case and tube are made of PFA resin.



Technical Description of Essential Uses	Due to the housing made of PFA resin, this leakage sensor has higher stability against organic solvents than other products. ・ The following characteristics can be obtained by using PFA resin for the leakage sensor. - This leakage sensor functions stably for the detection of organic solvents. - There is no alternative to this function ・ This leakage sensor is used for the following applications. - Liquid leakage detection in semiconductor wafer cleaning and developing processes - Detection of tank leakage ・ There are concerns about the following effects due to the unavailability of this technology : - Cleaning and development of a semiconductor wafer using an organic solvent cannot be carried out safely. ・ For the above reasons, the prohibition of PFA resin in leakage sensors affects safety and should be exempted from this restriction indefinitely.
Chemical resistance	Resistant to chemicals and solvents fluids
Cleanliness performance	Cleanliness performance without elution and volatilization of components from components
Required derogation period	13.5 years or more Note: This application should have the same derogation period as semiconductor manufacturing processes.
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes. Yield deterioration in the semiconductor manufacturing process

11. External protection of fiber unit for Measurement use

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	External protection of fiber unit for Measurement use / 8536.70.00.00
CAS RN	25067-11-2 26655-00-5
Regulated candidate substance name	Polymeric PFAS / FEP, PFA
Generic name for the final product	Fiber unit
Common name for application parts	housing and tube
Detailed application description	(see below)

Detailed application description

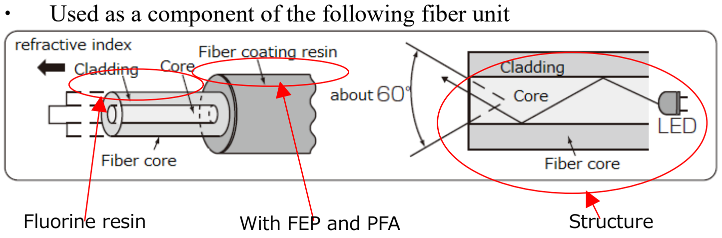
Fiber unit with chemical Liquid detection

- This sensor is used for the following applications.
  - Liquid leakage detection in semiconductor wafer cleaning and developing processes
  - Detection of tank leakage
  - Passage detection in places where there is a possibility of contact with chemical liquid

[Be included in the component] : Parts that are in an inseparable composite state at the time of purchase

Plastic Optical Fiber

- Used as a component of the following fiber unit



- This is a step index type multimode fiber (using the refractive index difference between core and clad). Fluorine resin is used for the clad. No alternative material has been proposed by the manufacturer at present. In this type of fiber, the basic optical characteristics of the fiber are determined by the refractive index difference between core material and clad material, and the material is selected by the manufacturer in consideration of the manufacturing method. Users use commercially available fiber. FEP is used for the clad and jacket, and PFA is used for the jacket and outer coating.

[Products : fiber units]

	Detection method and part of use	Purpose and materials used	Principle using PFA characteristics
Liquid level detection		The tip detection part is made of PFA, and the tube material which may come into contact with liquid is also covered with PFA, a material which is easily fused with the tip. In order to make the tip small and non-electric, a commercially available plastic optical fiber cable is	Use refractive index difference between PFA and liquid  No Liquid (Incoming Light) With Liquid (Light Shielding) Detection part It uses the difference in refractive index between liquid and liquid.

		used for guiding the detection light, and fluorine resin (specific material is not disclosed by the manufacturer) is also used as the clad material.	Detection principle ・It utilizes the return light difference due to the refractive index difference (hereinafter referred to as n) between the material of the tip cone and the external contact material. ・Without liquid : In a state of lower refractive index than PFA (n ~ 1.35) (air n ~ 1), most of the light emitted from the projection is reflected by the inner surface of the cone and returns to the light receiving portion to enter. ・Liquid : The liquid has a large refractive index equal to or higher than that of PFA (water n ~ 1.33, ethyl alcohol n ~ 1.36), and the amount of light that is substantially transmitted through the conical surface and returns to the light receiving portion decreases. ・The presence or absence of liquid is determined by this light amount difference.
Leak detection		The detection head and cable, which may come into contact with liquid, are covered with PFA.	Use refractive index difference between PFA and liquid  Detection principle is the same as "liquid level detection"
Chemical resistance	Transparent example 	The detection head and cable, which may come into contact with liquid, are covered with PFA.	Sealing performance is ensured by fusing the tip of the PFA detection head and the tube. 
Technical Description of Essential Uses	Due to the housing made of PFA resin, this fiber unit has higher stability against organic solvents than other products. • The following characteristics can be obtained by using PFA resin for the fiber unit.

	- This fiber unit functions stably for the detection of organic solvents. - There is no alternative to this function ・ This leakage sensor is used for the following applications. - Liquid leakage detection in semiconductor wafer cleaning and developing processes - Detection of tank leakage ・ There are concerns about the following effects due to the unavailability of this technology : - Cleaning and development of a semiconductor wafer using an organic solvent cannot be carried out safely. ・ For the above reasons, the prohibition of PFA resin in leakage sensors affects safety and should be exempted from this restriction indefinitely.
Chemical resistance	Resistant to chemicals and solvents fluids
Cleanliness performance	Cleanliness performance without elution and volatilization of components from components
Required derogation period	13.5 years or more Note: This application should have the same derogation period as semiconductor manufacturing processes.
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes. Yield deterioration in the semiconductor manufacturing process

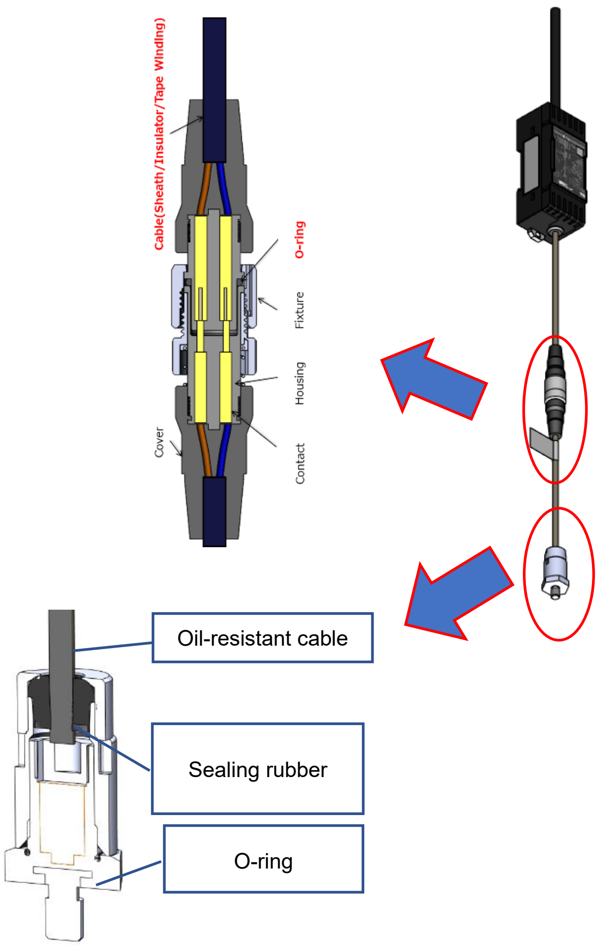
12. Hermetic seal for optical junction unit for vacuum environment

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Hermetic seal for optical junction unit for vacuum environment / 8536.70.00.00
CAS RN	Unidentified
Regulated candidate substance name	Polymeric PFAS / Fluorocarbon rubber
Generic name for the final product	Junction unit for vacuum environment
Common name for application parts	O-ring
Detailed application description	Optical junction unit for vacuum environment are used for photoelectric sensors that enable detection in vacuum chambers in the semiconductor and LCD manufacturing processes. Junction unit for vacuum environment is used for a photoelectric sensor that enables detection inside a vacuum chamber by transmitting light from a fiber amplifier through a fiber unit. PFAS is used in O-ring for seal for air and vacuum environment. The optical coupler is provided with sealing ability to pass the detection light through the wall of the vacuum device. The O-ring for sealing is made of fluorine rubber to keep high temperature, high seal and high cleanliness.  Fig. Optical junction unit for vacuum

Technical Description of Essential Uses	To keep high temperature, high seal, and high cleanliness in a vacuum environment, materials other than fluorocarbon rubber are not appropriate.
Heat-resistant	Heat resistance to withstand 200°C
Cleanliness performance	Cleanliness performance without elution and volatilization of components from components
Required derogation period	13.5 years or more Note: This application should have the same derogation period as semiconductor manufacturing processes.
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes. Yield deterioration in the semiconductor manufacturing process

13. Vibration Sensor

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Vibration Sensor / 9026.10.20.80,
CAS RN	Unidentified
Regulated candidate substance name	Cable : THV, ETFE, PTFE O-ring : FKM, HNBR FH-11-65 Sealing rubber : FH-11-65
Generic name for the final product	Same as above application
Common name for application parts	Oil-resistant cable, O-ring, Sealing rubber
Detailed application description	(1) Used in the cable for Vibration Sensor (2) Used in the sealing between the housing case and wires (3) Used in the sealing between the housing case and base



Technical Description of Essential Uses	(1) Cable Fluororesin which has resistance to both water-insoluble and water-soluble cutting oil is used in the cable sheath. This prevents the cutting oil from penetrating inside of the cable. (2) Sealing rubber Fluororesin which has resistance to both water-insoluble and water-soluble cutting oil is used in the sealing rubber. This prevents the cutting oil from penetrating inside of the cable. (3) O-ring Fluororesin which has resistance to both water-insoluble and water-soluble cutting oil is used in the O-ring. This prevents the cutting oil from penetrating inside of the cable.

14. Connector Cable

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Connector Cable / 8544.42.90, 8544.49.20.00
CAS RN	Unidentified
Regulated candidate substance name	[Cable] THV, ETFE, PTFE, Soft fluoropolymer [O-ring] FKM, HNBR + fluororubber
Generic name for the final product	Circular Connector Cable
Common name for application parts	1. Cable 2. O-ring
Detailed application description	1.Used for the cable of both Socket Connector Cable and Plug Connector Cable 2.Used for the O-ring of Socket Connector Cable << Exterior photo >>  << Schematic Cross-sectional View >>  3) Cable Fluororesin, which is less likely to be deteriorated by either water-insoluble or water-soluble cutting oils, is used for the cable sheath. This prevents penetration of cutting oils into the cable.

15. Pressure Sensors

Essential Application	
Main use sector	Medical devices Electronics and semiconductors etc.
Application/ HTS code	Pressure Sensors / 9026.20.40.00
CAS RN	9011-17-0
Regulated candidate substance name	FKM (fluororubber)
Generic name for the final product	Pressure Sensors
Common name for application parts	O-ring Guard plate for switches
Detailed application description	FKM (fluororubber) is used as the material for the O-rings and guard plate for switches to prevent the liquid being measured from entering the inside of the product. Technical Description of Essential Uses	As this is a general-purpose senser, substances to be measured are not known. Therefore, FKM (fluororubber) which has excellent characteristics such as oil resistance, chemical resistance, and solvent resistance and is well-balanced between workability and cost is used.

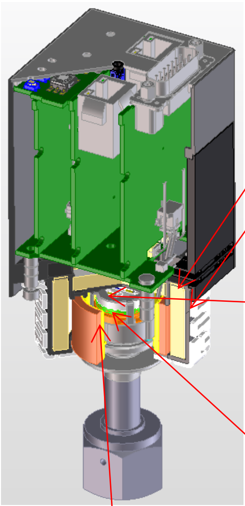
16. Sapphire Capacitance Diaphragm Gauge

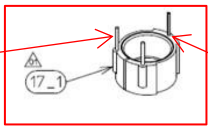
Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Sapphire Capacitance Diaphragm Gauge / 9026.20.40.00
CAS RN	Unidentified
Regulated candidate substance name	Polymeric PFAS / FKM, PFA, TFE, PTFE
Generic name for the final product	Sapphire Capacitance Diaphragm Gauge
Common name for application parts	Thermal insulation and Cable
Detailed application description	The sapphire capacitance diaphragm gauge is used in deposition equipment and etching equipment in the semiconductor manufacturing process.

■ Integrated Model

Components corresponding to a heater operating temperature of MAX 250°C



Heater board connection cable



Thermistor

	■Separated Model Components compatible with gauge head operating temperature of MAX 250°C Technical Description of Essential Uses	There is no fluorine-free material with equivalent heat resistance.
Heat-resistant	Heat resistance to withstand 250°C
Required derogation period	13.5 years or more Note: This application should have the same derogation period as semiconductor manufacturing processes.
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes. Yield deterioration in the semiconductor manufacturing process

17. Coating and protective covering for diaphragm of industrial pressure transmitter

Essential Application	
Main use sector	Energy sector Petroleum and mining etc.
Application/ HTS code	Coating and protective covering for diaphragm of industrial pressure transmitter / 9026.20.40.00
CAS RN	FEP : 25067-11-2 PFA : 26655-00-5 PCTFE : 25038-89-5 PTFE : 9002-84-0
Regulated candidate substance name	Polymeric PFAS / FEP, PFA, PCTFE, PTFE
Generic name for the final product	Industrial pressure transmitter
Common name for application parts	Diaphragm, Flange
Detailed application description	 Pressure transmitter Diaphragm/wetted parts coating Industrial pressure transmitters are instruments used for measuring pressure in pipes and tanks, particularly in applications that require flow or liquid level measurement. They are commonly utilized in various large-scale equipment, such as industrial chemical plants.
Technical Description of Essential Uses	Industrial pressure transmitters are used to measure corrosive fluids such as chemicals. The measurement of corrosive fluids such as chemicals accounts for 10% of all industrial pressure transmitter applications. Industrial pressure transmitters are required to have the performance to withstand the measurement of these corrosive fluids. To measure corrosive fluids with industrial pressure transmitters, coatings and protective films such as FEP are required on the parts that come into contact with corrosive fluids. ・ As an alternative to coatings such as FEP, there is a possibility that resin coatings such as epoxy can be used. However, substitute materials are poorly resistant to various chemicals in industrial chemical plants and cannot withstand corrosive fluids.

	• With alternative technologies and materials, the pressure transmitter itself connected to the piping must be replaced periodically by shutting down the facility or every time corrosion of the wetted parts occurs, which could be as early as every few months. Pressure transmitters with diaphragm coatings and protective films using FEP etc. can operate stably for at least 10 years without replacement. There are concerns about the following impacts due to the unavailability of this technology • The unavailability of FEP etc. for diaphragm coatings and protective coatings for industrial pressure transmitters will affect the production and supply of chemical products by significantly reducing production efficiency in plants producing corrosive fluids such as chemicals For the above reasons, the prohibition of coating and protective films of diaphragms by FEP etc. on industrial pressure transmitters should be exempted indefinitely from this restriction because of the economic burden caused by the increased frequency of replacement due to equipment shutdown. From the viewpoint of disposal, restrictions should not be applied because the diaphragm coating and protective film of FEP etc. for industrial pressure transmitters allow the pressure transmitter to be used until it reaches its original service life, which generally leads to a reduction in waste.
Chemical resistance	Corrosion resistance with corrosive fluids
Required derogation period	13.5 years or more Note: This application should have the same derogation period as petroleum and mining.
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

18. Displacement measurement sensor

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	**Displacement measurement sensor / 9032.89.20 00**
CAS RN	647-42-7
Regulated candidate substance name	3,3,4,4,5,5,6,6,7,7,8,8,8-Tridecafluorooctanol
Generic name for the final product	Same as above application
Common name for application parts	Diffractive Lens
Detailed application description	Fig. 1 shows the appearance of the displacement measurement sensor. This sensor is a displacement sensor based on the chromatic confocal method, and the material that is targeted for regulation this time is used in the diffractive lens, which is the core optical component of this sensor. Fig. 2 shows an outline of the optical system inside the housing. A diffractive lens can diffract white light, and the light beam angle can be changed for each wavelength. And this precisely conversion (wavelength to angle) directly affects the performance of the sensor. *The chromatic confocal method: One of the principle of the displacement measurement that white light is irradiated to the object to be measured by changing the focus position for each color (wavelength), and only the focused wavelength light is received as reflected light, and the height is determined.  Fig.1 the appearance of the displacement measurement sensor

	 Fig.2 an outline of the optical system inside the housing
Technical Description of Essential Uses	Without using a diffractive lens, the principle of measurement of this sensor cannot be worked. For the displacement measurement sensor based on the chromatic confocal method, it is essential for using the diffraction lens to change the focus position on the object to be measured for each wavelength. So, it is extremely difficult to realize a sensor of this method without using a diffractive lens. The diffractive surface cannot be molded without using this material. Diffractive lens controls the direction of light by means of a diffraction phenomenon caused by extremely fine and complicated structures of nm (nano meter) order on the optical surface. It is extremely difficult to replace the material of the diffractive lens, because it is a dedicated material designed in consideration of the moldability of diffractive surface, releasability, refractive index, Abbe number, phase information, the long-term reliability and so on.
Low friction / Wear resistance	Adhere cellophane tape (Nichiban No.405) to the diffractive surface and instantly remove it in the vertical direction. After repeating the operation three times, the resin layer should not peel off.
Heat-resistant	High temperature and high humidity: No deterioration after left at 65°C, RH85%, 1000H Low temperature storage: No deterioration after 1000 hours storage at -15°C Thermal shock: -15°C to 60°C No deterioration after 100 cycles
Light fastness / Weather fastness	Wavelength 400 to 700nm, 1mW, no deterioration after 7 years or more irradiation
Low refractive index	Refractive index designed value +/- 0.001 accuracy
Other characteristics	Improved releasability during molding
Alternative material	None *As described in the non-substitution explanation above.

19. Displacement measurement sensor

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Displacement measurement sensor / 9032.89.20.00, 8536.5*
CAS RN	647-42-7
Regulated candidate substance name	3,3,4,4,5,5,6,6,7,7,8,8,8-Tridecafluorooctanol
Generic name for the final product	Same as above application
Common name for application parts	Hybrid lens
Detailed application description	Fig. 1 shows the appearance of the displacement sensor. The sensor is a triangulation-based displacement sensor, and the material that is targeted for regulation this time is used in the light-projecting lens and the light-receiving lens, which are the core optical components of this sensor. Fig. 2 shows an outline of the optical system inside the housing. The light emitted from the semiconductor laser is condensed on the surface of the object to be measured by the projection lens, and the reflected light from the object to be measured forms an image on the light receiving element via the light receiving lens. The height is measured by changing the imaging position on the light receiving element according to the distance from the housing surface to the object to be measured. The quality of collected light through the projection lens and receiving lens are extremely important factor that determine the performance in this type of the displacement measurement sensor. A dedicated lens design is required to improve these light collection qualities. Of these, the aberration of the optical system (lens) is important as a design index for improving the light collection quality. Reducing aberrations improves the quality of light collection of the lens. There are two main ways to reduce aberrations. (1) Use an aspherical lens (2) Combine multiple spherical lenses. If (2) is selected, the size of the optical system becomes large, which leads to an increase in housing size and cost. So, the aspherical lens is used in this sensor. As the name suggests, an aspherical lens has a complex aspherical shape rather than a spherical surface. In order to realize this complex shape, the material that is targeted for regulation this time is necessary.

	 Fig.1 the appearance of the displacement sensor  Fig.2 an outline of the optical system inside the housing
Technical Description of Essential Uses	The aspherical shape cannot be molded without using this material. Aspherical lens reduces lens aberration by forming an optical surface into a complex curved shape represented by a polynomial. Realization of this complex shape requires advanced molding technology and material properties customized for this application. Design information of the aspherical surface (material refractive index, Abbe number, curved surface shape, etc.) and moldability (especially, if it is not included the materials, the releasability deteriorates and the desired shape cannot be obtained), and it is extremely difficult to replace it with other materials because it is a dedicated material designed in consideration of long-term reliability in the environment where the displacement sensor is used.
Low friction / Wear resistance	Adhere cellophane tape (Nichiban No.405) to the diffractive surface and instantly remove it in the vertical direction. After repeating the operation three times, the resin layer should not

	peel off.
Heat-resistant	High temperature and high humidity: No deterioration after 70°C, RH95%, 1000H Low temperature storage: No deterioration after 1000 hours storage at -15°C Thermal shock: -15°C to 70°C No deterioration after 100 cycles
Light fastness / Weather fastness	Wavelength 660+/-20nm,1mw, no deterioration after 7 years or more irradiation
Low refractive index	Refractive index designed value +/- 0.001 accuracy
Other characteristics	Improved releasability during molding
Alternative material	None *As described in the non-substitution explanation above.

20. Safety Sensor

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Safety Sensor / 8536.50.90.65
CAS RN	113114-19-5, 116-14-3, 1478-61-1, 25038-71-5, 25190-89-0, 27029-05-6, 9002-84-0
Regulated candidate substance name	- Fluorinated polymer of 2,2,3,3-tetrafluorooxetane - Tetrafluoroethylene - Bisphenol AF - Ethene, 1,1,2,2-tetrafluoro-, polymer with ethene - Propene, 1,1,2,3,3,3-hexafluoro-, polymer with 1,1-difluoroethene and 1,1,2,2-tetrafluoroethene - 1-Propene, polymer with 1,1,2,2-tetrafluoroethene - PTFE
Generic name for the final product	Same as above application
Common name for application parts	Cable sheath, Insulator, Tape, Gasket, O-ring, Sponge
Detailed application description	 To ensure environmental resistance, the parts that make up the cables of the safety sensor and the parts that make up the protective structure are used.

Technical Description of Essential Uses	 In some cases, the safety sensor is installed near the extraction port of the processing machine and is exposed to oil mist. In harsh environments, NBR and other materials are not sufficient, and it has become difficult to substitute materials other than fluorine processed materials as materials that are resistant to cutting oil.
Water repellency/ oil repellency	No failure even in a coolant-contaminated environment.
Difficulty in replacing	When substituted with NBR or H-NBR, the physical properties change with cutting oil, causing cutting oil penetration and insufficient sealing pressure in the seal rubber.

21. Relay

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Relay / 8536.4*
CAS RN	Unidentified
Regulated candidate substance name	PFPE [Perfluoropolyether]
Generic name for the final product	Relay
Common name for application parts	Indicator, Armature + Yoke
Detailed application description	1. Sliding parts of internal relay Technical Description of Essential Uses	Since relays are required to have high mechanical durability and high reliability, sliding parts are coated with a fluorine-based lubricant for the purpose of reducing frictional resistance. The technically difficult points of substitution are as follows. ・ Because relay has contacts structure, contact reliability is reduced due to abrasion powder generated when plastic or metal parts mechanically operate. ・ Decrease in stability of relay operation due to increased friction of sliding parts. ・ Fluorinated lubricants are commonly used in several relays because they can be easily diluted with similar fluorinated solvents and can be applied evenly and easily dried.

22. Safety relay unit

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Safety relay unit / 8536.4*
CAS RN	69991-67-9, 60164-51-4, 1623-05-8, 25038-02-2 and more
Regulated candidate substance name	PFPE [Perfluoropolyether]
Generic name for the final product	Same as above application
Common name for application parts	Safety relay
Detailed application description	 It is used to reduce frictional resistance on the sliding part (card) of the safety relay built into the safety relay unit to achieve high mechanical durability and reliability.
Technical Description of Essential Uses	The technically difficult points of substitution are as follows. ・ Fluorinated lubricants are commonly used in several relays because they can be easily diluted with similar fluorinated solvents and can be applied evenly and easily dried. ・ Because relay has contacts structure, contact reliability is reduced due to abrasion powder generated when plastic or metal parts mechanically operate. ・ Decrease in stability of relay operation due to increased friction of sliding parts.
Low friction/wear resistant	When parts slide, there is no generation of abrasion powder that causes poor contact of contacts.
Remarks	Since this product relies on the built-in safety relay, please also refer to the application material for the safety relay.

23. Safety Relay

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Safety Relay / 8536.4*
CAS RN	69991-67-9, 60164-51-4, 1623-05-8, 25038-02-2 and more
Regulated candidate substance name	PFPE [Perfluoropolyether]
Generic name for the final product	Same as above application
Common name for application parts	Card, Contact
Detailed application description	1. Sliding parts of internal relay 2. Contact coating  <Internal structure> Technical Description of Essential Uses	Since relays are required to have high mechanical durability and high reliability, sliding parts are coated with a fluorine-based lubricant for the purpose of reducing frictional resistance. And it is used in coatings to protect contacts from dirt, reduce frictional resistance, and maintain high reliability. The technically difficult points of substitution are as follows. ・ Because relay has contacts structure, contact reliability is reduced due to abrasion powder generated when plastic or metal parts mechanically operate. ・ Decrease in stability of relay operation due to increased friction of sliding parts.

	· Fluorinated lubricants are commonly used in several relays because they can be easily diluted with similar fluorinated solvents and can be applied evenly and easily dried.

24. Relay / Safety Relay

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Relay / 8536.4* Safety Relay / 8536.4*
CAS RN	Unidentified
Regulated candidate substance name	PFPE (Perfluoropolyether)
Generic name for the final product	Same as above application
Detailed application description	 It is used to reduce frictional resistance on the sliding part of the relay built into the programmable logic controller to achieve high mechanical durability and reliability.
Technical Description of Essential Uses	Since relays are required to have high mechanical durability and high reliability, sliding parts are coated with a fluorine-based lubricant for the purpose of reducing frictional resistance. The technically difficult points of substitution are as follows. ・ Because relay has contacts structure, contact reliability is reduced due to abrasion powder generated when plastic or metal parts mechanically operate. ・ Decrease in stability of relay operation due to increased friction of sliding parts. ・ Fluorinated lubricants are commonly used in several relays because they can be easily diluted with similar fluorinated solvents and can be applied evenly and easily dried.
Remarks	Since this product relies on the built-in relay, please also refer to the application material for the relay.

25. Terminal with communication function / Programmable display

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Terminal with communication function / 8471.80.40 Programmable display / 8531.20.**
CAS RN	Unidentified
Regulated candidate substance name	Fluororubber
Generic name for the final product	Same as above application
Common name for application parts	O-ring, Waterproof packing
Detailed application description	A waterproof structure is created by sandwiching it between two housings and crushing it with the upper and lower housings. Some oil-resistant products use fluororubber to improve oil resistance and chemical resistance.  O-ring Technical Description of Essential Uses	Fluorine is generally used in products that improve chemical resistance, water repellency, and oil resistance.

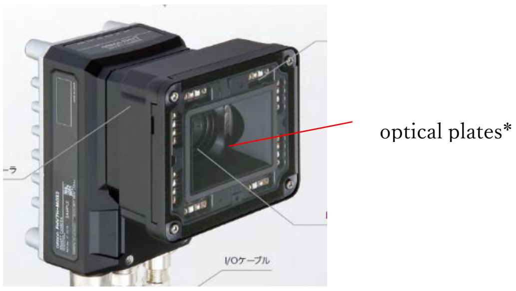
26. Image processing system

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Image processing system / 8525.80
CAS RN	Unidentified
Regulated candidate substance name	PFAS
Generic name for the final product	Image processing system
Common name for application parts	1: Control board protection coating for image processing system 2: Tube for wire protection of image processing system (2,3) 3: Coating for surface plate protection of image processing system (4) 4: Coating to ensure optical system functions of image processing system (5,8,9,10) 5: Packing to ensure the airtightness and water resistance of the image processing system (6,9) 6: Porous PTFE membrane to prevent condensation in image processing system (7) 7: Thermal radiation sheets for image processing system (11)
Detailed application description	1: Coating for maintaining the environmental resistance of the image processing system substrate. Substrate protective coating to protect against special environments (water droplets, foreign matter, gas).  Cited from: https://www.arbrown.com/products/humiseal/ 2: Tube for wire protection of image processing system -Shrink tubing for internal fan cable protection 
-Insulation and protection of various electric wires and parts, waterproof/drip-proof/anti-corrosion, and mechanical protection.

Cited from: https://ja.nc-net.or.jp/company/92714/product/detail/99785/

3: Coating to maintain the optical environmental resistance of image processing system

A coating that has water and oil repellency properties and allows fingerprints, sweat, sebum, and other stains to be easily wiped off. Increases contact angle and retains water and oil repellency.

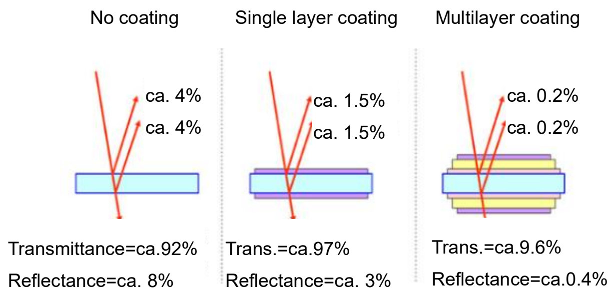


*A resin material that protects the inside of the sensor and transmits light.

Cited from: Water repellency/stain resistance (tokaioptical.com)

4: AR coating for smart image sensors

Coating to reduce light reflection and increase transmittance



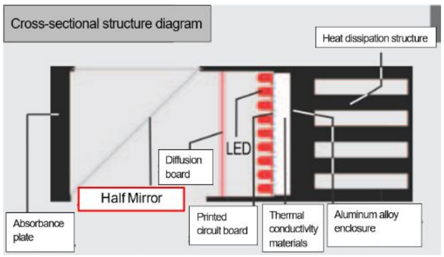
Cited from: https://coating.nidek.co.jp/article/information/type/a37 (nidek.co.jp)

-Half Mirror with water and dirt repellent coating

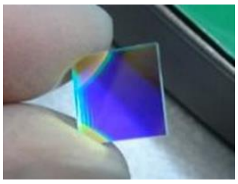
(Transmittance 50%, Reflectance 50%)

This coating has water and oil repellent properties and can easily wipe off fingerprints, sweat, sebum, and other contaminants. It has a high contact angle and possesses water and oil repellency.

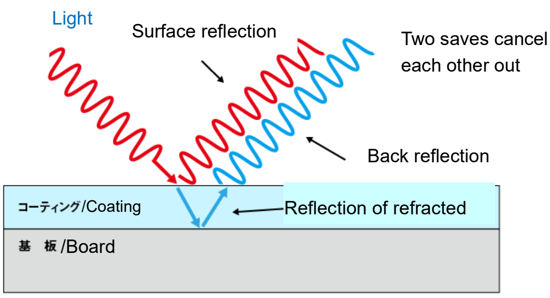
Appearance Cross-sectional drawing



-Coating that suppresses reflection on the surface of bandpass filters and infrared cut filters used in 3D vision sensors, cameras, etc.

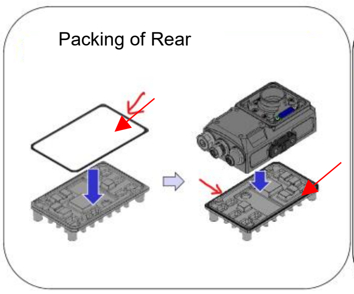


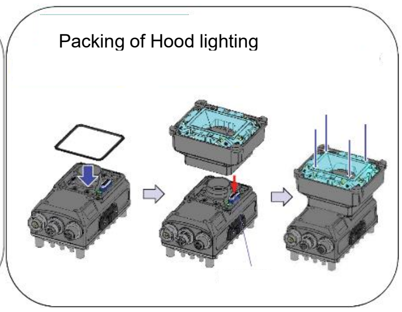
Anti-reflection mechanism



5: Packing to ensure the airtightness and water resistance of the image processing system

-Packing for waterproof IP67 security of smart image sensor





Packing of Hood Cover

	-Packing to ensure the waterproof specification (IP67) of the 3D vision sensor  6: Porous PTFE membrane to prevent condensation in image processing system It has a porous membrane and achieves both "waterproof/dustproof" and "breathability/moisture permeability". Cited from: https://www.nitto.com/jp/ja/products/temish_search/about/   7: Thermal radiation sheets for image processing system A resin sheet with thermal conductivity. By encapsulating a highly thermally conductive filler in a flexible resin sheet whose main ingredient is acrylic or silicon resin, the resin sheet, which originally does not have thermal conductivity, is given thermal conductivity. By installing it in close contact with the heat-generating parts mounted on electronic equipment, etc., it absorbs heat efficiently and dissipates heat away from the heat-generating parts, thereby preventing malfunctions and failures of the equipment. Appearance 
Technical Description of Essential Uses	1: A coating that protects equipment from water droplets, foreign matter, gas, and dirt in the usage environment and ensures functionality cannot maintain alternative characteristics. 2: Equivalent insulation and protection, waterproof/drip-proof, corrosion-resistant, and mechanical protection equivalent to the current performance are required.

	3: Since lighting equipment such as FL lighting is installed near the workpiece, it is necessary to ensure the lighting characteristics with an anti-fouling coating, and alternative characteristics cannot be maintained. Fluorine-based resin is often the main component in general antifouling coatings. It is possible to change to a product that does not contain PFAS as long as it does not affect the function/performance. 4: Window plates, optical lenses, liquid lenses, and IR cut filter coatings for maintaining environmental resistance cannot maintain alternative characteristics. The main ingredients are inorganic compounds such as MgF2 and SO2, but it is unknown whether they contain PFAS. If it does not affect the optical properties (transmittance, reflectance, wavelength components, etc.), it is possible to change to materials that do not contain PFAS. 5: Since the optical system of the image processing apparatus is installed near the object to be inspected, it is necessary to use highly airtight and water-resistant packing to maintain its function. The main component is rubber. 6: Fluororesin porous membrane. It combines the durability of fluororesin with the breathability of a microporous membrane structure. Fluororesin porous membrane. It combines the durability of fluororesin with the breathability of a microporous membrane structure. The PTFE porous membrane has hundreds of millions of micropores per 1cm2 and exhibits both waterproof and dustproof properties and high breathability at the same time. PTFE resin has excellent properties such as heat resistance, chemical resistance, and non-dusting properties, making it difficult to maintain alternative properties. 7: In order to maintain the processing performance of the image processing system, a high heat dissipation capability is required, and alternative characteristics cannot be maintained.
Heat-resistant	2: 125 degree Celsius (Equal to or better than the current situation.) 4: 200 / 200 degree Celsius
Light fastness/ Weather fastness	4: No functional deterioration in the range from UV light to infrared light (300nm to 2000nm)
Flame resistance	2: Flame resistance VW-1 or higher
Effect on reflectance/transmittance	4: Effect on reflectance/transmittance is within 0.3
Substitution	Substitution unknown

27. Coding for sliding rubber parts of industrial controllers

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Coding for sliding rubber parts of industrial controllers / 9032.89.60.40
CAS RN	9002-84-0
Regulated candidate substance name	Polymeric PFAS / PTFE
Generic name for the final product	Industrial controller
Common name for application parts	Packing
Detailed application description	A PTFE-coated lubricant is applied to the outer circumference of the packing to make it easier to separate the front bezel from the case. Since the housing is made of resin, there is a risk of solvent cracking, and grease cannot be used.  Fig.1 Overall product  Fig.2 Packing installation explanatory diagram
Technical Description of Essential Uses	・ The film does not peel off when applied to rubber parts. (Good adhesion) ・ Good lubricity and no effect on plastics. (No solvent cracks occur)
Coating durability	Coatings on rubber parts do not degrade over time
Sliding performance	Sliding performance for mounting and dismounting
Chemical stability	No impact on plastic cases due to chemical stability (no volatiles or leachables)

28. Temperature sensor

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Temperature sensor / 9032.89.60.40, 8538.90.40.00, 9025.19.80
CAS RN	Unidentified
Regulated candidate substance name	1. Conductor coating / FEP 2. Protective tube / FEP 3. FEP tube /FEP 4. Coating /FEP, PFA
Generic name for the final product	Temperature sensor
Common name for application parts	1. Conductor coating 2. Protective tube 3. FEP tube 4. Coating
Detailed application description	1. Used in the coating for the thermocouple wires 2. Protection of the swage part 3. Protection of the sheath 4. Used in the fluorine coating for protective tube and sheath Technical Description of Essential Uses	1. Conductor coating It is used to ensure heat resistance, moisture resistance and chemical resistance; however, there is no substitutable parts. 2. Protective tube It is used to ensure heat resistance, moisture resistance and chemical resistance; however, there is no substitutable parts. 3. FEP tube It is used to ensure heat resistance, moisture resistance and chemical resistance; however, there is no substitutable parts. 4. Coating It is used to ensure heat resistance, moisture resistance and chemical resistance; however, there is no substitutable parts.

Humidity sensor installed in an environment in which condensation appears on the sensor itself, such as inside the HVAC duct and the outside air intake section.</td></tr>
<tr><td>Technical Description of Essential Uses</td><td>The following features can be obtained by using fluoride polyimide for humidity sensor
The humidity sensor works stably for a long period in an environment where the sensor is condensed (100% humidity).
Nothing to replace this function.
The humidity sensor has higher stability under high temperature, high humidity and organic solvent atmosphere than other products due to the humidity sensitive membrane using fluorinated polyimide.

The prohibition of this technology is concerned about the following effects.</td></tr>
</table>

	• It won't be able to properly measure and control humidity on HVAC system in an environment in which condensation appears on the sensor itself. • Other polymer materials such as methyl methacrylate resin (PMMA), polyimide, polysulfone, etc. can be candidates as alternative technologies and materials. • Alternative technology requires replacement of the sensor every time condensation occurs. For example, it is known that condensation appears on a humidity sensor which is inserted into an outside air intake duct several times a year depending on the weather. Humidity sensors without moisture sensitive membrane using fluorinated polyimide for this application will require replacement at least once a year. Moisture sensitive membranes using fluorinated polyimide can withstand at least 8 years of use. • For the reasons mentioned above, the ban on fluorinated polyimide in humidity sensors should be exempted indefinitely because of the economic burden of increased replacement frequency. • From the point of view of disposal, the use of fluorinated polyimide in the humidity sensor should not be restricted as it generally leads to waste reduction.
Heat-resistant	180°C as a humidity sensitive film
Light fastness/ Weather fastness	Weather fastness: 100%RH
Water-repellent	Electrical insulation in condensing environments
Required derogation period	13.5 years or more
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

30. Safety controller

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Safety controller / 8536.4*
CAS RN	69991-67-9, 60164-51-4, 1623-05-8, 25038-02-2 and more
Regulated candidate substance name	PFPE [Perfluoropolyether]
Generic name for the final product	Same as above application
Common name for application parts	Card Contact
Detailed application description	  It is used to reduce frictional resistance on the sliding part (card) of the safety controller built into the safety relay unit to achieve high mechanical durability and reliability. And it is used in coatings to protect contacts from dirt, reduce frictional resistance, and maintain high reliability.
Technical Description of Essential Uses	The technically difficult points of substitution are as follows. • Fluorinated lubricants are commonly used in several relays because they can be easily diluted with similar fluorinated solvents and can be applied evenly and easily dried. • Because relay has contacts structure, contact reliability is reduced due to abrasion powder generated when plastic or metal parts mechanically operate. • Decrease in stability of relay operation due to increased friction of sliding parts.

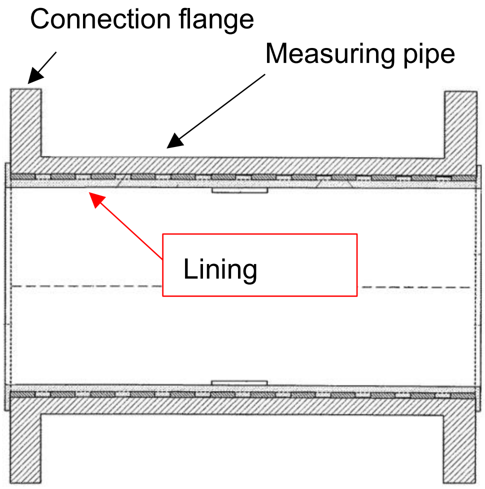
Low friction/wear resistant	When parts slide, there is no generation of abrasion powder that causes poor contact of contacts.

31. Switching power supply / Transformer

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	Switching power supply / 8504.3* Transformer / 8504.3*
CAS RN	9002-84-0, 26655-00-5, 25038-71-5
Regulated candidate substance name	PTFE [Polymer of 1,1,2,2-tetrafluoroethene] PFA [Tetrafluoroethylene-co-perfluoro (Alkyl vinyl ether)] ETFE [Polyethene-co-tetrafluoroethene]
Generic name for the final product	Same as above application
Common name for application parts	Insulation Wire Non-heat shrinkable Tube
Detailed application description	1. Used for the cable of Switching power supply/ Transformer 2. Used for tube of Seal parts << Schematic Cross-sectional View >> Cable  Tube  1. Insulated wires ETFE or PFA insulated wires are used for transformers installed in power supply equipment, and the main component is ETFE or PFA. ETFE and PFA resin have a low dielectric constant and a high heat resistance of 200°C, so the wire coating can be made thinner. It is essential for miniaturization and weight reduction of equipment. 2. Non heat shrink tubing The transformer installed in the power supply equipment uses non-heat shrinkable polytetrafluoroethylene (PTFE) tube, and the main component is PTFE. Even though the PTFE tube is thin, it has high insulation performance and heat resistance. There is no alternative material that can be used in applications where there is not enough space for insulation and meets the requirements in tight spaces.

32. Measuring pipe lining material for industrial electromagnetic flowmeters

<table>
<tr><th colspan="2">Essential Application</th></tr>
<tr><td>Main use sector</td><td>Energy sector
Petroleum and mining etc.</td></tr>
<tr><td>Application/
HTS code</td><td>Measuring pipe lining material for industrial electromagnetic flowmeters / 9026.10.20.40</td></tr>
<tr><td>CAS RN</td><td>ETFE : 25038-71-5
PFA : 26655-00-5</td></tr>
<tr><td>Regulated candidate substance name</td><td>Polymeric PFAS /
ETFE, PFA</td></tr>
<tr><td>Generic name for the final product</td><td>Industrial electromagnetic flow meter</td></tr>
<tr><td>Common name for application parts</td><td>Measuring pipe</td></tr>
<tr><td>Detailed application description</td><td>



Industrial electromagnetic flowmeters are inserted into pipes that require measurement and are used as part of large-scale equipment such as industrial chemical plants.</td></tr>
<tr><td>Technical Description of Essential Uses</td><td>Industrial electromagnetic flowmeters measure corrosive fluids such as chemicals as an application.
The measurement of corrosive fluids such as chemicals is 30% of the applications of industrial electromagnetic flowmeters.
Industrial electromagnetic flowmeter is required to have performance that can withstand the measurement of corrosive fluid.

In order to measure corrosive fluids with industrial electromagnetic flowmeters, PFA and ETFE measurement pipe linings are required in the flow path where the corrosive fluids come into contact.
• Other polymeric materials, such as rubber and resin, may be used as substitutes for the lining of measuring pipes with PFA and ETFE. However, the alternative materials have poor resistance to various chemicals in industrial chemical plants</td></tr>
</table>

	and cannot withstand corrosive fluids. ・ In alternative technologies and materials, it is necessary to replace the industrial electromagnetic flowmeter itself because the electromagnetic flowmeter itself connected to the pipe is stopped and the corrosion status is periodically checked, and when corrosion occurs, the flow measurement cannot be performed. Electromagnetic flowmeters using ETFE and PFA measuring pipe linings can operate stably for at least 10 years without confirmation. There are concerns about the following impacts due to the unavailability of this technology ・ Production efficiency in production plants for corrosive fluids such as chemicals will drop significantly due to the inability to use lining materials for measuring pipes using PFA and ETFE for industrial electromagnetic flowmeters. This affects the production and supply of chemical products. For the above reasons, the prohibition of lining of measuring pipes by PFA and ETFE in industrial electromagnetic flowmeters should be exempted indefinitely from this restriction due to the economic burden caused by the increase in the frequency of periodic checks and replacements due to equipment shutdowns. From the viewpoint of disposal, restrictions should not be applied because the use of PFA and ETFE lining of measuring pipes in industrial electromagnetic flowmeters allows the electromagnetic flowmeter to be used until it reaches its original service life, which generally leads to a reduction in waste.
Heat-resistant	Must withstand fluids up to 160°C
Chemical resistance	No corrosion from corrosive fluids
Wear resistance	Less wear from abrasive slurry fluids
No-adhesion	Less sticking with sticky slurry fluids
Required derogation period	13.5 years or more Note: This application should have the same derogation period as petroleum and mining.
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

33. Fill Fluid for chlorine or oxygen pressure measurement

Essential Application	
Main use sector	Energy sector Petroleum and mining etc.
Application/ HTS code	Fill Fluid for chlorine or oxygen pressure measurement / 9026.10.20.40
Application	Fill Fluid for chlorine or oxygen pressure measurement
CAS RN	79-38-9/9002-83-9/113114-19-5
Regulated candidate substance name	PFAS-based lubricant oil / PCTFE / Perfluoropolytrimethyleneoxide
Generic name for the final product	Industrial Pressure Transmitter
Common name for application parts	Fill Fluid for chlorine or oxygen pressure measurement
Detailed application description	Pressure Transmitter 1) Measuring Principal A pressure transmitter consists of a barrier diaphragm that contacts the process pressure, a center diaphragm that protects the sensor, and a sensor that detects the pressure. If there is a difference in pressure on each barrier diaphragm, the fill fluid that carries the pressure creates a pressure difference on either side of the sensor, which distorts the sensor and changes its resistance. Measure the pressure by converting the resistance change of the sensor. Standard type Remote type Technical Description of Essential Uses	In addition to the following items, the properties required for the fill fluid include fluidity even at low temperatures, low viscosity, and nonflammability. The only fill fluid that offers all of these is the fluorinated fill fluid, and there is no alternative. In addition to the following items, the properties required for the fill fluid include fluidity even at low temperatures, low viscosity, and nonflammability. The only fill fluid that offers

	all of these is the fluorinated fill fluid, and there is no alternative. The diaphragms that come into contact with process fluids may be damaged due to corrosion or abrasion during use. When broken, the fill fluid comes into direct contact with the process fluid, but otherwise does not leak into the environment. This product is a WEEE target model and is in a controlled state for disposal. Silicon oil is the most likely alternative, but it reacts with chlorine and oxygen at high temperatures and pressures and explodes in the worst case.
Heat-resistant	Sealed liquid is required to have heat resistance.
chemical resistance	Stable against strong corrosive acids and alkalis.
chemical stability	Does not react with chlorine and oxygen even under high temperature and pressure.
electrical insulation	Since the fill fluid is in direct contact with the sensor, high electrical insulation performance is required.
Required derogation period	13.5 years or more Note: This application should have the same derogation period as petroleum and mining.
Socio-economic impact	Problem with the safety of the worker. Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

34. Mass Flow Controller seal

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Mass Flow Controller seal / 9026.10.20.40
CAS RN	Unidentified
Regulated candidate substance name	Fluorine rubber / FKM
Generic name for the final product	Mass Flow Controller Mass Flow Meter Piping joints used for measurement and control equipment
Common name for application parts	O-ring
Detailed application description	O-rings are used as sealing parts to prevent external leakage at joints between different parts. **<Mass flow controller usage example>** Technical Description of Essential Uses	FKM is used for various gases with excellent heat resistance, chemical resistance, ozone resistance, etc., especially when using flammable oxygen gas, it is used due to its high heat resistance and ozone resistance, and the alternative product is a special rubber material, but it becomes a fluorine-based rubber material and the use of fluorine-based substances is unavoidable. If fluorine-based materials are not used, safety is significantly impaired.
Heat-resistant	The flexibility of rubber does not change from -10°C to +60°C
Chemical resistance	Chemical resistance to withstand components contained in combustible gases
Ozone resistance	Resistant to ozone gas
Required derogation period	13.5 years or more
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

35. Mass Flow Controller lubricant oil

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Mass Flow Controller lubricant oil / 9026.10.20.40
CAS RN	Unidentified
Regulated candidate substance name	PFAS-based lubricant oil / PFPE (Perfluoropolyether)
Generic name for the final product	Mass Flow Controller Mass Flow Meter Piping joints used for measurement and control equipment
Common name for application parts	lubricant
Detailed application description	Mass flow controllers and mass flow meters are used for flow control and flow measurement of various industrial gases.  Lubricating oil is applied to joint screws and O-rings to prevent screw galling and improve the assembly of O-rings.
Technical Description of Essential Uses	Ordinary grease and oil cannot be used because they may become a source of ignition when flammable oxygen gas is used, so their safety is significantly impaired.
Chemical stability	Chemical stability that does not react to combustion-supporting gases such as oxygen
Required derogation period	13.5 years or more
Socio-economic impact	Problem with the safety of the worker. Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

36. Control valve of mass flow controller

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Control valve of mass flow controller / 9026.10.20.40
CAS RN	9002-84-0
Regulated candidate substance name	Polymeric PFAS / PTFE
Generic name for the final product	Mass Flow Controller
Common name for application parts	Control valve
Detailed application description	Mass flow controllers are used for flow control of various industrial gases.  PTFE is used as the material of the valve body of the flow control valve of mass flow controller. See part (10) in the figure below (the right is a partial enlarged view).  Cross-sectional view of the product   Cross-sectional view of the valve  Enlarged view

Technical Description of Essential Uses	PTFE has high corrosion resistance and heat resistance. As an alternative, rubber materials will be used, but it will be fluorine-based rubber materials and the use of fluorine-based substances is unavoidable.
Heat-resistant	Heat resistant to withstand operation from -10°C to +60°C
Chemical resistance	Chemical resistance to withstand components contained in combustible gases
Ozone resistance	Resistant to ozone gas
Required derogation period	13.5 years or more
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

37. Fittings for micro-flow rate liquid flow meter for semiconductor manufacturing process

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Fittings for micro-flow rate liquid flow meter for semiconductor manufacturing process / 9026.10.20.40
Application	Fittings for micro-flow rate liquid flow meter for semiconductor manufacturing process
CAS RN	26655-00-5 9002-84-0
Regulated candidate substance name	Polymeric PFAS / PFA, PTFE
Generic name for the final product	Micro flow rate liquid flow meter
Common name for application parts	Fitting
Detailed application description	Micro flow liquid flow meters are used to measure micro flow rates of fluids used in semiconductor manufacturing processes. If impurities are mixed in the fluid used in the semiconductor manufacturing process, it will adversely affect the yield of semiconductor production. The liquid flow path inside the micro flow rate liquid flowmeter is composed of a quartz glass tube that does not elute into the fluid. Fluororesin is used for the fitting of the micro flow rate liquid flow meter. Technical Description of Essential Uses	Semiconductor manufacturing process is required high level chemical controls, due to chemical contamination makes negative influences on quality of products. PTFE and PFA which are inert to various chemicals and also include low additives, are suitable materials for flow paths in semiconductor manufacturing process. Impact of prohibition using PFA, PTFE It will be impossible to keep miniaturization technology used in current semiconductor manufacturing process.

	To avoid this problem would require a great deal of effort and technical innovation.
Chemical resistance	Resistant to chemicals and solvents fluids
Cleanliness performance	Cleanliness performance without elution and volatilization of components from components
Required derogation period	13.5 years or more Note: This application should have the same derogation period as semiconductor manufacturing processes.
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes. Yield deterioration in the semiconductor manufacturing process

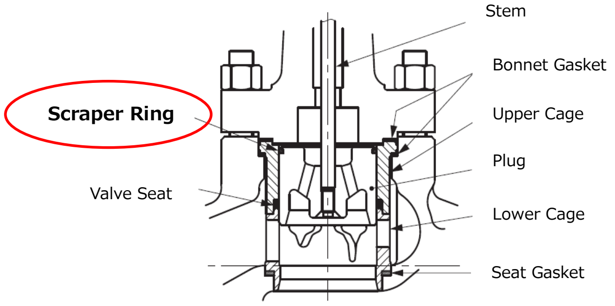
38. Control valve seat ring

Essential Application	
Main use sector	Energy sector Petroleum and mining etc.
Application/ HTS code	Control valve seat ring / 8481.**
CAS RN	9002-84-0
Regulated candidate substance name	Polymeric PFAS / PTFE
Generic name for the final product	Control valve
Common name for application parts	Seat ring
Detailed application description	Control valves are used in a variety of different markets that controls fluid flows in plumbing installed in air conditioning system of building, and Industrial plants, for example petrochemical and power plant. Seat ring is a component of control valves that has a function of stopping the flow by contacting with the plug when it is fully closed.  fig1. Control Valve for fig2. Control Valve for HVAC
Technical Description of Essential Uses	In case of the control valve in fig1, the tight contact load with the PTFE seat ring is generally lower than the contact load with metal seat ring. In case of the control valve fig2, the ball rotates to control flow while sliding with the seat ring. By using the PTFE for the seat ring, it makes possible to reduce operation torque of ball because of low friction. Hence it is enough to operate control valves with PTFE seat ring by downsized actuator. As the results, the downsizing of actuators contributes to reduce usage of metal materials and consumption of energy for the valve operation.

	In general, the friction coefficient of PTFE (0.1 or less) is approximately 1/5 that of metal (approximately 0.5), and the torque required to rotate the plug is approximately 1/5 in proportion to the friction coefficient. Add that, corrosive and high temperature fluid flows through control valves. So, excellent chemical and heat resistance are required to control valves. PTFE fills all of characteristics aforementioned. Furthermore, it has proven track record of long-term use in various fields. It is extremely difficult to use alternate materials simultaneously satisfy the requirements of heat resistance, chemical resistance, sliding performance and seal performance. Hence it is hard to replace PTFE.
Heat-resistant	Heat resistance that can withstand high temperatures of 230°C
chemical resistance	Resistant to water control chemicals and steam containing chemicals
Sliding performance	Wear resistance due to sliding, sliding performance.
Seal performance	High sealing performance with low clamping force
Required derogation period	13.5 years or more Note: This application should have the same derogation period as petroleum and mining.
Socio-economic impact	Upsizing of equipment. Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

39. Material for scraper rings in industrial control valves

<table>
<tr><th colspan="2">Essential Application</th></tr>
<tr><td>Main use sector</td><td>Energy sector
Petroleum and mining etc.</td></tr>
<tr><td>Application/
HTS code</td><td>Material for scraper rings in industrial control valves / 8481.**</td></tr>
<tr><td>CAS RN</td><td>9002-84-0</td></tr>
<tr><td>Regulated candidate substance name</td><td>Polymeric PFAS /
PTFE</td></tr>
<tr><td>Generic name for the final product</td><td>Industrial Control valve</td></tr>
<tr><td>Common name for application parts</td><td>VALVE SCRAPER RING</td></tr>
<tr><td>Detailed application description</td><td>



Industrial control valves are installed in pipes of various industrial plants, that are used to control flow of fluids.
Scraper Rings can scrape fluid attached on a cage of the control valve. Scraper Rings have functions to prevent plug-cage sticking.</td></tr>
<tr><td>Technical Description of Essential Uses</td><td>Industrial control valves control corrosive fluids such as chemicals depend on facilities, therefore they must be able to use for the corrosive fluids.
However, it is difficult to identify some corrosive fluid because we can hardly grasp intermediate substances produced by chemical reactions in the chemical production process. Therefore, it is necessary that the control valves have wide range of chemical resistance.

PTFE scraper rings are indispensable parts contacted with corrosive fluid for control flow of the fluid.
Other polymer materials, such as rubber and resin, might be able to substitute for PTFE as the material of scraper rings. However, it is considered that the alternative materials are not suitable, because they do not have enough resistance to various chemicals of chemical plants.
If PTFE substitutes for the alternative material, the control valves and other facilities are regularly stopped to maintain to check corrosive status. Then if corroded parts are found, they should exchange new parts.</td></tr>
</table>

	If use of PTFE scraper ring is prohibited, following influence is concerned. - Productivity of the plants manufacturing the corrosive fluid such as chemicals will decrease markedly, thereby influencing production of chemical products. - Prohibition of PTFE scraper ring will cause increase of maintenance number, thereby increasing economic load and industrial waste from the maintenances. For above reasons, Prohibition of PTFE scraper ring should be exempt from this restriction indefinitely.
Heat-resistant	Heat resistance that can withstand high-temperature fluids of 230°C
chemical resistance	Corrosion resistance with corrosive fluids
Wear resistance	Less wear from abrasive slurry fluids
No-adhesion	Less sticking with sticky slurry fluids
Required derogation period	13.5 years or more Note: This application should have the same derogation period as petroleum and mining.
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

40. Lining and throttling mechanism materials for industrial control valves

Essential Application	
Main use sector	Energy sector Petroleum and mining etc.
Application/ HTS code	Lining and throttling mechanism materials for industrial control valves / 8481.**
CAS RN	25038-71-5 26655-00-5 9002-84-0
Regulated candidate substance name	Polymeric PFAS / ETFE, PFA, PTFE
Generic name for the final product	Industrial Control valve
Common name for application parts	VALVE BODY
Detailed application description	Industrial control valves are installed in pipes of various industrial plants, that are used to control flow of fluids. Industrial control valves are used to control corrosive fluids such as chemicals. Technical Description of Essential Uses	Industrial control valves are required to be able to withstand the control of corrosive fluids at high temperatures. In order to control corrosive fluids with industrial control valves, main body linings and throttle mechanisms made of PFA, ETFE and PTFE are required in the flow passages where corrosive fluids come into contact. ・ It is possible that other polymer materials such as rubber and resin can be used as alternative materials for body lining and throttle mechanism using PFA, ETFE, and PTFE. However, alternative materials have poor resistance to a wide variety of chemicals in industrial chemical plants and cannot withstand corrosive fluids. ・ If it is assumed that metal materials such as chromium and nickel alloys will be substituted, it is necessary to periodically stop the equipment and check the corrosion status of the control valves connected to the pipes. When corrosion occurs, fluid control becomes impossible, so it is necessary to replace the industrial control valve itself.

	The use of PFA, ETFE, and PTFE as lining and throttling mechanism materials for industrial control valves may cause the following concerns: ・ The production efficiency in plants handling corrosive fluids, such as chemicals, may significantly decrease, thereby impacting the production and supply of chemical products. For above reasons, Prohibition of PTFE scraper ring should be exempt from this restriction indefinitely. In terms of disposal, the restriction should not be applied to valves containing PFA, ETFE, and PTFE since these components can be used until the product reaches its original service life, leading to a reduction of waste in general.
Heat-resistant	Heat resistance that can withstand high-temperature fluids of 140°C
chemical resistance	Corrosion resistance with corrosive fluids
Wear resistance	Less wear from abrasive slurry fluids
No-adhesion	Less sticking with sticky slurry fluids
Required derogation period	13.5 years or more
Socio-economic impact	Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

41. Valve for air volume and room pressure control

<table>
<tr><th colspan="2">Essential Application</th></tr>
<tr><td>Main use sector</td><td>Medical devices
Construction products etc.</td></tr>
<tr><td>Application/
HTS code</td><td>Materials for ensuring slidability, corrosion resistance, chemical resistance, and solvent resistance for airflow valves / 8481.**, 8415.10</td></tr>
<tr><td>CAS RN</td><td>26655-00-5
9002-84-0
24937-79-9
25038-71-5</td></tr>
<tr><td>Regulated candidate substance name</td><td>Polymeric PFAS /
PFA, PTFE, PVDF, ETFE</td></tr>
<tr><td>Generic name for the final product</td><td>Valve for air volume and room pressure control</td></tr>
<tr><td>Common name for application parts</td><td>Body, Pivot arm, S-link, Shaft, Spring, Cone, Brackets, Seal, Tap, e-crip, Bush, Slider, Sleeve, Cap, Bolt</td></tr>
<tr><td>Detailed application description</td><td>
The two main applications of valves are below.

(1) To be installed as a local exhaust ventilation system to prevent workers from being exposed to substances harmful to the human body, such as in chemical manufacturers and biotechnology research laboratories.
For example, when a worker opens or closes the door of the local exhaust device (red dotted frame in Fig.1), the differential pressure across the valve suddenly changes, but by taking advantage of the good sliding property, the valve can be instantly changed to the appropriate valve opening position to maintain exhaust at a constant air volume.
In addition, since valves must control fluids containing various chemicals and solvents, they must be resistant to corrosion, chemicals, and solvents.

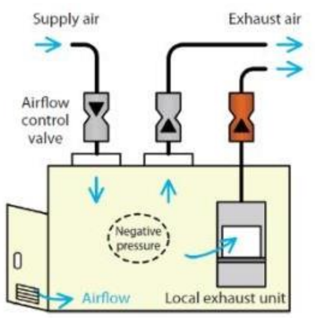

Fig.1 Example of air volume control in a chemical

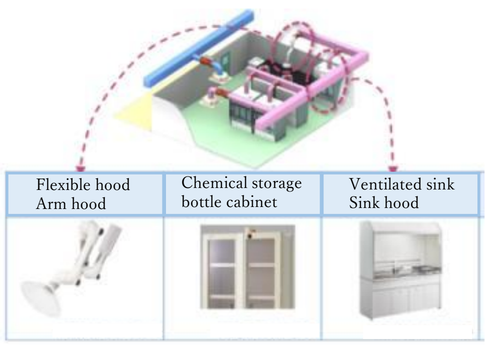

Fig.2 Other exhaust applications

(2) The device is installed in hospital rooms and wards as a negative-positive pressure control device to secure hospital beds for patients with infectious diseases and to protect healthcare workers from infection risk.
Even when the differential pressure across the valve suddenly changes due to the opening and closing of the hospital room entrance door, etc., the air supply and exhaust valves respond instantly by taking advantage of their good sliding characteristics and change to the appropriate opening position, thereby always maintaining the pressure difference between the room and outside.
</td></tr>
</table>

	(see below)

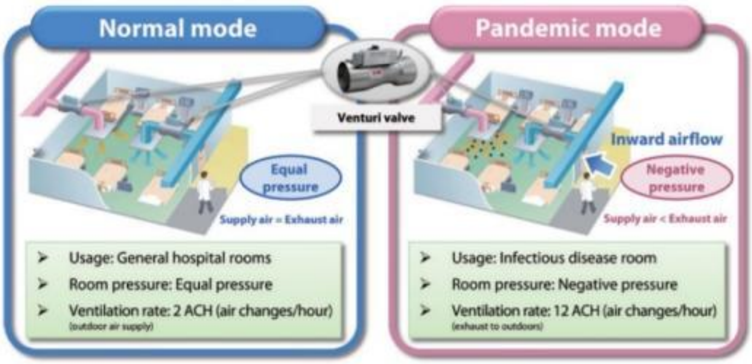

Fig.3 Image of negative and positive pressure control in a hospital room

The parts used in valves that include candidates for regulation are below.

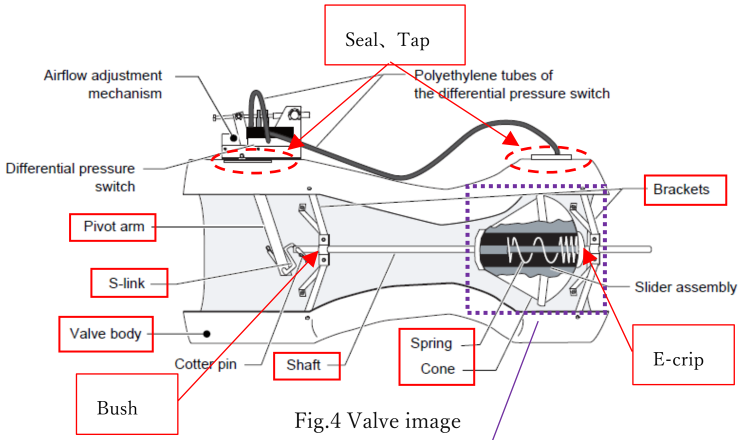

Fig.4 Valve image

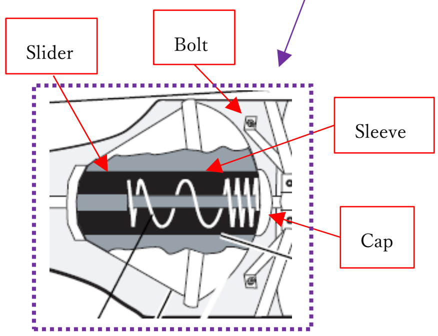

Fig.5 Slider assembly

(1) For valves that do not require corrosion resistance, chemical resistance, or solvent resistance, parts (Slider, Sleeve, Cap) containing PTFE should be used to ensure sliding properties.

(2) Valves that require corrosion resistance, chemical resistance, and solvent resistance use the following parts to ensure the above three functions and sliding properties.

- Parts containing PTFE (Slider, Sleeve, Cap, Bush, Seal, Tap)
- Parts containing PFA (Shaft, Spring)
- Parts containing PVDF or ETFE (Body, Pivot arm, S-link, Cone, E-crip, Bolt)

Technical Description of Essential Uses	As mentioned above in “Detailed application description”, valves must have the sliding property required to respond instantly to sudden disturbances, and the corrosion, chemical, and solvent resistance required to control fluids containing various chemicals and solvents. Therefore, it is necessary to place parts containing PTFE, PFA, PVDF, and ETFE for mechanisms that need to ensure sliding properties and for channel parts that are in contact with the control fluid. (1) Ensure sliding properties Other polymeric materials may be used as an alternative to PTFE for ensuring sliding properties. However, since there is no material with lower sliding resistance than PTFE, the sliding resistance force will increase and the sliding performance required for valves cannot be ensured. (2) Ensure sliding properties, corrosion resistance, chemical resistance, and solvent resistance Other polymeric materials, such as rubber and resin, may be used as alternatives to PFA, PTFE, PVDF, and ETFE for the purpose of ensuring the above four functions. However, the alternative materials cannot ensure the sliding properties, corrosion resistance, chemical resistance, and solvent resistance required for valves due to the deterioration of sliding properties as described in (1) and the lack of resistance to various chemicals and solvents. The following effects are feared as a result of the unavailability of these technologies. The inability to use PFA, PTFE, PVDF, and ETFE for valves will make it impossible to carry out normal operations at chemical manufacturers, biotechnology research facilities, hospitals, and other facilities. This will have a profound impact on the production and supply of medicines, the progress of research in biotechnology, and isolated medical treatment, including coronas. For the above reasons, the prohibition of the use of parts containing PFA, PTFE, PVDF, and ETFE in valves should be exempted from this restriction in terms of ensuring safety for the human body. In terms of disposal, the restriction should not be applied to valves containing PFA, PTFE, PVDF, and ETFE, since these components can be used until the product reaches its original service life, leading to a reduction of waste in general.
Heat-resistant	Heat-resistant max 93°C
chemical resistance	Resistant to chemicals, solvents and corrosive fluids
Sliding performance	Wear resistance due to sliding, sliding performance
No-adhesion	No-adhesion of foreign matter
Required derogation period	13.5 years or more
Socio-economic impact	Problem with the supplying specific pharmaceuticals. Problem with the safety of the biohazard test. Problem with the safety of pandemic countermeasures. Shorter operational lifetime. Increased frequency and costs of maintenance. Increased operational downtimes.

42. RFID tag and antenna

Essential Application	
Main use sector	Metal plating and manufacture of metal products Electronics and semiconductors etc.
Application/ HTS code	RFID tag and antenna / 8523.52.00.**
CAS RN	2655-00-5, 31784-04-0
Regulated candidate substance name	PFA (perfluoroalkoxy alkane)
Generic name for the final product	RFID tag and antenna
Common name for application parts	Cover
Detailed application description	 For chemical and spatter resistance, fluoroplastic-coated covers are attached to the tags and antennas.
Technical Description of Essential Uses	These RFID tags and antennas are specially designed for use in environments where chemicals are used or spatter flies from welding, etc. They are difficult to replace in order to maintain durability.

43. Ionizer

Essential Application	
Main use sector	Electronics and semiconductors etc.
Application/ HTS code	Ionizer / 8421.39.**
CAS RN	Unidentified
Regulated candidate substance name	Teflon
Generic name for the final product	Ionizer
Common name for application parts	Air tube
Detailed application description	A tube to send ionized air to the nozzle Technical Description of Essential Uses	Since electrical discharge causes increased concentration of ozone, an ozone-resistant air tube is required.

The Japanese electric and electronic (E&E) industrial associations – JEITA, CIAJ, JBMIA and JEMA (JP4EE) – hereby express gratitude to the Minnesota Pollution Control Agency (MPCA)'s for years of efforts to preserve, improve and prevent diminution of the natural environment of the State. We conduct our businesses in the US and all over the world and are firmly committed to protecting human health and the environment and to complying with chemical substance legislations as defined by the countries and regions where we operate. Also, we support active prevention or minimizing chemical pollution by PFAS. In this spirit, we have carefully and conscientiously examined the Request for comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837, and would like to submit our comments and recommendations.

We would highly appreciate the MPCA would carefully consider our input.

General comment:

I. The restriction should be considered based on the risk assessment.

PFAS are a huge group of substances that include many different substances with varying levels of risk. Highly hazardous PFAS such as PFOS and PFOA are already restricted under the Stockholm Convention on Persistent Organic Pollutants (POPs). If other PFAS for which a hazard classification has not yet been identified are to be restricted, as a theory, a proper risk assessment should be conducted and the regulation should focus on applications with high exposure potential and well-established alternative technologies based on the outcome of the risk assessment.

Especially for the risk of fluoropolymers, Chemical industry explains as follows:

> "*Fluoropolymers do not pose a risk to human health or the environment as they are non-toxic, not bioavailable, non-water soluble, non-mobile and do not bio accumulate.*"

In complex articles such as electric and electronic equipment (hereinafter, EEE), most of PFAS essential uses are due to the use of fluoropolymers. If MPCA cannot provide more reasonable justification to restrict such fluoropolymers, it would be appropriate for MPCA to reconsider the proposed measures at least for fluoropolymers. If it is impossible because of the structure of the law, applications of fluoropolymers should be designated as CUU.

II. About essentialities of PFAS which is currently used in EEE

We would like to explain why and how PFAS is essential for certain uses as follows. Details are also specified in the answer to questions below and attachments.

Fluorinated materials are characterized by the combination of several properties, such as; Optical properties (e.g. high transparency, low refractive index), electrical properties (e.g. low dielectric constant, low dielectric loss tangent), durability (e.g. heat resistance, weather/light resistance, chemical resistance), surface functions (e.g. water repellent, oil repellent, low surface tension) and others (e.g. piezoelectric properties, high vapor pressure).

There are printed circuit boards where low dielectric constant, heat resistance and flame resistance are required, and fluorinated materials are suitable and actually used for this application. Non-fluorinated material cannot exist that can satisfy these three properties simultaneously. There are non-fluorinated materials that have each of these properties, but they cannot be mixed together to make an article that satisfies all three at the same time. Even if they could be mixed together, the material mixed would not satisfy heat resistance, as the lowest property of the three substances would appear with regard to thermal properties. The same applies to transparency, low refractive index, low dielectric constant, weather resistance and chemical resistance. When mixed with other materials, they are affected by the poor properties of the other materials and cannot maintain their good properties.

The cases where alternatives to fluorinated materials exist are limited to applications where only one properties, such as heat resistance, water repellency or insulating properties are required, and non-fluorinated materials cannot be used in applications where multiple properties must be achieved.

III. About the difficulties in replacing a substance in the complex articles.

For complex articles such as EEE, even a single substance survey will not work unless the entire global supply-chain responds appropriately to the survey.

When PFAS alternative which is considered really feasible would be found in the future, it is necessary to evaluate not only the safety of the potential PFAS alternative as chemicals but also fulfilment of the required performance with keeping safety and reliability using the alternative in each final product model.

Even if some alternatives are proposed by chemical manufacturers, there is no guarantee that the same performance as before can be obtained. When the substance concerned may be contained in parts having very important functions in products, product design will have to be carefully reviewed and it would take a long period. Even though some "similar" parts without the substance become available, many processes would be needed until the reliability and durability of a whole product can be finally guaranteed. Each level of article manufacturers (of parts, of components or units, and of finished products) must have their own technical processes for reviewing and developing substitution, testing its quality and reliability, and acquiring certification on applicable standards such as on safety as necessary.

Following is necessary step for typical EEE when substituting a substance for which viable alternatives are established. Please note that there are currently no feasible alternatives for essential uses of PFAS in EEE described in our Attachments.

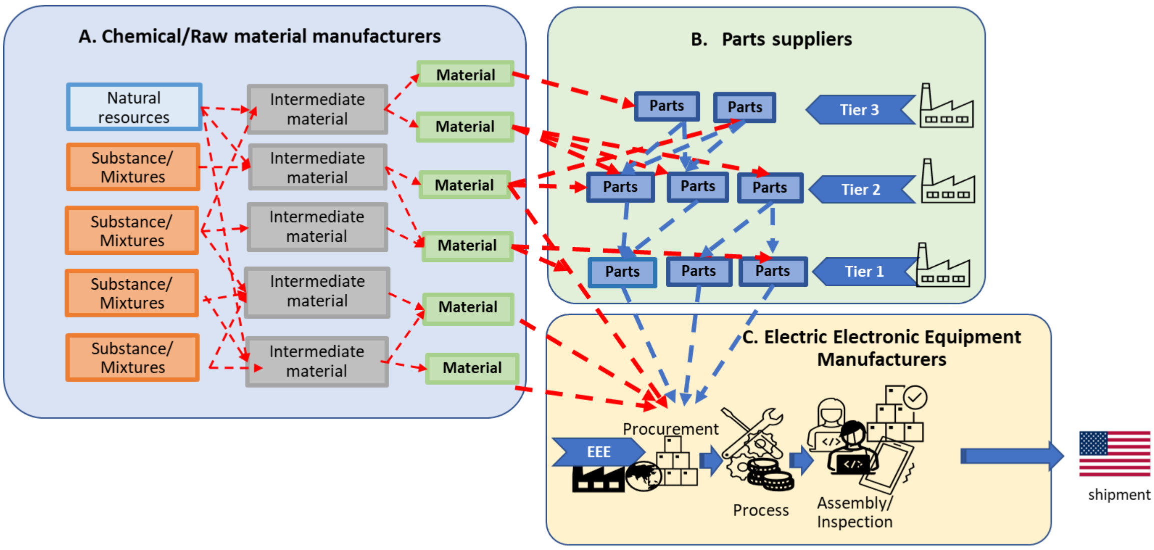
i. Procurement and Assessment of Substitute Parts with Suppliers

This includes following two actions:

- Identification of parts / materials containing PFAS
- Development and evaluation of alternatives at suppliers

EEE is composed of a large number of parts that may exceed tens of thousands of complex items. In addition, there are thousands of primary suppliers who supply parts directly, in complex and multi-layered supply chains with secondary and tertiary suppliers that supply parts for those parts. PFAS is a huge group of substances, and as the identifiers such as CAS RN are not specified for PFAS, the investigation becomes extremely difficult for the EEE manufacturers.

After the substance-containing parts / materials are identified, replacement by alternative products must be investigated.



ii. Internal Quality Assessments

Evaluation items differ depending on the category of the final product (i.e. EEE), but they can be roughly divided into the following items:

a. performance evaluation

b. long-term reliability evaluation

For performance evaluation, following actions are necessary: processing / molding test of purchased parts /materials, assembly test, and mechanical / electrical performance evaluation.

For long-term reliability evaluation, it includes an accelerated test under high temperature and high humidity conditions.

iii. Quality and Safety Certification

As an example, final products (EEE) acquiring IEC 62368-1 “Audio/video, information and communication technology equipment - Part 1: Safety requirements” certification needs to be certified for each individual product, but the acquisition period varies depending on the product specifications. It includes following steps:

a. the preparation of application documents to the issuance of type tests and test reports;
b. conducting factory audits of suppliers, if necessary.

In addition, changing the parts may require re-acquisition of other certifications such as EMC or energy conservation, which may take longer time.

iv. Supplier Coordination and Manufacturing Changes

At production plant of final product and parts / material suppliers, parts inventories are usually stocked for a certain period. In addition, lead time for new orders to suppliers after completion of replacement evaluation is necessary for another certain period. These periods cannot be uniformly shown since they vary depending on product type. Based on the supplying amount and timing of these inventories and alternative parts / materials and sales status of the final product, we determine the production plan. At the same time, manufacturing changes will be made to switch to alternative parts/materials. Necessary actions include changing the manufacturing process, designing prototype/verification, preparing prototype for pre-mass production /verification, and confirming mass production / quality.

IV. The definition of PFAS should be more clarified in harmonization with existing and well-known definitions.

Lastly, there are PFAS which are difficult to judge whether the Minnesota PFAS Law applies to or not due to uncertainty of the definition of PFAS under the Law. We would sincerely recommend implementing rules on reporting or Currently Unavoidable Uses to include supplementary explanation which enables to clarify the definition, or to harmonize with following definition (section 705.3 of TSCA SECTION 8(a)(7) REPORTING AND RECORDKEEPING REQUIREMENTS FOR PERFLUOROALKYL AND POLYFLUOROALKYL SUBSTANCE).

“Per- and polyfluoroalkyl substances or PFAS means any chemical substance or mixture containing a chemical substance that structurally contains at least one of the following three sub-structures:

(i) R-(CF2)-CF(R′)R″, where both the CF2 and CF moieties are saturated carbons;
(ii) R-CF2OCF2-R′, where R and R′ can either be F, O, or saturated carbons; or
(iii) CF3C(CF3)R′R″, where R′ and R″ can either be F or saturated carbons.

We would like to ask the MPCA to examine our input carefully taking into account the risk and benefit of the PFAS uniform ban.

JP4EE answers to the questions from the MPCA

Our input to the questions from the MPCA is as follows. Please note that we attach the attachment 1 to 6 as reference, which are those we have submitted to the State of Maine. There might be description which does not perfectly fit this Request for Comments:

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

We believe the definitions are necessary. The definition should be harmonized among the States in order to ease sharing information among the authorities and to avoid unnecessary confusion in industries.

Concretely, we think the definition in 2. Definition (I) under the posting draft[1] proposed by the Maine Department of Environmental Protection (DEP) is appropriate and reasonable.

> *"Essential for Health, Safety or the Functioning of Society" means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations.*
>
> *Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction."*

PFAS is the huge group of the industrial chemicals taking indispensable uses on complex articles such as EEE at present, and we consider that all the EEE is indispensable for the "daily functions" based on current information and communication technologies.

The procedures for judging the above are so-called socio-economic impact assessment. As the guidance for such assessment focusing the possible effects on society which may be caused by regulating a substance, we consider *"Guidance on the preparation of socio-economic analysis as part of an application for authorization*" for EU REACH Regulation is detailed and still useful as a reference in this field.

> The European Chemicals Agency (ECHA): *"Guidance on the preparation of socio-economic analysis as part of an application for authorization"* (2011)
>
> https://www.echa.europa.eu/documents/10162/2324906/sea_authorisation_en.pdf/aadf96ec-fbfa-4bc7-9740-a3f6ceb68e6e

As for the Specific criteria for determining what uses of PFAS are considered CUU, we consider that the conditions set out in the Article 5(1)(a) of EU RoHS DIRECTIVE 2011/65/EU, a global pioneer legislation on the restriction of substances in EEE, should be referred for the PFAS in the complex articles. That is, PFAS use in a

[1] It can be downloaded from the following site. (Press the description, "Ch 90 Draft Rule".)
https://www.maine.gov/tools/whatsnew/index.php?topic=dep-rulemaking&id=10415809&v=govdel

specified application in the complex articles such as EEE should be deemed as CUU, where any of the following conditions is fulfilled:

- *their elimination or substitution via design changes or materials and components which do not require any of the PFAS materials or substances is scientifically or technically impracticable,*
- *the reliability of substitutes is not ensured,*
- *the total negative environmental, health and consumer safety impacts caused by substitution are likely to outweigh the total environmental, health and consumer safety benefits thereof.*

Nevertheless, although we can propose the criteria, we would like to highlight that it is not possible to determine YES or NO using uniform criteria. Especially for evaluating substances contained in complex articles, necessary evaluation cannot be determined by such simple YES/NO judgement.

When evaluating the possible alternatives for substances in the finished products (both as chemicals and as articles), we really would like to ask the MPCA to evaluate sufficiently with consideration and understanding of the various critical points of view from all the related stakeholders.

In particular, there are two ways to substitute a substance in an article:

(1) change the material and replace the substance with another substance,

(2) change the product design and replace the parts themselves containing the substance with another parts (or mechanism).

The feasible choice may depend on the substance or the product.

In the method (1), the substance in the article may be required not only for a certain technical function considered as "essential" for the substance, but also for a wide variety of other combined general functions. In many cases, the necessary combination is completely different for each targeted product / article / mixture / process / service. When manufacture of a certain article needs multiple combined “general” functions in addition to the technical functions considered as those comprising the "essentiality" of the substance, then the possible substitute must be a substance that can simultaneously satisfy such complex specifications. If a candidate alternative has only the "essentiality" function, it would not be able to be a substitute for the use in such article.

In contrast, judging the possibility of substitution by method (2) inevitably requires evaluation of the "essentiality" of the parts or components that comprise the finished products. For example, if a part/component is a fundamental and general purpose one used in various products, its "essentiality" is considered to be high. In such cases, it would be almost impossible to replace it by design changes of the whole wide variety of related final products. On the other hand, if it is used in limited components/structures and can be replaced by another design/ technology, the "essentiality" of the part/component itself is not so high. In such cases, if the “most harmful chemical substance” itself is inevitably used in the manufacture of the component and the "essentiality" of the substance itself may be considered as high, it might be substituted by changing the component to another.

That is, it is necessary to evaluate the imperatives of the use of a substance based on their chemical properties, but evaluation of the "essentiality" of the finished products using the substance, especially in complex articles, is also important and necessary to promote the substitution.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Before considering the cost of PFAS alternatives, no feasible alternative has been found in the first place.

We have continuously been investigating and reviewing the PFAS applications in EEE, and we consider that most of the applications we found out would need derogations from the restriction. Fluorinated materials are generally several to dozens of times more expensive than non-fluorinated materials, and if fluorinated materials could be replaced by non-fluorinated materials, component and equipment manufacturers would have adopted them. However, we have no choice but to use the expensive high-performance materials with PFAS if the products need the indispensable properties that can only be achieved with fluorinated materials.

We believe that socio-economic cost by uniform PFAS ban without appropriate preparation should be dully considered rather than the cost of PFAS alternatives.

For EEE, as we explain in attachments, PFAS are required in many applications.

During the use of articles like EEE, it is presumed that an exposure amount of PFAS is generally negligibly low compared with the exposure of the PFAS as chemicals own. For large extent of PFAS uses which are unavoidable (i.e. Unavoidable Uses) are caused by the use of fluoropolymer and it is particularly considered as low risk.

Under such situation, premature uniform restriction of PFAS would prevent the ICT-based life that Minnesota citizens currently enjoy.

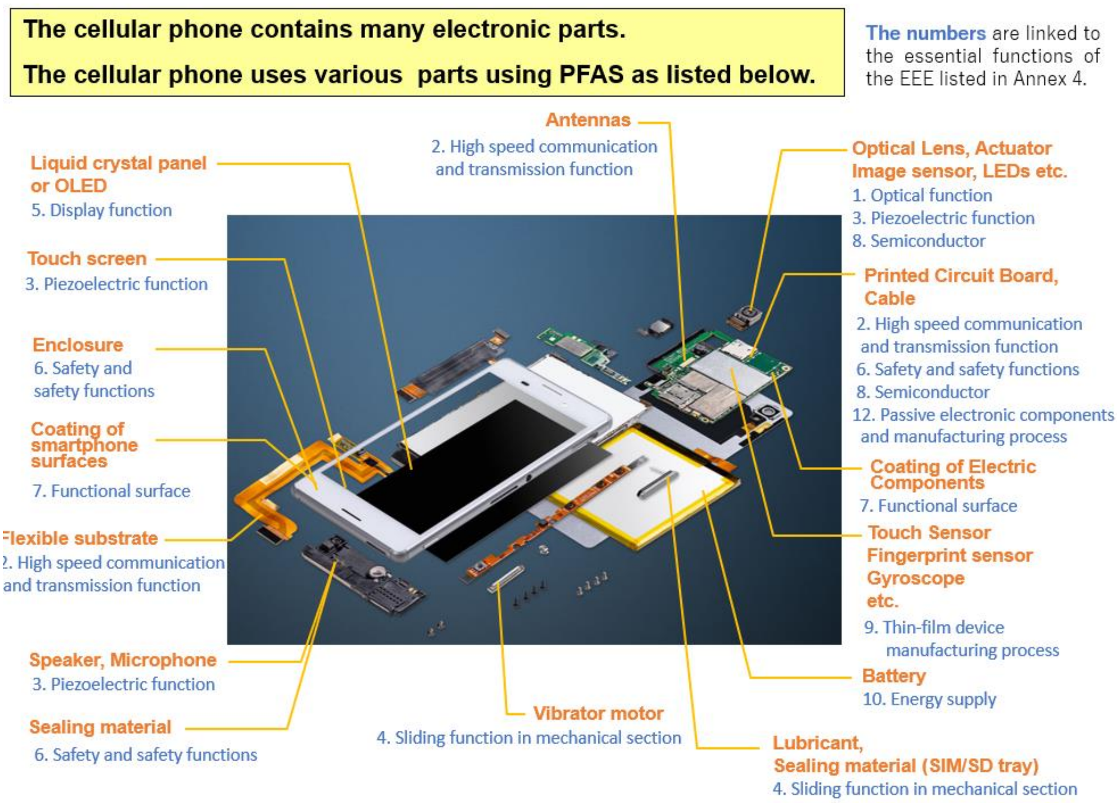
PFAS is widely contained in many critical components such as semiconductors horizontally used in EEE but in very small volume. Therefore, if PFAS is banned in all the applications, almost all the semiconductor and EEE would not be able to be manufactured and used.

Such uniform restriction of PFAS may lead to defective substitution which cannot attain necessary performances but also ensure safety, reliability and durability of the whole products. The end-users will be affected most seriously. This may lead collapse of the whole social infrastructure based on IT and semiconductor technologies.

If only semiconductors listed as "potential derogations marked for reconsideration" in current dossier are finally derogated and the adequate derogations for other applications listed in our Attachment 3 are not set for electronics, the functions necessary for EEE described in Annex 4 and uses exampled in its Column G become non-available, or could be only used in a condition where their performances are remarkably inferior. From about 1970s, PFAS became used in EEE industry widely. Therefore, if PFAS is uniformly restricted, the level of the performances of EEE may return to those at the late 20th century.

For example, about display function, the performance of the thin liquid crystal displays such as TV or monitors, which are widely used today, would return to the level at the latter half of the previous century. More concretely, if the flat panel displays are not able to be manufactured because of PFAS ban, display cannot but return to the cathode ray tube technology which does not use PFAS. We wonder whether consumers in the State of Minnesota would really accept such inferior level of performance or not. Even if accepted, long time has passed since global industry stopped production by such an analog technology, and the supply chain for it has been also abolished, and the production factory does not exist anymore either. If PFAS is banned uniformly, the factories for the old-type products without PFAS must be rebuilt, but it will take several years.

If the large-capacity communication becomes unavailable by PFAS ban along with the inferior display performance, current technologies such as the street view, the surveillance camera or automatic driving by using information via satellites will become also unavailable. If the piezoelectric function is not usable by PFAS ban, the touch panel would not function, either. In addition, the modern minimization and mobilization by making use of the high functional materials using PFAS would become completely impossible, then the smartphone with current performance cannot be produced anymore. Please also see page 2 of our Attachment 2, which illustrates the essential applications of PFAS used in a smartphone.



If the minimization becomes impossible, many products will inevitably return to bigger and heavier ones, and the resulted wastes would remarkably increase. In addition, as operating the bigger products needs more electricity, uniform PFAS ban would cause negative effect also from the point of view of energy efficiency.

Furthermore, the degradation of performance of the motors or the medical equipment, etc. would directly have significant effect on the human safety issues. Unachieved "intended function" leads to "lowering the performance". We sincerely recommend MPCA to examine carefully what degree of deterioration of performances relating to EEE would be acceptable in the modern society.

Considering the potential impact at the uncountable level mentioned above, we believe that the unavoidable PFAS applications should be kept usable under the reasonable management and that the society had better to keep obtaining the benefit from them. We consider that THIS would be a better measure balancing with the socio-economic aspects and in line with the environmental policy along with the economic growth.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

Some consideration may be needed, but we do not have any concrete information on this issue.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

Before considering the cost of PFAS alternatives, no feasible alternative has been found in the first place.

Also, we have serious concerns that the risk assessment of PFAS was not properly conducted before questioning the safety of PFAS alternatives. Please refer to our general comment “I. The restriction should be considered based on the risk assessment”.

The risk assessment caused by the substances in the articles should be also conducted properly. During the use of articles like EEE, it is presumed that an exposure amount of PFAS is generally negligibly low compared with the exposure of the PFAS as chemicals own. The blanket restriction on PFAS will affect many industries. We hope that you will consider our recommendations and information in the following sections and make a scientific and technical decision about the need for and feasibility of regulation.

If the uniform restriction of PFAS in the articles is really planned by MPCA after the proper risk assessment, the assessment of safety of potential PFAS alternatives shall be conducted not only at the substance level but also at **finished product level**. That is, regarding an assessment of alternatives of complex articles like EEE, it also needs an evaluation from the aspect of whether the performance of the final product will not be deteriorated and whether the safety and reliability of the final products will continuously be maintained. This evaluation is inevitably conducted with “socio-economic impact assessment”. Please refer to our answer to question 1 and 2 as above.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

The timeline must be examined on case-by-case basis.

There are currently no feasible substitutes which can attain the performance needed for EEE for the applications listed in column E of Attachment 5 which we provide as our answer to Question 7. We would like to request the MPCA to set the derogations for them, as the feasibility in EEE becomes assessable only after the viable substitute materials are established. Please see Attachment 6 for the explanation of reasons why the candidate substitutions are not feasible in the actual EEE.

The complex article manufacturers consider that the date set for a derogation should not be an expiry date of the derogation but be a date for reviewing it, if MPCA has to dare setting some timeline. We consider 15 years-interval would be practical and feasible to review the CUU for example, in considering the broad coverage of PFAS group, the time for the chemical industry to develop the new materials and wide-variety of the final applications in EEE.

Only if practicable PFAS alternatives which can attain necessary performance to EEE would be available at the point of the review, it is for the first time possible to examine the timeline for substitution.

A transition period of at least 4 years would be generally needed for the replacement of the chemicals for which alternatives already exist, even in the case of threshold at 1,000 ppm order. However, since PFAS is very huge group of substances, we cannot assume the necessary transition period.

Even if some alternatives are proposed by chemical manufacturers, there is no guarantee that the same performance as before can be obtained. When the substance concerned may be contained in parts having very important functions in products, product design will have to be carefully reviewed and it would take a long period. Even though some "similar" parts without the substance become available, many processes would be needed until the reliability and durability of a whole product can be finally guaranteed. Each level of article manufacturers (of parts, of components or units, and of finished products) must have their own technical processes for reviewing and developing substitution, testing its quality and reliability, and acquiring certification on applicable standards such as on safety as necessary.

On the other hand, if there is no available practicable PFAS alternative at the point of the review, the CUUs should be continued to be valid and be reviewed after another 15 years.

In addition, EEE used for social infrastructures, such as medical practice (such as clinical, diagnostic, inspection, analysis, monitoring and others) and industrial and other types of monitoring, control, analysis, measurement equipment and manufacturing equipment (such as Factory Automation devices, etc.), in laboratories, infrastructures of transportation, lifelines, security, disaster preventions, communications and process control of many types of productions (here in after collectively called as “EEE for social infrastructures”) are widely used in society.

EEE for social infrastructures is produced in small numbers for use over long periods without modification or changes; it must be reliable and needs long-term test for reliability. Certificates and approvals are required for some of EEE for social infrastructures. Their number of parts is large and there are many custom parts, moreover safety confirmation needs to be performed much more strictly than for consumer products. Therefore, it requires longer time to complete the substitution and needs special consideration in reviewing CUU in future.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

For PFAS in complex articles at least, we have already indicated the conditions to be recognized as CUU in our answer to question 1 . We believe CUU should be granted if it explains that any of items indicated there can be fulfilled. It is necessary to conduct an assessment of substitution potential per each final product.

As for the assessment procedure, the guidance on Socio Economic Impact Assessment under EU REACH Regulation can be used as reference, as we indicated in our answer to question 1 above.

However, If the primary objective of the law is to reduce risk, PFAS uses with low potential exposure, such as internal component of EEE or fluoropolymers, should not be subject to the PFAS restriction in the first place.

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Since we believe it is important for MPCA to understand how PFAS are used in various applications in EEE, we prepare detailed list and explanation on PFAS CUU in EEE as follows. Please note that these attachments were also submitted to application of CUU in the State of Maine.

(1) JP4EE Attachment 1 :

We would like to submit a list of Electric and Electronic Equipment (hereinafter, EEE) which may use PFAS by using the Global Product Classification (GPC) brick category code. GPC category is based on the purpose of the products and is not based on the technologies on which the products rely. Therefore, GPC for EEE disperse to many categories.

EEE covers so many various product categories, but the technologies and materials and parts used in EEE are basically common. For supplementary explanation on EEE, please see our Attachment 2.

(2) JP4EE Attachment 2 Supplementary Explanation on EEE.

(3) JP4EE Attachment 3 - List of EEE Functions needing PFAS.

This document lists the functions and properties necessary to EEE, which need PFAS materials to attain required performances.

(4) JP4EE Attachment 4 - Explanation on EEE Functions in Attachment 3

This document is Supplementary Explanation on the functions of EEE needing PFAS shown in our Attachment 3 on EEE Functions needing PFAS.

(5) JP4EE Attachment 5 - List of PFAS essential uses in EEE.

The list explains CUU in EEE as per OECD categories of PFAS as chemical materials. The list links the functions listed in Attachment 3 above and includes the reasons why these PFAS cannot be substituted.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

We believe some initial CUU determinations are necessary in order for predictability and transparency of the law. Also, we would like to ask MPCA to harmonize CUU operations with other States like the State of Maine as much as possible to avoid confusion among the States. It is not realistic that CUU is different among the States.

We also believe that the assessment method (procedure) should be created for better transparency. For example, the guidance on Socio Economic Impact Assessment under EU REACH Regulation can be used as reference, as we indicated in our answer to question 1 above. Nevertheless, even if the assessment method exists, we would like to highlight that the assessment cannot be uniformly determined by simple YES/NO as we stated above.

9) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

As we stated in General comment I and our answer to Question 4, risk-based approach should be taken rather than hazard-based approach in case of selecting substances to be potentially restricted. We believe that such approach can reduce more risk with less time and resources without inconvenience to people in the State of Minnesota.

Conclusion:

We hope our input would provide substantive information to ensure the smooth and practical implementation of PFAS management to realize a healthy environment and a sustainable economy for the present and future generation in the State of Minnesota.

We wish to work together with the MPCA to make the Rule feasible for implementation. Should you have any questions, please do not hesitate to contact the JEITA secretariat.

Sincerely yours,

Koji Ueno
Senior Manager for Green Innovation
Business Strategy Division
Japan Electronics and Information Technology Industries Association (JEITA)
Ote Center Bldg.,1-1-3, Otemachi, Chiyoda-ku, Tokyo 100-0004, Japan

koji.ueno@jeita.or.jp

About Japanese electric and electronic (E&E) industrial associations:

About JEITA

The objective of the Japan Electronics and Information Technology Industries Association (JEITA) is to promote the healthy manufacturing, international trade and consumption of electronics products and components in order to contribute to the overall development of the electronics and information technology (IT) industries, and thereby further Japan's economic development and cultural prosperity.

About CIAJ

Mission of Communications and Information network Association of Japan (CIAJ). With the cooperation of member companies, CIAJ is committed to the healthy development of info-communication network industries through the promotion of info-communication technologies (ICT), and contributes to the realization of more enriched lives in Japan as well as the global community by supporting widespread and advanced uses of information in socio-economic and cultural activities.

About JBMIA

Japan Business Machine and Information System Industries Association (JBMIA) is the industry organization which aims to contribute the development of the Japanese economy and the improvement of the office environment through the comprehensive development of the Japanese business machine and information system industries and rationalization thereof.

About JEMA

The Japan Electrical Manufacturers' Association (JEMA) The Japan Electrical Manufacturers' Association (JEMA) consists of major Japanese companies in the electrical industry including: power & industrial systems, home appliances and related industries. The products handled by JEMA cover a wide spectrum; from boilers and turbines for power generation to home electrical appliances. Membership of 291 companies, http://www.jema-net.or.jp/English/

About electric equipment manufacturers' coalition of medical devices, and analysis, measurement, test, control and monitoring instruments that have endorsed this paper:

About JAIMA

The Japan Analytical Instruments Manufacturers' Association (JAIMA) is a sole industry association of Analytical Instruments in Japan, which established under the Japanese law. JAIMA is to contribute to the development of the Japanese economy and the cultural lives of citizens in Japan through efforts to improve and advance technologies related to analytical instruments and the analytical instruments industry for the purpose of the advancement of science & technology.

About JEMIMA

Japan Electric Measuring Instruments Manufacturers' Association (JEMIMA) is the only one association representing this industry in Japan. Electric measuring instruments support all kinds of manufacturing industries as so-called "Mother tools" that support innovative activities for research, development, design and manufacturing.

JEMIMA has active committees that collect technical and market information of electric measuring instruments, and provide member companies with useful information for their businesses. Regarding regulations such as environmental, safety and EMC (Electro-Magnetic Compatibility) issues, JEMIMA has been investigating details and providing proposals to legislative organizations summarizing requirements from the industry in cooperation with international related organizations.

Through these activities, JEMIMA will continue to contribute to the steady growth of electric measuring instruments and related industries in Japan.

About JFMDA

The Japan Federation of Medical Devices Associations (JFMDA) was founded in February 1984 by medical device associations consisting of manufacturers and suppliers of medical and health-care devices, equipment, instruments and materials. Since then, JFMDA has been addressing various national and international issues related to all its member associations. By taking appropriate actions on these issues, and through the support of innovation and sustainable supply of medical devices and technologies to the world, JFMDA has contributed to the growth of the industries it represents and to the improvement of welfare and health care in Japan. JFMDA became a legal entity as of January 6th, 2014.

About JIMA

Japan Inspection Instruments Manufacturers' Association (JIMA) is a corporation aggregate of manufactures and sellers for non-destructive inspection instruments and systems. JIMA is the only industry group in Japan for non-destructive inspection instruments. JIMA would eventually contribute to the safety of social capital and facilities, and quality assurance in various productions through non-destructive inspection technology, and supports the safety and reassurance of people's lives.

About JMIF

Japan Measuring Instruments Federation (JMIF) is an industrial association for measuring instruments manufacturers and related organizations/companies in Japan. JMIF was established in 1952 to develop the whole measuring instruments industry through improvement of measuring instruments, aiming to contribute to the eventual development of the Japanese economy and society.

The main activities by JMIF include supporting new technology development, conducting demand trends survey, developing domestic and overseas markets, and enhancing global cooperation.

About NECA

NIPPON ELECTRIC CONTROL EQUIPMENT INDUSTRIES ASSOCIATION (NECA) was established in 1964 and promoting the growth of the electric control equipment fields such as Relays, Switches, Sensors, PLC/FA System Equipment and others, Safety Control Equipment. NECA has 30 companies as regular members and 35 companies as support members, and shipping amount of relevant products were 812.3billion Yen in FY2022. Our website provides further information on our recent news and activities:
https://www.neca.or.jp/en/

About SEAJ

Semiconductor Equipment Association of Japan (SEAJ), founded in March 1985, promoted by the major semiconductor equipment manufacturers, is a nationwide organization of semiconductor manufacturing equipment, flat panel display (FPD) manufacturing equipment and equipment manufacturers that applied their technology and related equipment manufacturers.

SEAJ had existed as an incorporated association from July in 1995. From April 1st in 2012, SEAJ has been authorized by Cabinet Office as a General Incorporated Association that related to the reform of the public-interest corporations system.

The Japanese semiconductor manufacturing equipment, FPD manufacturing equipment and equipment industries that applied their technology is playing great role in supporting the world's semiconductor industry due to the manufacture of semiconductors, FPDs that lay the foundation of the advanced information oriented industries by supplying manufacturing equipment and the indispensable producer goods to the semiconductor industry to Japan and abroad.

In order to promote the development of the semiconductor manufacturing equipment industry and other related industries and to contribute to the further development such as investigative research on production and distribution, proposing and indicating the direction of semiconductor equipment technologies, investigating and studying the area of Emerging Technology, the activities of popularization and enlightenment by conducting of various seminars and lectures, planning of project and promotion of standardization.

About IGMA

The Industrial Gas Detectors and Monitor Manufacturers Association (IGMA) is the organization that promotes the further spread of safety equipment used in various industries such as oil refining, petrochemicals, chemical plants, and civil construction. It contributes to the prevention of workplace accidents such as explosions involving high-pressure gases, flammable gases, toxic gases, harmful gases, as well as poisonings and oxygen deficiency incidents.

Supplementary Explanation in Relation to Japan 4EEIA Input for Maine PFAS CUU

Electric and Electronic Equipment (hereinafter, EEE) covers so many various product categories, but the technologies and materials and parts used in EEE are basically common.
Therefore, **we believe that EEE should be treated as one category under Maine PFAS CUU in most cases*.**

*Some product categories such as medical or measurement equipment may need additional applications in addition to those for the other EEE.

In order to have Maine EPA understand EEE using PFAS more concretely, we would like to use the categories under EU RoHS Directive 2011/65/EU, a global pioneer legislation on EEE, to show illustrative examples of PFAS use.

Please note that each category also covers wide variety of products and no one can make an exhaustive list, though we select typical GPC Family codes covering EEE as much as we found. The composition of GPC is different from RoHS, but we consider these can help to show the necessary PFAS applications in EEE better.

Products under other sectors such as automotive, military, space and aviation also need similar applications as EEE if they use electric parts.

<Slide 1>

The cellular phone contains many electronic parts.

The cellular phone uses various parts using PFAS as listed below.

The numbers are linked to the essential functions of the EEE listed in Annex 4.

Antennas
2. High speed communication and transmission function

Liquid crystal panel or OLED
5. Display function

Optical Lens, Actuator Image sensor, LEDs etc.
1. Optical function
3. Piezoelectric function
8. Semiconductor

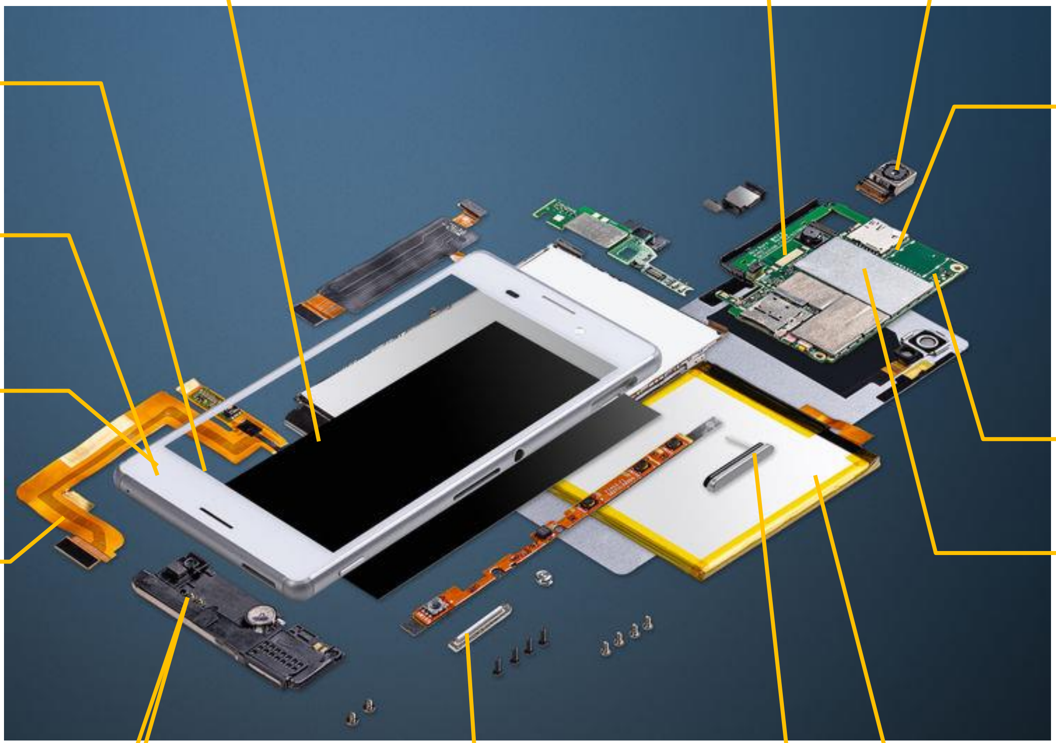
Touch screen
3. Piezoelectric function

Printed Circuit Board, Cable
2. High speed communication and transmission function
6. Safety and safety functions
8. Semiconductor
12. Passive electronic components and manufacturing process

Enclosure
6. Safety and safety functions

Coating of smartphone surfaces
7. Functional surface

Coating of Electric Components
7. Functional surface



Flexible substrate
2. High speed communication and transmission function

Touch Sensor Fingerprint sensor Gyroscope etc.
9. Thin-film device manufacturing process

Speaker, Microphone

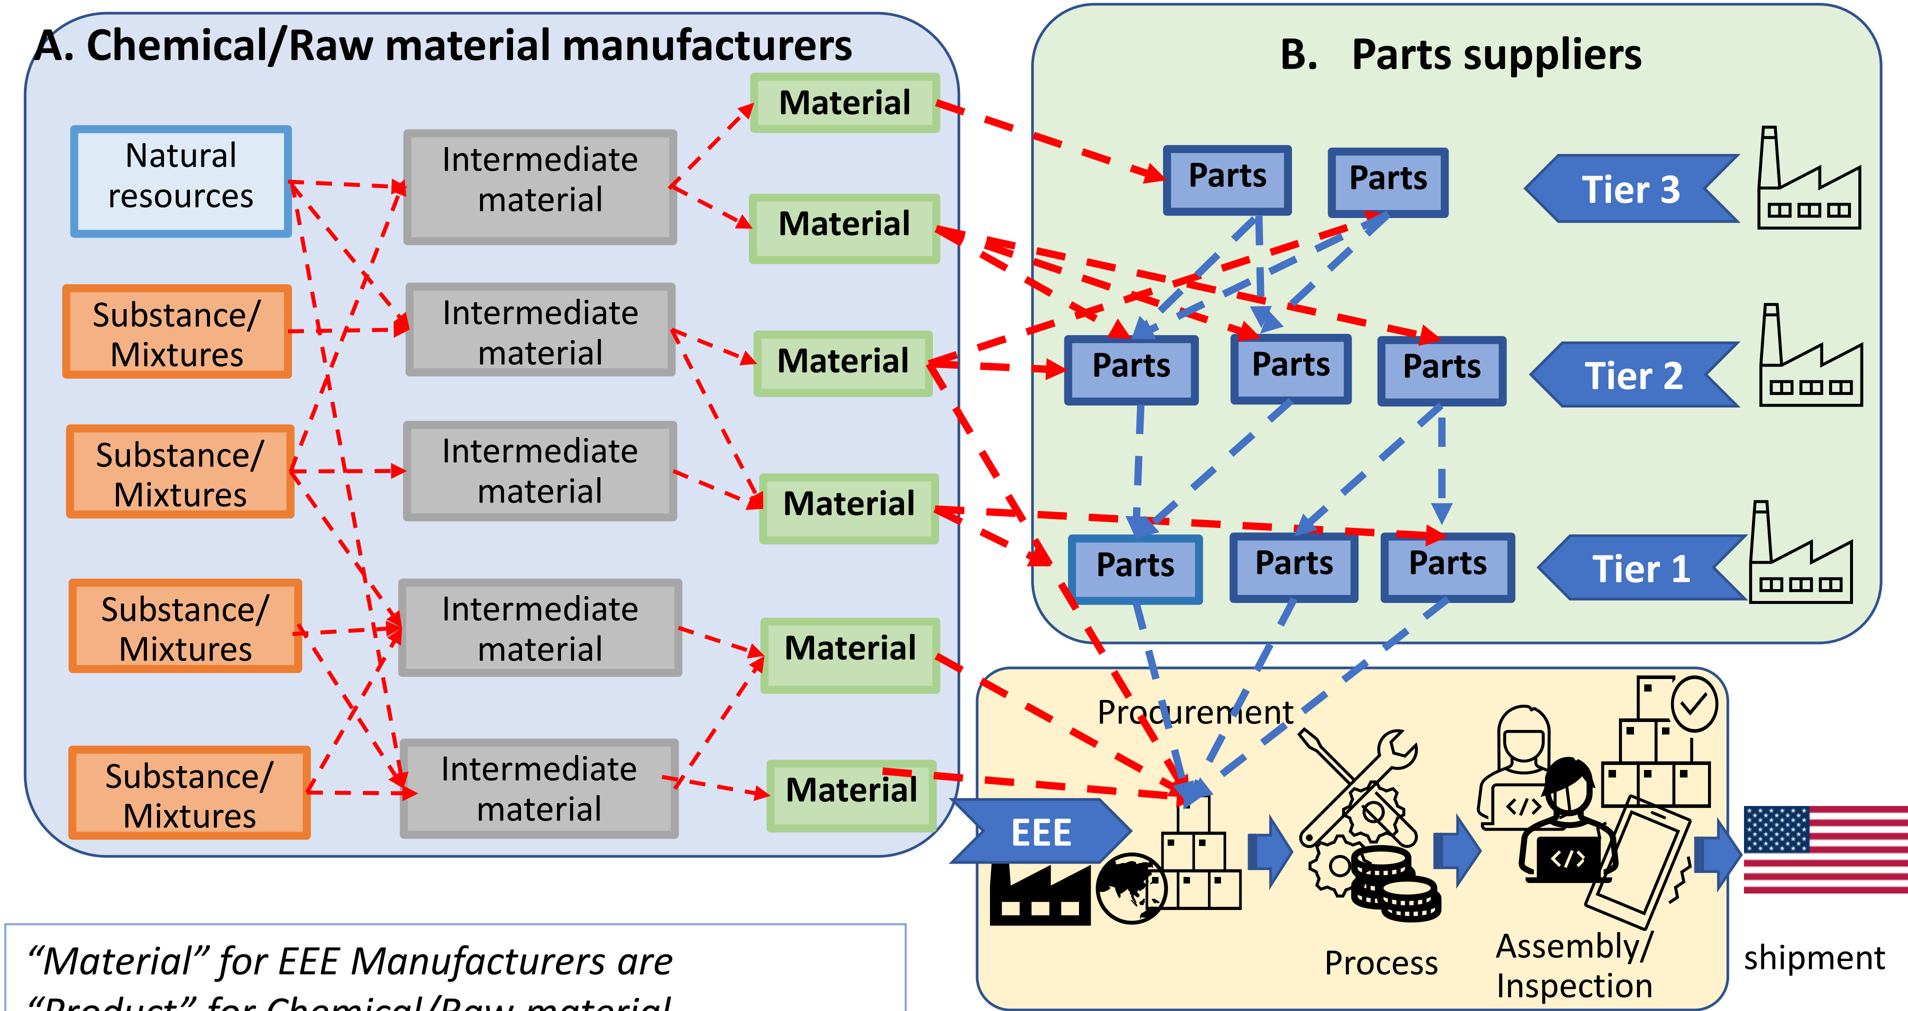
Complexity of supply chain of EEE and related sectors



"Material" for EEE Manufacturers are "Product" for Chemical/Raw material Manufacturers, and thus "lubricant" sector are also related to EEE sector. Likewise, "Semi-conductors" or "batteries" are indispensable to EEE as parts for EEE manufacturers, for example.

C. Electric Electronic Equipment Manufacturers

Categories of EEE covered by EU RoHS (1/8)

Category	Title and examples (with GPC family code)	
1	Large household appliances. For example: Refrigerators(72010000); Freezers(72010000); Other large appliances used for refrigeration(72010000); , conservation and storage of food(72010000); Washing machines(72020000); Clothes dryers(72010000); Electric stoves(79010000); Other large appliances used for cooking and other processing of food; Electric heating appliances(79010000); Electric radiators(79010000); Other large appliances for heating rooms, beds, seating furniture(79010000); Electric fans(79010000); Air conditioner appliances(79010000); Other fanning, exhaust ventilation and conditioning equipment(79010000);	

Categories of EEE covered by EU RoHS (2/8)

Category	Title and examples (with GPC family code)	
2	**Small household appliances.** For example: Vacuum cleaners(72020000); Carpet sweepers(72020000); Other appliances for cleaning(72020000); Appliances used for sewing, knitting, weaving and other processing for textiles(70010000); Irons and other appliances for ironing(47200000); , mangling and other care of clothing; Toasters(72020000); Fryers(72020000); Grinders, coffee machines and equipment for opening or sealing containers or packages(72020000); Electric knives(72020000); Appliances for hair-cutting, hair drying, tooth brushing, shaving, massage and other body care appliances(72020000); Clocks, watches and equipment for the purpose of measuring, indicating or registering time(68010000); Scales	

Categories of EEE covered by EU RoHS (3/8)

Category	Title and examples (with GPC family code)	
3	IT and telecommunications equipment. For example: Personal computers(65010000); Laptop computers(65010000); Notebook computers(65010000); Notepad computers(65010000); Printers(65010000); Copying equipment(65010000); Pocket and desk calculators(62060000); and other products and equipment for the collection, storage, processing, presentation or communication of information by electronic means; User terminals and systems; Facsimile(66010000); Telephones(66010000); Smartphone(66010000); Cellphone(66010000); Answering systems(66010000); and other products or equipment of transmitting sound, images or other information by telecommunications(66010000)	

Categories of EEE covered by EU RoHS (4/8)

Category	Title and examples (with GPC family code)	
4	**Consumer equipment.** For example: Radio sets(66010000); Television sets(68010000); Videocameras(68020000); Video recorders(65010000); ; Hi-fi recorders(65010000); Audio amplifiers(68010000); Musical instruments(68010000); And other products or equipment for the purpose of recording or reproducing sound or images, including signals or other technologies for the distribution of sound and image than by telecommunications(68010000)	
5	**Lighting equipment. (78030000)** For example: Luminaires for fluorescent lamps with the exception of luminaires in households(78030000); All kinds of lamps; Other lighting or equipment for the purpose of spreading or controlling light;	

Categories of EEE covered by EU RoHS (5/8)

Category	Title and examples (with GPC family code)	
6	**Electrical and electronic tools.** For example: Drills(82010000); Saws(82010000); Sewing machines(82010000); Equipment for turning, milling, sanding, grinding, sawing, cutting, shearing, drilling, making holes, punching, folding, bending or similar processing of wood, metal and other materials(82010000); Tools for riveting, nailing or screwing or removing rivets, nails, screws or similar uses Tools for welding, soldering or similar use(82010000); Equipment for spraying, spreading, dispersing or other treatment of liquid or gaseous substances by other means(88010000); Tools for mowing or other gardening activities(72020000)	7	**Toys, leisure and sports equipment.** For example: Electric trains or car racing sets(86010000); Hand-held video game consoles(65010000); Video games(65010000); Computers for biking, diving, running, rowing, etc.(65010000); Sports equipment with electric or electronic components(71010000); Coin slot machines(95160000)	

Categories of EEE covered by EU RoHS (6/8)

Category	Title and examples (with GPC family code)	
8	Medical devices. (51150000) For example: Radiotherapy equipment; Cardiology; Dialysis; Pulmonary ventilators; Nuclear medicine; Laboratory equipment for in-vitro diagnosis; Analysers; Freezers; Fertilization tests; Other appliances for detecting, preventing, monitoring, treating, alleviating illness, injury or disability *Note: The products in this category may need additional special applications in addition to those for the other EEE.	

Categories of EEE covered by EU RoHS (7/8)

Category	Title and examples (with GPC family code)	
9	Monitoring and control instruments including industrial monitoring and control instruments. For example: Smoke detector(91030000); Heating regulators; Thermostats(79010000); Measuring, weighing or adjusting; appliances for household or as laboratory equipment(62060000); Other monitoring and control instruments used in industrial installations (e.g. in control panels)(78020000) *Note: The products in this category may need additional special applications in addition to those for the other EEE.	
10	Automatic dispensers. For example: Automatic dispensers for hot drinks; Automatic dispensers for hot or cold bottles or cans; Automatic dispensers for solid products; Automatic dispensers for money(62060000); All appliances which deliver automatically all kind of products	 

Categories of EEE covered by EU RoHS (8/8)

Category	Title and examples (with GPC family code)	
—	Other EEE not covered by any of the categories above. For example: Industrial manufacturing equipment(11030000); Ignition modules and other electrical and electronic engine control systems for non-mobile equipment (such as non-road professional use equipment) (11030000); motor-operated adjustable furniture such as height-adjustable desks, elevation beds and chairs, excluding medical devices and wheelchairs(75010000); motor-operated building elements such as shutters, blinds, screens, awnings, pergolas, curtains, doors, gates, windows, skylights(91030000); all other products using electric and electronic parts(78020000). *Note: The products in this category may need additional special applications in addition to those for the other EEE.

JP4EE Attachment 4- Explanation on EEE Functions in Attachment 3

Application examples and PFAS essentiality in Electrical and Electronic Equipment.

Contents

1. Optical function and required properties

(1) Optical function

Essential for EEE (Electrical and Electronic Equipment) to control transmission, reflection, diffusion etc. of light.

For example, camera imaging and optical communication of fiber optic cables.

(2) Required properties for parts and components

- Low refractive index, high light transmittance, high durability

  e.g.) Lens (high sensitivity), image sensor (high sensitivity), LED antireflection coating (energy saving), optical fiber (high-speed transmission)

- Transparency/No absorption in visible light (approx. 380 to 770 nm) and water and oil repellency.

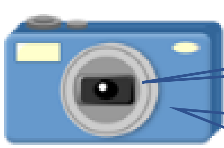
  e.g.) Protective coating for lenses (high durability), encapsulant for LEDs (high reliability, energy saving)

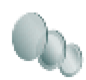
＊( ) indicates achievable performance

<Application examples>

[Digital camera, Surveillance camera, etc.]

Parts in which PFAS is used





Lens
Protective coat

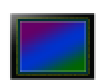


Image Sensor
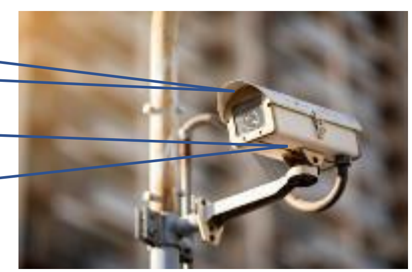
Optical filter
Anti-reflective film
Thin Film fablication Process



Protective Coating of Lenses

Light reflection occurs between objects with different refractive indices, and the greater the difference in refractive index, the greater the reflection. If light is reflected at the interface between air and lenses with different refractive indices, it will result in loss. Therefore, a layer with a low refractive index, which is intermediate between the refractive indices of air and lens, can prevent reflection and reduce loss. In addition, to protect the lens, stain resistance and durability through water and oil repellency are also essential.

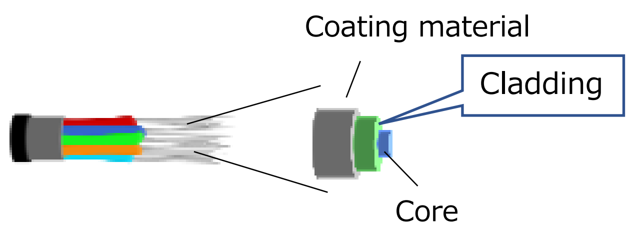
1. Optical function and required properties

<Application examples>

Parts in which PFAS is used

[Optical fiber]

Essential for high-speed communication and transmission functions



<u>Cladding Material of Optical Fiber</u>

Optical fiber has a concentric structure in which a core with a high refractive index is covered with a layer with a low refractive index called cladding, and light is confined and transmitted within the core. Losses occur when light is reflected at the interface between the coating material and core, which have different refractive indices. A layer with a low refractive index prevents diffuse reflection. Durability (heat, moisture, and scratch resistance) is also essential for the application.

1. Optical function and required Properties

(3) Required properties for materials and comparison with non-PFAS materials

Required properties for materials	Materials					Note
	Fluoro-Polymers*	Quartz glass	PMMA	Acrylic	Silicone	
Refractive index (n_d)	1.33～1.42	1.45	1.49	1.48	1.42	・When materials with different refractive indices are mixed, light is refracted and scattered at the interface between the substances, resulting in loss of transparency and cloudiness, so a single composition is necessary. ・For anti-reflection (high transmittance), a materials with a refractive index intermediate between that of air and that of lenses is desirable, especially for glass.
Water and oil repellent	○	×	×	×	△	
Flexibility	○	×	×	△	○	

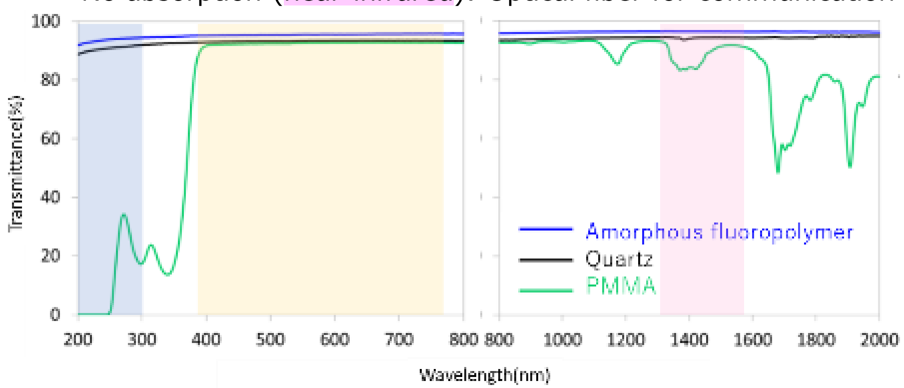
＊ PTFE,PFA,FEP,ETFE,PVDF

○=Excellent; △=Usable; ×=Not well suited for use

<Light transmittance versus wavelength>

High transmittance over a wide wavelength range

- No absorption (UV): UV LED encapsulant
- No absorption (visible light): Coating materials
- No absorption (near-infrared): Optical fiber for communication



＊Source: https://www.agc-chemicals.com/file.jsp?id=file/Cytop_tech14_EN.

- Materials must have a low refractive index (intermediate between the refractive index of air and that of lenses) for optical applications, which are achieved by controlling the transmission, reflection, and diffusion of light. In addition, water and oil repellency and flexibility are also essential to ensure the reliability and durability of devices.
- These must be realized with a single material (A higher refractive index means that light is not focused (scattered) and the intensity of light is reduced, resulting in reduced sensitivity of the device.

There is no material other than fluoropolymers that can achieve a good balance of low refractive index, water and oil repellency, and flexibility (there is no alternative material).

1. Optical function and required properties

(4) Social impact when PFAS cannot be used (example)

1) Fluorine material cannot be used in the camera, resulting in poor imaging performance

- The lack of clarity of the camera lens reduces the security performance of surveillance cameras, and the larger size of the camera lens is required to compensate for the lack of clarity, which is counter to energy conservation.
  In addition, if water and oil repellent coatings cannot be applied to the camera lens, reliability will be reduced and product life will be shortened (more frequent replacements and replacements will be required).

2) When fluorine material could not be used as cladding material for optical fiber

- Optical fiber is a waveguide for propagating light and supports high-speed communication and transmission functions as a transmission path for optical signals in the field of optical communications, an essential function of EEE. In the information society, demand for communication is increasing rapidly. The communication speed is reduced due to the deterioration of transmission loss (the speed is reduced in the Internet, where real-time communication is interfered with), and this will prevent the progress of digital communication in the future.
- If fluorine material cannot be used for the cladding material, the light confinement function in the core is reduced, so it is necessary to thicken the core or increase the number of single wires to increase light intensity. This also deteriorates the handling performance during installation and other operations. Furthermore, because the size of the light source will be changed, the entire optical system will need to be redesigned.
- In additional, the power consumption of the equipment will also increase, which is contrary to energy conservation.

2. High-speed communication/transmission function and required properties

(1) High-speed communication and transmission functions

EEE essential functionality to achieve high-speed, high-capacity communications by using high-frequency radio waves (low transmission loss) with telecommunications and infrastructure equipment.

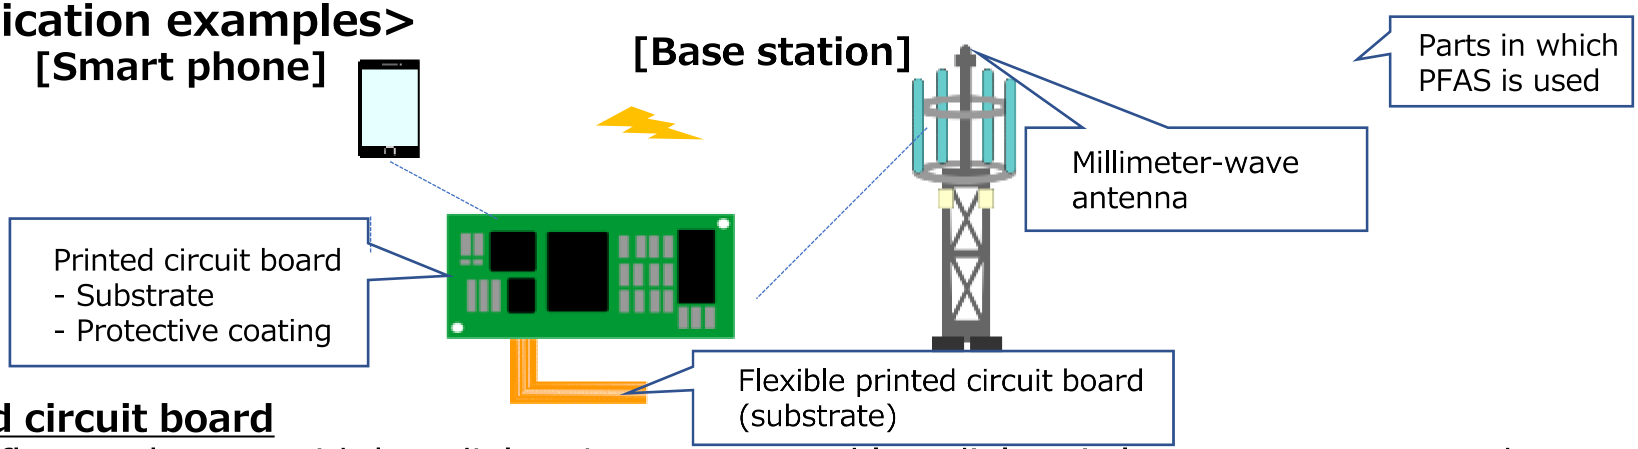
(2) Required properties for parts and components

- Low dielectric constant and dissipation factor at high frequencies and small frequency dependence. Furthermore, high reliability (heat resistance, flame retardance, and long life) is also essential. Therefore, all the performance must be satisfied at the same time.

e.g.) Printed circuit boards for high-speed transmission and millimeter wave radar such as 5G, coaxial cables, satellites and antennas in the millimeter wave band: (high-speed, high-capacity communication, high reliability and energy saving)

＊( ) indicates achievable performance

<Application examples>



<u>Printed circuit board</u>

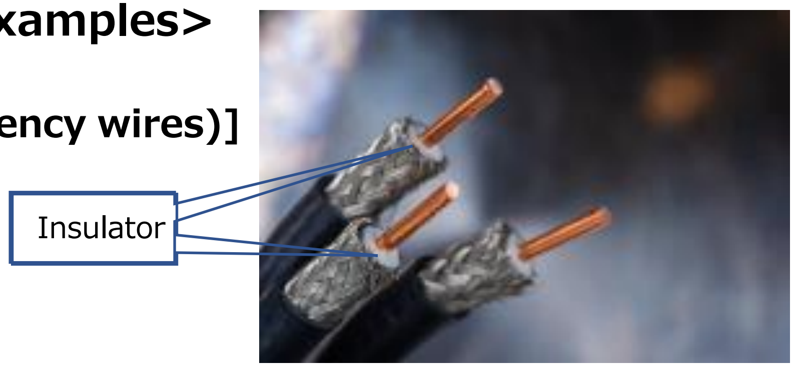
When fluoropolymers with low dielectric constant and low dielectric loss tangent are used as the substrate, the signal energy is not attenuated. This is due to the low rate at which part of the energy is lost internally as heat when current flows. In addition, flame resistance is essential for heat resistance and safety for component mounting. The long life required for base stations can be achieved at the same time, ensuring high reliability.

2. High-speed communication/transmission function and required properties

Parts in which PFAS is used

<Application examples>

[Coaxial cables (high-frequency wires)]



Coaxial cables (high-frequency wires)

The relative dielectric constant of the insulator must be close to that of air (relative dielectric constant: 1) to reduce transmission loss (attenuation of electrical signals due to heat). PTFE has a low relative dielectric constant of 2.1 and is both flame retardant and highly durable to ensure equipment reliability.

2．High-speed communication/transmission function and required properties

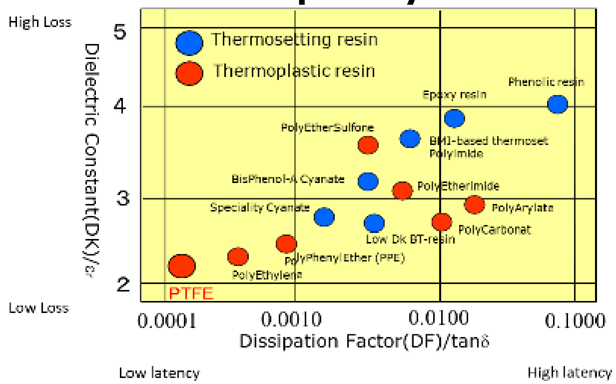
(3) Required properties for materials and comparison with non-PFAS materials

Required properties for materials	Fluoro-polymers*	FR-4 epoxy	Modified polyphenylene oxide（PPO)	Polyimides (PI)	Polyethylene (PE)	Liquid crystal polymer（LCP)	Note
Dielectric constant (ε)	2.1	4～5	3.5	3.2	2.3	2.9	When mixing different materials, inferior properties appear.
Dielectric tangent (tanδ)	0.0006	0.015	0.002	0.002	0.001	00035	
Thermal resistance Non-combustibility	◎	△	〇	〇	×	◎	

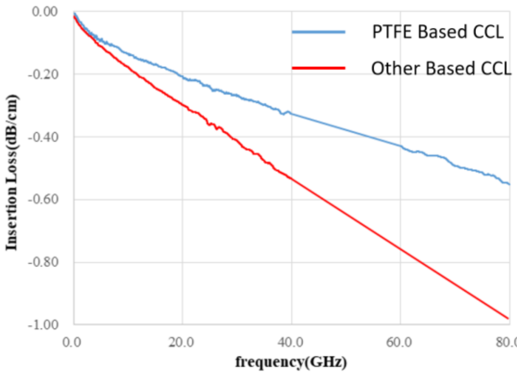
*PTFE,PFA,FEP

◎=Superior; 〇=Excellent; △=Usable; ×=Not well suited for use

<Requirements and frequency characteristics of the equipment>



Characteristics of dielectric constant and dielectric tangent in resin materials



Frequency dependence of transmission loss

＊Source
Nippon Pillar Packing co.,Ltd.
https://www.pillar.co.jp/en/

・The use of high frequencies such as millimeter waves is essential for electrical and electronic equipment for high-speed and high-capacity communications, and transmission losses need to be as low as possible. The material must have a low dielectric constant, low dielectric loss tangent and low frequency dependence to reduce transmission losses at high frequencies (signal energy loss by heat). Furthermore, the high-frequency equipment needs to be highly heat-resistant and reliable, as it is used for millimeter-wave sensors in base stations and ADAS (Advanced Driver-Assistance Systems). These need to be realized in a single substance.
There are no materials other than fluoropolymers that combine low dielectric constant and low loss at high frequencies with high heat resistance and high reliability (no alternative materials).

2. High-speed communication/transmission function and required properties

(4) Social impact when PFAS cannot be used (example)

1) When fluoropolymers cannot be used for high-frequency substrates for smartphones and base stations

- High-speed and large-capacity communication is increasingly required in the information society, but if fluoropolymers cannot be used, transmission losses at high frequencies will increase and large-capacity communication (e.g., video communication) will be delayed. Furthermore, the board generates heat due to high transmission losses, leading to heat generation in the equipment. Therefore, the equipment needs to be designed for cooling (contrary to energy saving).
- Heat generated by the equipment also affects the product life of other components (e.g., capacitors) mounted on the board, thus shortening the life of the equipment (requiring more frequent replacement or exchange).

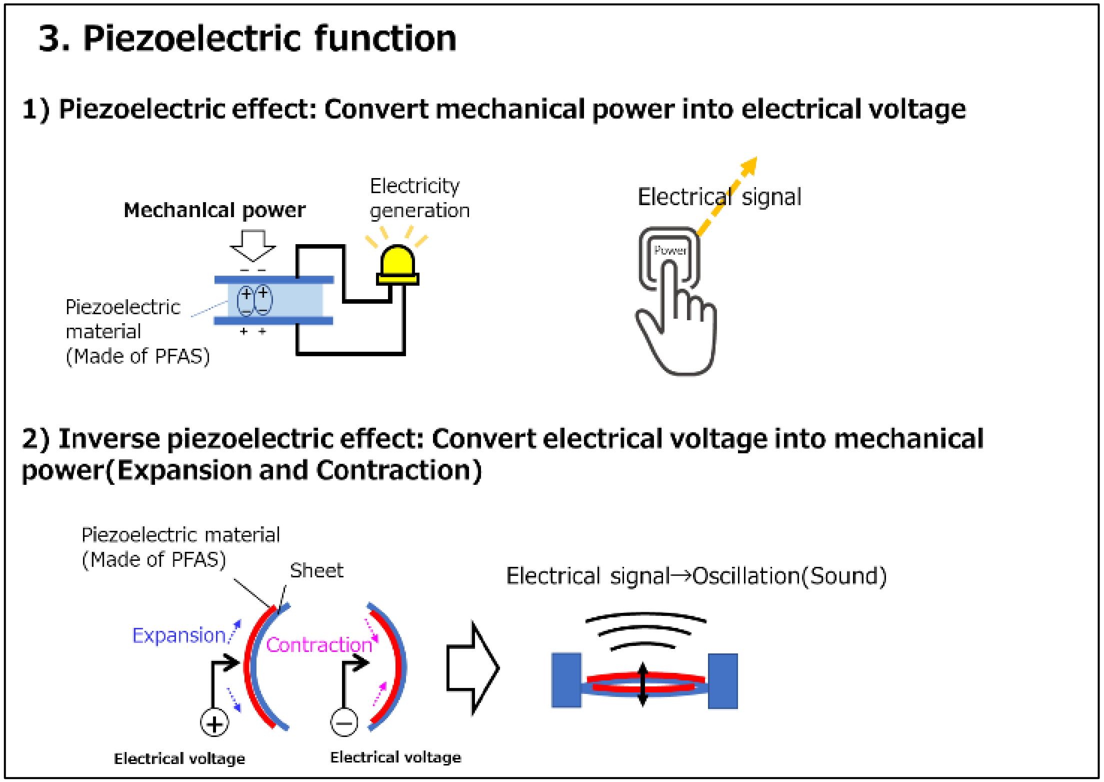
2) When fluoropolymers cannot be used for millimeter-wave radar substrates

- Millimeter waves are used in sensing technology to enhance safety in driving, for example in ADAS (Advanced Driver-Assistance Systems). If fluoropolymers cannot be used in substrates and antennas for high-speed millimeter-wave communications, instantaneous sensing isn’t possible due to the delay in radio waves, which significantly affects human safety. In addition, as vehicles are used in particularly harsh environments, high reliability characteristics (such as heat resistance, moisture resistance and long life) must be met at the same time.
- If millimeter-wave radars have short life, they will require maintenance and replacement within a short period of time, increasing waste and maintenance costs.

3．Piezoelectric function and required properties

(1) Piezoelectric function

Essential for EEE to the performance of crystalline materials in converting mechanical strain into voltage and voltage into mechanical strain.



3． Piezoelectric function and required properties

(2) Required properties for parts and components

- The material must have a high piezoelectric coefficient (the higher the coefficient, the better the response) that converts mechanical strain into voltage and voltage into mechanical strain, and must also satisfy processability and durability (high temperature and high humidity) at the same time.

e.g.) Touch panel, Sensor, Speaker, Headphones, Inkjet printer head：（Freeform、Cost reduction, high reliability)

＊( ) indicates achievable performance

<Application examples>

[Pressure sensor for healthcare]

Parts in which PFAS is used

e.g.：Wrist-mounted pulse wave sensor

Pressure sensor
(Core device of the product)

Pressure sensors for healthcare

Flexibility is essential in addition to piezoelectricity for pressure sensors that require installation on curved surfaces.（e.g.：Wrist-mounted pulse wave sensor)

This flexibility cannot be achieved with inorganic piezoelectric materials, and even with organic piezoelectric materials, only fluoropolymers can achieve high voltage coefficients and high reliability (heat and moisture resistance) in the operating environment as sensors. Since the organic piezoelectric material is in film form, high productivity and large area can be achieved, and low-cost sensors can be provided.

3． Piezoelectric function and required properties

(3) Required properties for materials and comparison with non-PFAS materials

	Organic type		Inorganic type		
Required properties for materials	Copolymers VDF with trifluoroethylene	Polylactic acid	Piezoelectric crystals	PZT（Ceramic piezoelectric materials）	PZT（Piezoelectric films）
Piezoelectric constant d_{33}（pC/N）	～40	7～12	2.0	100～600	100～600
Durability	○	△	◎	◎	○
Fabrication of thin films	◎	◎	×	×	◎
Pliability	◎	◎	×	×	×
Cost reduction	◎	◎	△	○	×

◎=Superior; ○=Excellent; △=Usable; ×=Not well suited for use

・They are inferior to inorganic materials in terms of piezoelectric constants and reliability. However, ceramic materials are generally brittle and difficult to process, making it difficult to form and process them as large-area, thin-film materials. Flexibility and large area, which can only be achieved with organic piezoelectric materials, and lower cost due to significant changes in the production process are important factors that cannot be realized with inorganic piezoelectric materials. Important Technologies Supporting Wearable Electronics.

(4) Social impact when PFAS cannot be used (example)

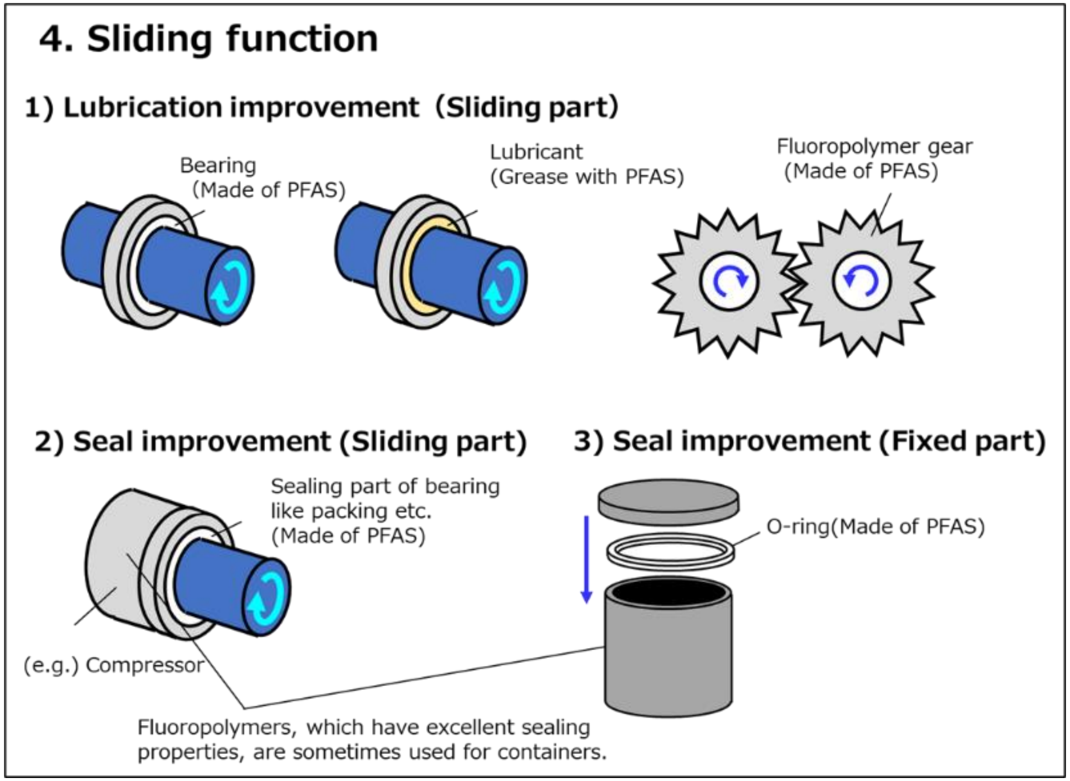
■ When fluoro resin could not be used for piezoelectric element as pressure sensor for biomedical

- In the healthcare field, there is a need for sensor devices that can more easily and accurately monitor daily vital information (heart rate, respiration, etc.) in a "non-constrained" manner without any hassle or feeling of being worn. Since these sensors are attached to the arm or body for measurement, they need to be curved in shape, lightweight, and sensitive so as not to interfere with daily life. The only organic piezoelectric material that satisfies these requirements is fluoro resin-based in terms of sensitivity.
- In order to live a long and healthy life, the need for sensors for health care, which are also used to manage physical condition, is increasing rapidly. For medical support, it will continue to be necessary to develop sensors that are inexpensive and can be used by anyone, and if PFAS cannot be used in this regard, the potential of future technologies will be destroyed.

4. Sliding function in mechanical section and required properties

(1) Sliding function

Essential function for EEE to control and ensure the smooth movement of driving parts or sealed parts, such as camera zoom lenses, motors, compressors, etc.



(2) Required Properties for Parts and components

- Two or more high-reliability properties such as lubricity and flame retardance must be achieved simultaneously in one material.

  e.g.) Motors, bearings, gears, camera lenses, grease, lubricants (high durability, high reliability)
- Two or more high-reliability properties such as flame retardance, chemical resistance, and water repellency, must be achieved simultaneously in one material.

  e.g.) Packing, O-ring (high durability, high reliability)

＊( ) indicates achievable performance

4. Sliding function in mechanical section and required properties

<Application examples>

[Camera]

Sliding functions in camera's mechanism section

Numerous sliding parts are required to work stably at high speed, with high precision, over a long period, and in harsh environments.

Cameras must satisfy functionality and performance requirements even in harsh environments such as extremely cold, deserts, and tropical regions. If substances derived from lubricant adhere to the lens or sensor, the image will be significantly affected. In addition, the recent trend toward reducing environmental impact requires longer product life. Considering these factors, the lubricants that can be used are limited to fluorine-based lubricants.

<Typical functions of a camera and the role of fluorinated lubricants>

① Autofocus lens drive unit

Image formed on the sensor surface by changing the distance between the lens and the image sensor surface

➡ **Instantly drive on the order of microns to achieve high-speed/high-precision focus adjustment**

② Shutter mechanism

Controls exposure time of image sensors down to a few thousandths of a second

➡ **Contribute to higher speeds and lower dust emissions for shutter blades and driving components**

③ Zoom mechanism

Use a rubber ring on the plastic tube to prevent dust from entering the zoom inside.

➡ **Ensure smooth operation and improves water repellency.**

④ Buttons, dials, etc.

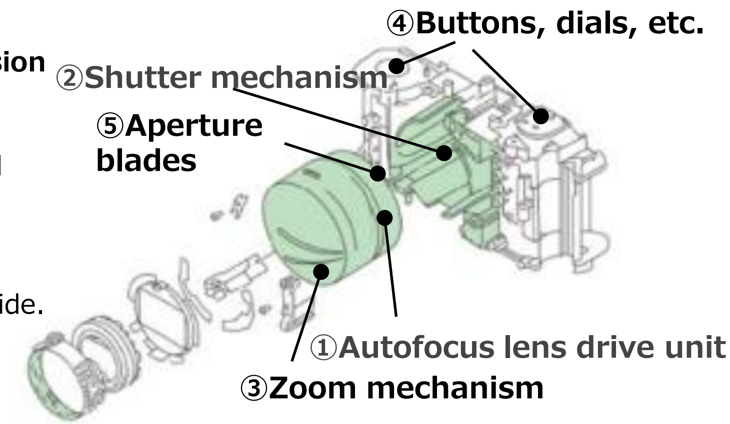
High precision/stable operation, high wear resistance, long product life

➡ **No effects on electrical components and contribute to stable operation and long product life.**

⑤ Aperture blades

The multiple blades that make up the aperture mechanism must be positioned with high precision.

➡ **Provides lubricity and high durability to the blade to ensure reliable operation.**



© 2020 Harves Co., Ltd.

Parts using fluorinated lubricants

Cameras require high-speed, high-precision drive/operation and long-life characteristics in harsh environments ⇒ Use of lubricants is essential

4. Sliding function in mechanical section and required properties

<Application examples>

[Laser processing machine ： 1）Lens focus adjustment component]

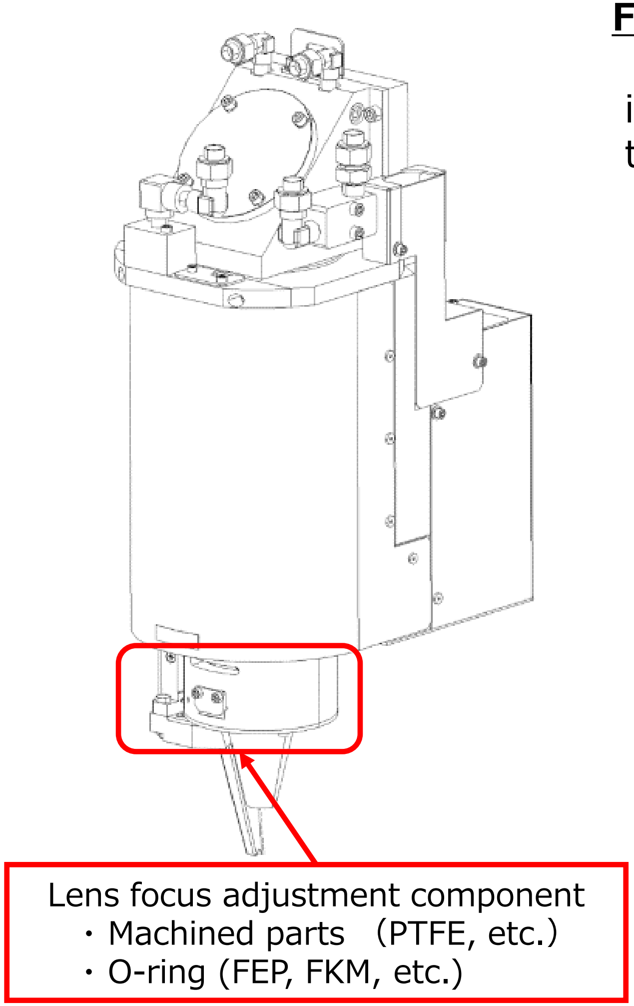


Fig. External view of machining head

<u>Focusing mechanism on processing head</u>

The processing head has a structure that rotates and slides inside the lens focus adjustment component in order to adjust the focus.

- ・ The focus should be changed arbitrarily according to the materials to be processed.
- ・ High sliding capability is required.

<Functions realized by using PFAS>

- ◆ Prevention of damage due to rubbing between parts
- ◆ Prevention of adhesion between parts by reducing friction
- ◆ Extending the life of parts by improving abrasion resistance
- ◆ Prevention of combustion in the case of heat input such as radiated beam
- ◆ Airtightness to prevent dust from attaching on the lens (lens burn prevention)

<Required properties for parts and components>

Lubricity, abrasion resistance, flame retardant, airtightness

For use in more demanding industrial conditions, these PFAS is the only material that satisfies the required properties at the same time.

4. Sliding function in mechanical section and required properties

<Application examples>

[Laser processing machine ：2）Shaft driving part]

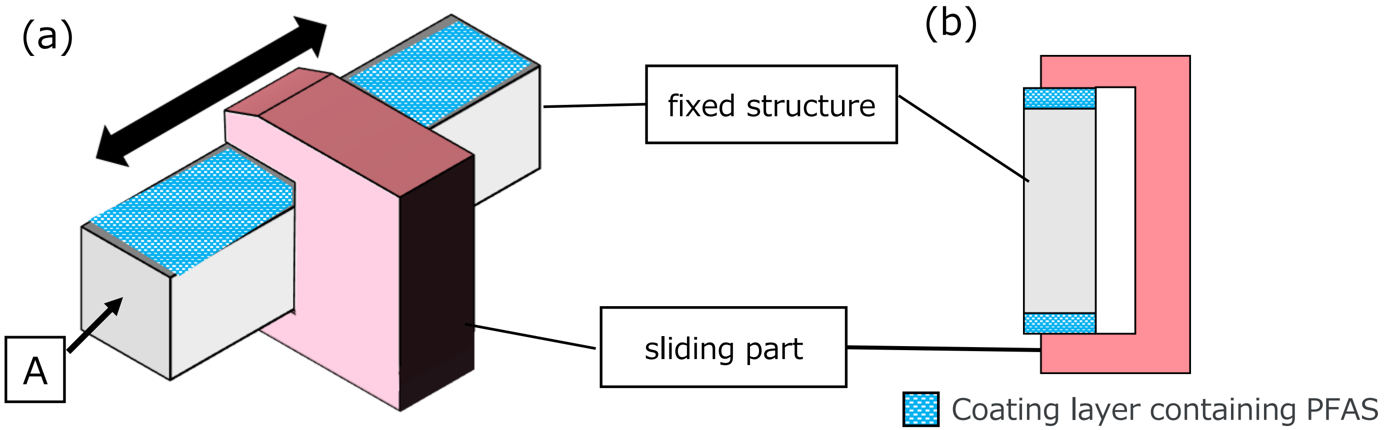

Fig. Simplified diagram of shaft driving part (a)bird-eye view, (b)view from the direction of arrow A (see Fig. (a))

Mechanism of shaft drive part

Laser processing machine must be operated in an environment with a lot of dust including minute fragments of processing materials.

From the viewpoint of dust prevention, the sliding part and the fixed structure are operated in close contact.

<Functions realized by using PFAS>

- Prevention of damage due to rubbing between parts
- Prevention of noise due to rubbing between parts
- Prevention of adhesion between parts by reducing friction
- Extending the life of parts by improving abrasion resistance
- Prevention of combustion in the case of heat input such as radiated beam

<Required properties for parts and components>

Coating for lubricity, abrasion resistance, flame retardancy, and antifouling

For use in more demanding industrial conditions, these PFAS is the only material that satisfies the required properties at the same time.

4. Sliding function (and 6. Safety and safety functions) in mechanical section and required properties

<Application examples>

[Laser processing machine : 3) Laser oscillator]

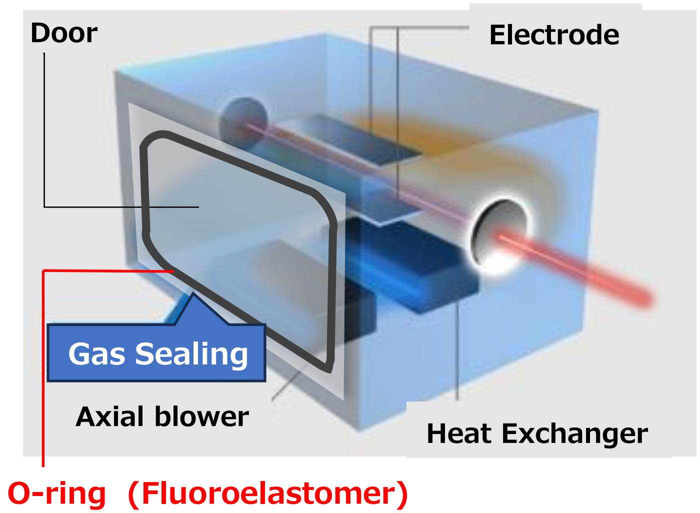

Fig. Simplified diagram of vacuum container

Mechanism of Vacuum container of the laser oscillator

Vacuum container of the laser oscillator must be sealed from outside air and held under the high vacuum or in the laser medium gas environment.

The vacuum container is equipped with an openable door sealed by an O-ring to enable maintenance of internal components.

The O-ring used in the vacuum container must be made of a material that can withstand high temperatures, ultraviolet irradiation, and ozone gas generation caused by discharge during laser oscillation.

Fluoroelastomer is the only material available that satisfies these properties.

＊ In addition to the door, O-rings are used for sealing such as the holding part of optical components.

<Functions realized by using PFAS>

Under the high vacuum, high temperature, ultraviolet radiation, and ozone gas environments,

- ◆ hermetic sealing with low outgas
- ◆ long-term retention of airtightness

<Required properties for parts and components>

Heat resistant, airtightness, corrosion resistant

To ensure occupational safety when using lasers, hermetic seals (PFAS) are essential from the aspect of “6. Safety and safety functions”.
For use in more demanding industrial conditions, these PFAS is the only material that satisfies the required properties at the same time.

4. Sliding function in mechanical section and required properties

(3) Required properties for materials and comparison with non-PFAS materials

1) Articles: Bearings, Gears, Rolls, Sealing materials (Packing, O-rings, etc.)

＊Please see also "6. Safety and safety functions"

■ Resins

Properties	Fluoropolymer	Other Resins						
	PTFE	PE	PVC	POM	PC	PS	PP	ABS

Gas permeability ($cc \cdot cm/cm^2 \cdot sec \cdot atm$)	1	1	400	15	15	3

◎=Superior; ○=Excellent; △=Usable; ×=Not well suited for use

- **Fluoroelastomers have overwhelmingly excellent chemical resistance, ozone resistance, and insulation properties in addition to heat resistance and flame resistance, compared to other rubber. They also have excellent gas barrier properties (the smaller value, the less gas permeates.), so they are used in sealing materials (packing) that also require heat and chemical resistance and cannot be substituted.**

↓

- Fluoroelastomers are also more expensive than commonly used materials, and therefore they are not used blindly. They are only used selectively in applications where they cannot be substituted under severe conditions, even in required properties for safety and safety functions that are essential for EEE. (There is no alternative material because of selective use.)

4. Sliding function in mechanical section and required properties

2) Preparations: Greases, Lubricants, Protective coating materials

a. Lubricating components

Properties	Fluoropolymer Perfluoropolyethers, etc.*	Molybdenum disulfide	Graphite
Light load lubricity	○	×	×
non-conductive	○	○	×
Polite resistance	○	×	×

*PTFE, PCTFE, PFPE

○=Excellent; ×=Not well suited for use

b. Solvents

Properties**	Fluorosolvent	Petroleum oil	Silicone oil
Chemical Attacks on Plastics	Low	high	low
Generation of volatile gases	low	low	high
Risk of contact failure	not	not	Yes
Temperature viscosity change	low	high	low
flammability	not	Yes	not

** HFE, HFO

Major compositions : a. Lubricating components + b. Solvents
➡ Fluoropolymers + Fluorosolvents is best

- **Only "fluoropolymers and fluorinated solvents" have lubricity, thermal stability, and no negative effects on components (i.e., there are no alternatives).**

4. Sliding function in mechanical section and required properties

(4) Social impact when PFAS cannot be used (example)

1） <u>If fluorine material cannot be used in the cameras, the functional degradation will occur.</u>

- Furthermore, the U.S customers will not be provided with high-performance cameras year after year. Cameras that are significantly less capable than the current ones will likely miss or fail to record key moments in news, sports, events, etc., and will have a significant impact on their coverages with photos and videos in the U.S.
- If the camera lens cannot be coated with a sliding function coating, it will lead to a decrease in reliability and shorten the product life. (more frequent replacements and replacements will be required).
- The performance of mechanical sections such as focusing and zooming is reduced, making it difficult to capture fast-moving subjects.

2） <u>If fluoropolymers cannot be used for safety and high reliability components such as O-rings and packings,</u>

- The safety of electrical and electronic equipment cannot be guaranteed, which in turn places people and the environment in an unsafe situation. Such components are widely used in sections that must simultaneously meet high reliability (safety) requirements such as heat resistance, insulation, flame resistance, and solvent resistance, especially in equipment for professional use. Examples include industrial equipment such as EEE and other production equipment (heating furnaces, molding machines, robots, semiconductor manufacturing equipment, etc.), infrastructure equipment, medical equipment, and analytical instruments.
- If fluoropolymers with excellent water repellency and lubricity cannot be used, the waterproof performance of EEE cannot be guaranteed and product life will be shortened.
- Since fluoropolymers with excellent solvent and chemical resistance cannot be used, it is difficult to meet the required performance, especially in medical devices, analytical instruments, and semiconductor manufacturing equipment, which are likely to come in contact with chemicals and solvents, due to lack of reliability and frequent maintenance replacement, which also affects the life of the equipment.
- Lack of equipment reliability not only leads to increase of waste, but also significantly affects work safety in professional use.

5．Display function (Liquid crystal) and required properties

(1) Display function (Liquid crystal)

Function to display information such as text, graphics, and video by controlling pixel luminance and reflectance by giving each pixel on the screen an On, mid-tone, or Off signal.

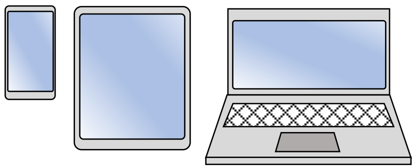
(2) Comparison with other devices as a display

Table 1: Comparative characteristics of LCD, CRT, and OLED

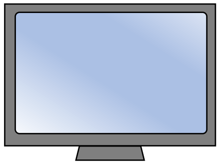
Character	LCD	CRT	OLED
Weight	Light	Heavy	Light
Volume (thickness)	Thin	Large (Thick)	Thin
Large Screen	Available	Unavailable	Available
Power consumption	Low	High (2x of LCD)	1.3x of LCD
High resolution	High	Unfeasible	High
Response speed	Mid	High	High
Contrast ratio	Mid	High	High
Brightness	Mid	High	Lower than LCD
Durability	High	Low Degradation of phosphers	Low Degradation of phosphers
Price	Low	Unavailable	High
Repairability	Easy	Hard	Hard

Table 1 shows that the characteristics of LCDs are better balanced than CRTs and OLEDs

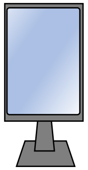
<Application examples>



- ✓ Smartphone
- ✓ Tablet
- ✓ PC



TV



Digital Signage

5．Display function (Liquid crystal) and required properties

(3) Required properties for materials and comparison with non-PFAS materials

- The introduction of fluorine into liquid crystalline compounds has the effects shown in the table below.
- The decrease in Δε has the tendency to increase the drive voltage, but the decrease in viscosity η with the introduction of fluorine results in a rather low threshold voltage due to the decrease in elastic constants. As a result, low voltage drive becomes possible with the introduction of fluorine. This low-voltage drive leads to lower power consumption and contributes to global environmental sustainability.
- There is no other liquid crystal material with these characteristics other than fluorine-based liquid crystals, which cannot be replaced by cyanide-based liquid crystals.
- In particular, the large temperature dependence of the threshold voltage of cyanide-based liquid crystals and their slow response are fatal defects in moving image displays.

General properties and characteristics of materials and properties required for liquid crystal displays.

Properties	Cyano−based LC compounds	Fluorine-based LC compounds	Effect
Viscosity η	High: 20cp	Low: **10cp**	Low viscosity generates high speed response
Refractive index anisotropy	Large	Large	Same Optical properties
Specific resistance	Low: 1.0 E+13Ωcm	High 1.0 E+15Ωcm	Reliability, Preventing image sticking
Dielectric anisotropy ⊿ε	High: 20	Low:10	Low driving voltage
Birefringence index ⊿n	High: 0.2	Low: 0.1	Wider viewing angle
Wavelength dependence of birefringence	High: 0.02	Low: 0.01	Wide operating temperature range
High voltage holding ratio at high temperature	Low: 90%	High: 99%	Reliability, Wide operating temperature range, Preventing image sticking
Temperature dependence of threshold voltage	High: 0.5V	Low: 0.1V	Wide operating temperature range
Temperature range for nematic phase	Narrow Under 100 (deg/C)	Wide Over 100 (deg/C)	Wide operating temperature range

5. Display function (Liquid crystal) and required properties

Fluorine-based LCDs are now capable of displaying moving images, which was not possible with cyanide-based LCDs, thus expanding the range of applications.

Table 2: Comparison of information to display between fluorine-based and cyano-based liquid crystals

Information to display	Cyano-based liquid crystal	Fluorine-based liquid crystal
Text & Graphics	Suitable	Suitable
Still Image	Can be used	Suitable
Video (TV, etc.)	Not suitable	Suitable
Application	Mainly Black and White type (Segment or Passive matrix) • Calculator, Watch (clock) • Simple indicator (Speedometer, etc.) • Old cell phones	Mainly full color type (Active matrix) • TV, Information Display • Current PC monitor (Note PC) • Navigation panel, Smartphone • Tablet, etc.
Usage environment (temperature range)	Mainly indoors	Possible outdoors

Table 2 shows that fluorinated liquid crystals are essential for video display applications.

5. Display function (Liquid crystal) and required properties

(4) Social impact when PFAS-based LCD cannot be used

1) Requirements for electronic displays in an advanced information society.

- An electronic display that converts and displays electronic information into visual information such as characters, graphics, and moving images is essential, and the following items shown in Table 1 are necessary.
  - Portability (small thickness): Measures against the freedom of installation
  - Support for large screens: Measures for increased amount of information and production of presence
  - Low energy consumption: Measures against global warming
  - High resolution: Measures for increased amount of information and production presence
  - Fast response: Measures for video compatible
  - High Contrast Ratio: Measures for Realism
  - High brightness: at least for normal indoor environments
  - Long product life: less waste
  - Availability, including price: penetration in the market
  - Repairability: less waste

2) LCD suitable for video using fluorinated liquid crystal material.

- The development of fluorinated liquid crystal materials (A kind of PFAS) has enabled LCDs to achieve a fast response that cannot be achieved with cyano-based liquid crystal materials, and a small change in driving voltage in response to temperature changes according to brightness of backlight. Those makes LCDs compatible with TV broadcasting (moving images). Cyano-based liquid crystal materials are used for display media that do not require moving images, such as calculators.

3) Current status of electronic displays

- LCDs using fluorinated liquid crystal materials have almost eradicated CRTs from the electronic display market due to their overall superiority over CRTs in terms of requirement 1) above. Although OLED is partially superior to LCD, it is inferior to LCD as a whole, so replacement from LCD is not progressing.

5. Display function (Liquid crystal) and required properties

■ Particular, the unavailability of LCDs would have a negative impact on society in the following respects

4) Low energy consumption

- The power consumption of a display with the same screen size as an LCD is 200% for a CRT and 130% for an OLED, as shown in Table 1. CRTs generate electron beams to illuminate light-emitting materials, and OLEDs require high voltages to drive current through light-emitting organic materials that are insulators. Both of these require high power consumption. When LCDs become unavailable, we have no choice but to change to CRT or OLED. This means an increase in energy consumption, which has implications for energy consumption reduction, climate change countermeasures, and energy security.

5) Product life

- LCDs are non-illuminated displays and consist of an LCD panel, which controls light transmission according to pixel information, and a light source 'backlight' is put behind the LCD panel.
  - A liquid crystal (LC) panel changes the transmittance of a pixel by controlling the alignment of LC molecules with a low voltage not supply any current. Since LC molecules do not degrade because their energy levels (or active states) do not change during operation.
  - Inorganic LEDs that emit light when current is applied are mainly used for the backlight of the light source. LEDs, which are semiconductors, have a longer lifetime than OLEDs and their peripheral circuits also have a longer life.
- Self-emitting displays such as OLEDs or CRTs convert the energy given to the pixels into light. Luminescent substances whose energy levels (or active states) are excited by the given energy are transformed into non-emitting light substances by chemical reactions without emitting due to a certain probability. As a result, the luminous brightness decreases with the passage of time of use. The light-emitting organic substances used in OLEDs decrease their brightness faster and their lifetime is shorter than light-emitting inorganic substances used in CRTs.

5. Display function (Liquid crystal) and required properties

6) Repairability

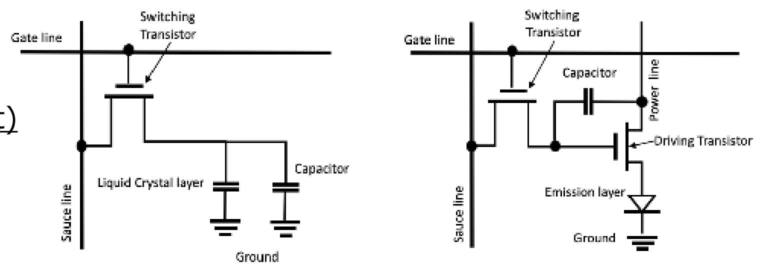
- Display failures can be broadly classified into physical or mechanical damage and component deterioration. Non-illuminated display LCDs consist of an LCD panel and a backlight, so any one of the failed components can be repaired or replaced. Deteriorated backlights can be replaced and components can be easily recycled. On the other hand, faulty repairs are not possible for self-luminous displays OLEDs and CRTs, which can only be replaced. Replaced self-luminous displays are not easily recyclable and become waste.

7) Availability

- CRTs are only produced for special purposes on a limited basis, and are not available for general use. However, the depth close to the display size is necessary, and it cannot correspond to the advanced information society. LCDs and OLEDs have transistors in pixels, but as described below, OLEDs have more complicated pixel transistors and wiring structures than LCDs, which is disadvantageous in terms of cost.

	LCD	OLED
Structure	1 transistor and 2 lines	2 transistors and 3 lines
Transistor	1. Switching A swithing transistor which controls applied voltage to change the orieintation of liquid crystal on the pixel	1. Switching A switching transistor which determines whether or not current flows through the pixel 2. Driving A driving transistor which adjusts the amounts of current to controle the luminance of the emission layer
Line	1. Gate Control switching transistor 2. Sauce Apply voltage to liquid crystal	1. Gate Control switching transistor 2. Sauce Control Driving transistor 4. Power Apply current to emission layer

PIxel structure of LCD (left) and OLED (right)



6．Safety and safety functions and Required properties

(1) Safety and safety functions

Basic and as prerequisite elements and functions for EEE to ensure safe use of equipment and to minimize damage in the event of fire, etc.

(2) Required Properties for Parts and components

- Two or more high-reliability properties, such as heat resistance, flame retardance, chemical resistance and high airtightness (low gas permeability) must be achieved simultaneously in a single material.

e.g.) Cables, Tapes, Protective coatings, Encapsulants and Tubes (safe and reliable)

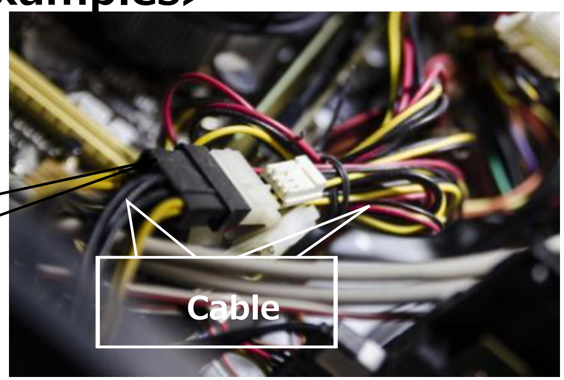
- Prevent dripping of resin components to minimize damage in the event of a fire (enhance flame retardant property)

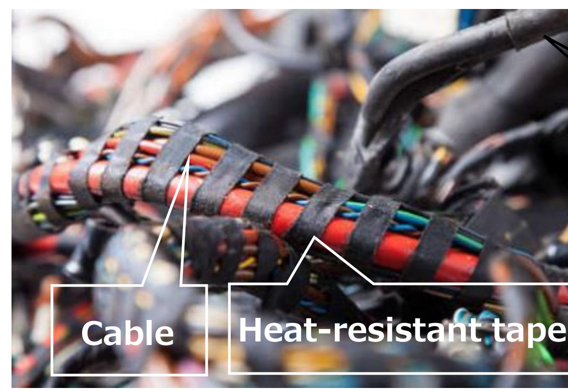
e.g.) Equipment such as PCs and smartphones, Enclosures for power supplies, batteries, etc., Components that make up parts (Safety)

*( ) indicates achievable performance

<Application examples>

[Cable, Tape, Connector,]





Cables, tubes, tapes, etc. (Covering ,Protective Material)

Insulation (low dielectric constant), bendability (flexibility), flame resistance, and resistance to heat and cold are essential for cables, and chemical resistance is required depending on the environment in which the cable is used. In particular, only fluoropolymers simultaneously achieve the high safety requirements of heat resistance, chemical resistance, insulation, and flame retardance.

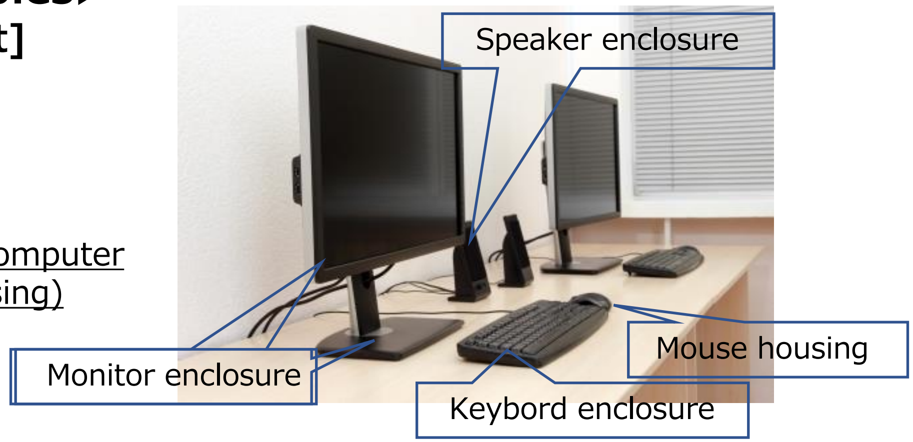
6．Safety and safety functions and Required properties

<Application examples>

[Anti-dripping agent]

Parts in which PFAS is used

e.g. : Personal computer (equipment housing)



Anti-Dripping agent

Resins used for housings for TVs, PCs, etc. must be certified to UL94 (the Standard for Safety of Flammability). Especially for resins that require a high flame retardance above V-0 grade, it is necessary to prevent the generation of burning particles that can lead to ignition, and an anti-drip agent is indispensable. In order to increase the melt tension of low-viscosity resin, the anti-drip agent itself must have extremely high melt viscosity and be high flame-retardant, and only PTFE achieves these requirements.

6. Safety and safety functions and Required properties

(3) Required properties for materials and comparison with non-PFAS materials

■Resins

Properties	Fluoropolymers				Other Resins			
	PTFE	FEP	PFA	ETFE	PVC	PEEK	PI (Film)	Polyolefin resin
Heat resistance Continuous use temperature,℃	260	200	260	150	60～105	180～200	150～200	90～125
Chemical resistance	◎	◎	◎	○	△	△ Oil-proof and Acid resistance NG	○	△ Solvent resistance NG
Flex resistance	○	○	○	◎	△ impact resilience	△ Too rigid	△ Too rigid	△
Cold resistance	○	○	◎	○	△	△～○	○	△～○
Electrical insulation (Dielectric constant, ε)	◎ (2.1)	◎ (2.1)	◎ (2.1)	○ (2.3～2.8)	△ (4～6)	△ (3.2～4.5)	△ (2.8～3.2)	△～○ (2.3～4)
Flame retardancy (Limiting oxygen index)	◎ (>95vol%)	◎ (>95vol%)	◎ (>95vol%)	○ (31vol%)	◎ (45vol%)	○	◎	△ Chemical resistance is reduced by flame retardant

◎=Superior; ○=Excellent; △=Usable; ×=Not well suited for use

・Fluoropolymers have overwhelmingly excellent chemical resistance and insulation properties in addition to heat resistance and flame retardance. Since they also have a very low dielectric constant, they have excellent insulating properties per thickness, leading to thinner base materials, which in turn leads to smaller and lighter electrical and electronic equipment (energy saving).

↓

・Fluoropolymers are more expensive than commonly used materials, and therefore they are not used blindly. They are only used selectively in applications where they cannot be substituted under severe conditions, even in required properties for safety and safety functions that are essential for EEE. (There is no alternative material because of selective use.)

6． Safety and safety functions and Required properties

■Rubbers

Properties	Fluoroelastomers		Synthetic rubbers			
	FKM	FEPM	Silicone	EPDM	CR	NBR
Heat resistance max use temperature,℃	230	230	230	150	100	120
Chemical resistance	○	○	△	△	○	○
Ozone resistance	◎	◎	○	○	×	×
Cold resistance	△	△	△～○	△～○	△～○	△
Electrical insulation (Dielectric constant ,ε)	△ (3～4)	△～○ (2.5～3.5)	△ (3.2～10)	△～○ (2.5～3.5)	× (7.5)	× (15～20)
Combustibility	◎	◎	△ Chemical resistance is reduced by flame retardant	△ Chemical resistance is reduced by flame retardant	○	△
Gas permeability (cc·cm/cm^2·sec·atm)	1	1	400	15	15	3

◎=Superior; ○=Excellent; △=Usable; ×=Not well suited for use

- Fluoroelastomers, like fluoropolymers, have overwhelmingly excellent chemical resistance, ozone resistance, and insulation properties in addition to heat resistance and flame resistance, compared to other rubber. They also have excellent gas barrier properties (the smaller value, the less gas permeates.), so they are used in sealing materials (packing) that also require heat and chemical resistance and cannot be substituted.

↓

- Fluoroelastomers are also more expensive than commonly used materials, and therefore they are not used blindly. They are only used selectively in applications where they cannot be substituted under severe conditions, even in required properties for safety and safety functions that are essential for EEE. (There is no alternative material because of selective use.)

6. Safety and safety functions and Required properties

(4) Social impact when PFAS cannot be used (example)

1） If fluoropolymers and fluoroelastomers cannot be used for safe and highly reliable components such as cables, protective tubes, sealing materials, and pipe,

- The safety of electrical and electronic equipment cannot be guaranteed, which in turn places people and the environment in an unsafe situation.
- Such components are widely used in sections that must simultaneously meet high reliability (safety) requirements such as heat resistance, insulation, flame resistance, and solvent resistance, especially in equipment for professional use (They are also used around engines of automobiles and other vehicles). Examples include industrial equipment such as EEE and other production equipment (heating furnaces, molding machines, robots, semiconductor manufacturing equipment, etc.), infrastructure equipment, medical equipment, and analytical instruments. Lack of equipment reliability also affects equipment life, including frequent maintenance and replacement, leading to increase of waste and, of course, a significant impact on work safety in professional use.

6. Safety and safety functions and Required properties

2） <u>If PFAS cannot be used as an anti-drip agent,</u>

- Resins used for housings of TVs, PCs, and other products, as well as resins used around power supplies and heat-producing component in electrical components, may be required by law to be certified to UL94; the Standard for Safety of Flammability. In order to satisfy these standards, the addition of flame retardants is definitely needed. Especially for resins that require a high flame retardance above V-0 grade, it is necessary to prevent the generation of burning particles that can lead to ignition, and an anti-drip agent is indispensable.
- In some cases that halogenated flame retardants are regulated by law, and inorganic flame retardants and phosphate ester flame retardants must be used, however, inorganic flame retardants require the addition of large amounts of flame retardants to achieve sufficient flame retardant effects, resulting in a loss of resin properties. On the other hand, phosphate ester flame retardants are limited to resins (that easily carbonize with oxygen) due to the flame retardant mechanism (formation of carbonized layer during combustion). Flame-retardant resins made from a polymer alloy of polycarbonate and styrene resin (PC/ABS) with a phosphate ester flame retardant are widely used in Home appliances and OA equipment. However, phosphate ester flame retardants plasticize resins, causing them to drip more easily, so PTFE (a fibrillated fluoropolymer increases the melt tension of low viscosity resins and has an anti-dripping effect) must be added as a flame retardant aid in order to achieve V-0 grade. The addition of an anti-drip agent can also reduce the amount of flame retardant used.

7. Functional surface and required Properties

(1) Functional surface

Essential functions for EEE, such as water-repellent, oil-repellent, non-adhesive, solvent-resistant, moisture-resistant, and weather resistant on surfaces touching with substances for the purpose of stain-proofing and protecting equipment.

(2) Required properties for materials used in parts and materials

- A newly high strength film such as heat resistant, solvent resistant, and water/oil repellent is formed on the surface of the base material.

  ⇒ Baking coating of resin (powder coating) _Adding new functions where there is a requirement for film thickness and high durability. Base materials are limited to metals, ceramics, glass, etc. due to processing temperatures, and cannot be applied to plastics.

  e.g.) Inner surface treatment of cooking appliances (high durability, safety), iron (high durability, high quality), Machines and Equipment (high durability, safety)

- In order to protect the functionality of equipment, a thin film is given to the surface of the base material to provide not only stain resistance but also weather resistance, moisture resistance, insulation properties, etc.

  ⇒ Application coating : A film is formed by foaming and drying at room temperature, so it can be applied to a wide range of base materials.

  e.g.) Touch panel protection (high durability), exterior protection of outdoor equipment (high durability), substrate circuit protection (high durability, safety)

7. Functional surface and required Properties

<Application example>

[Cooking appliances]

Parts and materials using PFAS

<u>Inner pot and surface treatment of cooking appliances: Fluoropolymers baking coating (powder coating)</u>

Inner pots and surface of cooking appliances require functions such as heat resistance to bear cooking temperatures, Antifouling for food baking and cleanliness, and anti-bacterial measures. In order to realize these functions at the same time, fluoropolymers baking coating is applied. Baking coating is a method of forming a film by applying fluoropolymers powder such as PTFE to a heat-resistant base material like metal, ceramic, or glass and heating , melting it to form a coating. In addition, it is the only material and method that can simultaneously ensure water and oil repellency, acid resistance, and non-adhesiveness, which are the characteristics of fluorine material. Particularly in the case of the Automatic Bread Maker, it is essential to use a material that allows the baked bread to be removed from the container without burning. And also particularly in the case of a microwave oven, it is necessary to use a material that does not affect electromagnetic waves for safety reasons. It's because fluoropolymers is baked on, it does not peel off by scratching and dissolve in water, oil, or seasonings, so it can be used safely for the life of the device, contributing to the reduction of waste during long-term use. In addition, fluorine treatment of cooking appliance prevents food from burning, which is said to be carcinogenic, and thus greatly contributes to human health.

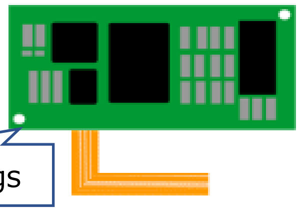
This technology is also used in machinery and equipment for durability and safety purposes because, unlike general coatings, it can form coatings of several tens of micrometers or more.

7. Functional surface and required Properties

<Application example>

Parts and materials using PFAS

[Printed circuit board]



[touch panel]

When used as a coating or protective film on the surface of a touch panel, it must also satisfy the properties required in "Optical Properties (1. Optical Functions)".

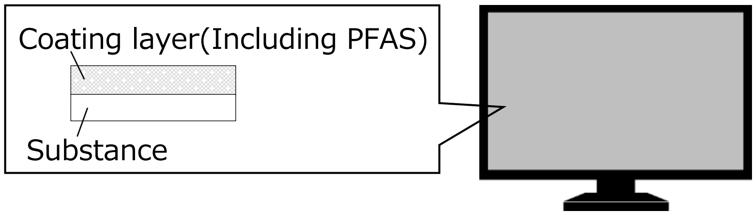
<u>Protective coating of printed circuit board : applied coating</u>

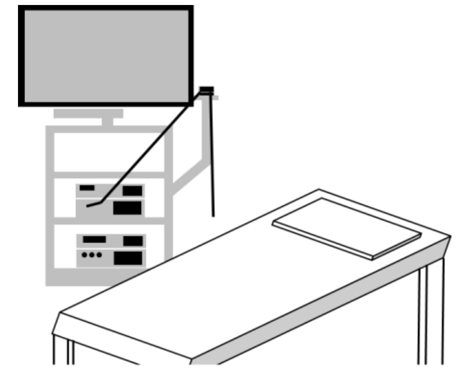
Printed circuit boards are the core of electrical circuits and are used in all kinds of electrical and electronic equipment. And environment these devices are used vary widely. In particular, for mobile devices such as smartphones and cameras, outdoor equipment, and in-vehicle equipment, measures must be taken to prevent migration caused by condensation owing to sudden temperature changes (such as moving from a cold outdoors to indoors), humidity caused by rain, etc. It is necessary to take measures to ensure reliability and safety, such as measures against short circuits due to sticking dust and measures against solvents to prevent leakage from electrolytic capacitors, batteries, etc. In addition to being water and oil repellent, fluorine materials are stain and moisture resistant, and have high solvent resistance and insulation properties that do not cause contact error. Therefore, there is no alternative material with equivalent performance, so fluorine materials are only for protective coatings for printed circuit boards.

7. Functional surface and required Properties

<Application example>

[Optical film for liquid crystal display]





<u>"Molecular orientation" and "Film thickness control" in optical film materials for liquid crystal displays : Coating</u>

Fluorine materials are used as coating agents in coating layers in optical films for liquid crystal displays. Since the fluorine atom has highest electronegativity, the fluorine material is characterized by having a low surface tension. The high optical performance required for optical films for liquid crystal displays can be achieved by low surface tension, which is a major feature of fluorine materials.

<u>Technologies required for optical films for LCD displays</u>

(1) Control of coating layer thickness
The coating layer can be applied evenly due to the low surface tension and wettability with the coating layer substrate.

(2) Control of molecular arrangement in coating layer
Due to its low surface tension and hydrophobicity, the fluorine-containing coating agent is unevenly distributed on the surface, resulting in uniform alignment of molecules in adjacent coating layers.

It is difficult to meet the required performance without fluorine materials, and as a result, we are concerned that it will become difficult to supply displays not only for consumers but also for medical devices within the EU.

7. Functional surface and required Properties

<Application example>

[Optical sensor]

<u>Functional surface coating used for optical sensors in ink cartridges</u>

In order for an optical sensor to perform its functions with high precision, the surface of the sensor's light-emitting and light-receiving element must have good separation from the liquid to be detected (water-based ink), that is, it must be a water-repellent surface.
This sensor detects when the liquid container is not empty and stops the product before it is damaged.
The surface of the element must be kept clean at all times because the amount of remaining liquid is detected by the difference in the light absorption rate of the liquid or air.
The fact that the optical sensor remains clean allows the printer to perform accurate ink detection from the ink cartridge.
In addition to the water-repellent function, this coating must also satisfy optical properties (1. Optical function/2.transparency and low refractive index) because it is a sensor that uses light, and these two required properties must be met. PFAS is the only material that satisfies both requirements and is indispensable for highly accurate remaining amount detection technology as an optical sensor.
It is essential that the liquid on the optical sensor flows smoothly in order to grasp the remaining amount, but the silicone type has insufficient water repellency (higher surface free energy than fluorine type) and abrasion resistance. Because of its poor performance, it was unable to meet the technical characteristics required for the lowest line of optical sensors.

7. Functional surface and required Properties

(3) List of required properties for materials and general physical properties

■ Resin baked coating (powder coating))

Properties	Fluoropolymer	Epoxy resin	Polyester resin	plating	DLC
Heat resistance max use temperature,℃	～350℃	～200℃	～230℃	◎	◎
Abrasion resistance	○	△	△	○	○
Water and Oil-repellent property	○	×	×	×	×
Chemical resistance	○	○	×	○	○
Weather resistance	○	×	○	○	○
Note	Since the film thickness is 30 μm or more, the base material with high strength and excellent durability is limited, and a dedicated factory (dedicated supplier) is required.			When the means are changed, the performance as an inorganic film can be secured, but the surface wetting performance is NG.	

○=Excellent; △=Usable; ×=Not well suited for use

- Powder coating has characteristic of high strength and durability of the coating film, and is often used for home appliances, industrial equipment, medical equipment, automobile parts, etc. fluoropolymers are excellent in all performances, but because of their high heat resistance, the treatment temperature during processing is high, and they are also expensive as materials, so they are appropriately selected and used according to the purpose.
- Fluoropolymers is often used in home appliances, especially in kitchen equipment. As alternative technology there is DLC, plating, but these films do not have water and oil repellency, so they do not meet the required properties.
- In the case of Fluoropolymers, they have not only baked coating but also chemical resistance, so it does not leach into water or oil, and has no environmental impact.
- Ensuring durability through high coating film strength extends product life and contributes to waste reduction.

7. Functional surface and required Properties

■Application coating

Properties	Fluoropolymers		Silicone	Acryl	Urethane
	Resin-type	Modified silane-type			
Heat resistance	○	○	○	×	×
Abrasion resistance	○	○	△	×	○
Water and Oil-repellent property	○	○	○～△	×	×
Moisture resistance	○	○	×	△	△
Electrical insulation	○	○	△ (Risk of contact failure by low-molecular weight siloxane)	○	○
Chemical resistance	○	○	○	△	△
Weather resistance	○	○	○～△	×	△
Light permeability	○	○	△	○	△

○=Excellent; △=Usable; ×=Not well suited for use

・Fluorine materials satisfy most of the performance requirements, but they are very expensive, so they are used only in carefully selected cases when multiple performance requirements must be satisfied at the same time. Therefore, because it is used out of necessity, it is used in applications in which other materials cannot be substituted.

・Adding functions and modifying surfaces by coatings is used to improve durability, ensure safety, and prevent failures of equipment use, extend product life and contribute to reducing waste.

↓

・Fluoropolymer is more expensive than common materials, so fluorine materials should not be used thoughtlessly. It is necessary to achieve multiple required performances at the same time, and it should be used carefully only in applications where it cannot be replaced (fluorine materials are essential so there is no alternative material).

7. Functional surface and required Properties

(4) Social impact when PFAS cannot be used (example)

1） When fluorine resin cannot be used for cooking equipment

- The inner pot and inner walls of cooking equipment are heat resistant to withstand cooking temperatures, stain resistant to prevent food from burning and to ensure cleanliness. Antibacterial measures are necessary.
  In order to realize these at the same time, a fluororesin baking coating is applied.
  Because the fluororesin is baked on, it does not peel off due to scratches, etc., and does not dissolve in water, oil, or seasonings, so it can be used safely for the life of the device, contributing to the reduction of waste during long-term use. Fluorine treatment of cooking utensils also contributes greatly to human health, as it prevents food from burning, which is said to be carcinogenic.
- Powder coating is carried out at a exclusive factory (exclusive supplier), so blindly discontinuing it would cost the supplier their livelihood. Also, if you change the process (plating, DLC), these will also be handled by a exclusive factory (exclusive supplier).
  Since it is necessary, large-scale investment is required due to the problem of supply and demand balance, and it cannot be replaced immediately.

7. Functional surface and required Properties

2） <u>When fluororesin cannot be used for printed circuit boards</u>

- Printed circuit boards are the core of electric circuits and are used in all kinds of electrical and electronic equipment, and the environments in which such equipment is used vary widely. And the material properties of fluorinated coatings (moisture resistance, water repellency, solvent resistance, and insulation) are used to protect the electric circuits, thereby ensuring the reliability and safety of the equipment. Therefore, if fluorinated coating materials are not available, the electrical circuits of printed circuit boards will become unsafe because they will short-circuit and break, or in the worst case, catch fire. In addition, the life of the equipment is shortened, leading to replacements and increased waste, resulting in significant social losses, both economically and environmentally.

8. Semiconductor and required Properties

Please refer to the submissions of the relevant industrial associations.
As PFAS are also used in the manufacturing process of semiconductors and in semiconductors as itself, both should be considered excluded.
Since MEMS* and thin film devices are also manufactured in the same process as semiconductors, both should be treated as semiconductors.
Therefore please consider to exclude semiconductors, MEMS, and thin-film devices as they are essential devices for electrical and electronic equipment.

* MEMS：Micro Electro Mechanical Systems

Many reports have been published on semiconductors, focusing on PFAS. Please obtain them from the following URL and consider them.

Battery Association of Japan

< Solar cells >

Comments on the impact of PFAS regulations under REACH regulations in Europe were submitted by solar panel stakeholders, including the Solar Power Technology Research Association (PVTEC).

Please contact the solar panel stakeholders for the details.

10. Energy supply (Battery, Fuel cells, Solar cells) and required Properties

< Fuel cells >

■ Social impact when PFAS can’t be used in fuel cells

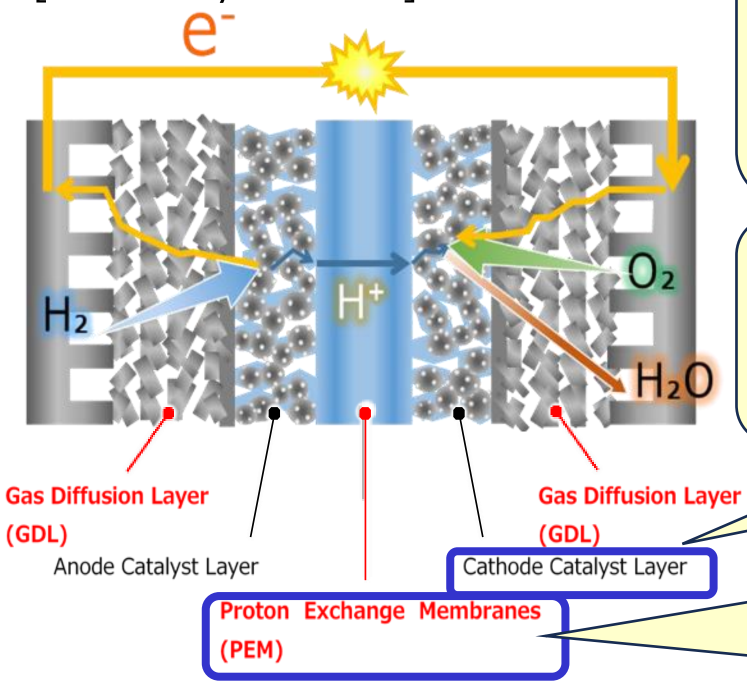
Mass production of fuel cells, indispensable energy supply technology for decarbonization utilizing hydrogen, would become impossible, which adversely affects the realization of a decarbonized society.

■ Required properties for parts and components

For the core materials, Proton exchange membrane, Catalyst layer (ionomer) and Electrode water repellent, Rubber seal, etc.), resistance to strong acidity and high temperature steam is required in order to ensure a product life of 90 K hours in the harsh environment of the cell.

< Application example >

[Stationary Fuel Cell]



● Rubber Seals

[Function] Devide the cathode air and the anode hydrogen air around each cell.
[Required properties] Prevent leakage of H2 and O2 under steam and high oxygen atmosphere under Highly acidic (pH=2-3), and high temperature (100℃)
=>Only FKM (Fluororubber) can be applied.

● Catalyst Layer (Ionomer)

[Function] Bond Proton Exchange Membrane and Diffusion Layer.
[Required properties] Pass both H2 and O2 under highly acidic (pH=2-3), and high temperature (100 ℃) steam.
=>Only Per-fluorosulfonic-acid (PFSA) can be applied.

● Proton Exchange Membrane (PEM)

[Function] Transfer protons from anode to cathode.
[Required properties] Ensure product life of 90 K hours under highly acidic (pH=2-3), and high temperature (100 ℃) steam.
=>Only Per-fluorosulfonic-acid (PFSA) can be applied.

11. Refrigeration, Air-conditioning and heat pump sector RACHP (Refrigerant) and required Properties

Fluorine gases are indispensable for the manufacturing process and operation of electrical and electronic equipment.
Please refer to the submissions of the relevant industrial associations, and consider to exclude fluorine gases for electrical and electronic equipment.

Please refer to the submissions by JRAIA

＊JRAIA

Japan Refrigeration and Air Conditioning Industry Association

12. Passive electronic components, manufacturing process and their required Properties

◆Passive electronic components

Passive electronic components are essential components in the electrical circuits of electrical and electronic equipment that protect semiconductors, filter electrical signals, and attenuate, store, and emit electrical energy.

<Application example>

1) Electrode formation process with safety function for film capacitors

■What is a Film capacitor?

Film capacitors are capacitors that use plastic film as the dielectric and are one of the essential passive components in the circuit configuration of electrical and electronic equipment.

[Example of appearance of Film capacitors]

[Applications]

It is widely used in home appliances, game machines, measuring devices, medical devices, solar power generation, mobile phones, etc.

With the electrification of automobiles, the use of electric cars in automotive applications has expanded.

12. Passive electronic components, manufacturing process and their required Properties

■ Safety function of film capacitor

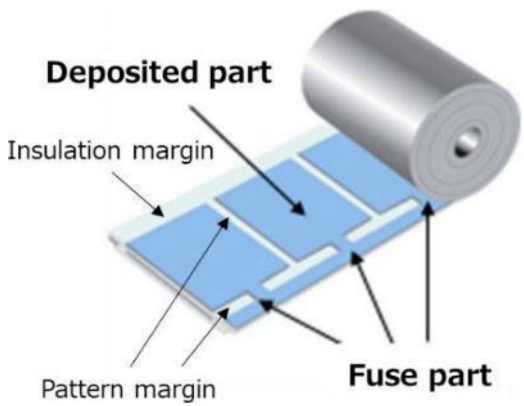


Fig. Internal electrode structure of film capacitor

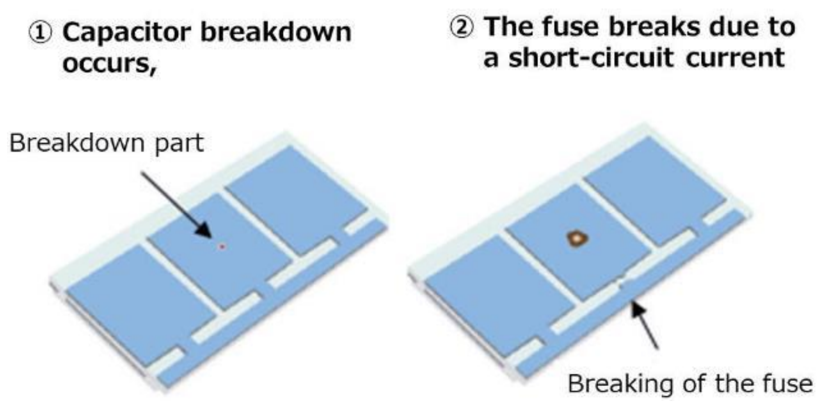

Fig. Safety function of film capacitor by fuse

For film capacitors, it is necessary to separate the deposited electrodes with a "pattern margin" and install an internal electrode pattern (fuse) to protect against overvoltage and overcurrent, and to install an "insulation margin" to ensure insulation between different electrodes.

This fuse is indispensable for the safety function of film capacitors. When a local breakdown occurs, the fuse breaks due to a short-circuit current, and the cell where the breakdown occurs due to the breaking of the fuse is electrically cut off from other cells to maintain the overall function of the capacitor.

In film capacitors, PFPE, a type of PFAS, is used to form pattern margins and insulation margins in the manufacturing process.

In particular, the use of high voltage is increasing in applications for electrification of automobiles. In order to ensure safety of the equipment, film capacitors must have safety fuse.

12. Passive electronic components, manufacturing process and their required Properties

■ Safety function of film capacitor

Manufacturing process of film capacitor using PFPE

To form a fuse, PFPE oil is deposited on a plastic film (oil masking with PFPE), followed by metal deposition. Because no metal is deposited in the oil-masked area, fuses and insulation margins are formed. It is necessary to make the area without metal deposition as thin as possible because it becomes a loss part without generating capacitance. In addition, since the fuse part must be formed as thin as possible in order to enhance the operability, the dimensional accuracy of the order of 0.01 mm is required for oil masking by PFPE (refer to figure below). This technology can only be achieved with highly water-repellent/oil-repellent fluorinated compounds, and no other useful alternative materials exist.

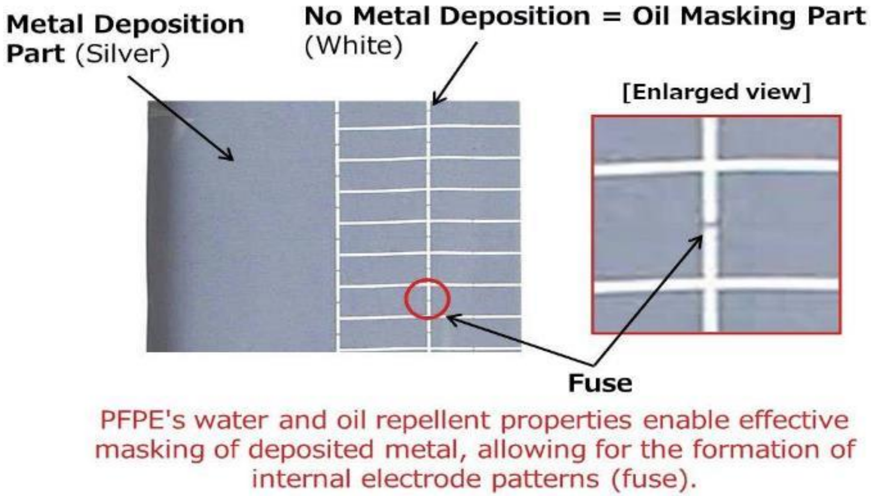

Fig. Appearance of the internal electrode pattern (fuse)

PFPE oil achieves high temperatures during metallization process which takes place under vacuum. Most of the properties of this oil are relevant for process itself and final product performance.

- A non-outgassing oil with a low evaporation loss is required for evaporation under vacuum.
- Chemical stability, non-corrosive, electrical insulation and high dielectric strength are mandatory properties due to this oil is in contact with the main part of film capacitors, which is the metallized film (metallized film = dielectric base film + metal layer).
- Thermal stability, heat resistance at extreme temperatures and non-flammability are also properties required for the oil considering the evaporation process.

Forming a fuse with oil masking using PFPE

12. Passive electronic components, manufacturing process and their required Properties

■ Concerns about substitution

As disclosed in the patent(平3-59981), when paraffin oil or silicone oil is used as an oil other than PFPE (perfluoroalkyl polyether) to form margins, deposited metal may also adhere to the masked margins. This causes problems with the insulation function, which is the original purpose. In addition, bleeding occurs at the boundary between the vapor deposition part and the margin part, and the margin itself becomes discolored, making it impossible to form patterns and fuses with high precision. In addition, bleeding occurs at the boundary between the vapor deposition part and the margin part, and the margin itself becomes discolored, making it impossible to form patterns and fuses with high precision.

At present, there is no prospect of a technology or material that can replace the oil masking performance of PFPE. Therefore, restrictions on PFPE in the film capacitor manufacturing process should be exempted.

(4) 特公 平 3—59981

7

ては、上記した転写ロールの他に、噴霧塗布手段が好適に用いられるほか、装置的な制約の許す範囲で各種印刷手段も用いられる。更に、蒸着はベルジヤーを用いたバツチ方式により行うこともできる。蒸着方式としては、狭義の真空蒸着のほか、各種スパツタリングも可能であり、それに応じて真空度も、例えば10^{-1}～10^{-6}Torrと巾広い範囲が選択可能である。更にフイルムあるいはシート状基材への蒸着は片面に限らず、両面に実施してもよいことは云うまでもない。

以下、代表的な実施例、比較例により、更に具体的に本発明を説明する。

オイル供給装置6として、転写ロールの代りに、スリツト状開口部を有する中空パイプ状噴霧塗布装置を用いる以外は、第1図に示したような、オイルマスク方式の半連続式蒸着機を用い、＊

8

＊オイルの種類を変えて蒸着を行つた。基材フイルム2としては、ポリエチレンテレフタレートのフイルム（厚み2μ、巾500㎜、長さ20000ｍ）を用い、その片面にフイルムの巻取り速度240ｍ／minでAlを蒸着した。蒸着機A内のオイル供給装置設置部の真空度は約10^{-2}Torr、Al蒸着される近辺の真空度は1～3×10^{-4}Torrであつた。オイルは8㎜間隔毎に巾1㎜でフイルム面に蒸気として噴出付着させた。またAl蒸着部の表面抵抗は1.7Ω／□（膜厚として約400Å）になるようにした。

異なるオイルを使用して得られたコンデンサ用金属化フイルムについて、巻取られたロール状態でのマージン部における金属付着量および金属化フイルムの蒸着部とマージン部との境界のボケを目視観察した結果は第1表の如くであつた。

第　1　表

オイルの種類		マージン部における金属の付着状態（色）	ボ　ケ
名　称	平均分子量		
パーフロロアルキルポリエーテル（n=14）	2500	なし（白色、テープマスクと同等）	なし
流動パラフイン(1)	310	有（やや薄ねずみ色）	あり小
流動パラフイン(2)	420	有（やや薄ねずみ色）	あり大
ジメチルシリコーン	800	大（黒褐色）	マージン部着色のため観察不能

更にメタノールを含浸させたガーゼでマージン部を拭きとつて発光分析にかけたところ、流動パラフインおよびジメチルシリコーンを使用したものからはAlが検出されたが、パーフロロアルキルポリエーテルを使用したものからは検出されなかつた。

上記第1表からわかるように、オイルマスク方式によるマスキングの効果はオイルの種類によつて大きな差があり、パーフロロアルキルポリエーテルの特異性が極めて明確である。

次いで、パーフロロアルキルポリエーテルの各種フイルムに対するAl蒸着のマスキング効果を見るために、ベルジヤー型蒸着試験機を使用して実験した。パーフロロアルキルポリエーテル（平均分子量2500）を綿棒に含浸させて各種のフイルムに巾約5㎜の線状に塗布し、フイルムのオイル塗布面にAlを蒸着した。比較のため、ポリエチレンテレフタレートフイルムについてのみ、流動パラフイン（平均分子量310）を塗布したものも実験した。

蒸着後のフイルムについて、オイル塗布部へのAlの付着状態およびオイル塗布部の外周の乱れを観察した結果を第2表に示す。

Only PFPE meets all the requirements for film capacitor foil metallization:
thermal and chemical stability, low evaporation loss, non-corrosion, electrical insulation, high dielectric strength and heat resistance at extreme temperatures.

12. Passive electronic components, manufacturing process and their required Properties

2) Electrode formation process of Electric Double Layer Capacitor (EDLC)

■ Electric Double Layer Capacitors (EDLCs) one of the essential passive components in the circuit configuration of electrical and electronic equipments. EDLCs are used as power storage devices in backup power supplies for electrical and electronic equipment, leveling of output fluctuations in renewable energy, and energy regeneration systems for automobiles.

■ Electrode formation for EDLC (used as binder)

⇒ High dispersibility in activated carbon, chemical and electrical stability, and high reliability (heat resistance and durability) can be secured, and the characteristics of EDLC are stabilized, so the performance and reliability of the backup power supply can be guaranteed.

[Application example : Backup in case of vehicle power failure]

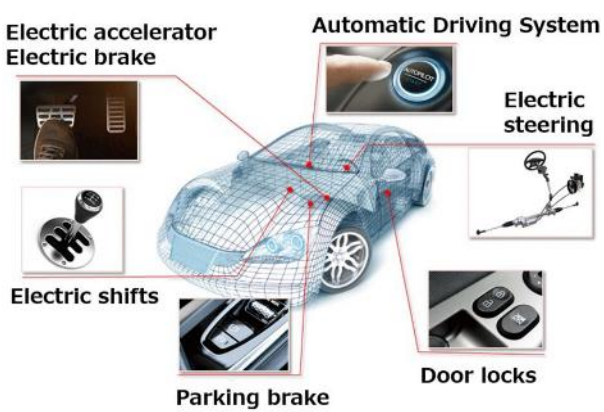

Fig. Examples of use in automotive applications

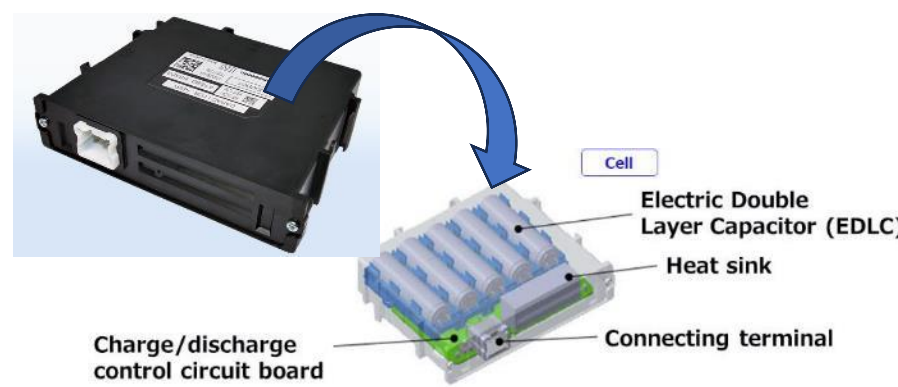

Fig. Backup power supply (power storage device) configuration

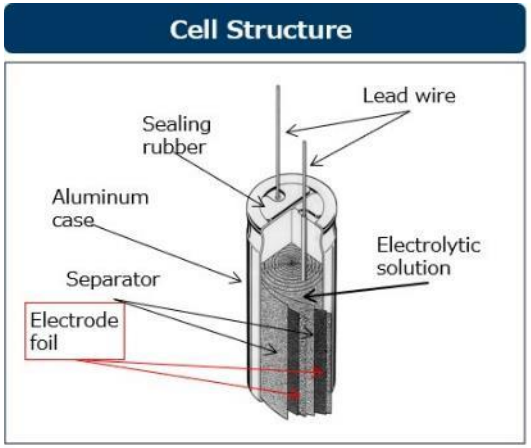
12. Passive electronic components, manufacturing process and their required Properties



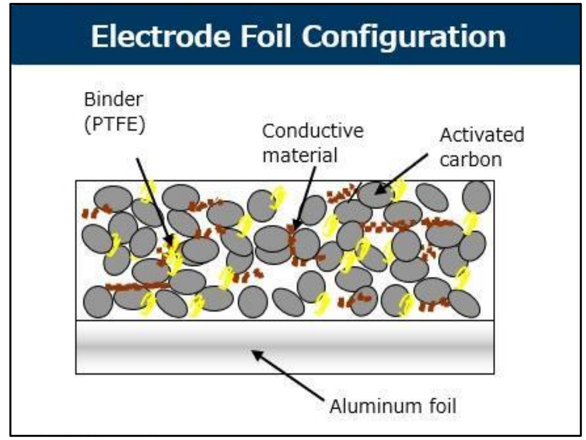


Fig. Cell structure and electrode foil configuration of EDLC

<PTFE Binder>

PTFE bonds activated carbon and aluminum foil. Fibrillated PTFE can hold activated carbon in small amounts

Electrodes are required to store a large amount of electric charge and realize high-speed charge/discharge, while at the same time they are required to have durability and reliability against vibration and impact. As with lithium batteries, the binder must have chemical stability that can withstand electrolytes, durability against electrochemical oxidation/reduction, and heat resistance. In addition, in order to achieve low resistance, it is necessary to form an electrode using a small amount of binder. PTFE is the only binder that simultaneously satisfies these required properties (there are no alternative materials).

Re: MPCA Request for Comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

General Comments

We request that the Agency exclude HFC, HCFO, HFO and f-gas-based products (hereinafter called f-gas) from the scope of the proposed regulations. F-gas are small molecules that have been demonstrated under Montreal Protocol to identify low hazard for potential impacts on humans. Furthermore, because of their chemical and thermal stability, F-gas are widely used as refrigerant, foam expansion agent, propellent, and solvents that are found in many different products, ranging from heating, ventilation and air conditioning (HVAC＆R) systems to aerospace equipment. Of course, most of HFCs have Global Warming Potential (GWP), so they are subject to use restrictions and are being phased down under the American Innovation and Manufacturing (AIM) act. As this phasedown proceeds, the industry will transition to alternative low GWP substances like HFOs. Compliance with the notification requirement will be exponentially more complex and burdensome if F-gas are not excluded. Such alternatives have been approved for use according to the Significant New Alternatives (SNAP) Program which utilizes a comparative risk framework to assess and list new alternatives as acceptable substitutes.

More specific comments to MPCA's nine questions appear below.

1. Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Yes, MPCA should define criteria for determining "essential for health, safety and functioning of society." However, an "essential" assessment should only be initiated when there is deemed to be a risk to human health or the environment from the use of an intentionally added PFAS in a product. On this point, we reiterate that F-gas have been demonstrated to satisfy internationally accepted under Montreal Protocol. If there is no concern about risk during the use of an intentionally used PFAS in a product, such as a F-gas, MPCA and stakeholder time and resources should not be wasted on an essentiality analysis. Neither should residents of Minnesota be denied access to a myriad of products important to their daily lives simply because those products contain F-gas.

If a potential risk to human health or the environment is identified, MPCA should look to the considerations articulated in the Maine DEP's most recent regulatory proposal:

> ***"Essential for Health, Safety or the Functioning of Society"*** *means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws*

and regulations. Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction.

More generally, the concept of "essential" must be interpreted broadly in order to be workable. Under a narrow interpretation of "essential" it may be argued that products such as cell phones, laptop computers, or automobiles are not "essential to the functioning of society" since society can continue to function without these conveniences. But this narrow, and in our view inappropriate, interpretation fails to properly account for the fact that these types of products are highly beneficial and are an essential feature of our society. Similarly, under a narrow interpretation of "essential" it could be argued that products such as refrigeration units are not "essential to health" since people can live healthy lives without refrigeration. However, this narrow interpretation ignores the critical role that refrigeration plays in supporting good health by preventing food spoilage and preserving pharmaceuticals. These are a few examples of the types of products that, if they became unavailable, would cause massive social and economic dislocation. To avoid this type of disruption we strongly urge the Agency to adopt a broader interpretation of "essential".

Finally, we urge MPCA to take notice of a report recently issued by the Department of Defense (DOD), highlighting the criticality of certain PFAS chemistries across a broad swath of applications of strategic and national importance. Based on an extensive survey of known uses of PFAS chemistries, DOD concluded as follows (emphases added):

PFAS are critical to DoD mission success and readiness and to many national sectors of critical infrastructure, including information technology, critical manufacturing, health care, renewable energy, and transportation. DoD relies on an innovative, diverse U.S. industrial economy. Most of the structurally defined PFAS are critical to the national security of the United States, not because they are used exclusively in military applications (although a few are) but because of the civil-military commonality and the potentially broad civilian impact.

DOD went on to warn that:

Emerging environmental regulations focused on PFAS are broad, unpredictable, lack the specificity of individual PFAS risk relative to their use, and in certain cases will have unintended impacts on market dynamics and the supply chain, resulting in the loss of access to mission critical uses of PFAS. These market responses will impact many sectors of U.S. critical infrastructure, including but not limited to the defense industrial base.

In developing regulations interpreting the concept of "essential" the Agency should heed DOD's warning and ensure that the term is interpreted broadly enough to encompass uses of PFAS that are critical to national infrastructure and supply chains.

MPCA should also consider whether a F-gas is required to meet a specific performance standard or legal requirement. In such cases, they should be deemed "essential" and that designation should extend to the supply chain for that product (or product component).

2. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

- The cost of alternatives should not be considered a critical factor in determining the definition of "reasonably available".

- F-gas are generally more expensive than other alternatives and are therefore used when potential alternatives cannot meet specific performance requirements. Because F-gas are generally more expensive, the costs of alternatives should not be a factor in evaluating potential alternatives. Where questions of "essential for health, safety, or the functioning of society" are concerned, MPCA should focus on performance, reliability, and availability.

3. Should unique considerations be made for small businesses with regards to economic feasibility?

- We suspect that Minnesota's PFAS law will disproportionately affect small businesses, as no small business considerations were an express part of the legislature's deliberations. For example, small businesses may not have the capacity to comply with the statute's reporting requirements, which are extensive and will require significant effort to plumb the value chain for each product (or product category) that may need to be reported.
- Small businesses may also be disproportionately affected by any costs associated with testing products for the presence of PFAS, testing and qualifying potential alternatives, and the replacement of any equipment.
- The Maine DEP is contemplating some provisions for small businesses, and we encourage MPCA to examine those closely.

4. What criteria should be used to determine the safety of potential PFAS alternatives?

- MCPA should consider reduced potential for risk to human health and the environment should compare the use of the alternative with the F-gas currently in use in the specific product or product component under consideration.
- MCPA should articulate the criteria or information that will be used for comparative evaluations of potential risk.
- MCPA should also consider sustainability impacts such as water use, emissions reduction, energy efficiency, and reliability, including avoiding the use of highly flammable and/or toxic substances.
- Finally, MCPA should consider the approved substitutes under the Significant New Alternatives Policy (SNAP) program, which utilizes a comparative risk framework to assess and list new alternatives as acceptable substitutes.

5. How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

- Unavoidable use determinations should last until safer and more sustainable alternatives are discovered and can be implemented at scale in the economy.

- Therefore, significant changes in available information should trigger a re-evaluation. Re-evaluation should apply not only to the use of a substance with a CUU, as well as any alternative that was identified as the basis for denying at CUU.

- In no case should re-evaluations take place more frequently than 10 years. MCPA should consult with potentially affected industries to determine if a longer re-evaluation period may be necessary to evaluate alternatives or otherwise provide information for the re-evaluation process.

6. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

- MCPA will need to establish a process by which manufacturers and users can request a CUU determination from MCPA. The process should be flexible enough to accommodate multiple uses of a substance instead of going use by use. The latter would pose a huge time burden on both MCPA and stakeholders.

- The converse process creates even more challenges in terms of allowing adequate time to respond to a request in terms of collecting or generating date to respond to a "not a CUU" request.

- The information requirements for either request should be identical. No party in the process should have a relatively higher or lower bar for substantiating its request.

Any process around the granting or re-evaluation of a CUU must protect trade secrets. As noted in ACC's November 28, 2023, comments on the Planned New Rules Governing Reporting by Manufacturers Upon Submission of Required Information about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4828:

Some types of proprietary information the Agency will request derive independent economic value and are the subject of efforts to maintain its secrecy. Such information may also be recognized as confidential by federal or other state agencies, and trade secrets that are inadvertently disclosed may compromise national security and infrastructure. Therefore, in the proposed rule, the Agency must provide clear instructions regarding the specific steps that must be taken to officially assert and/or substantiate a trade secret claim for information submitted that qualifies as a trade secret under Minnesota law, including the timeline by which such claims must be made relative to the reporting deadlines.

The Agency also should define in regulation a process whereby a manufacturer is to be notified if its trade secret is subject to a public records request or is inadvertently disclosed by the Agency or any organization with which the Agency collaborates or contracts in the administration of the reporting program, including other states and any organization that designs, operates, or otherwise administers the reporting platform. The Agency should not enter into data sharing agreements with any organization, including but not limited to other states, if the Agency cannot assure that those organizations possess equivalently protective policies for trade secrets submitted to Minnesota. As we have previously noted in comments to the State of Maine, we are particularly concerned about how commercially valuable trade secret information will be managed by the Interstate Chemicals Clearinghouse (IC2) of which the Agency is a member.

7. In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

- Refrigerants: Most refrigerants used in civil and military cooling and refrigeration applications are defined as PFAS according to the definition included in DEP's PFAS in Products regulations. Many next-generation refrigerant alternatives adopted by U.S. industry (and U.S. households) between now and the end of 2025 may also be defined as PFAS according to these regulations. Under the AIM Act and EPA technology transition regulations, the U.S. economy is in the process of switching from one set of PFAS-classified refrigerants (e.g., HFCs) to a new generation of refrigerants (e.g., HFOs), which are also, in the broadest definitions, considered to be PFAS. HFOs belong to a class of materials with ultra-low global warming potential, making them ideal tools in meeting decarbonization goals and replacing legacy high-global-warming products. Due to the specific engineered properties of HFOs and HFO blends, transitioning away from these products would necessitate substantial capital investment and major disruption of supply chain. HFOs and blends are often required to meet regulatory, or compliance obligations set by the US EPA or state environmental agencies, including global-warming-potential threshold, flammability criteria, building codes, and other efficiency standards. HFOs and HFO blends have a lack of clear environmentally friendly alternatives that simultaneously meet customer needs for safety, efficiency, and cost.

- Foam Blowing agents: HFOs for foaming agent use are mainly used as a raw material for rigid polyurethane foam. Rigid polyurethane foam is widely used as a heat insulator for consumer and industrial applications. Rigid polyurethane foam consists of minute independent bubbles formed by urethane resin, and gas derived from a blowing agent is sealed inside the bubbles. By using HFOs with low thermal conductivity such as HFO-1233zd(E), HFO-1336mzz(Z) and HFO-1224yd(Z) for that gas, rigid polyurethane foam can achieve higher thermal insulation performance than non-PFAS insulation materials. In addition, urethane resin has high specific strength and good resistance to low temperatures and dimensional stability. Taking advantage of these features, rigid polyurethane foam is mainly used as heat insulating material in the normal to low temperature range. Major thermal insulation applications are in houses, frozen and refrigerated warehouses, refrigerators, vending machines, plants handling low-temperature fluids such as LNG, LNG carriers, and liquid oxygen and liquid hydrogen tanks of large rockets.

  The most common foaming method for rigid polyurethane foam is to vaporize the blowing agent by reaction heat, so the blowing agent used for this method must have a low thermal conductivity of its gas and a boiling point near room temperature. Spray applications used on construction sites requires the foaming agent to be nonflammable. Other characteristics are required, such as adequate solubility in the urethane raw material, chemical stability and non-toxicity, and non-flammability.

  Non-PFAS compounds have high thermal conductivity and flammability and cannot meet all requirements that HFO blowing agents can.

- Fire Suppression: F-gas are used in "clean agent" fire suppression in naval vessels, aircraft, ground combat vehicles and closed space in civil buildings. Most known clean agent, low-corrosion, low-weight, low-toxicity alternatives will likely be classified as PFAS, broadly defined. According to DoD report, since the advent of regulations against halogenated agents, Naval vessels commonly utilize an HFC clean agent in compartments subject to flammable/combustible liquid fuel fires such as engine modules and hazardous material storage spaces. Expanding new technology like AI, DX, etc., Data Center installation are growing.

Non-flammable, non-liquid fire suppression system protect servers in DC resulting data secured.

- Solvents:
  1) F-gas based solvents are being used as electronic and dielectric fluids that are used in civil and military radars and high-power electronics, electrical system/utility system components and semicon mfg process because of their dielectric and heat transfer properties.
  2) F-gas based solvents are being used for degreasing/cleaning products and contact cleaners in vapor degreasing and flux removal. And also, for degreasers are used to effectively remove grease, oil, tar, and other substances from military equipment to increase its operating efficiency. These degreasers leave no residue, have no flash or fire point, and serve as an alternative to legacy solvents (e.g., n-propyl bromide, trichloroethylene, tetrachloroethylene).

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

- Yes, MPCA should propose some initial CUU determinations as part of the rulemaking process. It is our hope that the sooner CUUs are identified, the sooner some markets can have greater certainty about the regulatory environment.

9. Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

- Some "currently unavoidable use" determinations will require MCPA to determine whether reasonably available alternatives exist. The bases for such determinations must be consistent, fair, transparent, and well-defined.

The Department should propose objective criteria for determining when alternatives are or are not "reasonably available," taking into consideration factors such as performance, safety, total cost of ownership, and reduced potential for risk to human health or the environment when compared to products or product components made with alternatives to F-gas.

Thank you for allowing us to provide our information. Please feel free to contact us directly if you have questions or need additional information.

Sincerely,

Who We Are

This document has been prepared by a collaboration of BioPhorum members who appreciate the opportunity to respond to questions 1-9 below as requested by the Minnesota Pollution Control Agency.

BioPhorum is a global biopharmaceutical manufacturing industry collaboration comprising all major manufacturers and their key suppliers (over 150+ companies, representing > 98% of all biopharmaceuticals manufactured worldwide).

The Biopharmaceutical industry, represented here by BioPhorum, acknowledge the concerns raised regarding the potential adverse effects of various per- and polyfluoroalkyl substances (PFAS) materials on human health and the environment, and fully support efforts to minimise and mitigate the presence of these, and other potential substances of concern in our manufacturing processes and products. Our industry sector shares a responsibility to work with all relevant stakeholders to manage the transition away from materials of concern while maintaining our ability to ensure the safety and wellbeing of patients and the communities in which we operate. Any efforts to restrict usage and production of materials of concern by our industry must be pragmatically considered; the risk of drug shortages and therefore failure to supply medicines to patients must be evaluated against the risk the materials pose to the environment and to that very same population.

Biopharmaceutical drugs (biologics), a subsector of the pharmaceutical industry, include therapies such as monoclonal antibodies, antibody drug conjugates, therapeutic proteins, cell and gene therapies, mRNA and vaccines which treat a wide range of disease indications including immunology, neurology, infectious diseases, diabetes, oncology, cardiovascular conditions, and others. Advancements in biomedical science hold vast potential for growth of the biopharmaceutical market and the ability of these drugs to treat chronic diseases that were previously untreatable is increasing biologics demand enormously with newer therapies under development increasingly being in the biopharmaceutical category.

Today, 50% of the top 100 drugs sold globally are biopharmaceuticals, with predications that this will increase to 55% of all innovative drug sales by 2027 [2], and the industry generates global annual revenues of USD 163 billion.

While this specific response is focussed on the biopharmaceutical sector, BioPhorum and its member companies recognise that the scope of PFAS use and resulting impact of proposed restrictions on other industries is far wider across the Pharmaceutical and Healthcare industries and beyond. It should also be noted that while this submission on unavoidable uses has been prepared in response to the State of Minnesota, any restrictions on the use of PFAS within the biopharmaceutical industry will impact the supply of drugs to the whole of the US (and rest of world).

1. **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**

   In the case of regulating PFAS as a broadly defined group of substances, the specific hazards, if any, for an individual substance are unknown; therefore, defining criteria for "essential for health, safety, or functioning of society" requires multiple risk-based analyses, a complex task.

   The reasoning is that the hazard profile of an individual PFAS substance by itself may differ from the hazards associated with use of that PFAS substance by a downstream user in a specific medicinal application.

Any PFAS use required for manufacture, packaging and safe delivery of medicines or medicinal product to patients should be considered **essential for health, safety, or the functioning of society.**

2. **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

   If costs are considered in this context, then consider the full scope of activities that drive monetary costs. For example, consider monetary and economic constraints such as time to substitute (feasibility, product performance, and implementation), raw material availability, logistics, regulatory authority approvals, etc.

   The costs of any substitution, where feasible, are currently unknown but will be significant. Timelines from concept through to final qualification and regulatory approval of alternatives is likely to take a minimum of 20 years.

3. **Should unique considerations be made for small businesses with regards to economic feasibility?**

   Considerations regarding small businesses should include the ability to support niche markets that a supply chain may be dependent upon. Small businesses may not have adequate resources to drive innovation in the Research and Development space and to qualify alternatives.

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

   The biopharmaceutical industry is required by US Federal Food and Drug Administration to follow Good Manufacturing Practices (GMP) to use materials that are not reactive or additive to our product streams and assure patient safety. The specific PFAS materials utilized by our sector are non-hazardous fluoropolymers (PVDF, PTFE, FKM, FPM, FEP*, etc.) and are proven to present negligible reactive properties. They are particularly beneficial in terms of not adding anything unintentional to medicinal products during drug substance or drug product manufacturing processes (i.e., they best meet the GMP requirements of being non-additive or reactive with the medicine – per 21 CFR 211.65). With any change to materials there is a risk of regrettable substitution (i.e., replacing PFAS components with alternative materials which have properties that have unintended detrimental impact to the quality of the drug).

   *PVDF (Polyvinylidene fluoride), PTFE (Polytetrafluoroethylene), FKM (Fluoroelastomer Polymer), FPM (perfluoro elastomers), FEP (fluorinated ethylene propylene), ETFE (ethylene tetrafluoroethylene)

   Any PFAS materials utilized in biopharma manufacturing processes and by healthcare providers are disposed of at end-of-life by thermal oxidation and do not, therefore persist in the environment.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

Due to end-of-life destruction by thermal oxidation diverting any waste from landfill, permanent CUU determination would be most appropriate for PFAS materials used in biopharmaceutical manufacturing.

Periodically reviewing the status of a Currently Unavoidable Use of a PFAS substance would continue to drive innovation, seeking alternates to be identified and applied in products. In any product category designated as a CUU, the progress toward alternates should be anticipated and therefore a periodic review may be assigned.

This should be also applied to medical and dosing devices and pharmaceutical products in development and clinical trials since these processes will continue to use PFAS materials until suitable alternatives are identified.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

The MPCA should consider uses identified in this response in Appendix 1 as CUU (essential for health safety and functioning of society in general, and for patient safety specifically).

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

Dosing delivery devices, biopharmaceutical products and the equipment necessary to research, develop, manufacture, and bring these products to market are included in our response.

100% of the biopharmaceutical products currently being developed or already licensed for sale in the US utilize PFAS somewhere in the development, manufacture, testing, storage of intermediates, drug substance or drug product or in the drug delivery systems. If PFAS used in these processes are not classified as CUU and thus banned, the drugs would be removed from the market until PFAS alternatives (if they exist) could be developed, sourced, validated, and approved for use, thus preventing patient access to life saving therapies.

A PFAS containing component can be present in a product that is placed on the market in multiple different ways due to the complexity of the products they are used in. For example, an FKM based O-Ring could be imported as a stand-alone spare part or accessory, in a complex item used as a replacement part in a pump, in a pump itself, in a hardware system containing a pump or in a larger installation containing a hardware system. This level of complexity in the ways these materials may be placed on the market makes it impossible to provide an exhaustive list of potential GPC or tariff codes impacted.

The biopharmaceutical industry is required by US Federal Food and Drug Administration to follow Good Manufacturing Practices (GMP) to use materials that are not reactive or additive to our product streams. Specific PFAS materials (PVDF, PTFE, FKM, FPM, FEP*, etc.) are required as they are proven to present negligible reactive properties. They are particularly beneficial in terms of not adding anything unintentional to medicinal products during drug substance or drug product manufacturing processes (i.e., they best meet the GMP requirements of being non-additive or reactive with the medicine – per 21 CFR 211.65). It should be noted that the **BioPharma Industry acts as downstream users of PFAS materials and does not own the technical solution outside of end-application qualification.**

Refer to Appendix 1 for a non-exhaustive list of identified CUUs.

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

The MPCA should initially consider the CUU identified in this response in Appendix 1 (essential for health safety and functioning of society in general, and for patient safety specifically).

Would the rulemaking process allow impacted stakeholders to provide additional clarifying information to further the rulemaking process? If so, then it is reasonable for the MPCA to propose initial CUU determinations for select categories and solicit stakeholder engagement.

9. Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination

No further comment.

Appendix 1: PFAS Applications in Biopharmaceutical Manufacture, Supply, and Delivery/Dosage (a non-exhaustive list)

			Industry Application (final product brick reference)						
Product containing PFAS / Application	**PFAS Type**	**Function of product**	**Manufacture of Pharmaceutical drug (10005845)**	**Manufacture of combination product pharmaceutical drug (10005845) plus medical device (10005844)**	**Potential Alternatives**	**Feasibility of replacement**	**Cost to replace**	**Patient safety/drug quality impact risk**	**US Harmonized tariff code for PFAS material/component where known Note: products may also be included as part of more complex items, see product type explanation in document**
Sterile Liquid filtration membranes	PVDF	Ensures patient safety, ensures sterility of final product and safety of patient during drug delivery	x		(PES Nylon Cellulose)	50%	Very high	High	8421990180

POLARIS
Think Outside

February 29, 2024

Mr. William Moore
Minnesota Pollution Control Agency
Office of Administrative Hearings
600 North Robert Street
P.O. Box 64620
St. Paul, Minnesota 55164-0620

RE: New Rules Governing Current Unavoidable Use Determinations about Products Containing PFAS

Dear Mr. Moore,

Polaris Industries Inc. (Polaris) appreciates the opportunity to provide comments to the Minnesota Pollution Control Agency (MPCA), as you consider new rules pertaining to the unavoidable use of products containing Per- and Polyfluoroalkyl Substances (PFAS). As the global leader in powersports, we understand that to execute at the highest levels, you must utilize the expertise of those who best understand a product and its applications. We welcome this chance to submit industry insights and a vested stakeholder perspective on such a critical issue.

Polaris was founded in 1954 in Roseau, Minnesota and now employs almost 4,000 employees at our state-of-the-art facilities across the state and nearly 9,000 employees at twelve total facilities nationwide. Polaris is the #1 market share leader in powersports for off-road, on-road and marine, and named to be one of the most ethical and trustworthy companies in the U.S. in 2023.[1] In addition, the outdoor recreation industry brought in more than $563 billion nationally, with $11.7 billion of that coming from the state of Minnesota in 2022, with ATVs and Motorcycles bringing in $421 million alone, ranking Minnesota 10th in the nation for impact to the state economy.[2] This significant footprint and overall impact to the industry, both in Minnesota and across the country, translates to hundreds of thousands of ORVs, ATVs, snowmobiles and motorcycles in circulation, with an even greater number of components, parts, apparel and equipment potentially impacted by rules such as these.

In keeping with the request from MPCA for continued stakeholder engagement, we have provided commentary below in response to several key MPCA questions listed in the *Request for Comments* document shared earlier this month.

1. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

If costs of PFAS alternatives are considered in the definition of "reasonably available," determining what "*reasonable*" means, regarding the availability of and overall costs for components, parts, materials, and goods for powersports equipment, is a subjective exercise. Therefore, understanding and identifying a baseline for the term "reasonable" is critical for any future consideration of a viable PFAS alternative.

The U.S. Federal Government defines a reasonable cost in business practices as the following:

---

[1] Ethisphere and Newsweek.
[2] Bureau of Economic Analysis Outdoor Recreation Satellite Account, U.S., and States, 2022.

"*A cost is reasonable if, in its nature and amount, it does not exceed that which would be incurred by a prudent person in the conduct of competitive business."* [3]

The key to the above definition when determining a "reasonable" baseline for availability and cost is that these items would not "…*exceed that which would be incurred by a prudent person in the conduct of competitive business."*

Current business practices at Polaris ensure that we utilize a system of proven processes to identify and procure components, parts, materials, and goods. These same proven processes are then employed for testing, validating, and incorporating these items into our machines. We are continually striving to eliminate duplicative efforts and to streamline the daily work of the company, so that we can maximize efficiencies and ultimately, minimize overall costs whenever possible. These processes are critical because cost is not simply a comparison of prices between two competing products.

The costs associated with identifying, testing, validating, and implementing a new material into a product redesign is an expensive, and often years long activity. These activities are done to make sure new parts and components meet critical performance, durability, safety, and quality requirements, and may dwarf the extra costs associated with a PFAS alternative item, if one is even commercially available at the time.

Consequently, the costs associated with utilizing potential PFAS alternatives extend far beyond the product manufacture. New and unproven materials may require more frequent, and more expensive, maintenance costs. They may not provide the same level of durability as current PFAS products do now, leading to a premature failure of the machine/machine parts and an increase in overall waste and costs to both Polaris and our customer base unnecessarily.

The real-world costs of identifying and integrating PFAS alternatives into our machines are based on a series of complex procurement and manufacturing activities. These unknown costs could be significant and detrimental to both the upfront and long-term costs of our products, creating a snowball effect of delayed procurement, production, testing and delivery timelines.

Considerations for the total incurred cost (not simply costs of individual parts, components, materials, and goods) must be based upon the existing processes and procedures found in the marketplace today. As stated in the definition above, a "reasonable" cost should not "…*exceed that which would be incurred by a prudent person in the conduct of competitive business."*

2. What criteria should be used to determine the safety of potential PFAS alternatives?

Since our inception in 1954, Polaris has prided itself on creating industry leading technologies in the powersports space. Due to the nature of how our machines are used in the field, rider safety has been

[3] Acquisition.gov, 31.201-3 Determining reasonableness.

and will always be the number one priority when manufacturing any of our off-road, on-road or marine products.

With that in mind, Polaris equipment and powersports machines in general, must meet highly demanding industry wide technical specifications due to the challenging environments in which these types of machines operate. We design our products to operate for decades under extremely harsh, demanding, and arduous environments. In these environments, materials, parts, and components need to meet rigorous design and testing standards to ensure the safety of the person operating the machine, as well as any other passengers involved.

The technical functions of the components/systems in our equipment help inform the safety and operational design requirements of the machines in our lineup. These technical characteristics often include, but are not limited to, the following variables below:

- **Pressure** - Various systems, such as the hydraulic and engine systems, experience extreme pressure environments.
- **Temperature** - Powersports equipment often contends with cyclical temperature cycling due to machine exposure to outdoor conditions; temperatures ranging from as -57°C to 230°C.
- **Mechanical** – Machines expose parts and components to a high degree of mechanical wear and tear. Sealing parts must survive the shear forces due to the mechanical movement of the equipment.
- **Chemical Resistance** - Seals interact with various fluids and gases, requiring a high degree of chemical and corrosion resistance to ensure the reliability of exposed parts. Exposure to substances such as fuel, hydraulic fluid, coolant with additives like 2-ethyl hexanoic acid, and carboxylic acids, exhaust gas fumes (highly acidic) and engine oil (highly alkaline).
- **Electrical and Flammability Resistance** – Weight, power, and fuel of the machine creates electrical and flammability risks. Components, parts, and systems must include design elements to mitigate these risks.
- **Vibration** – Shaking up to 45.0 mm/s which can cause high frequency fatigue to components due to the repeated strain imposed. The mechanical alternating stress between joint components will make joints undergo cyclic tension and pressure, which may cause the generation, expansion, and extension of cracks.
- **UV Exposure** - Long-term durability against factors such as ultra-violet (UV) light due to exposure to outdoor environments.
- **Material Weight** – The use of lightweight materials to reduce energy consumption and CO_2 emissions.
- **Durability** – Equipment must remain highly reliable over periods of up to, and beyond, 20 years.
- **Environmental** - Withstand use and exposure in harsh environments that can vary from extremely dusty, humid, wet, muddy, and damp. The operation of such equipment is over extended periods of time.

Many parts or components used in our products have varying levels of PFAS included in them, which ultimately provide the material properties required to satisfy the various functions and protections highlighted above. Without a commercially available equivalent that can satisfy these highly technical specifications, the equipment, or individual safety and performance systems, these parts/components/equipment/ would most likely fail, causing immediate and dangerous safety hazards for the operator and other riders/passengers.

It is critical to the safety of the end user, that any replacement material meet the current performance requirements and standards, while still offering the same safety, durability, and quality of product containing intentionally added PFAS.

3. ***How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?***

Commercially available PFAS alternatives for most parts, components and equipment used on Polaris machines do not exist in today's marketplace. Furthermore, a lack of viable and proven alternatives means that integrating PFAS alternatives once available into our product line, without extensive testing, could compromise the integrity of our machines and ultimately the safety of our riders.

Changes to materials and formulations which affect fit, form, function, performance, or safety must undergo extensive testing to ensure any new designs meet internal quality benchmarks, design specifications, and outside regulatory requirements. Due to the challenges inherent to the powersports industry, it is extremely difficult to estimate specific timelines needed to identify, test, and qualify alternative chemical substances for each end use. Any estimation of time for consideration of unavoidable use would be based on the following assumptions:

- A suitable and viable alternative exists (although as described above, there are no known current technical alternatives for most PFAS parts, components, and equipment).

- Polaris procurement and compliance teams do not encounter dead ends during their material assessments, and suitable characteristics are identified the first-time test are completed.

- National and Worldwide supply chain issues do not hamper shipping and transportation timelines.

- Manageable timelines for incorporation of PFAS alternatives. Implementing changes across all product lines simultaneously is unrealistic from both a cost and practical application of workflow perspective as test cells, qualified staff, and other resources are all limited. The higher the number of PFAS substances used in the components and systems of the end-product, the longer the timeline will be.

One recent example of reasonably proposed timelines (which in this instance only takes into consideration one chemical compound) is the EPA ruling on Decabromodiphenyl ether and Phenol, Isopropylated Phosphate (3:1) or better known as PIP 3:1. The precedent set forth from this EPA ruling granted a 15-year transition period for new equipment and 30-year transition period for replacement parts.

Again, these transition periods were simply for one chemical substance, so a 15 to 30-year window of allowable transition time, dependent upon commercially viable and available parts, is a reasonable working time-frame.

Any transition away from PFAS requires significant time and resources to simply identify and qualify any PFAS-free material for use in or on our machines. Validating PFAS alternatives will be a lengthy regulatory, environmental, and proofing process, which if rushed could have detrimental consequences.

4. ***In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.***

Polaris' powersports lineup includes more than 30 brands across the off-road, on-road and marine categories, which translates to thousands of existing parts and components potentially containing PFAS, both for warranty replacement purposes and integration into new machines.

Many of the affected products, parts and components would fall into the below categories:

- **Seals:** All of our machines and boats use fluids to ensure the equipment continues to perform their intended functions. Fluid applications include hydraulic fluid, oil, fuel, refrigerants, coolant, among others. Sealing technology, such as O-rings and gaskets, prevents fluid leaks and ensures water, dirt, dust, and debris stays out of the equipment.
- **Hoses:** Similar to seals, hoses are required and critical to the transmission of fluids from one location to another. Many hoses in the powersports industry use fluoropolymers to safeguard the durability of the machine by protecting its components from various internal pressure, temperature, and chemical stressors.
- **Paints:** These coatings protect our machines and boats from natural, chemical, weather, or water erosion and damage. Paint coatings can help extend the useful life, and maintenance requirements, for all of our product across the company lineup. Many paint providers use PFAS in their paints to improve the flow, spread, and glossiness of the coating, as well as to decrease bubbling and peeling. They are also used in specialty paints to give stain-resistant, and water-repellent properties.
- **Refrigerants/Coolants:** Temperature management is a crucial product design requirement in the powersports industry. Regulating and controlling engine temperatures ensures proper operation for peak performance within the temperature limits of the materials used.
- **Hydraulic Fluid:** Hydraulic fluid enables the transfer of power from the engine to end-use hydraulic systems in our machines and marine crafts. Hydraulic fluid is also heavily used within our manufacturing facilities and is a critical element for functionality in building off-road and on-road machines.
- **Exterior Finishes and Materials:** UV protection was an issue we mentioned in a previous section but remains a continued issue for parts and components such as dashboards, handlebar grips, fenders, seat covers, etc. PFAS acts in a way with these pieces, so that it protects from extended outdoor use and UV exposure by not severely degrading the exterior piece(s) by drying and/or cracking the piece(s) beyond normal wear and tear or safe functionality.
- **Electrical:** Protective coatings on electrical wires and within electrical systems insulate and protect key electronic functionalities for all of our machines and marine products. PFAS is regularly found within these protective coatings.

5. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Yes, please. Based on all of the available information on PFAS included materials and the lack of available alternatives, there should be an abundance of consideration given to initial determinations for unavoidable use.

Polaris Industries is appreciative of this opportunity to provide initial comments on the unavoidable use determinations and rule making process for products containing PFAS. We look forward to working together in obtaining the best possible outcome moving forward.

Should you have any questions or need further information, please don't hesitate to contact Daniel Carey at Daniel.Carey@Polaris.com.

Sincerely,

Mike Orlikowski

Request for Comments on Planned New Rules Governing CUU Determinations about products containing PFAS

UNIGASKET GROUP (hereinafter **UNIGASKET**) welcomes the opportunity to contribute to the process of request for comments on planned new rules governing Currently Unavoidable Use (CUU) determinations about products containing per-and polyfluoroalkyl substances (PFAS), issued by the Minnesota Pollution Control Agency (Revisor's ID Number R-4837).

In addition, **UNIGASKET** appreciates the work performed by the Minnesota authorities on protecting human health and the environment in front of the effects of the PFAS substances that are of concern.

1. Company description

We represent an international player in producing fluoropolymer hoses, thermoplastic tubing, and gaskets with high-added value for automotive and high-end professional appliances. Over the years, the Group, originally based in Italy, has expanded its presence in international markets thanks to the opening of its branches in the USA, Romania, Spain, the Netherlands, Poland, India, and Hong Kong, and the acquisitions of different companies. Thanks to this growth path, the Group has become vertically integrated, expanding its range, and developing high-tech products for hydraulic and pneumatic braking systems, for industrial, pharmaceutical, and high-tech industry applications. **UNIGASKET** is therefore an integrated and international group capable of offering innovative solutions to create products of tomorrow.

The Group currently comprises the following Companies:

- UNIGASKET S.R.L (Italy)
- ALLEGRI CESARE SpA (Italy)
- POLIPLASTIC S.R.L. (Italy)
- UNIGOMMA S.R.L (Italy)
- MTO Hose Solutions Inc (USA)
- MTO Hose of Texas Inc (USA)
- UNITAPE S.R.L. (Romania)
- UNIGASKET S.L. (Spain)
- POLYFLUOR BV (Netherlands)
- UNIGASKET POLSKA SP z.o.o (Poland)
- UNIGASKET INDIA Private Ltd (India)
- UNIGASKET HONG KONG Ltd (Hong Kong)

Our portfolio of products is composed of, but not limited to the following:

- Hoses and tubes (for brakes, engines, food, etc.)
- Tapes
- O Rings
- Gaskets and seals
- Other semi-finished products

The main products of our company, in economic terms, are hoses and tubes. These products are used by a large number of different industrial sectors, such as Automotive, Industrial, Medical, Pharmaceutical, Semiconductors, etc.

These are the sectors of use in which we are marketing our products:

- Appliances
- Automotive
- Chemical
- Electronics
- Food (e.g. coffee machines)
- Heating
- Heavy industry
- Industrial
- Medical/Pharmaceutical
- Pneumatics
- Push pull cable
- Sanitary
- Semiconductors

The main industrial sectors to which **UNIGASKET** is marketing its products, in terms of revenue and profit, are Automotive and Industrial.

In the Automotive sector, which includes motorbikes, scooters, racing vehicles, and extreme vehicles, our company is producing the hoses that drive the brake calliper, and the hoses used in several applications in the engine design. In both cases, the quality of our products is directly related to the safety of the vehicles and, therefore, to the safety of operators and passengers.

In the Industrial sector, our hoses are used to handle aggressive media in industrial applications, mainly in the chemical and pharmaceutical sectors. However, they can also be used in processes in which high or very low temperatures are reached, such as the Steel, Oil & Gas, and Cryogenic industries. They are the unique solution in the new Hydrogen industry due to their unique performances in terms of chemical resistance, flexibility, low permeation, and wide temperature range.

It is worth noting that our PFA tubes, able to offer high chemical resistance to aggressive and corrosive media, play an essential role in the Semiconductors sector, in which they are used to transport high-purity media in microchip manufacturing.

2. PFAS use

The base of our products are fluoropolymers. This is a specific family inside the vast PFAS group that covers fluoroplastics, such as PTFE, PVDF, ECTFE, FEP, PFA, etc., as wells as fluoroelastomers, such as FKM, FFKM, etc.

UNIGASKET is consuming the following fluoropolymers for the manufacturing of extrusion fluoropolymer-based products:

Acronym	Name	CAS #
PTFE	Polytetrafluoroethylene	9002-84-0
FEP	Fluorinated ethylene propylene	25067-11-2
PFA	Perfluoroalkoxy polymer	26655-00-5 / 31784-04-0
ETFE	Ethylene tetrafluoroethylene	25038-71-5 / 68258-85-5
ECTFE	Copolymer of ethylene and chlorotrifluoroethylene	25101-45-5
PVDF	Polyvinilidene fluoride	24937-79-9
FKM	Fluoroelastomer	9011-17-0
PCTFE	Polychlorotrifluoroethylene	9002-83-9

The most purchased fluoropolymer by UNIGASKET is PTFE in a proportion of about 76%, and the other 24% represents other fluoropolymers, such as PFA, FEP, ECTFE, etc.

Fluoropolymers have unique properties that distinguish them from other PFAS and they do not have the environmental and toxicological profiles associated with some substances in the PFAS group that are of concern (such as PFOA and PFOS).

Fluoropolymers are durable, stable, and mechanically strong in harsh conditions in a variety of sectors including but not limited to automotive, aerospace, environmental controls, energy production and storage, and electronics, as well as in technical apparel. They are also stable in air, water, sunlight, chemicals, and microbes, and chemically inert, meeting the requirements for low levels of contaminants and particulates in manufacturing environments critical for the food and beverage, pharmaceutical, medical, and semiconductor industries. Finally, fluoropolymers are biocompatible, non-wetting, non-stick, and highly resistant to temperature, fire, and weather. These unique characteristics make them a critical material for a broad range of industries and sectors, playing a diverse and crucial role for society, with few, if any, viable alternatives, and making them essential in numerous technologies, industrial processes, and everyday products.

Furthermore, fluoropolymers are known for being considered as Polymers of Low Concern (PLC) according to criteria established by the OECD, therefore they are themselves not hazardous materials. Taking this into consideration, it can be concluded that the use of fluoropolymers by **UNIGASKET** in the manufacturing of our products does not pose any kind of risk for human health or the environment during their complete life cycle.

We strongly believe that, since fluoropolymers are different from the other families of PFAS, there is no scientific, economic, or social basis to justify regulating them in the same way as all of the other PFAS.

3. Questions and responses

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

First of all, UNIGASKET would like to express its concern related to the use of the "essential use concept" as a basis to take regulatory decisions on chemicals. In our experience, this approach is generating significant controversy in Europe which has led to a continuous delay of its implementation at regulatory level. Indeed, it appears to be extremely complex to define correctly what is essential and what is not essential, particularly because uses that may not be regarded as essential today could be found to be essential in the future, when the application may no longer be available. A good example it the use of fluoropolymers in interior air purifying systems, which may have been identified as "nice to have only" before the COVID-19 pandemic but were found to the best systems to ensure efficient interior protection to reduce virus transmission; a ban on this use due to 'non-essentiality' may have prevented such systems from being available when they were desperately needed.

If still the essentiality concept is going to be used, the basic criterion should be related to the risk profile of the substance. Indeed, substances that do not have any recognised hazard profile should not be considered for any ban on their use. Moreover, substances with a potential hazard identified, yet posing a low risk throughout their life cycle should be as well excluded. It is noted that differentiations could be established between industrial and consumer uses, because for consumers even a low risk may be deemed unacceptable depending on the specific case under consideration.

It makes sense to regulate uses of most harmful chemicals. For these, uses should only be allowed if, first of all, the risk is reduced as much as possible; then, it would be necessary to prove that the use is necessary to grant an adequate protection for the health and safety of the population, to protect the environment, or to ensure an adequate functioning of society. In such cases, continuation of the use should be allowed if there is no viable alternative that can replace the substance concern.

We believe that this situation does not apply to fluoropolymers, because they do not pose significant risk during use, as demonstrated by their consideration of Polymers of Low Concern (PLC) following indications provided by the OECD on the subject. Furthermore, the risk management measures implemented in the production process, both our own and those of fluoropolymer producers, as well as developments in end-of-life treatment techniques of these materials, ensure that the (low) risk associated with the use of these materials throughout their entire life cycle can be adequately controlled. Still, we also assume that the uses of our fluoropolymer-based products would match any consideration of essentiality, because they are necessary to ensure health (e.g. by providing clean food transfer systems), safety (e.g. in vehicle brake systems), and there are no viable alternatives that can replace them.

In any event, a case-by-case analysis should be carried out for each of the substances included in the broad PFAS group, to consider the hazard classification and the risks associated with their use (considering the technical functions of the substance in each of its specific uses), rather than a general analysis of the PFAS group as a whole.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

UNIGASKET supports the inclusion of the cost as an economic criterion in the definition of the "reasonably available" concept for PFAS alternatives, together with the volume/stock criteria.

We understand that alternatives are substances (but also new techniques or processes) that reduce, eliminate, or avoid adverse effects, can perform the same function (considering all of the properties provided by the substance to be replaced), are available in enough quantities, and are economically viable compared to the substance to be replaced.

Therefore, the cost needs to be considered (together with the other criteria) during the analysis of alternatives.

As an example related to our products, when considering stainless steel as an alternative to the fluoropolymer-based tubes and hoses in the Industrial, Automotive, and Food sectors of use, there are no advantages related to risk and hazard reduction (as both substances are not classified), the performance of the products decreases (stainless steel is less flexible and its vibration resistance is lower) and, although it is sufficiently available in volume terms, the cost of using this alternative may go up to **five times higher**. Therefore, even if a sufficient improvement in the other criteria were achieved (which is not the case), a thorough cost analysis would be necessary to verify that the alternative would be feasible.

As for the threshold of cost increase that would be considered reasonable, it is difficult to generalise and a case-by-case analysis would be more appropriate. The same cost increase applied to the same product used in different sectors of use, or to different products, can have very different impacts.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

We believe that special consideration should always be given to small and medium-sized companies, since their resources in the face of changes and prohibitions are more limited, and the effect of cost increases is significantly larger than in big companies.

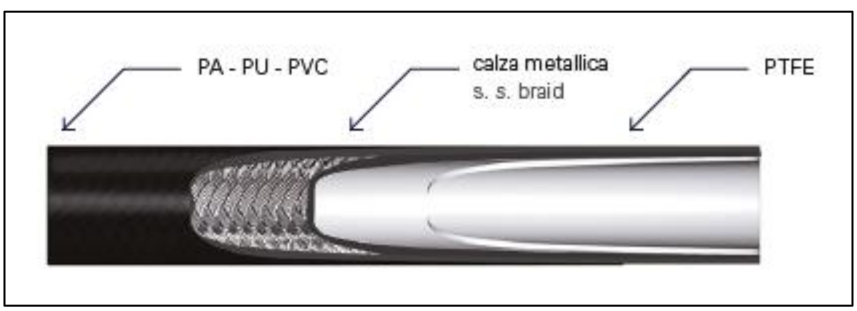
4) What criteria should be used to determine the safety of potential PFAS alternatives?

As commented in the response to question 1, the criteria that should be considered to determine the safety of potential PFAS alternatives would be the following:

- The hazard classification.
- The risk generated during the whole life cycle.

A substance that shows the same hazardous properties or worse than the substance to be replaced, cannot be considered as an alternative. In fact, this should be considered a regrettable substitution, as the potential adverse effects of the substance have been increased by the alternative rather than being eliminated or dampened.

On the other hand, if the use of an alternative increases the risk during the use of the product, it should not be regarded as such. An example related to our products is the substitution of stainless-steel braided hoses with inner PTFE tube by polyamide (PA) reinforced hoses in the brake system of vehicles.



Scheme of the different layers in a hydraulic brake hose.

The main technical problem of this substitution is that the thermal resistance of PA is lower than PTFE. Near the crimping area on the calliper side, it is possible to reach and maintain a temperature higher than the PA melting point temperature. It depends on the design of the vehicle (mainly in motorcycles), but if the brake hose is close to the engine or the exhaust, this situation could occur, representing an unacceptable risk for a safety component. In case that PA reaches the melting point temperature, the fluid could be spilled and not transmitted anymore, causing a sudden loss of the brake function, and compromising the safety of the rider.

In addition, using PA-reinforced brake hoses, even with the same intermediate layer material, at the same braided condition, and consuming the same brake fluid, the difference in water gain in the brake fluid before and after the tests is higher than using a brake hose with PTFE as inner material. This is due to the low moisture permeability of PTFE, which some studies estimate to be up to six times lower than that of PA. The presence of water in the brake fluid will affect the performance of the brake system, by decreasing the sensibility and, consequently, the brake performance of the vehicle in terms of the stopping distance, compromising the safety of operators, passengers, and third parties.

Finally, if the substitution leads to, for example, an increase in the volume of waste generated (because of a higher need for maintenance and replacement), or it worsens the recyclability possibilities (because recycling streams for that material do not exist or are very incipient), the substance should also not be considered as an alternative.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

UNIGASKET considers that CUU for fluoropolymers should be indefinitely maintained until real alternatives are available in the market.

Real alternatives mean those that comply with the following conditions:

- They can reduce, eliminate, or avoid adverse effects.
- They can perform the same function, providing the same properties.
- They are available in enough quantities.
- They are economically viable.

In order to verify that these alternatives are available, a re-evaluation of the state-of-the-art should be performed periodically, through open public consultation in which companies can provide scientific data and documents regarding the assessment of the hazard, performance, availability, and cost of the potential alternatives. It should be mandatory that any claim related to a potential alternative being available should be thoroughly supported with verified technical data that demonstrates equivalent performance to fluoropolymers at industrial scale (e.g. not just at lab tests). Likewise, a thorough hazard and risk assessment should be presented, in order to confirm that the potential alternative does not share similar or worse properties of concern compared to the material that it intends to substitute.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

To request the consideration of a use as CUU, stakeholders should provide MPCA with the following information:

- Information about the company and contact details.
- Type of product.
- Intended use or function of the product.
- Justification of the essentiality.
- Description of the role of PFAS in the product and its essentiality.
- Analysis of potential alternatives for this specific use.

MPCA could provide a format to standardise the request and compilation of this information.

After the evaluation of any CUU request (or groups of CUU requests), MPCA could publish it/them to be subject to a public consultation in which any stakeholder could provide information to support, supplement and reinforce, or oppose the proposed CUU.

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

UNIGASKET produces and markets different stainless-steel braided products and also non-braided products, both based on fluoropolymers. According to the last version of the Harmonized Tariff Schedule (HTS) of the USA (Revision 1 - 2024), these products have been coded as:

- 3917.21.00 Tubes, pipes, and hoses, rigid: of polymers of ethylene
- 3917.29.00 Tubes, pipes, and hoses, rigid: of other plastics

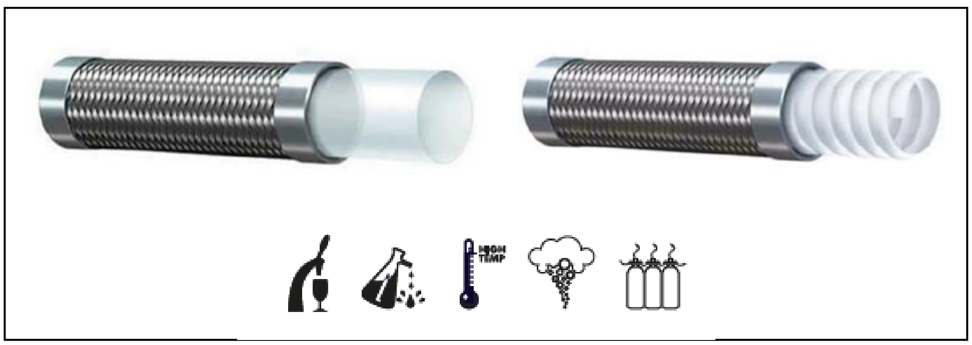
The stainless-steel braided products are marketed mainly in the **Automotive** sector of use, specifically for brake, engine, and cooling applications. The non-braided products are marketed mainly in the **Industrial**, **Food**, **Automotive**, and **Semiconductors** sectors of use, for many different applications.

Fluoropolymers are used as raw materials for the manufacture of our products due to their unique properties. It is the combination of properties that fluoropolymers provide that render fluoropolymer-based products the choice for all the above-mentioned sectors of use.

The main functional properties delivered by fluoropolymers in these sectors of use are the following:

Sector	Industrial	Food	Automotive	Semiconductors
Chemical resistance	X	X	X	X
Flexibility			X	
Low coefficient of friction	X	X		
Low permeability	X	X		
Low thermal expansion			X	
Mechanical resistance (durability)		X		
Purity				X
Temperature resistance (wide range)	X	X	X	

PTFE is the only material able to unify the main technical properties and safety standards in one solution for the **Automotive** sector of use. For this reason, PTFE braided hoses are the only solution able to unify the main required skills, such as reduced volumetric expansion (and therefore the high resistance to stress), temperature resistance, and chemical compatibility. The hoses in PTFE are also resisting better to vibrations and torsions.

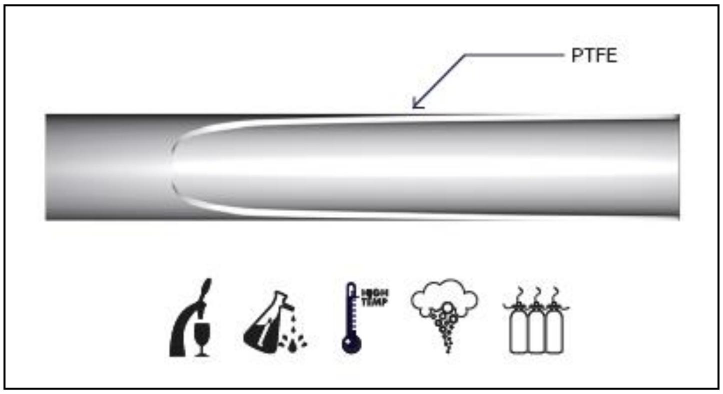


PTFE hoses with braided steel jacket (smooth or corrugated inner PTFE tube).

In the case of brake hoses, the inner tube is made with PTFE because this is the only material that is able to guarantee the thermal and chemical resistance that no other material can offer. The non-stick and smooth inside of the PTFE inner tube provides excellent oil flow. Furthermore, PTFE can resist the high temperature close to the calliper (around 250°C), provide the chemical resistance to withstand brake oil, deliver the low hygroscopic performance required, and support the working conditions (e.g., contact with UV Rays and Zinc Chloride on the road) which can affect the performance and safety. Finally, the stainless-steel braid ensures more protection of the inner PTFE and increases safety, while an external jacket in PVC/PA coating ensures better protection of the hose.

Our brake hoses are developed with brake calliper producers (e.g., Brembo Group) to offer the lowest volumetric expansion during the brake and, at the same time, the best safety performances in every working condition. This product meets and exceeds the requirements of multiple manufacturers of means of transport, ensuring that their vehicles always have full braking power.

On the other hand, the use of non-braided fluoropolymer-based products allows vehicle manufacturers to achieve high chemical and temperature resistance and good flexibility, which is not at the expense of stiffness and resistance, in a unique solution. PTFE tubes are manufactured according to high quality standards, such as BS EN ISO 13000-1:2021[1]. We extrude PTFE tubes with inner diameters from 1 mm to 100 mm.



PTFE flexible hoses without braided steel jacket.

Fluoropolymers offer higher performances to ensure the quality and safety of **Industrial** applications because there is no solution able to offer the same chemical and temperature resistances with the same flexibility of use. Our products (mainly hoses, pipes, and tubes) are used to handle aggressive media in industrial applications, offering flexibility in the use. They are used mainly in the chemical and pharmaceutical sectors, for which the properties of fluoropolymers are unique. They are also selected to be used in processes in which high or very low temperatures are reached, such as the steel, oil and gas, moulding of plastics, and cryogenic industries. In addition, they are the only solution in the new hydrogen industry due to their unique performances in terms of chemical resistance, flexibility, low permeation, and wide temperature range.

The fluoropolymer-based products that UNIGASKET manufactures for the **Industrial** sector of use are the following:

- Hoses for hydraulic applications used to transmit forces using hydraulic fluid;
- Tubing into the electrolyse cell for the production of the green hydrogen;
- Pipes used on robots equipped with grippers to transport aggressive fluids at high pressures and temperatures (-70°C to 260°C) thanks to the lack of absorption of humidity;

[1] BS EN ISO 13000-1:2021 – TC. Plastics. Polytetrafluoroethylene (PTFE) semi-finished products. Requirements and designation.

- Tubes with an internal non-stick core that do not contaminate the painting equipment and allow an excellent flow of air and pigment and in addition are able to withstand the vibrations and high operating temperatures typical of painting lines.
- Tubing used for the transport of compressed air, fluids, and gases at low pressure in the industrial field in contact with high temperatures.
- Tubing used to transfer particularly aggressive media with low pressure.

In the **Food** sector of use, PTFE is the only material that leads to optimal properties (chemical and temperature resistance, low coefficient of friction, and low permeability) to maintain the cleaning, sanitisation, and safety conditions of the food contact applications.

PTFE offers the highest performance to ensure quality and safety for the users (industrial, professional, and consumers). This fluoropolymer does not release any additives or elements into the media, so the use of PTFE tubes cannot be a source of chemical contamination in food or water. Furthermore, due to the non-stick properties of PTFE, food cannot adhere to the inside of the tube, preventing foodborne illnesses and cross-contaminations. Finally, due to its low permeability, it is not possible for food or water transported inside PTFE tubes to become contaminated from external sources and, at the same time, avoid odours and flavours from passing to water, beverages, and liquid food.

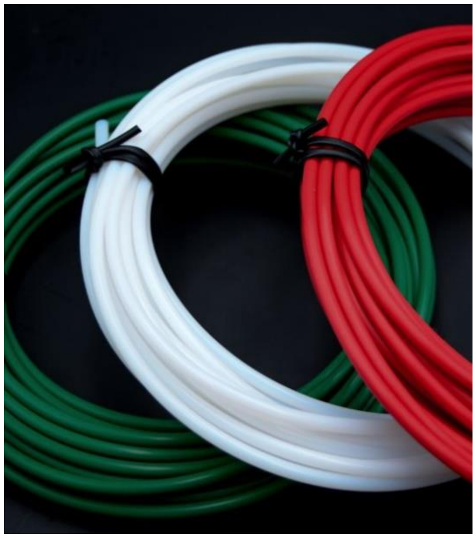
UNIGASKET offers a wide range of products using PTFE, FEP, and PFA able to meet the needs of those applications. These products are certified according to FDA regulations[2] and NSF standards[3]. We produce hoses that are used to handle food, water, and the cleaning media used in food processing machines or coffee machines for consumer, professional, and industrial use.

Due to the strict technical specifications on hygiene, sanitation, and working methods, manufacturers of coffee and food machines have chosen PTFE hoses as the best solution to guarantee high pressure and temperature to transfer hot water, or other food liquids, from the tank to the nozzle, guaranteeing the absence of contamination in the final product. This is due to the fact that fluoropolymers (mainly PTFE) combine the following characteristics:

- Food compatibility.
- It does not release odours and flavours.
- Temperature resistance.
- Chemical resistance to the chemical media used for sterilization and sanitization.
- Long operating life.

[2] PTFE tubes have been tested according to FDA 21 CFR 177.1550. The examined items meet the requirements and, therefore, the result of the tests is “Pass”. Test report 158250140c 001. TÜV Rheinland (Hong Kong) Ltd.
[3] Both PTFE and FPE used by UNIGASKET are “Authorized Registered Formulation (ARF)” according to NSF/ANSI Standard 51 – Food Equipment Materials.

Our special extruders allow UNIGASKET to produce PTFE thin wall tubes. The high tensile resistance and the high temperature resistance (up to 260°C) give the possibility to use our tube in food contact applications.



Thin wall extruded tubes in PTFE.

We extrude our tubing from 1mm internal diameter to 100mm. We could use special PTFE powders approved by FDA that allow to our hoses to be used in food and beverage industry. We have also tested our hoses according to the European Regulation 10/2011[4] and DM 174/2004[5] that have confirmed the possibility to use our tubing in water, food, and beverage contact.

The products that UNIGASKET manufactures based on fluoropolymers for the **Food** sector of use are the following:

- Food contact materials (e.g., pipes and gaskets for coffee machines) for consumer food preparation. The pipes are tasteless and odourless, free of phthalates, resistant to the liquids transported and to the products intended for cleaning, and able to comply with hygiene standards.
- Special gaskets, used in the production of big and little household appliances, are non-toxic, conductive, food compliant, and have a good performance at very high and very low temperatures.

[5] DECRETO 6 Aprile 2004, n. 174. Regolamento concernente i materiali e gli oggetti che possono essere utilizzati negli impianti fissi di captazione, trattamento, adduzione e distribuzione delle acque destinate al consumo umano. https://www.gazzettaufficiale.it/eli/id/2004/07/17/004G0204/sg

Fluoropolymers, PFA in particular, are the only materials able to offer the levels of purity required by the **Semiconductor** industry and, at the same time, to present a high chemical resistance in front of aggressive and corrosive media used in the production plant of microchips. In fact, they are currently the only raw materials approved for this type of application. For the **Semiconductor** industry it is absolutely essential to guarantee that the streams treated within the piping systems will remain with the highest possible purity. For this industry, levels of purity of part per trillion are required to ensure the highest possible quality, and to reduce production scrap rates for the user of high purity sulfuric acid. For this reason, any material to be used within this process must ensure an extremely low level of impurities, as well as a low level of leaching of the material used for the piping system into the product. For this reason, the semiconductor manufacturers have rejected all other alternatives due to technical problems that would prevent their production, which requires extreme purity, cleanliness, and zero contamination from other minerals or elements.

Cleanroom PFA tubes for Semiconductor applications.

During the last years, UNIGASKET has invested heavily with the aim of offering products with high added value which comply with the highest standards of cleanliness and hygiene particularly required in the hi-tech industry. Inside our ISO 7[6] certified cleanroom, we extrude tubes with high-purity fluoropolymers (in particular PFA and FEP) that are used in semiconductor applications.

[6] ISO 14644-1:2015. "Cleanrooms and associated controlled environments. Part 1: Classification of air cleanliness by particle concentration". According to this standard, cleanrooms certified as ISO-7 are required to have sixty air changes per hour of HEPA filtered air and less than 2,930 particles/meter^3 greater or equal to 5 microns.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

We understand that MPCA could define some initial CUU determinations considering the information received from companies during this process, provided that the information is considered enough and reliable to take this decision.

Regarding the uses and products presented by UNIGASKET in this document, we strongly believe that they qualify and meet the criteria to be considered CUUs. For this reason, we are at the disposal of the MPCA should any clarification of the information provided be necessary or should it be deemed necessary to complete it.

We also consider that, as previously explained, fluoropolymers are different from the other families of PFAS and, for this reason, there is no scientific, economic, or social basis to justify regulating them in the same way as all of the other PFAS. Therefore, as they are not hazardous materials and are considered as polymers of low concern, any industrial use of fluoropolymers should be considered CUU.

9) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

Nothing to add.

Executive Summary

Steam Thermal Solutions (part of Spirax Group) is a world-leading provider of steam and thermal solutions, offering a comprehensive range of products and services to help customers improve their energy efficiency, productivity, and environmental performance. Steam Thermal Solutions has over 100 years of experience and expertise in steam engineering and applications, serving industries such as food and beverage, pharmaceutical, chemical, oil and gas, power generation, and many more. Steam Thermal Solutions offers solutions for every stage of the steam and condensate loop, from steam generation, distribution, and utilization to condensate recovery and reuse. Steam Thermal Solutions also provides training, audits, consultancy, and digital services to help customers optimize their steam systems and achieve their sustainability goals.

Steam Thermal Solutions is committed to ensuring the safety and sustainability of its products and operations, as well as complying with the relevant regulations and standards in the markets where it operates. We are aware of the growing concern about the environmental and health impacts of per- and polyfluoroalkyl substances (PFAS), a group of chemicals that have been widely used in various industries for their water and oil repellency, heat resistance, and friction reduction properties. Steam Thermal Solutions thanks the Minnesota Department of Environmental Protection for the opportunity to share information on where and why fluoropolymers are used in our products and their applications, and where there are currently no suitable, available alternative materials that can meet the required performance characteristics.

Steam Thermal Solutions fully supports the restriction of specific, hazardous PFAS that pose a danger due to bioavailability, bioaccumulative and toxic properties. However, fluoropolymers (a group of polymers within the class of PFAS) meet the Organisation for Economic Co-operation and Development (OECD) criteria for polymers of low concern and are essential for various applications across multiple industries. Steam Thermal Solutions uses fluoropolymer materials in many products because of the very strong C-F bond as they are critical to achieve the chemical, heat and mechanical resistance required for the applications and industries that they are intended to support. One of the main applications of fluoropolymers in our industry is polytetrafluoroethylene (PTFE), a synthetic fluoropolymer that has exceptional chemical, thermal, and mechanical properties. PTFE is widely used as a sealant and in gaskets in various components and systems of Steam and Thermal Solution, such as valves, traps, regulators, pumps, meters, and controls. PTFE provides superior performance, reliability, and durability in high-pressure, high-temperature, and corrosive environments, which are essential for the efficient and safe operation of steam systems in various sectors, such as food and beverage, pharmaceutical, chemical, and power generation. Fluoroelastomer (FKM) is another fluoropolymer that is also used for the same rationale and has similar properties as PTFE. Furthermore, Steam Thermal Solutions' products that use PTFE and other fluoropolymer are supporting industrial process where the design and application of our products mean they have a prolonged longevity in use, and are not single use consumable products.

For the majority of these applications, there are currently no alternative materials. To the extent there are apparent alternatives, they are not sufficiently evaluated or approved for these applications, creating concerns on performance and safety, that can impact pharmaceutical, transport and food industries, amongst others. For these reasons, the products listed in this report and their associated applications should be considered Currently Unavoidable Uses (CUU).

We are not complacent or indifferent to the environmental and health concerns of PFAS. We are proactively engaging with our suppliers, subject matter experts, and industry partners to identify and evaluate potential alternatives to fluoropolymers in our steam and thermal solution products.

However, we also recognize the need for a careful and rigorous assessment of the technical feasibility, performance, safety, and environmental impact of any alternative material, to avoid any regrettable substitution that could compromise the quality and reliability of our products or pose similar or worse risks to human health and the environment as PFAS. Therefore, we urge the State of Minnesota to grant us additional time to conduct our research and testing, and to consider the specific needs and challenges of our industry, before imposing any restrictive or prohibitive measures on the use of PFAS.

Table of Contents

A summary of each Product Groups and the impact and availability of alternative materials is shown below. **Refer to Appendix A for details of product groups that are covered under each sections**.

Ball Valves

One of the key products that Steam and Thermal Solutions offers is ball valves, which are designed for control purposes and have characterized balls or seats, to give a predictable flow pattern. They are an economic means of providing control with tight shut-off for many fluids including steam.

Steam and Thermal Solutions Ball valves are used in a wide range of industries and sectors, such as chemical, pharmaceutical, food and beverage, oil and gas, power generation, pulp and paper, and water treatment. These industries and sectors rely on ball valves to control the flow of various fluids, gases, and vapours, as well as to isolate and regulate pressure and temperature. Ball valves are essential to the safety and smooth functioning of these industries and sectors, as they prevent leaks, overflows, explosions, and contamination, as well as optimize the efficiency, quality, and performance of the processes and products.

Ball Valves are crucial for Safety, and optimum operations.

Ball Valves are reliable shut-off valves designed to reduce maintenance time of the steam plant and create a safer environment. They provide reliable tight shut-off and require less maintenance. They are essential for controlling the flow of fluids in industrial applications, contributing to the safety and efficiency of operations. They are available in a wide range of sizes, materials, and body design options, providing a suitable model for any application. Their precision design provides compact valves. They are quick and easy to automate. They allow low pressure drop and high capacity. Their corrosion-resistant bodies ensure the long life of the product.

Fluoropolymer use in Ball Valves and how they are essential to the function.

The strategic use of PTFE (polytetrafluoroethylene) in Steam and Thermal Solutions ball valve components is essential for both functionality and safety. PTFE ensures smooth stem movement, creates tight seals, prevents fluid leakage, and enhances overall sealing performance. These properties collectively contribute to efficient valve operation, minimize risks of leaks, and maintain system integrity across various industries. In summary, PTFE's role in ball valve components is critical for reliable and safe valve functionality.

Non- Fluoropolymer Substitutes in Ball Valve Components

Research into non-Fluoropolymer substitutes for PTFE (Polytetrafluoroethylene) in ball valve components is progressing and demonstrating potential, although they have not yet been tested or applied in identical use-cases. These alternatives aim to replicate the unique properties of PTFE, including its ability to form tight seals, prevent fluid leakage, and enhance sealing performance. However, achieving the same performance as PTFE is challenging. PTFE's low friction, high temperature resistance, and chemical stability contribute to efficient valve operation and system integrity across various industries. Non-Fluoropolymer alternatives may not fully replicate these properties, potentially impacting their effectiveness in maintaining reliable and safe valve functionality. Therefore, while non-Fluoropolymer alternatives are being developed and show promise, they may not yet achieve the same performance as PTFE in all use-cases.

Safety Valves

Steam and Thermal Solutions Safety Valves are devices that protect pressurized systems by releasing a volume of fluid from within the plant when a predetermined maximum pressure is reached, thereby reducing the excess pressure in a safe manner. They are used in a wide range of industries and sectors, such as chemical, pharmaceutical, food and beverage, oil and gas, power generation, pulp and paper, and water treatment.

Safety Valves are crucial for Safety, and optimum operations.

Safety Valves are essential wherever a hazardous overpressure situation could occur. They safeguard against mechanical damage to equipment and surroundings, loss of product and production, damage to the environment, and injury and loss of life. They are used for boiler overpressure protection and other applications such as downstream of pressure reducing controls. Their primary function is to protect life and property. They are also used in process operations to prevent product damage due to excess pressure. Safety valves should be installed wherever the maximum allowable working pressure (MAWP) of a system or pressure-containing vessel is likely to be exceeded.

Fluoropolymer use in Safety Valves and how they are essential to the function.

PTFE (Polytetrafluoroethylene) and Viton or FKM, both types of Fluoropolymers, are used in various industrial applications due to their unique properties. In the context of Steam and Thermal Solutions Safety Valves, PTFE is used as Bush, providing a low friction surface, allowing for precise control over the valve operation. On the other hand, Viton is used in the soft seal disc Insert, O-ring. These components are critical for the valve’s operation, providing a seal that prevents leakage and ensures the valve operates correctly.

Non- Fluoropolymer Substitutes in Safety Valve Components

Research into non-Fluoropolymer substitutes for PTFE (Polytetrafluoroethylene) in Safety Valve components is progressing and demonstrating potential, although they have not yet been tested or applied in identical use-cases. These alternatives aim to replicate the unique properties of PTFE and Viton, including their ability to provide a low friction surface and form tight seals that prevent leakage. However, achieving the same performance as PTFE and Viton is challenging. The low friction, high temperature resistance, and chemical stability of PTFE and Viton contribute to precise control over valve operation and ensure the valve operates correctly. Non-Fluoropolymer alternatives may not fully replicate these properties, potentially impacting their effectiveness in maintaining reliable and safe valve functionality. Therefore, while non-Fluoropolymer alternatives are being developed and show promise, they may not yet achieve the same performance as PTFE and Viton in all use-cases.

Piston Actuated Valves

The function of the Steam and Thermal Solutions Piston Actuated Valve is to control the flow of fluid through the valve body by responding to a pneumatic control signal. Depending on the type of valve, the control signal can be either direct or reverse acting. A direct acting valve opens when the control signal increases and closes when the control signal decreases. Piston Actuators are used in a wide range of industries and sectors, such as chemical, pharmaceutical, food and beverage, oil and gas, power generation, pulp and paper, and water treatment.

Piston Actuated Valves are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Piston Actuated Valves are efficient, accurate, and easy to maintain stop valves for use on steam, condensate, and liquid systems. They are designed to reduce maintenance time of steam plants and create a safer environment. They provide reliable tight shut-off and require less maintenance. They are essential for controlling the flow of fluids in industrial applications, contributing to the safety and efficiency of operations.

Fluoropolymer use in Piston Actuated Valves and how they are essential to the function.

Steam and Thermal Solutions Piston Actuated Valves are constructed using a variety of materials, each selected for their unique properties. Fluoroelastomer (FKM) is employed in the O-rings and seals due to its resistance to high temperatures and excellent chemical stability. Polytetrafluoroethylene (PTFE) is used as seals. It provides a tight ANSI Class VI shutoff and contributes to the efficiency and reliability of the valve system. Lastly, Viton, a type of Fluoropolymer (a member of the PFAS family), is used as O-ring. It provides a robust and reliable seal in harsh environments. These materials collectively ensure the proper functioning and durability of Steam and Thermal Solutions valves.

Non- Fluoropolymer Substitutes in Piston Actuated Valve Components

Steam and Thermal Solutions Piston Actuated Valves utilize materials like, Polytetrafluoroethylene (PTFE), and Viton, a Fluoropolymer, for their unique properties. Alternatives to these Fluoropolymer materials could include other types of elastomers or plastics. However, these alternatives may not offer the same level of performance. For instance, FKM's high-temperature resistance and chemical stability, PTFE's contribution to efficiency and reliability with a tight ANSI Class VI shutoff, and Viton's robustness in harsh environments are characteristics that may not be matched by non-Fluoropolymer alternatives. Therefore, while alternatives exist, they may not provide the same durability and proper functioning as the Fluoropolymer materials used in Steam and Thermal Solutions valves.

DP Reducing Valves

Steam and Thermal Solutions DP reducing valves are devices that reduce the pressure of steam or other fluids by using a piston actuator. They are used in various industries, such as food and beverage, pharmaceutical, and chemical, to control the flow rate and temperature of processes. Reducing Valves are used in a wide range of industries and sectors, such as chemical, pharmaceutical, food and beverage, oil and gas, power generation, pulp and paper, and water treatment.

DP Reducing Valves are crucial for Safety, and optimum operations.

Steam and Thermal Solutions DP Reducing Valves accurately control downstream pressure, regardless of the upstream pressure or load variations. These valves are essential for well-designed steam systems that produce clean dry steam for delivery at high pressure. Lower pressure steam is usually needed at the point of use. Effective control demands an automatic valve that can reduce steam pressure accurately, reliably, and at a cost to suit the application.

Fluoropolymer use in DP Reducing Valves and how they are essential to the function.

Polytetrafluoroethylene (PTFE) is employed in the O-rings, seals, and stem seals of the valve, PTFE's high-temperature resistance and excellent chemical stability ensure a tight seal, preventing leaks and maintaining the efficiency of the valve system. It is essential to provide a reliable and durable seal that can withstand the high pressures and temperatures involved in these applications.

Non- Fluoropolymer Substitutes in DP Reducing Valve Components

DP Reducing Valve employs Polytetrafluoroethylene (PTFE) for their unique properties such as high temperature resistance and excellent chemical stability. Alternatives to these materials could include other types of elastomers or plastics. However, these alternatives may not offer the same level of performance. Therefore, while alternatives exist, they may not provide the same durability and proper functioning as the Fluoropolymer materials used in Steam and Thermal Solutions valves.

Blowdown Valves

Steam and Thermal Solutions Blowdown valves are designed for the removal of suspended/deposited solids and water from the bottom of steam boilers. It is used in conjunction with a Steam and Thermal Solutions blowdown timer to provide timed control of bottom blowdown, ensuring that the recommended boiler blowdown cycles occur with minimum heat loss, avoiding duplication or omission. Blowdown valves are used in a wide range of industries and sectors, such as chemical, pharmaceutical, food and beverage, oil and gas, power generation, pulp and paper, and water treatment.

Blowdown Valves are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Blowdown Valves are designed to accommodate blowdown water from the boiler and meet the Health, Safety & Environmental regulations. They are essential for maintaining plant safety and saving energy by eliminating stem seal leaks. Zero emissions are guaranteed which ensures these valves meet the most stringent worldwide emissions legislation.

Fluoropolymer use in Blowdown Valves and how they are essential to the function.

Steam and Thermal Solutions Blow Down Valves employ fluoropolymers such as PTFE and FKM. PTFE, a chemically inert polymer with a broad working temperature range, is used in valve components, making it ideal for seals exposed to wide-ranging chemicals and temperature extremes. FKM, characterized by its robust carbon-fluorine bonds, is a key component in the valve's O-rings, offering exceptional resistance to chemicals, heat, and oxidation. This makes it suitable for environments involving chemical handling, high temperatures, and explosives. In essence, the unique properties of both PTFE and FKM significantly enhance the functionality, safety, and efficiency of Steam and Thermal Solutions Blow Down Valves, enabling them to operate effectively under diverse conditions.

Non- Fluoropolymer Substitutes in Blowdown Valve Components

Steam and Thermal Solutions Blow Down Valves employ Polytetrafluoroethylene (PTFE) and Fluoroelastomer (FKM) for their unique properties. Alternatives to these Fluoropolymer materials could include other types of elastomers or plastics. However, these alternatives may not offer the same level of performance. For instance, PTFE's broad working temperature range and chemical inertness make it ideal for seals exposed to a wide range of chemicals and temperature extremes. FKM, characterized by its robust carbon-fluorine bonds, offers exceptional resistance to chemicals, heat, and oxidation, making it suitable for environments involving chemical handling, high temperatures, and explosives. These characteristics may not be matched by non- Fluoropolymer alternatives. Therefore, while alternatives exist, they may not provide the same durability and proper functioning as the Fluoropolymer materials used in Steam and Thermal Solutions valves.

BRV Valves

Steam and Thermal Solutions Body Relief valves (BRV) are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment. They are used in a wide range of industries and sectors, such as chemical, pharmaceutical, food and beverage, oil and gas, power generation, pulp and paper, and water treatment. They are essential for maintaining the quality and efficiency of the boiler system, as well as preventing scale formation and corrosion. BRV valves also help to control the pressure and temperature of the boiler by releasing excess steam and water.

BRV Valves are crucial for Safety, and optimum operations.

Steam and Thermal Solutions BRV are essential for maintaining safe operation of pressurised systems. They are properly installed, commissioned, used, and maintained by qualified personnel in compliance with the operating instructions. They are designed for use on steam, compressed air, and inert industrial gases. They protect life and property by preventing overpressure in plant.

Fluoropolymer use in BRV Valves and how they are essential to the function.

Steam and Thermal Solutions BRV, or Pressure Reducing Valves, are designed to control steam, compressed air, and inert industrial gases. They are constructed using a variety of materials for different components. The diaphragms are made from synthetic rubbers and fluoropolymers such as FPM (Fluorocarbon Elastomers), and FKM (Fluorocarbon Elastomers). These materials are known for their excellent heat, ozone, weather resistance, and resistance to oils, solvents, and chemicals. They provide a flexible and durable seal that can withstand high temperatures and pressures. The O-rings are made from FEPM (Fluoroelastomer) and PTFE (Polytetrafluoroethylene). FEPM is a type of rubber that is highly resistant to heat, chemicals, and aging. PTFE is a type of plastic known for its excellent chemical resistance, low friction, and high operating temperature range. They provide a tight and durable seal that can withstand harsh conditions. Other components such as the guide bush, protective films, pushrods assembly, and washer are made from PTFE, providing a durable and chemically resistant surface that can withstand harsh conditions.

Non- Fluoropolymer Substitutes in BRV Valve Components

Non- Fluoropolymer alternatives for Pressure Reducing Valves are being explored due to the potential environmental and health impacts of Fluoropolymer materials. However, these alternatives may not compare to the performance and safety of Fluoropolymer materials. Fluoropolymer materials, such as PTFE and FKM, are known for their outstanding chemical, thermal, and low-friction properties. They are used in various components of Pressure Reducing Valves due to their ability to withstand harsh conditions and provide durable seals. Non- Fluoropolymer materials may have different properties and might not work or have a shorter lifetime for certain products. Furthermore, they may not be easily available. Therefore, while non- Fluoropolymer alternatives are being developed, they currently do not match the performance and safety of Fluoropolymer materials.

Bellows Sealed Valves

Steam and Thermal Solutions Bellows Sealed Valves are environmentally sound solutions for steam systems and to guarantee zero emissions. The function of Bellows Sealed Valve is to provide reliable and leak-free isolation of steam and other fluids. The valve has a flexible metal bellows that seals the stem from the atmosphere and eliminates the need for gland packing. This prevents any emissions of steam or fluid and ensures safety and efficiency.

Bellows Sealed Valves are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Bellows Sealed Valves are engineered to maintain plant safety and save energy by eliminating stem seal leaks. Zero emissions are guaranteed which ensures these valves meet the most stringent worldwide emissions legislation. They are essential for maintaining plant safety and providing safe, well-made products.

Fluoropolymer use in Bellows Sealed Valves and how they are essential to the function.

The use of PTFE (Polytetrafluoroethylene) in the seat insert of Steam and Thermal Solutions Bellow Sealed Valves is crucial for their function. PTFE is known for its excellent chemical resistance, low friction, and high-temperature tolerance, making it an ideal material for valve seat inserts. In the

Bellow Sealed Valves, the PTFE seat insert plays a vital role in ensuring a tight seal when the valve is closed, thereby preventing leaks, and maintaining the efficiency of the system.

Non- Fluoropolymer Substitutes in Bellows Sealed Valve Components

Non- Fluoropolymer alternatives for Bellow Sealed Valves are being explored due to the potential environmental and health impacts of Fluoropolymer materials. However, these alternatives may not compare to the performance and safety of Fluoropolymer materials. Fluoropolymer materials, such as PTFE are known for their outstanding chemical, thermal, and low-friction properties. They are used as seat insert in Bellow sealed valves due to their ability to withstand harsh conditions and provide durable seals. Non- Fluoropolymer materials may have different properties and might not work or have a shorter lifetime for certain products. Furthermore, they may not be easily available. Therefore, while non- Fluoropolymer alternatives are being developed, they currently do not match the performance and safety of Fluoropolymer materials.

Float Traps

Steam and Thermal Solutions Float Traps are devices that automatically remove condensate and air from steam systems. It consists of a valve body, a seat, a float ball, and a lever mechanism. The float ball rises and falls with the level of condensate in the trap, opening and closing the valve.

Float Traps are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Float Traps are essential for maintaining a safe, lower carbon and energy-efficient steam system. They allow condensate to be removed from the steam system effectively, meaning that process efficiency can be optimised, equipment is protected, and the condensate can be re-used. They contribute to overall sustainability targets.

Fluoropolymer use in Float Traps and how they are essential to the function.

Fluoroelastomer (FKM) O-rings are a critical component in the function of Steam and Thermal Solutions Float Traps. These O-rings provide a robust seal that can withstand the high temperatures and pressures within the system, ensuring the efficient operation of the float trap. The FKM material is known for its excellent heat resistance and chemical stability, which makes it ideal for use in steam applications.

Non- Fluoropolymer Substitutes in Float Traps Components

Non-Fluoropolymer alternatives to Fluoroelastomer (FKM) O-rings are being developed and implemented. However, these alternatives may not achieve the same performance and safety as Fluoropolymer chemicals. The O-rings made of FKM are resistant from corrosion and heat damage, which is crucial for the function of Steam and Thermal Solutions Float Traps. While some non-fluorinated alternatives have shown to meet high specifications required for certain uses, more studies are needed to better understand their effects on humans and the environment. While the transition to non-Fluoropolymer alternatives is underway, it is important to ensure that these alternatives can meet the necessary performance and safety standards.

Sight Glasses and Gauges

Sight glasses monitor the discharge downstream of steam traps in pressurised condensate return lines. It is screwed directly into the steam trap providing a modular monitoring system, thus eliminating the need for a connecting nipple, minimising joints, and potential leak paths. The sight glass can also be installed in process lines to provide a visual indication of flow.

Sight Glasses and Gauges are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Sight Glasses and Gauges are used for quick and easy visual inspection throughout the system. They assess correct flow indication, detect blocked flow, identify any live steam, or vapour leakage, and inspect the colour of the product throughout the process. They are essential for maintaining plant safety and improving operational efficiency.

Fluoropolymer use in Sight Glasses and Gauges and how they are essential to the function.

PTFE (Polytetrafluoroethylene), commonly used in gaskets, Cap O-ring plays a crucial role in the functioning of Steam and Thermal Solutions Sight Glasses. These sight glasses allow for quick and easy visual inspection throughout the system. The PTFE gaskets/O-ring ensure a secure and tight seal, preventing any leakage of steam or vapour. In sanitary applications (such as pharmaceuticals, food processing, or biotechnology), maintaining hygienic conditions is crucial. PTFE’s unique conformity to deformation to ensure tight seal is essential. It ensures that there are no crevices or gaps where contaminants can accumulate.

Non- Fluoropolymer Substitutes in Sight Glasses and Gauges Components

Non-Fluoropolymer alternatives to PTFE gaskets/sealants are being explored. However, these alternatives may not achieve the same performance and safety as Fluoropolymer chemicals. Fluoropolymer are known for their water-resistant and non-stick properties, making them extraordinarily useful in various applications. They protect industrial equipment from contamination, corrosion, and heat damage, which is crucial for the function of Steam and Thermal Solutions Sight Glasses. While some non-fluorinated alternatives have shown to meet high specifications required for certain uses, more studies are needed to better understand their effects on humans and the environment. Therefore, while the transition to non-Fluoropolymer alternatives is underway, it is important to ensure that these alternatives can meet the necessary performance and safety standards.

PN Actuators

Steam and Thermal Solutions Actuators are devices that convert pneumatic or hydraulic pressure into linear motion. They are used on steam systems to control the flow of steam through valves, regulators, traps, and other components. Linear actuators can be adjusted to suit different operating conditions, such as pressure, temperature, and flow rate. Linear actuators are essential for maintaining the efficiency, safety, and reliability of steam systems, as they ensure that the steam is delivered at the right pressure and temperature to the end users.

PN Actuators are crucial for Safety, and optimum operations.

Steam and Thermal Solutions PN Actuators are essential for the operation of control valves. They accept a signal from the control system and, in response, move the valve to a fully open or fully closed position, or a more open or a more closed position. They are essential for maintaining safe operation of pressurised systems.

Fluoropolymer use in PN Actuators and how they are essential to the function.

Steam and Thermal Solutions PN Actuators employ PTFE and FKM materials in components like bearings and seals, that provides excellent fluid sealing, low friction, and resistance to wear and chemicals, ensuring the actuator’s durability and effective functioning. FKM is used in O-rings, providing chemical, thermal, and oxidation resistance, and a wide operational temperature range. This ensures a tight seal and prevents leaks in the actuator, even under high temperatures or when exposed to various chemicals.

Non-Fluoropolymer Substitutes in PN Actuators Components

It is understandable from Mainstream literature that research is underway for non- Fluoropolymer substitutes for PTFE and FKM. However, these alternatives might not match the performance and safety of Fluoropolymer chemicals. Fluoropolymers are renowned for their high temperature, water-resistant and low coefficient of friction properties, which are extremely beneficial in various applications. They safeguard industrial equipment from heat and corrosion damage, which is vital for Steam and Thermal Solutions PN Actuators. While some non-fluorinated alternatives have demonstrated the ability to meet certain high specifications, further research is required to fully understand their impact on humans and the environment. Therefore, it is crucial to ensure that these alternatives can meet the necessary performance and safety standards as the transition to non-Fluoropolymer alternatives continues.

Balanced Pressure Traps

Steam and Thermal Solutions Balanced Pressure Traps are maintainable thermostatic steam trap designed to remove condensate from clean (chemical free) steam systems with minimal condensate retention. They efficiently drain condensate from steam systems while preventing the loss of live steam. They work by using a flexible capsule that contains a liquid with a similar boiling point as steam. As the steam pressure changes, the capsule expands or contracts to open or close the valve. Traps are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Balanced Pressure Traps are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Balanced Pressure Traps adjust automatically to varying steam pressures. They have excellent air venting characteristics during plant start-up and during normal operation. They have large discharge capacities for their size. Their robust design of the internals gives a good life expectancy. They are essential for maintaining a safe, lower carbon and energy-efficient steam system.

Fluoropolymer use in Balanced Pressure Traps and how they are essential to the function.

In Steam and Thermal Solutions Balanced Pressure Traps, the optimal function of different components is ensured using specific materials. PTFE (Polytetrafluoroethylene), known for its excellent chemical resistance and low friction properties, is used in Seals, providing a tight seal and maintaining the efficiency of the steam traps. FKM (Fluoroelastomer), used in O-rings, is valued for its high temperature, oil, and chemical resistance, contributing to the durability and longevity of the O-rings, and enabling them to withstand harsh conditions within the steam traps.

Non-Fluoropolymer Substitutes in Balanced Pressure Traps Components

Non-Fluoropolymer alternatives for PTFE, FKM in Balanced Pressure Traps are being researched according to our understanding from the mainstream literature. However, these alternatives may not achieve the same performance and safety as Fluoropolymer chemicals. Fluoropolymers are known for their water-resistant and non-stick properties, making them extraordinarily useful in various applications. They protect industrial equipment from chemical, corrosion, and heat damage, which is crucial for the function of Steam and Thermal Solutions Balanced Pressure Traps. While some non-fluorinated alternatives have shown to meet high specifications required for certain uses, more studies are needed to better understand their effects on humans and the environment. Therefore, while the transition to non-Fluoropolymer alternatives is underway, it is important to ensure that these alternatives can meet the necessary performance and safety standards.

Direct Acting Pressure Reducing Valve (DRV)

Steam and Thermal Solutions DRV (Direct Acting Pressure Reducing Valve) works by balancing the downstream pressure via a pressure sensing pipe against a pressure adjustment control spring. The working principle of the Steam and Thermal Solutions DRV valve is based on the balance of forces acting on the diaphragm. DRV are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

DRV are crucial for Safety, and optimum operations.

DRV are essential for maintaining safe operation of pressurised systems. They are properly installed, commissioned, used, and maintained by qualified personnel in compliance with the operating instructions. They are designed for use on steam, compressed air, inert industrial gases and certain oils. They protect life and property by preventing overpressure in the plant.

Fluoropolymer use in DRV and how they are essential to the function.

PTFE (Polytetrafluoroethylene) material is used for the construction of components like Bearing bushes, Bushes, Pilot Seats, Pilot Valve Seats, ensuring the DRVs' safety and reliability. PTFE, known for its heat, electrical, and chemical resistance, low friction, durability, superior resistance to oil, and gas, thereby guaranteeing efficient performance even under demanding conditions.

Non-Fluoropolymer Substitutes in DRV Components

When considering non-Fluoropolymer alternatives, it is essential to recognize that they currently do not fully meet the performance and safety requirements established by Fluoropolymers. While these alternatives may offer advantages such as improved environmental profiles and reduced toxicity, they often fall short in terms of the unique combination of properties provided by Fluoropolymers. For instance, PTFE, known for its heat resistance, electrical insulation, chemical resistance, low friction, and durability, plays a crucial role in various DRV components, ensuring their reliability and long lifespan. There should be ongoing efforts aim to find safer alternatives, however, the current non-Fluoropolymer options do not match the unique performance characteristics and safety attributes of Fluoropolymer chemicals used in these critical products.

Liquid Drainers

One of the functions of liquid drainers is to remove condensate from compressed air systems without wasting any of the valuable compressed air. They are used to drain off water while preventing the escape of compressed air. Liquid Drainers are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Liquid Drainers are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Liquid Drainers are essential for maintaining operational efficiency. Condensate can cause corrosion, contamination, and energy loss if it is not drained properly. Liquid Drain Traps are built for the robust application of compressed air, providing precise control and greater efficiency.

Fluoropolymer use in Liquid Drainers and how they are essential to the function.

Fluoroelastomers (FKM) are employed in Liquid Drainer components particularly in the Valve Cones, and O-rings. FKM is characterized by its strong carbon-fluorine bonds, which give it exceptional chemical, thermal, and oxidation resistant properties. This makes it ideal for handling and transportation of chemicals and fuels, as well as high temperature and explosive environments. In the context of Steam and Thermal Solutions Liquid Drainers, these properties ensure the durability, safety, and reliability of the equipment, even under harsh conditions.

Non- Fluoropolymer Substitutes in Liquid Drainers Components

FKM, characterized by robust carbon-fluorine bonds, exhibits exceptional chemical, thermal, and oxidation resistance. This makes it suitable for handling and transporting chemicals, fuels, and operating in high-temperature and explosive environments, ensuring the durability and reliability of the equipment even under challenging conditions. It is important to note that non-Fluoropolymer alternatives currently do not fully match the performance and safety requirements set by Fluoropolymer chemicals. While these alternatives may offer certain advantages, such as improved environmental profiles or reduced toxicity, they often fall short in replicating the unique combination of properties of Fluoropolymers.

Air Eliminators

Steam and Thermal Solutions Air Eliminators are devices that remove air and other non-condensable gases from liquid systems. Air eliminators improve heat transfer efficiency, prevent corrosion, reduce noise, and prevent pump cavitation. They are essential for maintaining the quality and performance of the liquid system. Air Eliminators are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Air Eliminators are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Air Eliminators are essential for efficient running of the steam or liquid systems. They improve operational efficiency and reduce maintenance costs. They avoid leaving air in the system or wasting steam by venting air accurately.

Fluoropolymer use in Air Eliminators and how they are essential to the function.

Fluoroelastomers (FKM) are used in valve cones, valve heads, and O-rings of Steam and Thermal Solutions Air Eliminators due to their exceptional chemical, thermal, and oxidation resistant properties. FKM offers a wide operational temperature range, which is crucial for the efficient functioning of air eliminators. These properties make FKM an ideal choice for handling and transportation of chemicals and fuels, as well as high temperature and explosive environments.

Non- Fluoropolymer Substitutes in Air Eliminators Components

Fluoroelastomers (FKM) is employed in Steam and Thermal Solutions Air Eliminators. FKM, characterized by robust carbon-fluorine bonds, exhibits exceptional chemical, thermal, and oxidation resistance. This makes it suitable for handling and transporting chemicals, fuels, and operating in high-temperature and explosive environments, ensuring the durability and reliability of the equipment even under challenging conditions. It is important to note that non-Fluoropolymer alternatives currently do not fully match the performance and safety requirements set by Fluoropolymer chemicals. While these alternatives may offer certain advantages, such as improved environmental profiles or reduced toxicity, they often fall short in replicating the unique combination of properties of Fluoropolymers.

Hose Down Stations & Thermocirc

Hose Down Stations mix steam and cold water to economically produce hot water for hosing down. These products are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Hose Down Stations & Thermocirc are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Hose Down Stations mix steam & cold water to economically produce hot water for hosing down. They improve operational efficiency and have a compact design. They are crucial for safety and optimum operations in various industries that require hygienic and efficient cleaning of equipment and facilities. This reduces the risk of scalding, contamination, or corrosion, and ensures a consistent and reliable supply of hot water.

Fluoropolymer use in Hose Down Stations & Thermocirc and how they are essential to the function.

The Steam and Thermal Solutions Hose Down Station employs PTFE, FKM, Fluoropolymers known for their chemical resistance, low friction, and high-temperature tolerance.

Non- Fluoropolymer Substitutes in Hose Down Stations & Thermocirc Components

PTFE and other Fluoropolymers are known for their unique properties such as chemical resistance, low friction, and high-temperature tolerance, which make them ideal for use in various applications. Alternatives to PTFE, are being actively developed. However, currently they do not offer the same performance.

SA Control Valves

Steam and Thermal Solutions Self Acting (SA) Control Valves are devices that regulate the flow of fluids or gases in a pipeline. They work by opening or closing partially or fully, depending on the signal received from a controller. The controller monitors the pressure, temperature, level, or flow rate of the system and adjusts the valve position accordingly. The valve can be operated manually, electrically, pneumatically, or hydraulically. These valves are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

SA Control Valves are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Self Acting Control Valves are essential for various industries and applications that depend on precise and consistent control of fluids or gases. For example, they are used in the pharmaceutical industry to ensure the quality and sterility of the products, in the food and beverage industry to maintain hygiene and freshness, in the heating and cooling systems to optimize energy consumption and comfort, and in the water treatment and distribution to provide safe and clean water.

Fluoropolymer use in SA Control Valves and how they are essential to the function.

Steam and Thermal Solutions employes Fluoropolymers that are used in the construction of piston sealing rings due to their excellent heat resistance and low friction properties. These materials are crucial for maintaining the integrity and efficiency of the valve mechanisms. The piston sealing rings, made from fluoropolymers ensure a tight seal within the valve, preventing leakage and ensuring accurate control of steam, water, air, oil, and gases. This contributes to the robust design and precise control that are key features of Steam and Thermal Solutions Control Valves.

Non- Fluoropolymer Substitutes in SA Control Valves Components

Companies have been developing alternative non-fluoropolymers and metal-based solutions. However, these alternatives may not match the performance and safety of PFAS due to their unique properties. Additionally, the higher cost of non-fluorinated alternatives could limit their market adoption. Therefore, despite the existence and development of non-fluoropolymer alternatives, their use in applications such as piston sealing rings in control valves may face challenges related to performance, safety, and cost.

Gilflo Meters

Steam and Thermal Solutions Gilflo Meters are devices that measure the flow rate of steam, gas, or liquid in a pipe. These devices use a patented spring-loaded cone design that creates a differential pressure across the meter, which is proportional to the flow rate. Gilflo Meters are accurate, reliable, and easy to install and maintain.

Gilflo Meters are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Gilflo Meters can meter most industrial fluids, steams & gases. They ensure efficient running of the steam or liquid systems & reduce maintenance costs.

Fluoropolymer use in Gilflo Meters and how they are essential to the function.

Fluoropolymers are employed Gilflo meters for their unique properties, such as high temperature resistance, low friction, and excellent sealing capabilities, make it an ideal material for internal components. These materials ensure chemical as well as temperature resistance of Gilflo meters. It also contributes to the accuracy that is vital in various industrial applications where precise flow control and measurement are required.

Non- Fluoropolymer Substitutes in Gilflo Meters Components

Research into non-fluoropolymer substitution are becoming popular due to health and environmental concerns related to high fluorinated chemicals such as Fluoropolymer. However, they may not currently fully replicate or replace fluoropolymer’s unique properties, like its excellent sealing, heat and chemical inertness which are essential for applications like Gilflo meters. Despite their potential, these non-fluorinated alternatives are often more expensive, and some have been detected in the environment, potentially contributing to health risks. Therefore, more research is needed to ensure their safety and effectiveness across all applications.

EL Actuators

Electric (EL) Actuators are devices that convert electrical signals into mechanical movement. They are used to control the opening and closing of valves in steam systems, ensuring safety and optimal performance.

EL Actuators are crucial for Safety, and optimum operations.

Steam and Thermal Solutions EL Actuators regulate the flow of steam in different conditions and applications. They can handle high temperatures, pressures, and corrosive environments without compromising safety or efficiency. They also enable remote control and automation of valves, reducing manual labour and human error.

Fluoropolymer use in EL Actuators and how they are essential to the function.

Non- Fluoropolymer Substitutes in EL Actuators Components

In the construction of Steam and Thermal Solutions EL Actuators, PTFE (Polytetrafluoroethylene) and FKM (Fluoroelastomer) are employed in internal components including seals. Seal made of fluoropolymer such as PTFE, provides excellent chemical resistance and low friction properties, ensuring a tight seal and smooth operation, which are vital for the actuator's performance. Simultaneously, FKM is employed in O-rings, known for its high-temperature resistance and superior sealing capabilities, preventing leakage, and maintaining the actuator's integrity.

Air Vents

Air vents are designed to vent air from the system or to prevent wasting steam by venting air accurately.

Air Vents are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Air Vents are essential for efficient running of the steam or liquid systems. They improve operational efficiency and reduce maintenance costs. They avoid leaving air in the system or wasting steam by venting air accurately. Air Vents are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Fluoropolymer use in Air Vents and how they are essential to the function.

The use of fluoropolymer, mainly FKM, in O-rings is integral to the function of Steam and Thermal Solutions Air Vents. O-ring plays a crucial role in maintaining the integrity of the air vent, ensuring a tight seal, and preventing leaks. FKM makes O-ring resistant to a wide range of chemicals and temperatures, which is essential in steam systems where conditions can be harsh.

Non- Fluoropolymer Substitutes in Air Vents Components

Alternatives for Fluoropolymers are being explored due to environmental and health concerns associated with Fluoropolymers. However, they may not achieve the same performance and safety as Fluoropolymers chemicals, which are resistant to a wide range of chemicals and temperatures, essential in harsh conditions such as those in steam systems. Some non-fluoropolymer alternatives have been detected in the environment and may also pose health risks. Information on emerging fluoropolymer alternatives is often limited or lacking, and more studies are needed to better understand their effects. Therefore, while non-fluoropolymer alternatives are being developed, they may not yet match the performance and safety of Fluoropolymer chemicals in certain applications.

Hygienic Control Valves

Steam and Thermal Solutions Hygienic Control Valves are designed to regulate the flow of fluids in sanitary applications such as food, beverage, pharmaceutical, and biotechnology industries. Hygienic Control Valves ensure high levels of hygiene, accuracy, and reliability while minimizing contamination and energy loss.

Hygienic Control Valves are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Hygienic Control Valves are designed to meet the stringent requirements of hygienic processes. They are used in industries such as food and beverage, pharmaceuticals, and biotechnology where cleanliness and sterility are paramount. They help ensure product quality and safety.

Fluoropolymer use in Hygienic Control Valves and how they are essential to the function.

Fluorocarbon (FKM) and Polytetrafluoroethylene (PTFE) are vital to the functionality of Steam and Thermal Solutions Hygienic Control Valves. FKM, a fluoropolymer, is used in O-rings, Seal Washers, Body Seals, and Stem Seals. Its excellent resistance to media, ozone, and aging, stability in fuels, petroleum-based oils and greases, and aliphatic and aromatic hydrocarbons make it ideal for applications in the chemical and pharmaceutical industries with aggressive media and high process temperatures. PTFE, on the other hand, is used in Stem Bushes and Bearings in these valves, although specific references to its use in Steam and Thermal Solutions products were not found.

Non- Fluoropolymer Substitutes in Hygienic Control Valves Components

Steam and Thermal Solutions Hygienic Control Valves employ FKM and Polytetrafluoroethylene (PTFE), both types of Fluoropolymers, due to their unique properties such as excellent resistance to media, ozone, aging, and stability in various substances. These chemicals have unique desirable properties, such as stability under intense heat and the ability to repel water, oil, and stains, making them ideal for a wide range of applications, including those in the chemical and pharmaceutical industries. While non-fluoropolymer alternatives are being developed and show promise, currently they may not fully replicate the performance and safety of fluoropolymer chemicals in all applications.

TDS Blowdown

Steam and Thermal Solutions TDS Blowdown are devices that automatically remove excess dissolved solids from the boiler water, ensuring optimal boiler efficiency and preventing scale formation. They also help to prevent carryover of water and impurities into the steam, which can damage the equipment and affect the product quality. Devices are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

TDS Blowdown are crucial for Safety, and optimum operations.

Steam and Thermal Solutions TDS Blowdown Controls are used to control the level of Total Dissolved Solids (TDS) in the boiler water. High TDS levels can lead to damage and efficiency loss of the boiler and associated plant. Accurate blowdown methods are essential to maintain steam quality and system efficiency.

Fluoropolymer use in TDS Blowdown and how they are essential to the function.

TDS BlowDown system relies on the specific use of PFA, FKM, and PTFE in its components. PFA, or Perfluoroalkoxy alkanes, is used in Cable Insulation due to its excellent resistance to heat, electrical and chemical damage, and stress cracking. FKM, a type of synthetic rubber known as Fluoroelastomer, is used in Gasket Seals for its high resistance to heat, oil, and chemical exposure, which is crucial to withstand harsh operating conditions. PTFE, or Polytetrafluoroethylene, is used as seals. PTFE is known for its outstanding chemical resistance, wide temperature range, and low friction properties, making it an excellent choice for seals in solenoid valves and sensors, ensuring reliable operation even under the demanding conditions of a TDS BlowDown system.

Non- Fluoropolymer Substitutes in TDS Blowdown Components

Non-Fluoropolymer alternatives for PFA, FKM, and PTFE are being explored. These alternatives, that are currently not available, may not possess the same properties as Fluoropolymer chemicals, known for their excellent resistance to heat, electrical and chemical damage, and stress cracking. This could result in them not working as effectively or having a shorter lifespan for certain products. Despite these challenges, the development and use of non-fluoropolymer alternatives are crucial for environmental and health safety, necessitating further research to better understand the effects of emerging Fluoropolymer alternatives on humans and the environment.

Clean Steam Generators

Generates clean steam using demineralized water services and steam from standard boiler plant. Ultra compact clean steam generators are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Clean Steam Generators are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Clean Steam Generators provide high-quality clean steam, free from boiler chemicals. They are used in healthcare for sterilisation, ensuring the safety of medical instruments. They also help reduce the risk of wet packs during sterilisation.

Fluoropolymer use in Clean Steam Generators and how they are essential to the function.

PTFE (Polytetrafluoroethylene) plays a vital role in the efficient operation of Clean Steam Generators like those produced by Steam and Thermal Solutions. It is used in the gaskets and tubing of these generators, providing a reliable seal in feedwater lines which is crucial for their efficient functioning. PTFE's exceptional chemical resistance makes it suitable for handling demineralized water services, a key aspect of Clean Steam Generators' operation, and helps prevent contamination, ensuring the purity of the steam produced. Furthermore, PTFE maintains its integrity under high temperatures and pressures, conditions commonly found in steam generator tubes, ensuring the clean steam produced is not contaminated. Lastly, PTFE's non-stick properties, due to its low coefficient of friction, prevent adhesion and ensure smooth operation, which is vital for the efficient functioning of Clean Steam Generators.

Non- Fluoropolymer Substitutes in Clean Steam Generators Components

The exploration of non-fluoropolymer alternatives to PTFE is underway due to health and environmental concerns. These alternatives may not fully replicate PTFE's unique properties, such as exceptional chemical resistance, integrity under high temperatures and pressures, and non-stick properties, all of which are crucial for the operation of Clean Steam Generators. While the transition towards non-fluoropolymer alternatives is a positive step, it is essential to continue research and development to ensure these alternatives meet the necessary performance and safety standards for specific applications like Clean Steam Generators.

Vortex Meters

Steam and Thermal Solutions Vortex Meters measure the steam flow rate by detecting the frequency of vortices shed by a bluff body in the flow. They provide accurate, reliable, and cost-effective steam measurement for optimal energy efficiency and safety. Devices are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Vortex Meters are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Vortex Meters accurately measure and monitor the flow rate of electrically conductive liquids. They are used in various industries to improve energy efficiency and process accuracy.

Fluoropolymer use in Vortex Meters and how they are essential to the function.

Steam and Thermal Solutions Vortex Meters employ PTFE (Polytetrafluoroethylene) due to its unique properties. PTFE is known for its excellent chemical resistance, high-temperature stability, low friction, and superior sealing capabilities. These qualities make it an ideal material for various parts of the Vortex Meter, including the Packing Gland, Pressure Transducer Sealant, Body Cap Gasket, Cavity Filler, Seat, and Stem Seal. PTFE serves as an effective sealant, preventing leakage and ensuring the meter's accurate operation and prevent potential leaks that could affect the meter's functionality. When used as a Seat material, PTFE offers a durable and stable base, contributing to the meter's longevity.

Non- Fluoropolymer Substitutes in Vortex Meters Components

While PTFE's unique properties make it ideal for various parts of the Vortex Meter, rising health and environmental concerns over Fluoropolymers have led to a demand for alternatives. Several non-fluoropolymers alternatives are being developed. However, these alternatives may not fully match the performance and safety of PTFE, especially in harsh environments. Therefore, while PTFE-free materials are gaining popularity, they may not provide the same level of performance and safety in specific applications such as those found in Steam and Thermal Solutions Vortex Meters.

Other Boilerhouse

This Product Group contains devices including Water level gauges, which are devices that indicate the water level in a boiler or tank. They are essential for ensuring safe and efficient operation of boilers in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Other Boilerhouse are crucial for Safety, and optimum operations.

Steam and Thermal Solutions provides a range of boilerhouse products and systems that are essential for the safe and efficient operation of steam and hot water boilers These products contribute to plant safety, energy efficiency, and reliability.

Fluoropolymer use in Other Boilerhouse and how they are essential to the function.

The Steam and Thermal Solutions Water Level Gauge for Boilerhouses, crucial for monitoring liquid levels in tanks and process vessels, relies on the use of PTFE (Polytetrafluoroethylene) in its plastic tubes. PTFE's properties of high-temperature resistance, chemical inertness, and low friction make it ideal for the high-pressure, high-temperature environment of a boilerhouse. The gauge, which includes a tube available in both glass and PTFE plastic, is designed with packing seals and washers to prevent leakage. The PTFE tubes are essential as they can endure the boiler's high temperatures and pressures while offering a clear view of the water level.

Non- Fluoropolymer Substitutes in Other Boilerhouse Components

Non-fluoropolymer alternatives to PTFE are being explored for various applications due to their improved sustainability profiles. However, these alternatives may not fully replicate the unique properties of Fluoropolymers, such as extreme heat stability, chemical inertness, and low friction. In the context of the Steam and Thermal Solutions Water Level Gauge for Boilerhouses, the high-temperature resistance, chemical inertness, and low friction of PTFE are critical for enduring the boiler's high temperatures and pressures. Therefore, it is important to carefully evaluate the performance and safety of these alternatives in each specific use-case.

Quarter Turn & Rotary Control Valves

Quarter Turn & Rotary Control Valves are used to regulate the flow of steam, water, or other fluids in boiler systems. They offer precise and reliable control over a wide range of operating conditions, such as temperature, pressure, and flow rate. They also provide fast and easy operation, low maintenance, and high durability.

Quarter Turn & Rotary Control Valves are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Quarter Turn & Rotary Control Valves are used for diverting process media, facilitating maintenance, equipment removal, and shutdown. They provide a high degree of accuracy and repeatability for accurate temperature control.

Fluoropolymer use in Quarter Turn & Rotary Control Valves and how they are essential to the function.

The Steam and Thermal Solutions Quarter Turn & Rotary Control Valves use fluoropolymers such as PTFE and FKM. PTFE, or Polytetrafluoroethylene, is used in the seals due to its chemical resistance and low friction, ensuring a robust seal and smooth operation of the valve stem, which is crucial for preventing leakage and controlling flow precisely. FKM, or Fluoroelastomer, is used as O-rings. FKM's exceptional chemical, thermal, and oxidation resistance properties make it ideal for creating critical seals in various parts of the valve, preventing leakage, and ensuring effective operation under a wide range of conditions. In summary, PTFE and FKM are vital to the function, durability, reliability, and efficiency of these valves.

Non- Fluoropolymer Substitutes in Quarter Turn & Rotary Control Valves Components

Non-Fluoropolymer alternatives for PTFE and FKM are being explored in various industries. These alternatives, while promising, may not always achieve the same performance and safety as Fluoropolymer chemicals. The unique properties of PTFE and FKM, such as exceptional chemical, thermal, and oxidation resistance, low friction, and robust sealing capabilities, are vital to the function, durability, reliability, and efficiency of applications like the Quarter Turn & Rotary Control Valves from Steam and Thermal Solutions. Further development and testing may be required to ensure these non-fluoropolymer alternatives can match the performance of Fluoropolymer chemicals in all use-cases.

Electromagnetic Meters

Steam and Thermal Solutions Electromagnetic Meters are devices that measure the flow rate of conductive liquids, such as water, steam condensate, or chemical solutions. They work by applying a magnetic field to the liquid and measuring the voltage induced by the movement of the liquid through the field. Devices are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Electromagnetic Meters are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Electromagnetic Meters accurately measure and monitor the flow rate of electrically conductive liquids. They are used in various industries to improve energy efficiency and process accuracy.

Fluoropolymer use in Electromagnetic Meters and how they are essential to the function.

Steam and Thermal Solutions Electromagnetic Meters, which are designed to measure and monitor the flow rate of electrically conductive liquids such as impure water, pulps, and pastes, rely on the use of PTFE (Polytetrafluoroethylene) in their lining materials. The malleability of PTFE under pressure is a key characteristic that ensures the lining can withstand pressure changes within the meter without compromising its structural integrity. This not only contributes to the high performance of these meters but also enhances their reliability, making PTFE an indispensable component in the construction of these devices.

Non- Fluoropolymer Substitutes in Electromagnetic Meters Components

Steam and Thermal Solutions Electromagnetic Meters utilise PTFE (Polytetrafluoroethylene) for their lining materials, capitalising on its malleability under pressure for high performance and reliability. However, due to environmental and health concerns over Fluoropolymers such as PTFE, alternatives are being explored. Non-fluoropolymer is being developed but may not match the performance and safety of Fluoropolymer chemicals, particularly their heat stability. While these alternatives are environmentally safer, their adoption is challenging for industries reliant on Fluoropolymer unique properties.

Contamination

These products provide solutions to reduce the risk of product and process contamination. These systems detect changes in condensate conductivity and when a change occurs, a controller signals a dump valve to open, allowing the condensate to flow to drain.

Contamination is crucial for Safety, and optimum operations.

Steam and Thermal Solutions provides solutions to avoid food and drink contamination risk through steam. Unclean steam touching products risks contaminating them with rust, dirt, and chemical particles, making them unsafe for consumption. Steam and Thermal Solutions helps reduce potential food contamination risk in the process. These devices are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Fluoropolymer use in Contamination Air Vents and how they are essential to the function.

Steam and Thermal Solutions Contamination Control Systems employ Fluoroelastomer (FKM) gaskets. These gaskets are known for their resilience against aggressive fuels, chemicals, and a wide range of temperatures. This makes them particularly suitable for industries like oil and gas, and crucially, for contamination control systems. FKM gaskets help maintain system integrity by ensuring a tight seal and preventing leaks. Therefore, FKM's importance to Steam and Thermal Solutions Contamination Control Systems lies in its contribution to system reliability, safety, and integrity.

Non- Fluoropolymer Substitutes in Contamination Components

Non-Fluoropolymer alternatives to Fluoroelastomer (FKM) gaskets, polymer option for sealing applications, are emerging. However, these alternatives may not achieve the same performance and safety as Fluoropolymer chemicals, which are known for their water-resistant and non-stick properties. Furthermore, information on emerging Fluoropolymer alternatives is often limited or lacking, and more studies are needed to better understand their effects on humans and the environment.

Compressed Air Products

These products provide accurate monitoring and control of compressed air in a system. These products ensure air is delivered to the point of use at the right quantity and quality. They include a range of isolators, drain traps, and ancillaries specifically built for the robust application of compressed air. Devices are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Compressed Air Products are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Compressed Air Products ensure air is delivered to the point of use at the right quantity and quality. They include a range of isolators, drain traps, and ancillaries that prevent contamination, corrosion, and wastage of compressed air. They also ensure the pressure, temperature, and flow of the air are regulated and controlled according to the needs of the process. By using Steam and Thermal Solutions Compressed Air Products, customers can achieve safety, reliability, and efficiency in their compressed air systems.

Fluoropolymer use in Compressed Air Products and how they are essential to the function.

Steam and Thermal Solutions Compressed Air Products utilize seals made from PTFE (Polytetrafluoroethylene) in the design. The importance of PTFE in these seals lies in its unique properties. PTFE is known for its excellent chemical resistance which makes it suitable for use in a variety of environments. Furthermore, PTFE reduces friction which not only ensures a tight seal but also contributes to the longevity of the valve. This means that valves using PTFE seals can operate effectively, safely, and efficiently under various conditions for extended periods. Therefore, PTFE plays a crucial role in enhancing the performance and durability of Steam and Thermal Solutions Compressed Air Products.

Non- Fluoropolymer Substitutes in Compressed Air Products Components

Non-Fluoropolymer alternatives to PTFE are being developed. However, these alternatives may not currently fully replicate the unique combination of properties that PTFE offers, such as its exceptional chemical resistance, low friction, and longevity. Therefore, while non-fluoropolymer alternatives are promising, they may not achieve the exact performance and safety profile of chemicals like PTFE in all use-cases. It is important to note that the specific applications and performance can vary based on the product and its use within the compressed air systems of Steam and Thermal Solutions.

Sundries

A range of products are within this product group that collectively control the flow of media such as Steam, liquid in various applications. These devices are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Sundries are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Sundries products such as steam control products as well as packaging are crucial for safety and optimum operations because they allow precise and reliable control of the flow of media in various applications. They ensure that the pressure, temperature, and quality of the media are maintained at the desired levels, preventing leaks, damage, or contamination.

Fluoropolymer use in Sundries and how they are essential to the function.

PTFE and FKM are crucial to these products due to their unique properties. PTFE, used as seals, is known for its low friction, high-temperature resistance, and chemical inertness, ensuring smooth operation, preventing leaks, and enhancing overall performance and safety. FKM, used in O-rings, gaskets, is valued for its excellent resistance to high temperatures, oils, fuels, and other chemicals, making it ideal for components exposed to harsh conditions and requiring strong, durable seals. Together, these materials significantly contribute to the functionality and safety of these products.

Non- Fluoropolymer Substitutes in Sundries Components

In response to environmental and health concerns, alternatives to Fluoropolymer, including PTFE and FKM, are being explored. These alternatives, currently, may not match the performance and safety levels of Fluoropolymers, which are known for their excellent heat and chemical resistance, low friction, and strong, durable seals. These properties are crucial for the functionality and safety of these products Some novel alternatives have been found to have even longer half-lives in humans than PFOS and may also contribute to liver damage. Therefore, while the shift towards non-fluoropolymer alternatives is necessary, it presents challenges in terms of safety and performance.

Spiratrol

Steam and Thermal Solutions Spiratrol is a range of two-port control valves that regulate steam or water flow in various applications. They are designed to provide accurate and reliable control with minimal maintenance and low energy consumption. These devices are used in in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Spiratrol are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Spiratrol is a range of two-port self-acting temperature control valves, for steam applications. It is designed to be versatile and combine high flowrate capacity with wide rangeability and precise control.

Fluoropolymer use in Spiratrol and how they are essential to the function.

The Steam and Thermal Solutions Spiratrol is a two-port single seat globe valve that uses Polytetrafluoroethylene (PTFE) and Fluorocarbon (FKM) to enhance its safety, performance, and durability. PTFE, or Teflon, is used in the seals due to its heat, chemical, and electricity resistance, and its smoothness that reduces friction, ensuring smooth and reliable operation. FKM, or Viton, is used in the O-rings. Its high resistance to heat, oil, and chemical exposure makes it ideal for maintaining a tight seal, preventing leaks, and ensuring the valve's reliable operation, even under harsh conditions.

Non- Fluoropolymer Substitutes in Spiratrol Components

Non-Fluoropolymer alternatives are being explored for applications that currently use PTFE and FKM, such as the Steam and Thermal Solutions Spiratrol valve. These alternatives, including non-fluorinated polymers, aim to replace Fluoropolymer chemicals known for their heat stability and unique surfactant properties. However, these alternatives may not match the performance and safety levels of Fluoropolymer chemicals, particularly in terms of heat, chemical, and electrical resistance, and friction reduction. While the development of non-fluoropolymer alternatives is a step towards sustainability, it presents challenges in maintaining the performance and safety levels currently achieved with Fluoropolymer chemicals. Therefore, the transition to these alternatives needs careful consideration.

Boilerhouse Level Controls

Monitors boiler water levels safely and accurately. These controls monitor and maintain the water level in the boiler to ensure it stays constant at all loads. During periods of increased, sudden steam demand, the feedwater control valve open. These devices are used in in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Boilerhouse Level Controls are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Boilerhouse Level Controls are essential for the safe operation of steam boilers. They help meet the highly detailed and technical requirements surrounding the running of steam and pressure systems.

Fluoropolymer use in Boilerhouse Level Controls and how they are essential to the function.

In Steam and Thermal Solutions Boilerhouse Level Controls, PFA and PTFE are vital for functionality and safety. PFA, used as Insulation Sleeve, is known for its excellent heat and chemical resistance, providing insulation that protects the control system from high boiler temperatures, ensuring accurate readings and preventing damage. PTFE, used in Probe Sheathing, shares similar properties with PFA. It protects the probe from harsh boiler conditions, ensuring its longevity and reliability, which is crucial as the probe monitors and controls the boiler's water level.

Non- Fluoropolymer Substitutes in Boilerhouse Level Controls Components

Fluoropolymers, including PFA and PTFE, are commonly used in boilerhouse level controls due to their superior heat and chemical resistance. However, environmental and health concerns have prompted the search for alternatives. However, these alternatives may not be suitable for all applications, and their effectiveness can vary depending on the specific use-case. Moreover, non-fluoropolymer alternatives are often more expensive, which can limit their market uptake. Therefore, while non-Fluoropolymer alternatives exist, their adoption requires careful consideration of their performance, safety, cost, and environmental impact.

Mechanical Pump Packages

Steam and Thermal Solutions mechanical pump package are steam solutions that use the pressure of steam to create a vacuum and draw condensate from a steam system. The products can handle high temperatures and pressures, as well as corrosive or contaminated condensate. These Pumps are used in in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Mechanical Pump Packages are crucial for Safety, and optimum operations.

These pumps are designed to remove and recover condensate, using steam as their motive power. This helps to reduce maintenance costs and increase the efficiency of steam systems. These devices are used in in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Fluoropolymer use in Mechanical Pump Packages and how they are essential to the function.

PTFE (Polytetrafluoroethylene), a Fluoropolymer, is integral to the operation and safety of Steam and Thermal Solutions Mechanical Pumps. It is used in bushes and seals due to its unique properties like high heat resistance, low chemical reactivity, and electrical conductivity. In bushes, PTFE acts as an excellent lubricant, reducing friction and wear, which improves the pump's efficiency and longevity. Additionally, PTFE creates a secure seal, preventing fluid backflow and leakage, which is vital for the pump's performance and safety.

Non- Fluoropolymer Substitutes in Mechanical Pump Packages Components

In the context of Steam and Thermal Solutions Mechanical Pumps, the transition from Fluoropolymer chemicals like PTFE to non-fluoropolymer alternatives is a complex process. PTFE's unique combination of high heat resistance, low chemical reactivity, and electrical conductivity makes it an excellent lubricant and sealing material. Non-Fluoropolymer alternatives may mimic some of these properties but may not fully replicate them. While it is crucial to move towards more environmentally friendly options, it is equally important to ensure that these alternatives meet the necessary performance and safety standards. This transition also involves considering factors such as cost, availability, and regulatory compliance.

Isolation Valves Other

The product group contains valves that controls the flow of steam or condensate in a piping system. It allows for shutting off, diverting, or regulating the flow as needed. Isolation valves are essential for safety, maintenance, and optimal operations. Devices are used in in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Isolation Valves Other are crucial for Safety, and optimum operations.

These are essential for diverting flow or shutting down the system for safe maintenance of equipment. They also play a crucial role in maintaining plant safety and saving energy by eliminating stem seal leaks.

Fluoropolymer use in Isolation Valves Other and how they are essential to the function.

Steam and Thermal Solutions Isolation Valves utilize PTFE (Polytetrafluoroethylene) and FKM (Fluoroelastomer) as key components to enhance their functionality and safety. PTFE, used as seals, offers excellent sealing capabilities, providing a high level of shut-off tightness that ensures effective isolation of system sections when needed. On the other hand, FKM is employed in O-rings. These fluoropolymers can enhance shut-off under permissible system conditions, which is crucial for maintaining system integrity and preventing unwanted leaks.

Non- Fluoropolymer Substitutes in Isolation Valves Other Components

Steam and Thermal Solutions Isolation Valves currently utilize PTFE and FKM, both types of Fluoropolymers, to enhance their performance and safety. The development of non-fluoropolymer alternatives is underway, but these may not match the performance and safety levels of fluoropolymers. The strong carbon-fluorine bonds in fluoropolymers provide stability under high heat and resistance to degradation, making them ideal for applications requiring durability and heat resistance. Non-fluoropolymer alternatives may lack these properties, potentially impacting their performance. Transitioning to non-fluoropolymer alternatives also requires significant research and development, and their performance in real-world applications is yet to be fully understood. Therefore, while promising, non-fluoropolymer alternatives may not fully replicate the performance and safety characteristics of fluoropolymer chemicals in all use-cases.

Disc Check Valves

Steam and Thermal Solutions Disc Check valves are designed to prevent reverse flow of fluids in pipelines. They use a spring-loaded disc that opens when the flow is in one direction and closes when the flow is reversed. They are compact, lightweight, and reliable. Disc Check valves are used in in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Disc Check Valves are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Disc Check Valves prevent reverse flow in pipelines, contributing to the stability and efficiency of the system. They are particularly important in healthcare facilities, where they ensure the safe running of critical plant equipment.

Fluoropolymer use in Disc Check Valves and how they are essential to the function.

Fluoroelastomer (FKM) seals, play a crucial role in the operation and safety of Disc Check Valves. They are designed to endure high temperatures and pressures, preventing leakage, and ensuring the valve's effective and safe operation. The importance of FKM lies in its ability to withstand harsh conditions while maintaining the valve's performance and safety.

Non- Fluoropolymer Substitutes in Disc Check Valves Components

Non-Fluoropolymer alternatives to Fluoroelastomer (FKM) seals are emerging, offering customizable properties and potentially lower costs. However, these alternatives may not match the performance and safety of Fluoropolymer chemicals. Some of these alternatives have been detected in the environment, raising potential health concerns. Transitioning from Fluoropolymer to non-fluoropolymer alternatives can present technical challenges. Further investigation is needed to assess their performance, safety, and environmental impact.

Mechanical Pumps

Steam and Thermal Solutions Mechanical pump uses steam pressure to move condensate or other liquids through pipes. It has no moving parts and operates silently and reliably. It can handle high temperatures and pressures and reduce energy consumption. These pumps are used in in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Mechanical Pumps are crucial for Safety, and optimum operations.

These pumps are designed to remove and recover condensate, using steam as their motive power. This helps to reduce maintenance costs and increase the efficiency of steam systems.

Fluoropolymer use in Mechanical Pumps and how they are essential to the function.

PTFE (Polytetrafluoroethylene), a Fluoropolymer type, is integral to the operation and safety of Steam and Thermal Solutions Mechanical Pumps. It is used in bushes and seals due to its unique properties like high heat resistance, low chemical reactivity, and electrical conductivity. In bushes, PTFE acts as an excellent lubricant, reducing friction and wear, which improves the pump's efficiency and longevity. Additionally, PTFE creates a secure seal, preventing fluid backflow and leakage, which is vital for the pump's performance and safety.

Non- Fluoropolymer Substitutes in Mechanical Pumps Components

In the context of Steam and Thermal Solutions Mechanical Pumps, the transition from Fluoropolymer chemicals like PTFE to non-fluoropolymer alternatives is a complex process. PTFE's unique combination of high heat resistance, low chemical reactivity, and electrical conductivity makes it an excellent lubricant and sealing material. Non- fluoropolymer alternatives may mimic some of these properties but may not fully replicate them. While it is crucial to move towards more environmentally friendly options, it is equally important to ensure that these alternatives meet the necessary performance and safety standards.

Bimetallic Traps

Steam and Thermal Solutions Bimetallic Traps are devices that drain condensate from steam systems. They use two metal strips with different thermal expansion rates to open and close a valve according to the temperature of the condensate. This prevents steam loss and ensures efficient heat transfer. Traps are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Bimetallic Traps are crucial for Safety, and optimum operations.

Bimetallic steam traps can conserve energy by discharging sub-cooled condensate in applications that utilize sensible heat. They are robust and can withstand water hammer and corrosive condensate.

Fluoropolymer use in Bimetallic Traps and how they are essential to the function.

The devices’ robustness and reliability are attributed to use of Polytetrafluoroethylene (PTFE) in their seals. PTFE, with its low friction coefficient, high chemical resistance, and durability against a range of chemicals, is particularly beneficial in applications where seals must function in harsh or corrosive environments. Thus, PTFE plays a crucial role in the function and safety of these traps.

Non- Fluoropolymer Substitutes in Bimetallic Traps Components

Alternatives to Polytetrafluoroethylene (PTFE), a type of Fluoropolymer, have been developed due to concerns about PFAS's environmental and health impacts. However, these alternatives may not fully replicate the performance and safety of fluoropolymer chemicals, especially in applications where seals must function in harsh or corrosive environments. While these alternatives may offer similar properties, they might not provide the same level of robustness and reliability. Transitioning to these alternatives requires careful consideration of their environmental and health impacts, as well as regulatory requirements. Therefore, while non-fluoropolymer alternatives are available and continue to be developed, their adoption should be evaluated on a case-by-case basis.

Flash Vessels

Steam and Thermal Solutions Flash vessels are devices that separate the flash steam from the condensate in a steam system. They reduce the pressure and temperature of the condensate, allowing it to be reused or drained safely. Flash vessels also recover the flash steam, which can be used for heating or power generation. Devices efficiently prevent contamination of the boiler feedtank and / or heat transfer surfaces in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Flash Vessels are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Flash vessels are used to separate flash steam from hot condensate, which is essential to prevent contamination of the boiler feedtank and/or heat transfer surfaces. They also play a role in energy conservation.

Fluoropolymer use in Flash Vessels and how they are essential to the function.

Fluoroelastomer (FKM), a synthetic rubber, is crucial in Steam and Thermal Solutions Flash Vessels due to its remarkable resistance to heat, oils, and chemicals. FKM is used for O-rings these vessels, enhancing their durability and longevity. By withstanding high temperatures and pressures within the flash vessels, FKM contributes to the system's safety and efficiency, reducing the risk of leaks or failures that could lead to hazardous situations.

Non- Fluoropolymer Substitutes in Flash Vessels Components

FKM, a type of fluoropolymer, is crucial in applications like Steam and Thermal Solutions Flash Vessels due to its exceptional resistance to heat, oils, and chemicals. There are ongoing efforts to find non-fluoropolymer alternatives. However, these alternatives may not always achieve the same performance and safety as fluoropolymer chemicals. Some novel alternatives have been detected in the environment with potential health risks identified. Therefore, while non-fluoropolymer alternatives are being developed and show promise, they may not fully match the performance, safety, and cost-effectiveness of PFAS chemicals like FKM. Further research and development are needed to improve these alternatives and ensure their safety and effectiveness.

Blowdown Vessels & Heat Recovery

Steam and Thermal Solutions Blowdown Vessels & Heat Recovery products are devices that safely discharge the hot water and steam from boilers and capture the waste heat for reuse. They reduce energy consumption, lower emissions, and prevent boiler damage. Fluoropolymers are essential for their durability and corrosion resistance. Products are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Blowdown Vessels & Heat Recovery are crucial for Safety, and optimum operations.

Steam and Thermal Solutions Blowdown vessels accommodate blowdown water from the boiler, helping to meet health, safety, and environmental regulations. Heat recovery from boiler blowdown can reclaim large amounts of energy, reducing the need for boiler fuel.

Fluoropolymer use in Blowdown Vessels & Heat Recovery and how they are essential to the function.

PTFE (Polytetrafluoroethylene) plays a vital role in the functioning of Steam and Thermal Solutions Blowdown Vessels & Heat Recovery Systems, specifically in the seals. Its unique characteristics, including resistance to high temperatures, low friction, and superior sealing capabilities, make it a significant technology in these systems. The incorporation of PTFE contributes to the safe and efficient operation of these vessels and systems, even in extreme conditions.

Non- Fluoropolymer Substitutes in Blowdown Vessels & Heat Recovery Components

PTFE, a type of Fluoropolymer, is essential in many industrial applications, including blowdown vessels and heat recovery systems, due to its unique properties. However, environmental and health concerns have led to a demand for non-Fluoropolymer alternatives. Despite their promise, these alternatives may not always match the performance and safety of Fluoropolymer chemicals. More research is needed to understand their effects. Steam and Thermal Solutions is committed to exploring these non-Fluoropolymer alternatives for their products.

Separators

Steam and Thermal Solutions Separators remove condensate, dirt, and scale from steam lines, increasing the quality and efficiency of the steam. They also protect downstream equipment from corrosion and damage, reducing maintenance costs and downtime. Steam and Thermal Solutions Separators use Fluoropolymer coatings to resist erosion and abrasion. Separators are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Separators are crucial for Safety, and optimum operations.

Separators gather small water droplets from steam and separate them from the pipe flow. This reduces wet steam, maintains heat transfer efficiency, and reduces erosion and corrosion in the steam system.

Fluoropolymer use in Separators and how they are essential to the function.

Steam and Thermal Solutions Separators, which are engineered to collect small water droplets from steam and isolate them from the pipe flow, play a vital role in reducing wet steam, preserving heat transfer efficiency, and mitigating erosion and corrosion in the steam system. The incorporation of PTFE (Polytetrafluoroethylene), a type of Fluoropolymer known for its superior frictional properties, chemical resistance, and wide operational temperature range, is particularly significant. PTFE is commonly used in bushes within these separators, where it provides a low-friction, chemically resistant interface that ensures the smooth and dependable operation of the separator components, thereby enhancing the system's efficiency and safety.

Non- Fluoropolymer Substitutes in Separators Components

Steam and Thermal Solutions Separators currently use PTFE, a type of Fluoropolymer, due to its superior properties that ensure smooth and dependable operation. However, due to the environmental concerns associated with Fluoropolymer (a class of PFAS), known as "forever chemicals", there is an ongoing effort to find non-Fluoropolymer alternatives. These alternatives, while being developed and used, may not match the performance and safety levels of Fluoropolymer. The transition to non-Fluoropolymer alternatives is also complex, therefore, while the exploration and implementation of non-Fluoropolymer alternatives continue, matching the performance and safety of Fluoropolymer remains a challenge.

QL Series

QL Series is a range of 3-port control valves from Steam and Thermal Solutions. These valves are designed to regulate the flow of steam or water in various applications. QL Series are crucial for Safety, and optimum operations. They are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

QL Series are crucial for Safety, and optimum operations.

QL Series valves are designed to regulate the flow of steam or water in various applications, ensuring the safety and efficiency of the systems they are used in. Steam and Thermal Solutions, the manufacturer of QL Series valves, is committed to ensuring the safety and sustainability of its products and operations, as well as complying with relevant regulations and standards in the markets where it operates.

Fluoropolymer use in QL Series and how they are essential to the function.

The Steam and Thermal Solutions QL Series, a range of three-port control valves, relies on PTFE (Polytetrafluoroethylene) for its lining materials. PTFE is renowned for its superior chemical resistance, making it an optimal choice for control valves that encounter diverse media types. A key application of PTFE in these valves is the PTFE seal, which guarantees a secure closure, thereby preventing leaks and promoting the valve's safe and efficient functioning.

Non- Fluoropolymer Substitutes in QL Series Components

The Steam and Thermal Solutions QL Series of control valves traditionally use PTFE, a type of Fluoropolymer, for their lining materials due to its superior chemical resistance. However, due to environmental and health concerns related to Fluoropolymer, non-Fluoropolymer alternatives are being explored. However, these alternatives may not fully replicate the unique properties of Fluoropolymer chemicals, potentially impacting the performance and safety of applications such as the Steam and Thermal Solutions QL Series control valves.

Controls Packages

Steam and Thermal Solutions Control Packages are devices that regulate the flow, pressure, and temperature of steam in various applications. They are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Controls Packages are crucial for Safety, and optimum operations.

Controls are essential for maintaining safety, stability, and accuracy in steam systems. They help meet detailed and technical requirements surrounding the running of steam and pressure systems.

Fluoropolymer use in Controls Packages and how they are essential to the function.

Steam and Thermal Solutions Control Packages rely on Polytetrafluoroethylene (PTFE) for their guide bushes. PTFE's low friction, high-temperature resistance, and chemical inertness ensure smooth and consistent movement of the control valve stem, thereby enhancing the control package's accuracy and reliability. Furthermore, PTFE's chemical resistance safeguards the control packages from corrosion and wear, even in harsh industrial environments, thus extending their lifespan and reducing the need for frequent maintenance or replacement.

Non- Fluoropolymer Substitutes in Controls Packages Components

Steam and Thermal Solutions Control Packages utilize Polytetrafluoroethylene (PTFE) for its low friction, high-temperature resistance, and chemical inertness, which enhance the control valve stem's movement, accuracy, and reliability. PTFE's chemical resistance also extends the lifespan of the control packages and reduces maintenance needs by protecting them from corrosion and wear in harsh industrial environments. Non-Fluoropolymer alternatives aim to offer similar performance to PTFE, with some even demonstrating equal or improved performance in specific applications. Despite these advancements, non-Fluoropolymer alternatives may not always match the performance and safety characteristics of Fluoropolymer chemicals like PTFE in all use-cases.

Feedtank Ancillaries

Steam and Thermal Solutions Control Feedtank ancillaries in the context of Steam and Thermal Solutions refer to a range of additional equipment and components that support the operation of the feedtank in a steam system. These components work together to ensure the feedwater is in the best possible condition before it enters the boiler, improving the efficiency and longevity of the steam system. They are used in application such as clean steam, gas, and liquid supplies to centrifuges, freeze dryers, sterilisers, autoclaves, process tanks, humidifiers, and culinary equipment.

Feedtank Ancillaries are crucial for Safety, and optimum operations.

By ensuring the feedwater is in the best possible condition before it enters the boiler, Steam and Thermal Solutions Control Feedtank Ancillaries improve the efficiency and longevity of the steam system. They also help to prevent issues that could compromise safety, such as corrosion and equipment failure. Therefore, they are an essential part of maintaining a safe and optimally functioning steam system.

Fluoropolymer use in Feedtank Ancillaries and how they are essential to the function.

Feedtanks utilize Polytetrafluoroethylene (PTFE), a Fluoropolymer, is integral to the function and safety of Steam and Thermal Solutions Feedtank ancillaries. It is used in the plastic tubes, seals of feedtanks, which are critical components in the boiler house, serving as the junction for cold make-up water and condensate return. The use of PTFE ensures the durability and reliability of these systems, thereby enhancing their overall efficiency and safety.

Non- Fluoropolymer Substitutes in Feedtank Ancillaries Components

Alternatives may not match the performance and safety of Fluoropolymer chemicals. Non-fluorinated alternatives are not comparable to the performance of Fluoropolymer in terms of operating temperature, lubrication properties. The adoption of non-fluoropolymer alternatives is challenged by factors like performance, safety, and potential health risks.

ANIMAL HEALTH INSTITUTE
Representing manufacturers of animal health products

March 1, 2024

Animal Health Institute (AHI) Response to Request for Comments on: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Thank you for the opportunity to provide feedback to the Minnesota Pollution Control Agency (MPCA) on its planned new rules governing currently unavoidable use products. AHI is the U.S. trade association for research-based manufacturers of animal health products – the medicines that keep pets and livestock healthy. While some PFAS chemistries are known to be harmful, the active ingredients in animal health products are just the opposite: they have gone through federally required, rigorous safety testing before reaching the market, including evaluating the safety effects on the animal, humans, and the environment.

AHI members develop, manufacture, and distribute a range of animal health products, including pharmaceuticals, biologics (including vaccines), flea and tick preventatives, and medical devices (including diagnostics), to veterinarians, pet owners, and food animal livestock owners. PFAS, when broadly defined as a class of fluorinated organic chemicals containing at least one fully fluorinated carbon atom, can include the active ingredient in oral flea and tick medications, anesthetics used for routine as well as complex surgery, anti-inflammatory drugs, federally regulated packaging components of biologics and medical devices, as well as the active ingredients in topical flea and tick products and collars.

The broad definition of PFAS used in the Minnesota law encompasses both large-volume industrial uses as well as many much smaller and beneficial uses. It encompasses thousands of chemical substances that are not homogeneous. Large industrial, well-characterized chemicals that clearly pose human health threats should not be treated or regulated the same as small use chemicals whose properties are different, including the rates of degradation. While these small use compounds match the criteria set by the OECD for PFAS, they are not technically considered polyfluorinated or perfluorinated (they mostly have only one or a few terminal fluorinated methyl groups added to a much larger molecule) and do not fall under the criteria of concern in a technical sense as outlined by the competent authorities proposing to regulate PFAS.

There is a need for definition and clarity around the term "essential for health, safety or the functioning of society," whether that be specific criteria or more general guidance. The challenge for the MPCA will be crafting criteria/guidance that applies evenly and consistently to a broad range of uses and industries and that is flexible enough to accommodate these differences.

The MPCA poses several questions regarding alternatives to PFAS. In the animal health industry, there are several factors that come into play when discussing potential alternatives. As an overarching feature, however, it should be noted that the animal health products in view here are all strictly regulated by federal agencies, including the specific composition of the product, the way the product is manufactured and the labelling of the product. To the extent PFAS is used in any of these phases, it is the result of these chemistries being uniquely able to meet federal requirements regarding the product, its manufacturing and distribution. Thus, when contemplating alternatives manufacturers must consider the requirements imposed by these federal regulatory agencies.

MPCA asks discrete questions about the cost and safety aspect of alternatives. Alternatives should be evaluated on a cost/benefit basis. In theory it is possible to impose a de facto ban by requiring cost-prohibitive alternatives.

It is likely the threshold costs will vary considerably among industries and products. Under the federal regulations governing veterinary medicines and other animal health products (and unlike for the industrial chemicals), evaluation of their safety is a solid pillar of the approval process and this includes a.o. demonstration of safety for the user, the target animal species to be treated, and the environment ***before*** these products can enter the market.

In view of specific species, breed and individual animal sensitivities to medication, veterinarians need a wide range of products to treat a given condition or disease, but this is usually not the case in practice and treatment options may be limited. Finding suitable alternatives for active ingredients qualifying as PFAS under the definition is not an easy task.

The length of time for a CUU determination for a regulated health product, either animal or human, likely needs to be measured in decades, at least 20 years. There are no alternatives currently in sight for many of these veterinary uses. The known timescale for transitioning to alternatives in the animal pharmaceuticals space in general is lengthy, as basic research must be followed by generation of data to support the change, followed by regulatory approval from the governing federal agency.

For substances used in manufacturing equipment, in general, alternatives should be shown to quantitatively reduce risk. This will be complicated since each of the PFAS chemicals have a different risk profile and most have not even been characterized. However, the vast majority of those used for animal health products are fluoropolymers, which are considered to be of low concern by the OECD.[1]

A further complication for veterinary medicines is the information on the feasibility of alternatives can be very use-specific and regarded as business confidential. This makes screening and assessing the availability of alternatives a challenge. Over-reliance on publicly available information and little knowledge of the exact function of the substance, could mean that the conclusion "alternative = available" is too easily drawn. Any information on alternatives, in particular when provided by third parties other than manufacturer or downstream user, should be carefully assessed before being accepted and made available. The third party could be providing inaccurate information which fails to consider sectoral specific aspects such as performance and competitiveness. Making regulatory decisions on the assumption that alternatives exist, where this assumption is based on incorrect or incomplete information, risks leading to undesirable policy outcomes.

We believe the following groups of veterinary products should receive the CUU designation. Further, these designations should be made in the rulemaking, based on the most basic criteria that these are subject to rigorous federal regulatory oversight. These products are subject to a strict regulatory framework that requires data be submitted to the federal agency demonstrating consumer safety, user safety, target animal safety, proper manufacturing as well as environmental safety. Only products that meet all the requirements and demonstrate a positive benefit are allowed to be marketed. These federal regulatory frameworks that have considered the risks should not be overruled by the assessment of a broad grouping of chemicals where thousands of chemicals with vastly different risk profiles are treated homogenously.

Products to be designated CUU:

a. Any veterinary product intended for use in or on animals including diagnostic equipment or test kits and their components, or any product that is a veterinary medical device or a drug, biologic or parasiticide, or that is otherwise used in a veterinary medical setting or in veterinary medical

[1] Polymers of Low Concern - OECD

1325 G Street, NW ■ Suite 700 ■ Washington, D.C. 20005-3104

www.ahi.org

applications that are regulated by, or are under the jurisdiction of, the United States Food and Drug Administration pursuant to the Federal Food, Drug, and Cosmetic Act, 21 U.S.C. §§ 301 et seq., the United States Department of Agriculture pursuant to the Federal Virus-Serum-Toxin Act, 21 U.S.C. §§ 151-159, or the United States Environmental Protection Agency pursuant to the Federal Insecticide, Fungicide, and Rodenticide Act, 7 U.S.C. §§ 136 et seq. and all raw materials, intermediates, active pharmaceutical ingredients (APIs), and reagents in the broad sense required to synthesize and manufacture such veterinary products.

b. Manufacturing equipment for any veterinary product described in (a) that contains PFAS chemicals. Included in this category would be gaskets, O-rings, filters, membranes, tubes, inner layers of chemical reactors, primary packaging materials, tubes in analytical equipment or tape used to build inert laboratory scale equipment.

In conclusion, any veterinary medicine or product federally regulated to restore or protect the health and welfare of animals and the processes used to produce that medicine or product and control its quality should be considered as essential for health, safety, and the functioning of society for which alternatives are not reasonably available and therefore considered a currently unavoidable use. This designation should include the entire manufacturing process and not only the final product. We therefore respectfully request the Agency take this into account when publishing the rule.

Should you have questions regarding these comments please contact Ron Phillips, Senior Vice President, Policy, rphillips@ahi.org.

Industry PFAS CUU Project

PFAS Currently Unavoidable Uses Proposals (CUU)
Fifty-three (53) Proposals

Submission by Industry

This document is the guidance document to fifty-three (53) PFAS Currently Unavoidable Uses proposals being submitted by industry. Each CUU proposal is separate, but listed together in an orderly fashion for clarity and the convenience of regulators. Most of the proposals are for widespread uses of PFAS. These uses span across all industry segments and were included together. If required, they can be separated, but they would create between 300 and 400 separate proposals for regulators to review (for the 53 fundamental uses).

The Industry PFAS CUU project is made up of >50 companies that span consumer, professional, medical, industrial, and laboratory uses of PFAS. The CUUs listed here are based on very detailed work by each member of the project combined with tens of thousands of parts tested by Claigan Environmental in 2023 and 2024.

This submission should be the most comprehensive list of Currently Unavoidable Uses in physical products (articles), with detailed justifications and comparisons of alternatives.

The full CUU proposals and justifications are listed in detail in the accompanying spreadsheet PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx.

Claigan Environmental Inc.

Table of Contents

1. Summary

This report is a submission by Claigan Environmental Inc. (Claigan) on behalf of the Industry PFAS Submission Project ("PFAS Submission Project"). The PFAS submission project is made up of 50+ companies from a wide range of industries (consumer, professional, industrial, medical, oil and gas, laboratory equipment, textiles, electronic components, and retail sales.)

The PFAS Submission Project is focused primarily on the needs of complex products (articles). Claigan is both a restricted materials consultancy and a high-volume restricted materials testing laboratory. Each of the PFAS Submission Project submissions are based on contributions from all major sectors of industry, and 2023 and 2024 PFAS testing data from tens of thousands of parts.

The detailed justification of each CUU is covered in the accompanying spreadsheet PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx.

Each CUU entry includes

- A brief description of the Currently Unavoidable Use of PFAS
- A brief description of the type of product including industries and example products with HTS codes.
- A description of the intended use of the product and explanations on how it is essential for health, safety, or the functioning of society.
- A description of how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, citations will be provided for that requirement.
- A description of whether there are reasonably available alternatives for this specific use of PFAS.
- Plus
    - Whether the PFAS use includes PFOA or Long Chain Perfluoroalkyl Carboxylic Acids (LC-PFCA). Many of these PFAS uses do not include (nor degrade into) any PFAS found in drinking water and humans.

- PFOA / LC-PFCA presence is based on tens of thousands of parts tested in 2023 and 2024.

Important note 1 - due to the short timeline for the PFAS Currently Unavoidable Use consultation, each justification is only in brief with a detailed comparison of alternatives. Each justification can be further elaborated upon if needed.

Important note 2 - the regulation of chemical substances in medical devices is governed by the FDA. It is generally assumed that this preempts restrictions of PFAS in medical devices under state regulation, “A product for which federal law governs the presence of PFAS in the product in a manner that preempts state authority”. However, for completeness and until this question is fully solved, currently unavoidable uses of PFAS in medical devices are also included in this submission.

Important note 3 - The States of Maine and Minnesota adopted a broad definition for PFAS substances. The vast majority of PFAS substances, as defined by Maine and Minnesota, that are found in products are not found in the environment. The broad definition impacts PFAS use in multiple categories of products and equipment needed to make products. PFAS substances are used in these applications because they have unique properties that impart specific performance characteristics making them essential to a product’s function. The accompanying spreadsheet provides a detailed comparison of fluoropolymer, fluoroelastomer, and alternative materials for each application. The reason for the use of the fluoropolymer or fluoroelastomer is generally fairly obvious when you look at the application and the alternatives.

2. Related documents

2.1. PFAS Currently Unavoidable Uses Proposals spreadsheet - Industry PFAS Submission Project

2.1.1. PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx

3. Definitions

3.1. ***Currently Unavoidable Use of PFAS (CUU)*** - a use of PFAS that is essential for the health, safety, or functioning of society and for which alternatives are not reasonably available.

3.2. ***Widespread Use*** -

3.2.1. For essential uses of a PFAS-containing product, uses that are very high volume with widespread use are identified.

3.2.1.1. For example - fluoroelastomers and perfluoroelastomers have very widespread use in professional/industrial products (> 10M products per year sold in the US).

3.2.2. **For consumer uses** - Over 100 Million products sold in the US each year use this Currently Unavoidable Use of PFAS, or

3.2.3. **For industrial uses (including professional uses)** - Over 10 Million products sold in the US each year use this Currently Unavoidable Use of PFAS.

3.3. ***Forever chemicals***

3.3.1. *Substances that are either*

3.3.1.1. ***vPvB*** - Very persistent and very bioaccumulative

3.3.1.2. ***PBT*** - Persistent, bioaccumulative, and toxic

3.4. ***Machinery***

3.4.1. *Machinery includes all aspects of machinery including (but not limited to) manufacturing, construction, clean energy, water treatment, and forestry*

3.5. ***Laboratory***

3.5.1. *Laboratory includes all aspects of laboratory equipment including (but not limited to) water testing, life sciences, research and development, and medical testing.*

4. Key notes

4.1. Importance of PFAS

4.1.1. > 500 million products containing PFAS are sold in the US each year

4.1.2. Banning PFAS would eliminate

4.1.2.1. Laptops

4.1.2.2. The internet (unless servers are moved offshore)

4.1.2.3. Food processing

4.1.2.4. Water processing and treatment

4.1.2.5. Forestry

4.1.2.6. Life sciences

4.1.2.7. Oil and gas industry

4.1.2.8. Heart surgeries and biopsies

4.1.3. Banning PFAS without exception for Currently Unavoidable Uses would likely create the largest recession in the history of the United States.

4.2. Sources PFOA / LC-PFCA in Products

4.2.1. Most fluoropolymers and virtually all fluoroelastomers do not contain PFOA or LC-PFCA

4.2.2. The follow sections are based on 2022 - 2024 testing of products for PFOA / LC-PFCA and include explanation of how these substances are formed in very specific situations.

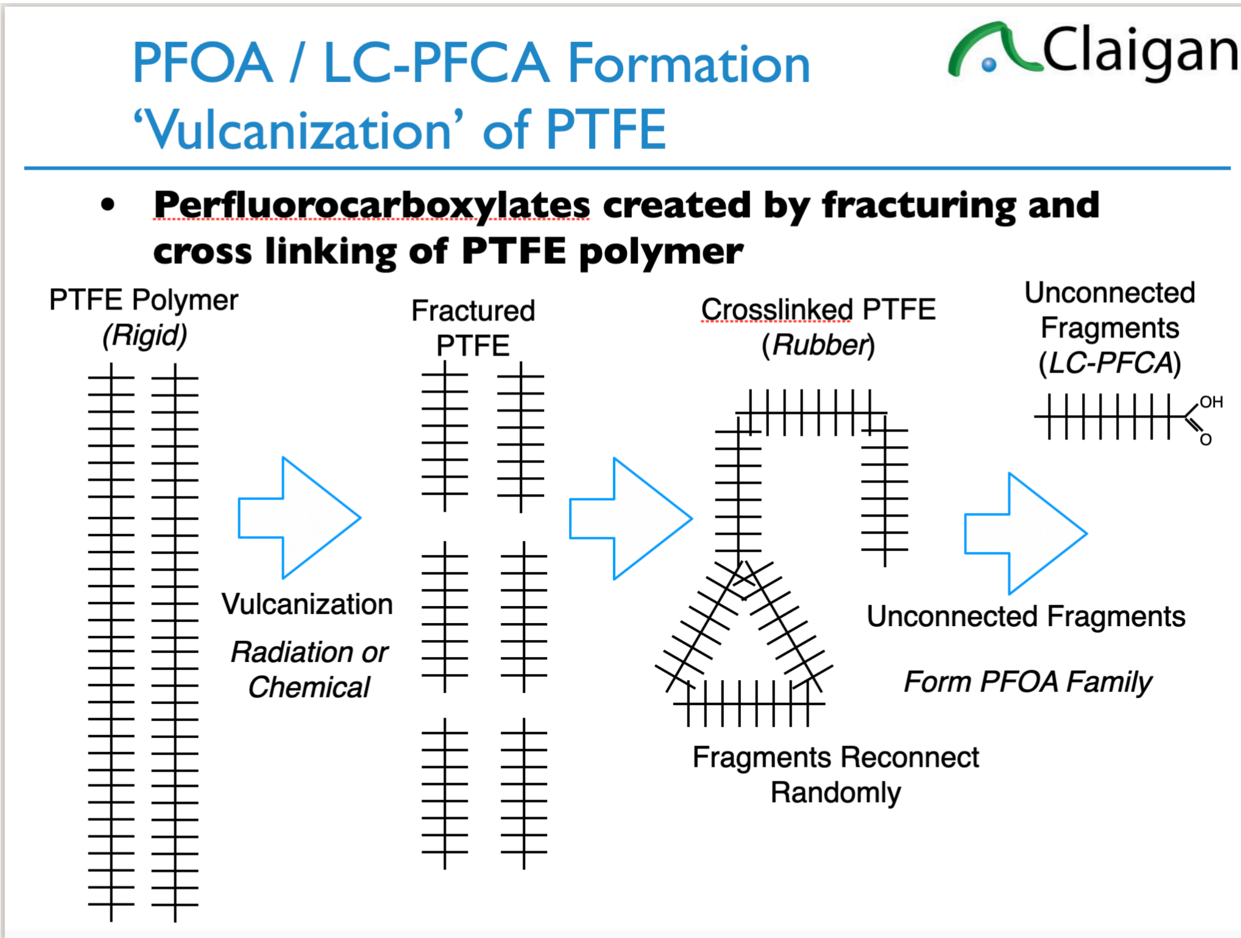
4.2.3. **Cause #1** of unintentional PFOA / LC-PFCA - Formation of LC-PFCA during vulcanization of rigid PTFE (or PVDF) into cross-linked rubber

4.2.3.1. Vulcanization / crosslinking of PTFE involves

4.2.3.1.1. Fracturing of long rigid PTFE polymer through radiation or chemical means

4.2.3.1.2. Reconnecting of fragments of PTFE in random directions (creating rubber instead of rigid polymer)

4.2.3.1.3. Some fragments react instead with air and create random sizes of perfluorocarboxylates.



4.3. **Cause #2** of unintentional PFOA / LC-PFCA - PFAS polymers (such as PFA or fluoroacrylates) that have a fluoromonomer side chain with a fragile C-O-C (carbon-oxygen-carbon) bond.

4.3.1. Formation of perflluorocarboxylates

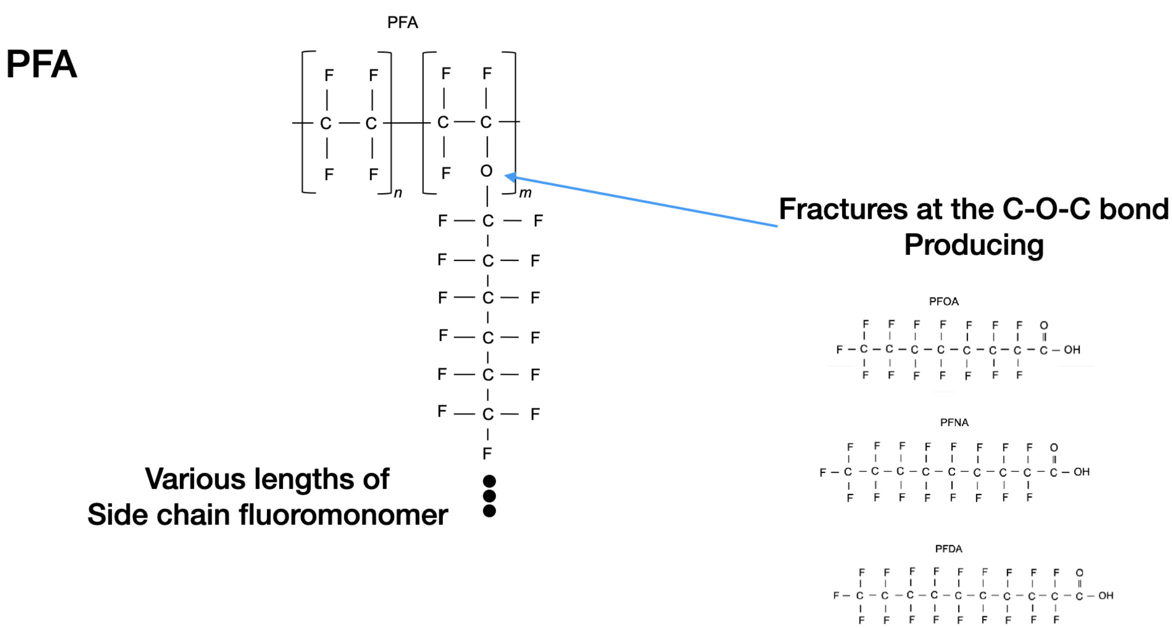
4.3.1.1. Fragile C-O-C bonds fracture during initial manufacturing and over time.

4.3.1.2. Fluoromonomer fragments are ‘fluorotelomers’, PFOA-like molecules with an extra 2 carbon hydrogens (such as 8:2 FTOH).

4.3.1.3. The fluorotelomer fragments react with air and water to slowly form perfluorocarboxylates

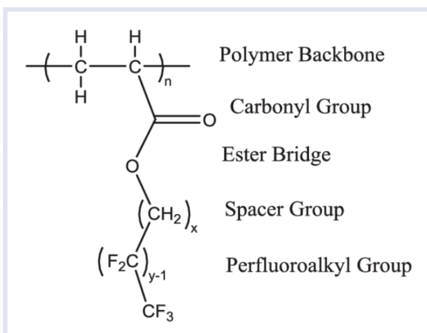
4.3.1.4. The lengths of eventual perfluorocarboxylates depend on the lengths of side chain monomers on the original PFA or fluoroacrylate polymer.

Formation of PFOA / LC-PFCA PFA (Perfluoroalkoxy Alkane Polymer)

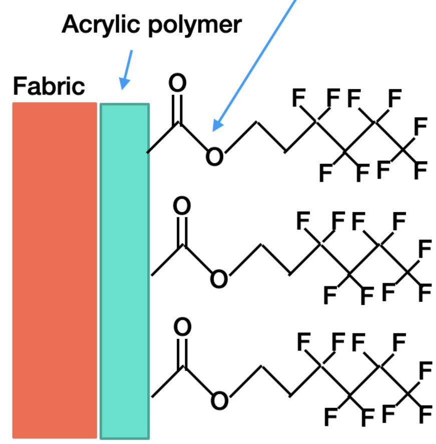


PFOA / LC-PFCA Formation Fluoroacrylates

- Fluoroacrylates have a 'side chain polymer'
  - Acrylic or other polymer
    - With chains of PFAS extending from polymer
    - *PFOA may be present as an impurity from PFAS side chain*
  - Example - water repellant coatings



Side chain PFAS



Side Chain PFAS

4.4. Perfluorocarboxylates and Perfluorosulfonates Found in Fluoropolymers and Fluoroelastomers

4.4.1. Presence of perfluorocarboxylates and perfluorosulfonates

4.4.2. 2022 to 2024 testing data by Claigan Environmental

Comparison	PTFE	PVDF	ETFE	Crosslinked PTFE	ePTFE	PFA	Fluoroelastomers	Fluoroacrylates	Fluorophosphates
Short Chain Perfluorocarboxylates (C4-C7)	Never	Never	Never	Commonly	Commonly	Commonly	Commonly	Commonly	Commonly

Long Chain Perfluorocarboxylates (C8-C14)	Never	Never	Never	Commonly	Commonly	Commonly	Never	Commonly	Commonly
Short Chain Fluorotelomers (C4-C7)	Never	Never	Never	Never	Never	Never	Never	Commonly	Commonly
Long Chain Fluorotelomers (C8-C14)	Never	Never	Never	Never	Never	Never	Never	Commonly	Commonly

Long Chain Fluorotelomers Sulphonates	Never	Never	Never	Never	Never	Never	Never	Never	Never

4.5. PFAS in Drinking Water and Humans

4.5.1. From this project and related testing data

4.5.1.1. ~99% of PFAS found in drinking water and humans is from <0.1% of products (primarily legacy fire extinguisher fluid and legacy foundation/concealer (C9-C15 fluoroalkyl phosphate in personal care products)).

4.5.1.2. ~99.99% of PFAS found in drinking water and humans is from <1% of products (a slight additional contribution from washing of waterproof fabrics contain fluoroacrylates).

4.5.1.3. The average silicone part has 100X more forever chemicals than the worst fluoropolymer (ePTFE). 200 ppm vs 2 ppm.

4.5.1.4. Based on ISO 10993-18 medical biocompatibility testing: Silicone, ABS, polystyrene, PVC, nylon, and polyurethane leak more dangerous chemicals into humans than fluoropolymers

4.5.1.5. Fluoropolymers are used because they are safer and more effective than their alternatives.

4.6. PFAS and Drinking Water - Kentucky 2023 PFAS testing of all drinking water sites

4.6.1. Kentucky 2023 drinking water sites testing

4.6.1.1. https://eec.ky.gov/Environmental-Protection/Water/Reports/Reports/2023-PFASFinishedDrinkingWaterResults.pdf

4.6.1.2. Kentucky was chosen because

4.6.1.2.1. Modern data (2023)

4.6.1.2.2. Comprehensive PFAS testing of each drinking water site

4.6.2. Sources of PFAS in drinking water

4.6.2.1. Based on the comparison of drinking water testing results and laboratory testing results of products

4.6.2.2. Legacy fire fighting foam

4.6.2.2.1. Fire fighting foam that uses C8 fluoro surfactants

4.6.2.2.2. Generally phased out of products a decade ago

4.6.2.2.3. Testing characteristic

4.6.2.2.3.1. Always - PFOS

4.6.2.2.3.2. Majority of situations - PFOA

4.6.2.2.3.3. Would not have - PFNA or PFDA (higher-length PFOA substances)

4.6.2.3. Modern fire fighting foam

4.6.2.3.1. Fire fighting foam that uses C4 or C6 fluoro surfactants

4.6.2.3.2. Common in modern fire fighting foam

4.6.2.3.3. Testing characteristic

4.6.2.3.3.1. Always - at least one of 6:2 FTS, PFHxS, PFBS

4.6.2.3.3.2. Majority of situations - PFHxA, PFBA

4.6.2.3.3.3. Would not have - PFOS, PFOA, PFNA, or PFDA

4.6.2.4. Cosmetics (Foundation and Concealer)

4.6.2.4.1. Foundation and concealer using C9-C15 Fluoroalkylphospate

4.6.2.4.1.1. Degrades over time into high concentration of PFOA, PFNA, and PFDA

4.6.2.4.2. Phased out in 2021/2022

4.6.2.4.3. Testing characteristic

4.6.2.4.3.1. Always - PFNA and PFDA (PFDA not included in Kentucky testing)

4.6.2.4.3.2. Majority of situations - PFOA

4.6.2.4.3.3. Would not have - PFOS or any sulphonate, or short-length fluoro carboxylates (PFBA, PFPeA, PFHxA).

4.6.2.5. Physical products

4.6.2.5.1. Primarily fluoroacrylate coatings of water-resistant fabric

4.6.2.5.1.1. Would release all lengths of perfluorocarboxylic acids during washing in detergent.

4.6.2.5.2. Common today

5. PFAS Currently Unavoidable Uses

5.1. The full details are contained in the accompanying spreadsheet PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx.

5.1.1. The comparisons are too large and detailed for a Word document and are instead summarized in an Excel file.

5.2. This document features several tabs with tables containing details about ***CUU's***.

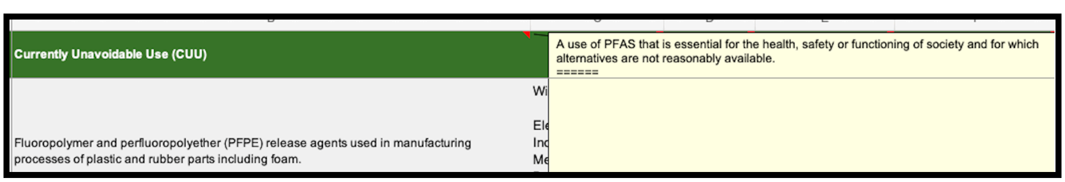
5.2.1. The CUU tab provides details about the specific ***CUU's*** as well as where and why they are specifically used.

5.2.2. The remaining tabs are the Alternative tabs. They provide the evaluation of alternative materials across a range of criteria applicable to the relevant use, which is labelled on the tab at the bottom of the document.

5.3. The core data is found within the tables, while further explanatory notes are found in the applicable column and row headers.

5.4. Cells with a red triangle in the top right corner have additional information pertinent to their respective row or column. They are found in Row 1 of the CUU tab and Column A of the Alternatives tabs. For example:

5.5. Additional details are revealed by hovering the mouse cursor over the cell (without clicking it). For example:



5.6. Additionally, this same information is captured in the document below.

6. Explanation of Currently Unavoidable Use (CUU) Proposal Tab

6.1. Columns A and B (CUU Number and Description) provide the numbering and descriptions for each ***CUU***.

6.2. Column C (Products) provides an overview of the applicable product families that require the listed Currently Unavoidable Use.

6.3. Column D (HS Codes) provides a list of HS Codes of products that require the listed ***CUU***. Some uses are so pervasive that the entire HS Code (Customs Code) chapters are listed.

6.4. Column E (Example Products) details a list of example products that require the applicable ***CUU.*** This list is representative and is not intended to be exhaustive.

6.5. Column F (Essential Use of Product) describes the intended use of the product and explains how it is essential for health, safety, or the functioning of society. It also describes if products using this CUU are ***Widespread*** or ***Industrial***.

6.6. Column G (Essential Use of PFAS) describes how the specific use of PFAS in the product is essential to the function of the product.

6.7. Column H (Comparison of Alternatives) describes reasonably available alternatives for this specific use of PFAS and compares them to the applicable ***CUU***. For further details, refer to the relevant Alternatives tab.

6.8. Column I (PFOA) identifies if this CUU contains any PFOA or Long Chain Perfluoroalkylcarboxylates (LCPFCAs). This column is based on 2023 and 2024 testing data of hundreds of representative parts for PFOA and LC-PFCAs.

6.9. Column J (Alternatives Tab) provides a direct link within the document to the identified tab comparing the performance of PFAS materials and alternative materials.

7. Alternatives Tabs

7.1. Row 1 (Comparison) identifies the alternative materials being evaluated.

7.2. Low Friction

7.2.1. Excellent - The material has a low coefficient of static friction. It is nearly frictionless.

7.2.2. Decent - The material has a lower coefficient of static friction but has some friction in use.

7.2.3. Poor - The material has a high coefficient of static friction. It displays strong friction during use and is not suitable for applications requiring low friction.

7.3. ***Chemical Resistance*** - the resistance to acids or bases may not be uniform for a material. The rating reflects the general potential applications of the material

7.3.1. Excellent - The material has superior resistance to acids and bases. Acid and bases have no discernible effect on the material.

7.3.2. Decent - The material is resistant to acids and bases but does exhibit some degradation. It should not be in extended contact with, or subject to, high concentrations of acids or bases.

7.3.3. Poor - The material is not resistant to acids and/or bases.

7.4. Water Resistance

7.4.1. Excellent - The material is hydrophobic (*i.e.* it is impermeable to water even as a coating).

7.4.2. Decent - The material is resistant to water, but not completely hydrophobic or waterproof.

7.4.3. Poor - The material is permeable to water.

7.5. Oil Resistance

7.5.1. Excellent - The material is oleophobic (*i.e.* it is impermeable to oil even as a coating).

7.5.2. Decent - The material is resistant to oil, but not completely oleophobic, oil-proof, or stain-resistant.

7.5.3. Poor - The material is permeable to oil.

7.6. Temperature Resistance

7.6.1. Excellent - The material can withstand temperatures above 150°C.

7.6.2. Decent - The material can withstand temperatures above 100°C, but is impacted by temperatures above 150°C.

7.6.3. Poor - The material is impacted by temperatures above 100°C.

7.7. Fire Resistance

7.7.1. Excellent - The material meets stringent fire/flame resistance standards.

7.7.2. Decent - The material has fire/flame resistance but does not meet the most stringent standards.

7.7.3. Poor - The material is not fire/flame resistant.

7.8. Flexibility

7.8.1. Excellent - The material exhibits good flexibility and is useful in most applications requiring flexibility.

7.8.2. Decent - The material has some rigidity, but still exhibits some flexibility.

7.8.3. Poor - The material is rigid and is not suitable for applications requiring flexibility.

7.9. Forever Chemicals (Initial)

7.9.1. Excellent - The material does not contain any substances with an EU harmonized classification of vPvB or PBT after manufacturing.

7.9.2. Decent - The material contains trace amounts (<1 ppm) of substances with an EU harmonized classification of vPvB or PBT after manufacturing.

7.9.3. Poor - The material contains amounts (> 1ppm) of substances with an EU harmonized classification of vPvB or PBT after manufacturing

7.10. Forever Chemicals (Over Time)

7.10.1. Excellent - The material does not degrade into substances with an EU harmonized classification of vPvB or PBT.

7.10.2. Decent - The material degrades lightly into substances (<1 ppm) with an EU harmonized classification of vPvB or PBT over time.

7.10.3. Poor - The material degrades into substances (> 1ppm) with an EU harmonized classification of vPvB or PBT over time.

7.11. Bio-compatibility

7.11.1. Excellent - The material passes US FDA and EU MDR biocompatibility testing and does not normally require toxicological justification.

7.11.2. Decent - The material passes US FDA and EU MDR biocompatibility testing but often requires toxicological justification.

7.11.3. Poor - The material does not generally pass US FDA or EU MDR biocompatibility testing or it requires significant toxicological justification.

7.12. Insulation

7.12.1. Excellent - The material has a low dielectric constant and is suitable for most insulating or electronics purposes.

7.12.2. Decent - The material has a medium dielectric constant and is only suitable for some insulating or electronics purposes.

7.12.3. Poor - The material has a high dielectric constant and is not normally suitable as an insulating material in electronics.

7.13. High-Density Applications

7.13.1. Excellent - The material is usable in applications requiring thin layers or high density.

7.13.2. Decent - The material is usable in applications that do not require thin materials, but it is not suitable for very fine or dense applications.

7.13.3. Poor - The material is not feasible as a thin film or in high-density applications.

7.14. Polymer Additive

7.14.1. Excellent - The material can be added to a wide range of polymers to provide additional properties.

7.14.2. Decent - The material can be added to some polymers to provide some level of additional properties.

7.14.3. Poor - The material is not suitable as a polymer additive.

7.15. Porous

7.15.1. Excellent - The material is permeable to air.

7.15.2. Decent - The material is partially permeable to air but is resistant to airflow.

7.15.3. Poor - The material is not permeable to air.

7.16. Durability

7.16.1. Excellent - The material has superior resistance to wear.

7.16.2. Decent - The material is partially resistant to wear but is not suitable for high-wear situations.

7.16.3. Poor - The material is not suitable for situations where wear resistance is required.

7.17. Optical Transparency

7.17.1. Excellent - The material is optically transparent.

7.17.2. Decent - This material has some optical transparency but is not suitable for applications requiring clarity and high transparency.

7.17.3. Poor - This material is not normally optically transparent

7.18. Structural

7.18.1. Excellent - The material is rigid with the ability to support its weight and any weight of the fluid it is transporting. It also has superior fatigue resistance.

7.18.2. Decent - The material can support its weight, but it is not as reliable for additional weight or fatigue.

7.18.3. Poor - The material cannot rigidly support its weight.

7.19. Radiation Resistance

7.19.1. Excellent - The material has superior resistance to gamma and e-beam radiation and does not exhibit degradation due to radiation.

7.19.2. Decent - The material has some resistance to gamma and e-beam radiation but exhibits degradation with repeat or high dosage exposure.

7.19.3. Poor - The material degrades in gamma or e-beam radiation.

7.20. Acceptable

7.20.1. A material is deemed acceptable if it receives an excellent or decent rating in non-critical properties. The material must receive an excellent rating in critical properties to be deemed acceptable.

7.20.1.1. Critical properties are identified where ratings (excellent, decent, poor) are shown in bold.

8. Acknowledgements

Special thank you to Nials Everett, Chris Scully, Julie Van Moorsel, Dr Tim Holt, and the entire Claigan Environmental staff and students for their contributions. And thank you to all of our industry members who contributed so much in such little time.

Letter of Support

Garmin International, Inc. stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.

In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Maine and Minnesota. This proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders. By engaging experts from various industries, Claigan Environmental has adopted a collaborative approach to address this complex issue.

Garmin International, Inc. actively participated in the consultation process and supports Claigan Environmental's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

Hitachi Energy Response to Minnesota Proposal

Current Unavoidable Uses (CUU) for Minnesota State - Chapter 60, H.F n°2310

In response to the Minnesota Pollution Control Agency (MPCA) plan for new rules governing how the MPCA determines and establish currently unavoidable uses of per- and polyfluoroalkyl substances (PFAS) in products, Hitachi Energy (HE) is committed to providing the most accurate and comprehensive information currently available for this response.

Questions made by Minnesota Pollution Control Agency (MPCA)

1. **Should criteria be defined for "essential for health, safety, or the functioning of society"?**
   If so, what should those criteria be?

Hitachi Energy supports MPCA initiative to protect human health, society, and the environment by controlling emissions of substances with known toxicological concerns. This goal needs to be achieved by employing a fact driven and risk-based regulatory approach in a sustainable manner, ensuring product reliability, and achieving critical targets such as the safety of the grid and the green energy transition. The group of PFAS is a large and inhomogeneous group of substances with very different physical and chemical properties, coming with vastly different levels of hazards. The human health, society and environmental implications of those substances are also different and depend on the nature and level of control of their use. Thus, sustainable regulation of PFAS should identify differentiated risk management measures in consideration of the risk of a specific substance in a specific use with its relevance for society.

We support the definition as outlined by the State of Maine's "Essential for Health, Safety or the Functioning of Society" and would encourage Minnesota to consider taking a similar approach/definition for efficiency and to harmonize the implementation of PFAS regulations.

According to Maine 38 M.R.S. §1614 (1) (B), the definition of "Essential for Health, Safety or the Functioning of Society" means: *"Products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations.*
Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction."

This could work efficiently as a model for Minnesota as well. In reference to the specific context of the energy sector, we believe that the following considerations should be included in the criteria:

“*A secure supply of electricity is essential for the health and safety of society. Electrical power grids additionally support the integration of renewable technologies and enable green electricity to be accessed. Therefore, products used under harsh environmental conditions and high voltage like transformers High-power semiconductors etc. should be considered as critical for the safety and functioning of society.* “

2. Should costs of PFAS alternatives be considered in the definition of “reasonably available”? What is a “reasonable” cost threshold?

A non-comprehensive list of factors that will contribute to the reasonable availability of suitable PFAS replacements are as follows:

- The ability to perform safely and reliably. Maintain functionality under conditions of high temperature, pressure, and adherence, while also meeting requirements for chemical compatibility and inertness.
- Society and environment effects of the replacement material including potential design changes of devices/equipment in size, complexity, etc. including the related carbon footprint and other environmental impacts.
- Scale of production and the level of industrialization of these alternatives. Availability of the alternative in the sufficient quality and quantity to support green transition happening in US and across the globe.
- Economic viability and product size and cost are an important factor to take into account in the alternative assessments.
- The compatibility of the replacement material with the currently installed product base.

Therefore, the transition to PFAS-free alternatives is a complex process that goes beyond just identifying technically suitable substitutes.

Based on the above criteria, we support the definition outlined by Maine for “Reasonably available” be used as a model for Minnesota.

Pursuant to Maine 38 M.R.S. §1614 (1) (B), “reasonably available” means: *“PFAS alternative which is readily available in sufficient quantity and at a comparable cost to the PFAS it is intended to replace and performs as well as or better than PFAS in a specific application of PFAS in a product or product component.”*

3. Should unique considerations be made for small businesses with regards to economic feasibility?

We shall not provide any comments on this question.

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

PFAS alternatives should not endanger the operation of power generation or power supply to people in the United States. PFAS alternatives should be able to withstand the harsh temperature, pressure, and chemical inertness properties required for reliability of the power grids.

PFAS replacements would need to meet standard rules and regulations as all other chemicals in the market used in electrical power systems do. Any alternative material must undergo vigorous testing and certification processes to ensure there is no risk to the functioning of the grid and thus of society.

Condition of use and full material lifecycle, as well as application type (e.g. consumer or industrial product) shall be taken into account in assessing the risks of the material with respect to health and environmental impact.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

The longevity of "currently unavoidable use" (CUU) determinations is a critical consideration. We firmly advocate for a reasonable and pragmatic timeframe that aligns with the lifespan of critical energy infrastructure.

We would highlight for certain applications that there are no alternative technologies and such discussions on replacements can only take place when technological advancements occur. In general terms, given the complexity of the electricity systems and the required lead times for developing alternative materials, new designs or construction of necessary updates/replacements, the development time may according to our experience last a couple of decades, if at all possible. We justify this time as finding appropriate PFAS replacements require scientific experimentation, alternative technology development, engineering feasibility operational processing, supplier qualification, quality assurance testing, and field testing by end-users.

Because of uncertainty of alternatives feasibility and very long development time needed even in best case, it is recommended to review the decisions depending on the progress in the technologies.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? (I) Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? (II) What information should be submitted in support of such requests? (III)**

- Question (I)

Ideally, regulatory standards around exceptional use cases of CUU of PFAS should be harmonized within the United States as much as practicable.

The determination of CUU should also differentiate between the industries making the request. Efforts to reduce PFAS from consumer goods is strongly encouraged, as there is significant contact with humans and high likeliness to be disposed of in landfills and waterways. Conversely, in highly specialized electrical grid equipment all PFAS are handled by trained and adequately protected professionals, our products have long use lifetimes, and our facilities will be decommissioned by professionals at the end of life.

- Question (II)

We do not recommend that stakeholders in other organizations should be able to make a PFAS unable to be claimed by CUU criteria. PFAS are used in many different ways and for different purposes. Such a per se request does not consider appropriately such variety and potential other criteria affecting health, safety and environment, i.e., the potential availability of alternative solutions must be seen in context of additional aspects and their damage potential. In turn, the availability of such a request could trigger the misuse of the regulation to gain an unfair competitive advantage promoting seemingly alternative solutions, which however may overall bear other and higher risks for health, safety and environment. This would eliminate competitive solutions within the industries to the disadvantage of the end consumers, and with the risk of additional damage for health, safety and environment.

- Question (III)

The following information should be used in support of CUU determination:

- Properties of specific PFAS.
- Use(s) of specific PFAS and fact-based impacts on health, safety, and environment.
- Technical alternatives and impacts on health, safety, and environment.
- Socioeconomical impacts of PFAS removal.
- The use of solid-state fluoropolymers in non-consumer products.
- No intent to release the PFAS into the environment.

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why.**

   Note: There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Electrical grid equipment including high voltage switchgear, transformers, HVDC equipment, monitoring devices, power electronics semiconductors and other power grid components use specific types of PFAS materials in order to meet quality and reliability requirements essential for grid operation in supplying electricity within the United States.

The primary specifications these materials must meet are long product lifetimes (often 40 years in operation), high material endurance, chemical inertness, material stability under extremely high temperature, pressure, and voltage. The mentioned product requirements are not easily substituted and in many cases there are currently no alternative technologies, thus defining Current Unavoidable Uses (CUU) by Minnesota Authorities is critical to our business and ensuring a high functioning electrical grid system in the United States.

Hitachi Energy acknowledges and fully supports the risk management of substances which are detected as environmental pollutants and potentially linked to negative effects on human health and the environment. The PFAS used in our electrical power equipment differ highly in risk level and properties compared with the PFAS which have been determined to be harmful to human health and the environment such as PFOS, PFOA, PFHxS, PFNA, or C9-C14 PFCAs. The majority of PFAS used in our products are either fluoropolymers or insulating gases. The amount of material used in our products is limited. More than 96% of globally used fluoropolymers, including PTFE and fluorinated elastomers used in electrical grid equipment, fulfill the widely accepted criteria for polymers of low concern as per OECD definitions.[1,2,3] We proved instructions that define how to properly recycle or incinerate such materials, e.g., PTFE components at end of life or at decommissioning. The fluorinated insulation gases used (e.g., Heptafluorobutyronitrile, C4-FN), replaces environmentally harmful sulfur hexafluoride (SF_6). C4-FN is classified as non-toxic through professional toxicological and ecotoxicological assessments as it does not accumulate in water, plants, or the soil and has an average atmospheric lifetime of 30 years.[4,5]

By design, electric power components from Hitachi Energy containing PFAS materials are secured on, or enclosed within associated products and where gas-tightness is assured in order to fulfill the product function and required by international standards.[5] Gas holding equipment is additionally monitored constantly through sensors to ensure functional integrity of the equipment. Release of such PFAS to the environment during normal use is then either not possible or extremely unlikely. PFAS release due to solid fluoropolymers during the 40 years of service life is not at all expected. Electric power grid products are exclusively maintained by trained professionals. Hitachi Energy also provides training and strict guidance to users of the products regarding safe and environmentally responsible means to dispose of the products as the end of life, in accordance with prevailing legislative requirements.

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Yes, CUU determination is critical to the operation of Electrical grids and power supply to people in the United States.

CUU determination as part of the rulemaking process could provide clarity and certainty for manufacturers and other stakeholders.

OECD concludes that PFAS as a definition only describes a class of diverse molecular structures with diverse physical, chemical, and biological properties and recommends that such diversity be properly recognized and communicated in a clear, specific and descriptive manner. Using PFAS as a descriptor is broad and generic and does not inform whether a compound is harmful[6]. While the lack of information for the majority of PFAS presents challenges for risk assessment, PFAS should not be grouped together for risk assessment purposes. “Persistence” alone is not sufficient for grouping PFAS for the purposes of assessing human health risk and it is inappropriate to assume equal toxicity/potency for PFAS without confirmatory information. CUU determination would enable to see the nuances between certain PFAS compounds, giving deeper understanding on the associated risks and rewards of certain compounds and gain a better understanding on a diverse class of compounds.

9. Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

Hitachi Energy recognizes the need to avoid emissions of substances with known toxicological concerns in order to best protect human health, society, and the environment. This goal needs to be achieved by employing a risk-based regulatory approach in a sustainable manner, ensuring product reliability, and achieving critical targets such as the safety of the grid and the green energy transition. To do so, any restriction of PFAS needs to be appropriately differentiated: the group of PFAS is a large and inhomogeneous group of substances with very different physical and chemical properties, coming with vastly different levels of hazards. The human health, society and environmental implications of those substances are also different and depend on the nature and level of control of their use. Thus, sustainable regulation of PFAS should identify differentiated risk management measures in consideration of the risk of a specific substance in a specific use with its relevance for society.

We suggest that Minnesota consider taking a unified approach for confidential business information (CBI) determination, based on the CBI determination made under Toxic Substance Control Act (TCSA).

These provide a broad approach of what is considered CBI and is well defined and used throughout the states.

In general, we agree that:

Confidential claims shall be asserted (and substantiated as necessary) at the time of submission.

CBI shall refer to sensitive information that business may want to keep confidential to protect their competitive position.

Additionally, we agree that:

Companies may claim certain information as CBI when:

- Specific information describing the processes used in the mass production or manufacturing process.
- Specific marketing and sales information.
- Information regarding specific characteristics of our products or details about how substances are used on them.
- Technical and R&D business information.

R·MOR™ PROTECTIVE WEAR By Lac·Mac

March 1, 2024

Katrina Kessler, Commissioner
Minnesota Pollution Control Agency (MPCA)
520 Lafayette Road North
St. Paul, Minnesota 55155-4194

Re: Comments on MPCA Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Dear Ms. Kessler,

Lac-Mac Limited (Lac-Mac) appreciates the opportunity to provide these comments[1] in response to MPCA's Planned New Rules Governing "Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837." This rulemaking is referred to as the PFAS in Products Currently Unavoidable Use Rule. The purpose of this rulemaking is to establish criteria and processes for MPCA to make decisions on what if any uses of intentionally added PFAS will qualify as currently unavoidable uses in products sold, offered for sale, or distributed in Minnesota.

Located in Canada, Lac-Mac is North America's leading manufacturer of reusable protective clothing for blood borne pathogen protection (surgical protection), liquid chemical splash protection, flame resistant/ARC protection for utilities, and high-visibility liquid-proof protection. We specialize in quality, high-performance, liquid-proof, breathable personal protective equipment (PPE) products. We sell our products in the United States, including in the state of Minnesota.

Minnesota's PFAS in Products Law bans the sale and distribution of certain products containing intentionally added PFAS starting in 2025 (e.g., carpets and rugs, cleaning products, cookware, textile furnishings, etc.), and then *all* products containing intentionally added PFAS starting in 2032. MPCA has the authority to exempt "currently unavoidable uses" of PFAS, which are uses that MPCA has determined to be "essential for health, safety, or the functioning of society and for which alternatives are not reasonably available." MPCA is seeking comment now on any relevant issues related to what should be "currently unavoidable uses" and, thus, exempt from this ban.

As MPCA develops its PFAS in Products Currently Unavoidable Use Rule, **we urge MPCA to determine, by rule, that PPE products like the products we sell are "currently unavoidable uses" of PFAS** and, therefore, would be exempt from any future prohibitions on the sale or distribution of PFAS-containing products in the State of Minnesota.

PPE is essential for the health, safety and functioning of society and for which alternatives are not reasonably available. PPE products provide critical protection for workers who are exposed to various physical and chemical hazards in the workplace. Particularly in chemical facilities and in healthcare settings, it is vital for safety and public health to ensure the workforce in Minnesota has continued access to necessary PPE. Our concern is that without an exemption for "currently

[1] Comments have been submitted electronically to: https://www.pca.state.mn.us/get-engaged/pfas-in-products-currently-unavoidable-use.

Bldg 2 - 847 Highbury Ave N,
London, ON, Canada N5Y 5B8
Phone: 1-888-452-2622 | Fax: 1-800-461-0001
www.lac-mac.com

unavoidable uses," PPE manufacturers like Lac-Mac or other companies will be forced to no longer sell its products in Minnesota and leave thousands of workplaces with far more limited options for available protective clothing, creating a public health emergency or exposing workers to more risks in the workplace. This is contrary to the intent of Minnesota's PFAS law, which is to protect individuals from exposures to chemicals.

Further, there is legal precedent for Minnesota to adopt this approach. The two other states that have enacted similar prohibitions on the sale of PFAS in apparel or textiles, California and New York, have provided exclusions for PPE:

> California Health & Safety Code 108970[2]: The law prohibits the manufacture, sale or distribution of textile articles containing regulated PFAS starting January 1, 2025. The law excludes from the definition of apparel "personal protective equipment."

> New York Env. Chapter 43-B, 37-0121[3]: The law prohibits the sale of apparel containing intentionally-added PFAS starting January 1, 2025. The law excludes from the definition of apparel "professional uniforms that are worn to protect the wearer from health or environmental hazards, including personal protective equipment."

The state of Maine's PFAS and Products Law, 38 MRSA 1614[4], which prohibits all products containing intentionally added PFAS starting January 1, 2030, also allows for exemptions for "currently unavoidable uses" of PFAS and defines this term the same as Minnesota's law. Maine is still developing its regulations to implement the law.[5] We have provided similar comments about PPE being classified as a "currently unavoidable use" to Maine's Department of Environmental Protection.

Therefore, Minnesota would be aligning with other states in exempting the use of PFAS in PPE from any ban so that essential medical supplies and worker safety garments will continue to be available for employers and workers.

We have also provided feedback in response to MCPA's questions in this rulemaking:

In developing the currently unavoidable use rule, the MPCA would appreciate comments on the following questions:

> 1**) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?** Criteria should consider whether the presence of PFAS contributes directly to the functional performance for delivering safety (such as PPE) which also provides an important health function.

> **2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?** Yes, to the extent a PFAS alternative solution will render the product non-competitive in the market (i.e., will the solution be economically viable?).

> **3) Should unique considerations be made for small businesses with regards to economic feasibility?** Considerations and viable solutions should be for all, whether large or small businesses.

---

[2]https://leginfo.legislature.ca.gov/faces/codes_displayText.xhtml?lawCode=HSC&division=104.&title=&part=3.&chapter=13.5.&article=.
[3] https://www.nysenate.gov/legislation/laws/ENV/37-0121.
[4] https://legislature.maine.gov/statutes/38/title38sec1614.html.
[5] Lac-Mac is submitting similar comments to the Maine Department of Environmental Protection for consideration as it develops rules to implement its PFAS in Products Law.

4) What criteria should be used to determine the safety of potential PFAS alternatives? Solutions should meet the same industry standards as the current PFAS containing product.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation? In our experience, 5 years is the minimum duration of time required to develop and fully test a new solution when changing a high-performance protective product. While most manufacturers are avidly working on solutions for a PFAS replacement, an appropriate window of time should be permitted to successfully deliver a safe and viable solution.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests? Consider whether the PFAS contributes directly to the protective performance attributes with no comparable alternative available. Consider whether the PFAS additive is a topical treatment or in solid state.

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination. PPE which provides the highest level of protection from BloodBorne Pathogens for surgical teams. Garments which provide protection from a host of hazards such as; Exposure to Electric Arc Flash, Organic and Inorganic Chemical Exposure and Protection from Flammable Hazards to name a few.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria? We would like to see MPCA include consideration for excluding personal protective equipment (PPE) which are essential for health and safety currently containing PFAS when evaluating unavoidable use determinations.

Thank you for the opportunity to comment and please contact Shelley Petrovskis if you would like more information from us.

Sincerely,

S. Petrovskis

Re: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl Substances (PFAS), Revisor's ID Number R-4837

Disclaimer: Nothing in this submission relates to firefighting foams or the chemical agents used in firefighting foam.

Note on Terminology: In this submission we use the term halogenated clean agents (HCAs) to refer to the fluorinated chemicals used in total flooding fire suppression systems and portable fire extinguishers. HCAs used in total flooding fire suppression systems are also commonly referred to as gaseous fire extinguishing agents.

The Halon Alternatives Research Corporation, Inc. (HARC) appreciates the opportunity to provide information to the Minnesota Pollution Control Agency (MPCA) in response to its request for comments on planned new rules on currently unavoidable uses of PFAS. HARC is a non-profit trade association formed to promote the development and approval of halon alternatives that serves as an information clearinghouse and focal point for cooperation between government and industry on issues of importance to special hazard fire protection. HARC members encompass all levels of the fire protection industry including agent manufacturers, equipment manufacturers, distributors/installers, recyclers, and end-users.

The fire protection industry has a strong record of taking voluntary actions and supporting regulations to reduce the environmental impact of halogenated clean agents (HCAs). In the early 1990s when informed that halons were potent ozone depleting substances (ODS), the industry immediately stopped any testing and training with halons, developed a voluntary code of practice for halon use, and supported the accelerated 1994 phaseout of halon production under the Montreal Protocol. To reduce the impact of the high global warming potential (GWP) hydrofluorocarbons (HFCs) used as alternatives to halons the industry developed a voluntary code of practice to minimize emissions[1] and a recycling code of practice[2], created a data collection program to estimate emissions[3], and supported the phasedown of HFC production under the Kigali Amendment to the Montreal Protocol. The HFC phasedown under the AIM Act has significantly reduced the use of HFCs in new fire suppression systems.

Need for a Currently Unavoidable Use determination for HCAs used in fire suppression

The HCAs used for fire protection that meet the definition of PFAS in the Minnesota law are FK-5-1-12, HFC-227ea, HFC-125, HFC-236fa, 2-BTP and HCFC Blend B. While there are non-PFAS alternatives for HCAs that have been available for several decades and are widely used, we write to inform MPCA that there are important uses of HCAs in facility, aviation and military applications for which non-PFAS alternatives do not exist and are not currently in development. As such we expect there to be continuing uses of HCAs for fire suppression well beyond January 1, 2032.

The development of new substances has been aggressively pursued within this sector for more than 30 years, well before the phaseout of halons, with millions of dollars and extensive time and efforts of myriad private and public organizations spent on development with limited success. An expectation that new options not already considered in the past can be developed and brought to market in 5, 10, or 20 years is not supported by historical experience. Several important fire risk applications (for example civil aviation and nuclear power plants) still require halon even after pursuing alternatives for 30 years.

It is this history that leads to the consensus within the fire protection community that it is highly unlikely new non-PFAS alternatives will suddenly be discovered. Below is a quote from the 2023 Progress Report of the United Nations Environment Program (UNEP) Technology and Economic Assessment Panel (TEAP) that sums up this consensus:[4]

"Furthermore, all known candidate clean agent chemical groups have already been researched, such that discovering alternatives that are zero ODP, low GWP, and non-PFAS is highly unlikely. Based on these factors, there is little to no financial incentive for companies to invest in the research and development of potential new fire suppression agents. As there are no new candidate fire suppressants available for consideration that are not PFAS under these broad definitions, it is anticipated that the only options that will be available after the 12-year derogation are the same ones available today."

The 12-year derogation mentioned in the above quote refers to the current proposal in the European Union (EU) Universal PFAS REACH restriction report for an exemption for "clean fire suppressing agents where current alternatives damage assets to be protected or pose a risk to human health" that would extend to around 2039.[5]

Possible wording of a Currently Unavoidable Use determination for HCAs used in fire suppression

Historically it has proven difficult to define a list of uses of HCAs for fire suppression that are essential/critical or in the case of the Minnesota PFAS law "currently unavoidable." The diversity of applications and the unique requirements of individual facilities makes it very challenging to claim that an alternative, non-PFAS technology is viable across a general use category such as data centers or control rooms. Each data center, for example, will have different criteria and requirements for the fire protection technology selected.

HARC would recommend that MPCA adopt language similar to what is in the EU F-gas regulation,[6] where HFC fire protection equipment can be sold after the January 1, 2025, prohibition if it is “required to meet safety requirements.” Tying the currently unavoidable use determination only to situations where alternatives do not meet safety requirements would significantly limit the future use of HCAs for fire suppression in Minnesota.

Below is proposed wording for a Currently Unavoidable Use determination for HCAs that combines language used in the Universal PFAS REACH restriction report and the EU F-gas regulations:

“Clean fire suppression agents where necessary to meet safety requirements”

Definition of product

The definition of “product” in the Minnesota PFAS law “means an item manufactured, assembled, packaged, or otherwise prepared for sale to consumers…” Fire protection equipment containing HCAs is not sold to consumers and is limited to commercial, industrial and military uses. The meaning of the second part of the definition that refers to “its product components, sold or distributed for personal, residential, commercial, or industrial use” is not clear. HARC is not aware that the product components of HCA-based fire protection equipment are used to produce other products that are sold to consumers. HARC would ask that MPCA clarify in the proposed rule whether the PFAS restrictions would cover total flooding fire suppression systems and portable fire extinguishers sold only for commercial, industrial and military use.

Recycling and emissions

Emissions of HCAs from modern fire protection equipment are extremely low. The Montreal Protocol Fire Suppression Technical Options Committee (FSTOC) 2022 Assessment Report uses an annual emission rate for HCAs of 3%.[7] This is a worldwide estimate that would include both developed and developing countries. The latest installment of the US EPA Vintaging Model, which estimates use and emissions of ODS alternatives in the United States, uses a 1.5% emission rate for HCAs in total flooding fire protection systems installed between 2003–2019 and 1% after 2019.[8]

Due in part to their low emission rates and high value, HCAs used in fire protection have historically enjoyed very high levels of recycling. Evidence of this can be seen in the continued availability of significant quantities of recycled halons for critical uses such as aviation even though it has been 30 years since production ended in the United States and 14 years since it ended worldwide. An EPA draft report on the HFC reclamation market contains a good discussion of halon and halon alternative recycling.[9] HARC agrees with EPA that the management of halons in the United States over the last several decades has demonstrated a model of collaboration between industry, government, and users. HARC believes this management model extends beyond halons so that most HCAs installed in fire protection equipment are recovered from decommissioned equipment and reused.

The Minnesota PFAS law contains an exemption in Subd. 8 for “the sale or resale of a used product." HARC is interpreting this to mean that recycled HCAs and fire protection equipment containing recycled HCAs could continue to be sold after January 1, 2032. Most of the servicing of HCA-based fire protection equipment is already performed using recycled agent and by 2032 we expect that most if not all new HFC-based fire protection equipment will be initially filled with recycled agent.[10] The combination of low emissions and the use of recycled agent for servicing and new equipment will significantly limit the size and environmental impact of a Currently Unavoidable Use determination for HCAs used in fire protection.

Overview of PFAS clean agents

The following Annex provides an overview of the PFAS chemicals used for fire suppression and their alternatives. Also enclosed is a technical note published by the FSTOC that lists all HCAs used for fire protection and provides information on their efficacy, physical characteristics, toxicity, environmental impacts, and international standards for their use. In addition, the report provides comparable information on non-PFAS alternatives to HCAs such as inert gases, powders, and water mist systems.

Conclusion

HARC is an advocate for human health and the environment, as shown by our 30-year history of taking voluntary actions and coordinating industry compliance with environmental regulations. We fully support efforts to reduce the use and emissions of PFAS. A Currently Unavoidable Use determination for HCAs used in fire protection that is limited to situations where alternatives cannot meet safety requirements would result in minimal PFAS emissions while continuing to provide for life safety and protection for high-value assets critical to society.

Please let us know if you have any questions or would like to discuss these issues in further detail.

Respectfully submitted,

ANNEX: OVERVIEW OF PFAS CLEAN AGENTS AND ALTERNATIVES

The following overview of PFAS chemicals used for fire suppression and their alternatives is broken down into three use categories: total flooding fire suppression, onboard aircraft fire suppression, and military.

OVERVIEW OF TOAL FLOODING FIRE SUPPRESSION

Background

HCA fire suppressants occupy a specialty market where there is a need to protect items that otherwise would be damaged by a fire extinguishing agent itself or a slow extinguishment process, and in enclosed spaces where many other fire suppressants would pose a risk to human health and safety. These specialty applications have unique challenges to providing fire and life safety. Clean agent fire systems are not normally required by code. They are an added expense to mitigate an unacceptable risk of losing assets, data or incurring downtime for a high-tech or historical preservation facility as a result of a fire. This risk analysis includes high value assets and business continuity, but also societal impact and security with the loss of critical services in the event of fire. In the interconnected electronic world, loss of telecommunications and internet access can pose significant societal impacts. This makes the grouping of applications for regulation within the category very difficult. In some cases, the assets within the protected hazard are critical, in others it is the function of those assets within the protected space that are of value, not necessarily the assets themselves.

PFAS used in total flooding fire suppression

The HCAs used for total flooding fire suppression that are defined as PFAS in the Minnesota law are: FK-5-1-12, HFC-227ea, and HFC-125. The chemical, physical, and thermodynamic properties, especially vapor pressure, differ among these agents and affect their storage, transport, atomization, and vaporization characteristics. These agents are stored as liquids in nitrogen-pressurized containers. Upon actuation of the fire extinguishing system, agent liquid is released into a pipe distribution system and discharged from nozzles into the protected enclosure as a vaporizing spray forming a uniform gaseous agent-air mixture throughout, thus the term “total flooding” fire extinguishing. Widely accepted standards require that the discharge time for systems using HCAs be completed in 10 seconds or less, which assures rapid flame extinguishment thereby minimizing damage to protected assets. The minimum design concentration (MDC) of agent in an enclosure is based on test procedures for the hazard type, described in an applicable national standard such as NFPA 2001[11] and is further tested and validated by approval agencies such UL and FM.

Fire extinguishing systems containing HCAs are used to protect a wide array of asset types, including:

1. Server rooms
2. Power supply rooms

3. Electrical switch gear rooms
4. Hospital (e.g., MRI labs)
5. Document storage vaults.
6. Cultural heritage structures
7. Anechoic chambers.
8. Chemical storage rooms
9. Flammable liquids
10. Battery Energy Storage Systems (BESS)
11. Marine
12. Oil and gas exploration
13. Military
14. Naval ships
15. Aerospace
16. Nuclear powerplant control rooms

Non-PFAS clean agent alternatives

Inert gases

Several inert gases (IG-01, IG-100, IG-55, and IG-541) are approved for use in total flooding fire extinguishing systems in occupied spaces. Inert gas agents are stored in high-pressure cylinders at pressures up to 300-bar or gas generated by a chemical reaction (energetics). Standards require that inert-gas fire extinguishing systems discharge in at most 120 seconds for Class A hazards (solid substances), and in at most in 60 seconds for Class B hazards (flammable liquids). Use of inert gas agents is permitted for occupied spaces provided that exposure of personnel to reduced oxygen concentrations is limited to 5 minutes where oxygen concentrations are 12% or greater.

Technical limitations affecting use of inert gas agents in place of HCAs are mainly due to (1) increased space and weight burden of inert gas cylinders, (2) where the inert gas agent concentration exceeds 62 percent at sea level equivalent they cannot be used in occupied areas.

Carbon dioxide (CO_2)

Carbon dioxide has a long history as an effective gaseous fire extinguishing agent in limited circumstances to protect against class B hazards. It is used in both total flooding and local-application fire extinguishing systems. However, carbon dioxide is fatally toxic at fire extinguishing concentrations, which severely limits its use in normally occupied enclosures except where certain requirements are met (NFPA 12).[12]

Not-in-kind alternatives to PFAS clean agents

Water-based systems

Sprinkler systems and water mist systems are both fire suppression systems and are widely used in hazard spaces where water is available at an adequate supply rate and quantity. Note that sprinkler systems are not tested and approved as fire “extinguishing“ systems. Ordinary sprinkler systems are intended to protect the facility and not necessarily the assets contained in it. Collateral damage to protected spaces and assets by water itself is, in some cases, a significant risk.

There are tested and approved total flooding type water mist fire extinguishing systems. Water mist systems are special hazard systems developed for the protection of specific hazards. There are no generally accepted design criteria for water mist systems, thus their effectiveness must be proven by fire testing on the hazard of interest. Collateral damage to assets by water itself is, in some cases, a significant risk.

Hybrid systems (water and inert gas)

These systems simultaneously discharge a fine water mist and inert gas such as nitrogen. They are approved for use as fire extinguishing systems in normally occupied spaces. The inert gas effects extinguishment through the dilution of oxygen while the fine water droplets provide cooling which also contributes to fire extinguishment. As with inert gas systems, personnel exposure times to reduced oxygen concentrations is limited to 5 minutes where oxygen concentrations are 12% or greater (NFPA 770).[13] Collateral damage to protected spaces and assets by water itself is, in some cases, a significant risk.

Powdered aerosol agents

A powdered aerosol fire extinguishing unit discharges a fixed amount of fine extinguishing powder, forming a flame-extinguishing powder cloud, which acts in a *total-flooding* manner. Powdered agents, as such, are not “clean” agents and can damage certain assets such as electronics. Under the US EPA SNAP program, two powdered aerosols are listed as acceptable for use in occupied spaces.

Applicability of alternatives to PFAS agents

For an alternative agent to be an acceptable replacement for a PFAS fire extinguishing agent (a “clean” agent) in an application it must be able to meet the critical regulatory requirements including:

1. Safe for human exposure at the agent fire suppression design concentration.
    a. At or below the No Observable Adverse Effect Level (NOAEL) concentration exposure to gaseous agents is limited to 5 minutes.
2. Extinguishment time at the minimum design concentration compliant with applicable standards.
    a. Class A fire (involving ordinary combustible materials, such as wood, cloth, and paper): Extinguishment time of 10 minutes or less.
    b. Class B fire (involving flammable or combustible liquids, petroleum greases, tars, oils, oil-based paints, solvents, lacquers, and alcohols): Extinguishment time of 30 seconds or less.

Other non-regulatory requirements may be deemed essential in some applications including:

1. Agent must be "clean," i.e., electrically non-conducting volatile liquid or gaseous agent which leaves no residue (liquid or solid).
2. The physical size of installed equipment (agent containers, piping, control equipment) must be able to fit in the available space.
3. The weight of the installed equipment must be less than the maximum allowed floor loading or vehicle capacity, as applicable.
4. The agent must be able to achieve the required "hold-time," i.e. the duration of protection after the end of agent discharge.

OVERVIEW OF ONBOARD AIRCRAFT FIRE SUPPRESSION

Background

Although the incidence of in-flight fires is low, the consequences in terms of loss of life are potentially devastating, and the use of HCAs to help guard against such events has been a key aspect of aircraft fire safety for over 50 years. Aviation applications are among the most demanding and critical uses of the fire suppression agents and require every one of their beneficial characteristics. Particularly important are the following:

- dispersion and suppression effectiveness, which must be maintained even at the low temperatures encountered at high altitude,
- minimal toxic hazard to the health and safety of ground maintenance staff and passengers and flight crew, who could be exposed to the agent and any decomposition products for periods as long as several hours, and
- weight and space requirements of the agent and associated fire protection system.

Also significant are short- and long-term damage to aircraft structure or contents resulting from the following:

- the agent or from its potential decomposition products in a fire,
- avoidance of clean-up problems,
- suitability for use on live electrical equipment,
- effectiveness on the hidden fire (the ability to indirectly extinguish fires), and
- the installed cost of the system and its maintenance over its life.[7]

Historically halons were used in active fires suppression systems to protect lavatories, engines nacelles, auxiliary power units (APUs) and cargo compartments, and in handheld extinguishers in the passenger cabin. After 30 years of research, testing and standard development, Halon 1301 systems are still being installed in the cargo compartments, engine nacelles and APUs of all new production aircraft. With the runout date for supplies of recycled halons possibly less than 10 years away, it is critical that alternatives begin being used as soon as possible. At a time when airframe manufacturers and OEMs have been acting with urgency and are close to gaining approval for halon replacements, the PFAS issue has the potential to set those efforts back several decades. Below is a quote from the 2023 Progress Report of the Montreal Protocol Technology and Economic Assessment Panel (TEAP) that expresses this concern:[4]

"A new factor that may affect the halon 1301 and 1211 run-out dates is the proposed PFAS regulations. There are many fluorine containing fire suppression agents which may be regulated under the pending PFAS regulations that only have halon as an alternative. Destruction of PFAS fire suppressants in lieu of recovery and re-use or a reluctance to decommission existing halon systems and convert to alternatives that would be considered PFAS may put additional pressure to continue reliance on halons."

PFAS used for onboard aircraft fire suppression and alternatives

HFCs

HFC-227ea and HFC-236fa are currently used in lavatory fire suppression systems on commercial aircraft as a replacement for Halon 1301. There are other HCAs in development for this use, but no non-PFAS alternatives have passed the Federal Aviation Administration (FAA) minimum performance standard (MPS). Based on the nature of the hazard and the small size of the required system, it is possible that a non-PFAS agent such as inert gas or water could be made to work in this application, however, no testing of these agents for this application has been successfully completed to date. Given the long lead times required to gain approval for the use of a new fire suppressant on aircraft, HFCs are likely to still be installed in lavatories on commercial aircraft after January 1, 2032.

2-BTP

Handheld extinguishers containing 2-BTP (2-bromo 3,3,3-trifluoropropene) are currently being installed on most new production aircraft as a replacement for Halon 1211, and some existing aircraft are expected to be retrofitted to 2-BTP extinguishers in the future. International Civil Aviation Organization (ICAO) standards called for all new production aircraft to be installed with handheld extinguishers containing a Halon 1211 replacement by 2018.[14] There are currently no other candidate agents for this use that are not also PFAS. Non-PFAS alternatives such as CO2, dry powder, and water have been tested for this use and failed to pass the handheld extinguisher MPS tests.

2-BTP is also under development to replace Halon 1301 in cargo compartments of commercial aircraft as part of a blend with CO_2. The FAA completed proof-of-concept testing for the 2-BTP/CO_2 blend in 2018[15] and cargo MPS testing was successfully conducted by the FAA in 2019.[16] Additional testing to an updated cargo MPS multiple fuels fire (flammable liquid / lithium battery / class A) was successfully completed in 2023. A non-PFAS alternative in the form of a hybrid water mist/inert gas system using nitrogen passed a previous cargo MPS in 2017, but has not been subjected to the latest version of the MPS and would require modification to pass the newer test standards.[17] Further detailed information on the status of efforts to replace Halon 1301 in cargo fire extinguishing systems is available in the International Coordinating Council of Aerospace Industries Associations (ICCAIA) Aircraft Halon Replacement Working Paper presented at the 41st Assembly of the International Civil Aviation Organization (ICAO) in 2022.[18]

OVERVIEW OF MILITARY FIRE SUPPRESSION

Background

Military fire protection systems are unique in that they must protect personnel and platforms from the consequences of combat damage and also protect against ‘peacetime’ fires. Fires due to combat events are generally very fast-growing and relatively large. Fire protection systems are required to counter these threats, often while allowing occupants to remain in the affected spaces. A point to consider when choosing extinguishing agent for spaces that are normally occupied is whether the enclosure must remain operational during combat operations or can be evacuated. If the enclosure must stay occupied during a fire event, then a limited number of agents are available for consideration due to toxicity concerns. However, if evacuation of the enclosure is an option, a wider range of agents is available similar to commercial applications.[7]

PFAS used for military fire suppression and alternatives

The full range of HCAs and non-PFAS alternatives have been investigated for military applications, including CO2, inert gases, HFCs, dry chemicals, and other gaseous chemicals. For some of these specialized applications, HFCs have been the only alternatives demonstrated to meet these stringent requirements. HFC-125, HFC-227ea and to a lesser extent HFC-236fa are used for fire and explosion suppression in critical military applications including the following:

- Protection of engine and crew compartments on military ground vehicles
- Protection of machinery spaces, engine spaces, command centers, fuel pump rooms and flammable liquid storage compartments on naval ships and submarines
- Protection of crew compartments and engines on military aircraft

Like civil aviation, 2-BTP is currently replacing Halon 1211 in handheld extinguishers on military aircraft.

Significant research has shown that there are no alternatives to HCAs that meet all military performance requirements. Thus, many of today’s fielded weapon systems and support equipment will remain in service for the foreseeable future. Barring mandatory decommissioning, these mission-critical HCA-based fire protection systems will need to be supported to at least 2050 and likely beyond. Fire protections systems on military vehicles, ships and aircraft can realistically only be replaced when major maintenance or modifications/upgrades are carried out since they are normally in service and operating all over the world. Given that the military sector is not a significant user of these chemicals in terms of global demand, industry sources have informed militaries that they have no plans to invest additional resources to develop alternative chemicals specifically for these unique applications. Therefore, military investigations into alternatives are limited to those chemicals that are used for other commercial applications.

Preface

Technical Note #1, *Fire Protection Alternatives to Halons, HCFCs and HFCs*, supplements Chapter 3, of the same title, of the 2018 Assessment Reports of the UNEP Halon Technical Options Committee (HTOC). The Halon Technical Options Committee elected to take this approach as much of the information that, while important to understand when developing strategies for selecting alternatives to halons, has been largely reported in prior editions of Assessment Reports. The Assessment Reports contain important new updates on evolving technologies, but this usually forms only a small portion of the chapter content. As such, it was deemed by the HTOC to make the *Alternatives* subject a stand-alone document that is referenced by future Assessment Reports. By this approach those having particular interest in the technical aspects of the *Alternatives* subject can access a self-contained document addressing those issues.

Following the Kigali Amendment to the Montreal Protocol, the role of the HTOC has broadened in that it now has to cover alternatives to high-GWP HFCs as well as halons, HCFCs and their alternatives. Therefore, the contents of this technical note have been expanded accordingly.

Table of Contents

List of Tables

1 Introduction

Halons were remarkably good fire extinguishants; following their production phase-out, only 25% of system applications were “in-kind” (vaporizing liquids that left no residue and acceptable toxicity), the other 75% being various other “not-in-kind” solutions (e.g., sprinklers, water mist, foam, dry chemical, carbon dioxide (CO_2)). For portable extinguishers, the split is approximately 20% “in-kind”, 80% “not-in-kind”.

There are several in-kind alternatives to halons. These started with hydrochlorofluorocarbons (HCFCs) and perfluorocarbons (PFCs), followed closely by hydrofluorocarbons (HFCs) and inert gases (IGs), and more recently by a fluoroketone (FK). The HCFCs and PFCs are no longer used in new total flooding fire extinguishing systems and their use is limited to supporting existing systems. Today, for all practical purposes, there are three types of in-kind alternatives to the ozone-depleting fire extinguishants (halons and HCFCs) used in new fire extinguishing systems - these are HFCs, inert gases and an FK. The FK and inert gases also represent low-Global Warming Potential (GWP) and no-GWP alternatives to the halons, PFC’s, HCFCs and high-GWP HFCs. The status of each class of gaseous fire extinguishing agent is summarized in Table 1.1 below.

Table 1.1: Alternatives to Halons, PFCs, HCFC and HFCs

Agent type	ODP	GWP	Status as alternative
Halons	High	High	N/A
PFCs	Zero	High	Can be viewed as halon alternatives, but only to support existing systems
HCFCs	Low	Low	Can be viewed as halon alternatives, but only to support existing systems
HFCs	Zero	High	Can be viewed as halon, PFC & HCFC alternatives
FK	Zero	Low	Can be viewed as halon, PFC, HCFC & HFC alternatives
HBFOs	Very low	Very low	Can be viewed as halon, PFC, HCFC & HFC alternatives
Inert Gas	Zero	Zero	Can be viewed as halon, PFC, HCFC & HFC alternatives

Since the 2014 Assessment Report, no substantial progress on potential alternatives has been reported. A hydrochlorofluoro-olefin, HCFO-1233zd(E), was proposed but has subsequently been withdrawn. More recently, the manufacturer has proposed a blend of this agent with the fluoroketone FK-5-1-12. Nevertheless, the HTOC is of the opinion that although research to identify potential new fire protection agents continues, it could be several years before a viable agent could possibly have significant impact on the fire protection sector. This could be as little as five years if the agent has undergone some development (e.g. CF_3I) or as much as ten years if the agent is only in the research and development phase.

1.1 Overview

Halons 1301, 1211, and 2402 are highly effective, important fire extinguishing chemicals. Unfortunately, halons are potent ozone depleting substances (ODSs), and, as such, were phased out of production, beginning in the mid-1990s under the terms of the Montreal Protocol and its amendments. Availability of halons today relies entirely on recovered and recycled materials. Several non-(ODSs) have been introduced for use as fire extinguishant alternatives. Technical Note #1 addresses several technical aspects of halon, HCFC and HFC alternatives. To begin, it is useful to understand different types of fires as they relate to selection of the best available alternative extinguishing agents.

1.1.1 Fire types and classification

There are several categories of fire types based on the physical or chemical nature of the fuel involved. The designation of the classification of fuel types varies by region and is summarized below.

Table 1.2: Classifications of fuel types by region

	Fuel Type Classification	
Region	United States	Europe, Australia & Asia
Ordinary combustibles (wood, paper, plastics, etc.)	Class A	Class A
Flammable liquids	Class B	Class B
Flammable gases	Class B	Class C
Electrical equipment	Class C	Class E
Combustible metals	Class D	Class D
Cooking oil or fat	Class K	Class F

1.1.2 Considerations in selecting a fire extinguishing agent

Halons, HCFCs and HFCs were not, and are not, used on fires involving combustible metals, nor for fire extinguishment in commercial cooking applications (hot cooking oils). These agents were commonly used for fire protection in applications involving the other listed fire classes - ordinary combustibles, flammable liquids, flammable gases, and electrical equipment. Each fire protection application involving one or more of these fire types has distinct characteristics that must be considered in selecting the best alternative fire protection technology. Examples of important application characteristics include:

- temperature, pressure, and altitude above sea level of the protected object or space;
- temperature of the location of the agent storage tanks;
- whether or not the space may be occupied at the time a fire occurs;
- whether fire extinguishing is to be achieved by directing agent directly onto or about a protected object or surface (local application);
- whether fire extinguishing is to be achieved by creation of a fire extinguishing atmosphere throughout a defined volume (total flooding);

- pressure strength of the enclosure;
- availability of a water supply;
- asset or operational value of objects and spaces being protected;
- ability to minimize collateral damage and thereby limit downtime of equipment;
- sensitivity of protected objects and spaces to collateral damage by water or combustion gases (including agent decomposition gases, if applicable).

Halons, as defined in Group II of Annex A of the Montreal Protocol, form a class of halogenated chemicals containing bromine that have been, and in some instances, continue to be used as gaseous extinguishing agents in a wide range of fire and explosion protection applications. As previously noted, halons are potent stratospheric ozone depleting chemicals when released to the atmosphere. Halons have been phased out of production under the Montreal Protocol. The phase-out of halon production has had a dramatic impact on the fire and explosion protection industry. Halons are clean (do not leave non-volatile residues), non-conductive, and highly effective. Halon 1301, in particular, is safe to breathe at concentrations typically employed for total flooding fire extinguishing systems and explosion prevention (inerting) applications. HFCs, the FK and the inert gases developed to replace halons are also clean, non-conductive and are safe to breathe at the concentrations employed. There are some cases where only the original halon or a high-GWP HFC are the only choices to meet fire protection requirements, e.g., crew spaces of armoured vehicles and low temperature inerting.

Halon 1211 was widely employed as a “streaming agent” in hand-portable and wheeled fire extinguishing units. Alternatives include HCFC Blend B (HCFC-123, PFC-14 and argon), HFC-236fa and the FK, which also represents a low-GWP alternative to halon 1211, HCFC Blend B, and the high-GWP HFC-236fa, in some applications. Non-ODS alternatives exist for most applications but there are some cases where only the original halon or the HCFC Blend B or a high-GWP HFC are the only choices to meet fire protection requirements, e.g., for halon 1211 and HCFC Blend B - Aircraft Rescue and Fire Fighting vehicles on airport ramps; for halon 1211 and HFC-236fa . Halon 2402 has been used in both total flooding and streaming agent applications and its alternatives are the same as for halons 1301 and 1211.

Selection of the best fire protection method in the absence of halons, while also avoiding HCFCs and HFCs, is often a complex process. Either alternative gaseous fire extinguishing agents, or other agent types or extinguishing methods, may be used, but the decision is driven by the details of the hazard being protected, the characteristics of the gaseous agent or alternative method, and the risk management philosophy of the user.

Gaseous extinguishing agents that are electrically non-conductive and which leave no residue are referred to as “clean” agents. (By this definition, carbon dioxide is also a “clean” agent. However, carbon dioxide is fatally toxic to people at concentrations in air that are well below fire-extinguishing concentrations and, therefore, cannot be deployed in spaces where people may be exposed.) Several alternative clean agents, and “not-in-kind” alternative technologies, have been introduced to the market to serve fire protection applications once served by halons. With the impending phase-out of HCFCs and the phase-down of HFCs under the Montreal Protocol, the purpose of this technical note is to provide a brief review of the alternatives to halons, HCFCs and HFCs that are available, including information on physical and chemical characteristics, fire protection capabilities, toxicity, and key environmental parameters.

1.1.3 Standards

There are numerous national and international fire protection standards that affect some of the measures of performance and guidelines for minimum concentrations of gaseous agents, depending on hazard type. Two of the most widely-adopted are NFPA 2001 and ISO 14520 and these standards do not agree exactly for each type of fire hazard. The minimum design concentrations for the various fire-hazard types are outlined below.

- Class A combustibles surface fire
    - NFPA 2001 and ISO 14520 have adopted different standards for the minimum design concentration for extinguishment of a Class A surface fire.
    - ISO 14520. The minimum extinguishing concentration for a Class A surface fire hazard shall be the greater of the extinguishing concentration values determined by the wood crib and polymeric sheet fire tests described in ISO 14520 Annex C of the agent-specific part. The minimum design concentration for a Class A fire shall be the extinguishing concentration increased by a safety factor of 1.3.
    - NFPA 2001. The minimum extinguishing concentration for a Class A surface fire hazard shall be the greater of the extinguishing concentration values determined by the wood crib and polymeric sheet fire tests described in NFPA 2001 Annex A. The minimum design concentration for a Class A fire shall be the greater of the following:
    - The Class A extinguishing concentration times a safety factor of 1.2; or
    - The minimum extinguishing concentration for heptane as determined by the cup burner method.
- ISO 14520 “Higher Hazard Class A” applications.
    - This classification of Class A hazards includes examples such as: cable bundles greater than100 mm in diameter; cable trays with a fill density greater than 20 % of the tray cross-section; horizontal or vertical stacks of cable trays (closer than 250 mm); equipment energized during the extinguishment period where the collective power consumption exceeds 5 kW.
    - The minimum design concentration for Higher Hazard Class A applications shall be the higher of the minimum design concentration for either Surface Class A combustibles surface fire, or 95 % of the minimum design concentration Class B fuel fire.
- Class B fuel fire
    - Both NFPA 2001 and ISO 14520 are now in harmony with respect to requiring a minimum safety factor of 1.3 applied to the greater of the heptane extinguishing concentrations determined by the cup-burner method[1] or a pan-fire test[2] where the fire hazard is due to Class B combustibles.
- NFPA 2001 Class C fire hazard – electrified equipment
    - Equipment operating at less than 480 volts.
        - The minimum agent design concentrations is 1.35 times the Class A extinguishing concentration.

---

[1] See NFPA 2001 Annex B or ISO 14520 Annex B.

[2] See NFPA 2001, Annex A or ISO 14520 Annex C.

- Equipment operating at greater than 480 volts.
  - The minimum design concentration for spaces containing energized electrical hazards supplied at greater than 480 volts that remain powered during and after discharge shall be determined by testing, as necessary, and a hazard analysis NFPA

The following two subsections provide an overview of toxicity and environmental aspects of alternatives to halons, and the same principles apply to alternatives to HCFCs and HFCs. More detailed information on these topics and other agent properties is presented later, addressing total flooding and streaming agents, respectively.

1.1.4 Agent Toxicity

In general, personnel should not be exposed unnecessarily to atmospheres into which gaseous fire extinguishing agents have been discharged. Mixtures of air and halon 1301 have low toxicity at fire extinguishing concentrations and there is little risk posed to personnel that might be exposed in the event of an unexpected discharge of agent into an occupied space. The acceptance of new agents for use in total flooding fire protection in normally occupied spaces has been based on criteria that have evolved over the period of introduction of new technologies into the marketplace. In the case of inert gas agents, the usual concern is the residual oxygen concentration in the protected space after discharge. For chemical agents, the primary health issue is cardiac effects as a consequence of absorption of the agent into the blood stream. The highest agent concentration for which no adverse effect is observed is designated the “NOAEL” for “no observed adverse effect level”. The lowest agent concentration for which an adverse effect is observed is designated the “LOAEL” for “lowest observed adverse effect level”. This means of assessing chemical agents has been further enhanced by application of physiologically based pharmacokinetic modelling, or “PBPK” modelling, which accounts for exposure times. Some agents have their use concentration limits based on PBPK analysis. The approach is described in more detail in ISO 14520-1, Annex G, (2016). Health issues for the other alternatives (e.g. CO_2, water mist, fine solid particulate) are described in more detail later in this document.

1.1.5 Environmental Factors

The primary environmental factors to be considered for halogenated gaseous agents[3] are ozone-depletion potential (ODP), global-warming potential (GWP), and atmospheric lifetime, values of which are noted in Tables 2.1, 2.2, 2.5, 2.12, 3.1, 3.2, 3.3 and 4.1. It is important to select the fire protection choice with the lowest environmental impact that will provide the necessary fire protection performance for the specific application. The use of any synthetic compound that accumulates in the atmosphere carries some potential risk with regard to atmospheric equilibrium changes. Perfluorocarbons (PFCs), in particular, represent an unusually severe potential environmental impact due to the combination of extremely long atmospheric lifetime and high

[3] Halogenated gaseous agents, include hydrochlorofluorocarbons (HCFCs), hydrofluorcarbons (HFCs), perfluorocarbons (PFCs), a fluoroketone (FK), a fluoroiodocarbon (FIC), a hydrobromofluoro-olefin (HBFO) and potentially a hydrochlorofluoro-olefin (HCFO), that are used for fire-fighting applications. Each of these chemicals is stored either as a liquefied compressed gas or as a liquid at room temperature, is electrically non-conductive, and leaves no residue upon vaporisation.

GWP. PFCs are no longer used as primary extinguishants in new systems, though a small amount of CF_4, less than 2 %, is used as an additive in HCFC Blend B, a streaming agent. PFC use in legacy systems is diminishing. Thus, PFC agents are not considered to be viable alternatives and are not addressed further. International agreements and individual actions by national governments may affect future availability of several compounds and subsequent support for installed fire protection systems that utilize them. Some examples are presented below:

- HCFCs are scheduled for a production and consumption[4] phase-out for fire protection uses under the Montreal Protocol in 2020 in non-Article 5 **(non-A5)** parties and 2030 in Article 5 **(A5)** parties. In November 2018, the parties to the Montreal Protocol agreed to adjust the Protocol and adopted a corresponding Decision XXX/2 to allow the use of newly produced HCFCs for the servicing of niche applications such as fire suppression and fire protection equipment existing on 1 January 2020 for the period 2020-2029 for non-A5 parties and also on existing equipment in 1 January 2030 for the period 2030-2039 for A5 parties.
- The United Nations Framework Convention on Climate Change (UNFCCC) has identified carbon dioxide, methane, nitrous oxide and the fluorochemicals HFCs, PFCs and SF_6 as the basket of long-lived (>1 year) gases primarily responsible for anthropogenic changes to the greenhouse effect and potentially subject to emission controls. All uses of fluorochemicals represent 4–5% of current worldwide greenhouse gas emissions from long-lived gases on a carbon equivalent basis and fire protection uses represent less than 1% of those fluorochemical emissions.
- In October 2016, at the 28th Meeting of the parties in Kigali, Rwanda, Decision XXVIII/1 contained an amendment to add HFCs to the Montreal Protocol and slowly phase down their production and consumption. Unlike the controls on ODS that require a complete phase-out of production and consumption of controlled uses, the controls on HFCs are intended to only significantly reduce production (on a carbon dioxide equivalent basis), but not eliminate it. Under the Kigali Amendment, the production phase down would begin in most non-A5 parties with a 10% reduction in 2019 and end with an 85% reduction in 2036. For most A5 parties, the phase down would begin with a production freeze in 2024 and end with an 80% reduction in 2045. The amendment provides for a slight delay in the phase-down schedules for a group of parties in Eastern Europe and a group of parties with high ambient temperatures.

- In the EU, Regulation (EU) No. 517/2014 (known as the F-Gas Regulation), establishes rules on containment, use, recovery and destruction of fluorinated greenhouse gases in order to protect the environment. Related ancillary measures impose conditions on the placing on the market of specific products and equipment that contain, or whose functioning relies upon, fluorinated greenhouse gases, and establishes quantitative limits for the placing on the market of HFCs.

[4] Consumption equals production plus imports minus exports for an individual country.

2 Total flooding agents

A "total flooding" agent is any of several inert gases or volatile chemicals that, when dispersed throughout a protected volume, creates a fire extinguishing atmosphere. A number of fire extinguishing agent technologies have been commercialized for use in total flooding applications. Attributes of these are summarized, below.

Several agents have been incorporated into consensus standards, specifically NFPA 2001, ISO-14520 and other national standards, for use in normally occupied spaces. These agents include certain inert gases, HFCs and an FK. These agents may be used for total flooding fire protection in normally occupied spaces provided that the design concentration is below the safe exposure threshold limits shown in Tables 2.1, 2.2, 2.4 and 2.8. In addition, these standards include an FIC, but due to its higher toxicity this agent is not approved for normally occupied spaces.

The United States Environmental Protection Agency (US EPA), under the Significant New Alternatives Policy (SNAP) program, has reviewed a number of materials as substitutes for halons as fire extinguishing agents. The approval status in the US of a number of such alternatives for use in total flooding systems are included as Annex A.

Agencies of other countries administer their own regulations on suitability of alternatives to halons. One example is in Germany, the Berufsgenossenschaftliche.

2.1 Halogenated Gaseous agents

The tables below summarize key attributes of commercially available, technically proven halogenated gaseous agents for total flooding fire protection using fixed systems. The attributes addressed relate to efficacy, toxicity, volatility, environmental and relative cost characteristics. Cost effectiveness is represented by an index that is benchmarked against carbon dioxide total flooding systems, averaged over a wide range of application sizes, exclusive of the cost of pipe, fittings and installation and is based on 2003 data. Owing to commercial confidentiality, it has not been possible to use more current data, but nevertheless the indices are believed to be relatively accurate.

Table 2.1: Non-ODS halogenated gaseous agents

Agent	FK-5-1-12	HFC-23	HFC-125	HFC-227ea
Efficacy	For use in occupied spaces MDC(A) = 5.3 vol% MDC(B) = 5.9 vol% (1)	For use in occupied spaces MDC(A) = 16.3 vol% MDC(B) = 16.4 vol% • Suitable for "inerting" some otherwise flammable atmospheres at concentrations below the LOAEL value. • Suitable for use at low temperatures (below -20 °C).	For use in occupied spaces MDC(A) = 11.2 vol% MDC(B) = 12.1 vol%	For use in occupied spaces MDC(A) = 7.9 vol% MDC(B) = 9.0 vol%
Toxicity	NOAEL = 10 vol% LOAEL > 10 vol%	NOAEL = 30 vol% LOAEL > 30 vol%	NOAEL = 7.5 vol% LOAEL = 10 vol% Approved for use in occupied spaces at up to 11.5 vol% based on PBPK modelling.	NOAEL = 9 vol% LOAEL = 10.5 vol% Approved for use in occupied spaces at up to 10.5 vol% based on PBPK modelling.
	Some acidic decomposition products are formed when a halogenated fire extinguishing agent extinguishes a fire.			
Safety Characteristics	Liquid at 20 °C B.P. = 49.2 °C	Liquefied compressed gas. B.P. = -82 °C	Liquefied compressed gas. B.P. = -48.1 °C	Liquefied compressed gas. B.P. = -16.4°C
Environmental Characteristics (2)	ODP = 0 GWP = <1	ODP = 0 GWP = 12 400	ODP = 0 GWP = 3170	ODP = 0 GWP = 3350
Cost-Effectiveness, avg. for 500 to 5000 m^3 volume (2003 data)	~1.7 to 2.0	~2.0 to 2.3	Not available	~1.5

Note 1: MDC(A) and MDC(B) refer to the minimum design concentration for a Class A or Class B fire hazard.
Note 2: Source: IPCC 5^{th} WGI Assessment Report, 2013: http://www.climatechange2013.org/

The agents addressed in Table 2.2 are ODS. While use of these agents is permitted for use in new fire extinguishing systems in many jurisdictions, the practice at present is primarily to use these agents to recharge legacy systems and to choose non-ozone-depleting agent for new systems.

Table 2.2: HCFC agents

Agent	HCFC Blend A 82 weight% HCFC 22 9.5 weight% HCFC 124 4.75 weight% HCFC 123 3.75 weight% isopropenyl-1-methylcyclohexane	HCFC-124
Efficacy	For use in occupied spaces MDC(A) = 7.9 vol% MDC(B) = 9.0 vol%	For use in unoccupied spaces MDC(A) = (1) MDC(B) = 8.7 vol%
Toxicity	NOAEL = 10 vol% LOAEL > 10 vol%	NOAEL = 1 vol% LOAEL = 2.5 vol%
	Some acidic decomposition products are formed when a halogenated fire extinguishing agent extinguishes a fire.	
Safety Characteristics	B.P. = -38.2 °C	B.P. = -12.1 °C

HFC Blend B (4)	14.7 (5)	14.7	-	5	7.5	5

Note 1: Minimum design concentration as given in Table 5 of ISO 14520-(agent-specific volume), where available.

Note 2: A halocarbon agent may be used at a concentration up to its NOAEL value in normally occupied enclosures provided the maximum expected exposure time of personnel is not more than five minutes. A halocarbon agent may be used at a concentration up to the LOAEL value in normally occupied and normally unoccupied enclosures provided certain criteria are met that depend on agent toxicity and egress time. The reader is referred to NFPA 2001-1.5 (2018) and ISO 14520-G.4.3 (2015) for details of the recommended safe exposure guidelines for halocarbon agents.

Note 3: Exceptions, halon 1301 design concentration is taken as the historical employed value of 5%.

Note 4: Not approved for use in occupied spaces.

Note 5: Agent manufacturer did not provide Class A extinguishing concentration data. Class A design concentration in this case was taken as Class B design concentration.

Note 6: Agent exposure guidance is as indicated in ISO 14520-1 (2015) Annex G.

The table below summarizes the environmental attributes of halocarbon agents including ODP, 100-year GWP, and atmospheric lifetime.

Table 2.5: Halogenated gaseous agents used in total flooding applications – environmental factors

Generic Name	Ozone Depletion Potential (1)	Global Warming Potential, 100 yr. (2)	Atmospheric Life Time, yr. (2)
Halon 1301	10	7,140	65
HCFC-22 (component in HCFC Blend A)	0.055	1,760	11.9
HCFC-124 (component in HCFC Blend A)	0.022	527	5.9
HCFC-123 (component in HCFC Blend A)	0.02	79	1.3
HFC-23	0	12,400	222

FK-5-1-12	0.872	2.63	0.540	1,480	2.00	25, 34.5, 42 or 50
HFC Blend B	0.733	2.22	0.616	929	2.67	25 or 42

Note 1: Agent quantities based on a safety factor of 1.3. Nominal maximum discharge time is 10 seconds in all cases.
Note 2: Mass and volume ratios based on "Minimum Class B Fire Design Concentrations." See Table 2.4.
Note 3: Fill density based on 25 bar pressurization except for HFC-23.
Note 4: Agent cylinder volume per m^3 of protected volume = (Agent Mass, kg/m^3 of protected volume)/(Maximum Fill Density, kg/m^3 cylinder) = ($V_{CYL}/V_{ProtVol}$). For halon 1301 cylinder volume per m^3 of protected volume = (0.331 kg/m^3 hazard)/ (1,121 kg/m^3 cylinder) = 0.0002953 m^3 cylinder/m^3 of protected volume.

2.2 Inert gas agents

Inert gas clean agents have zero ODP and zero GWP.[5] There have been at least four inert gases or gas mixtures commercialized as clean total flooding fire suppression agents. Inert gas agents are typically used at design concentrations of 35 vol % to 50 vol %, which reduces the ambient oxygen concentration to between 14 vol % to 10 vol %, respectively. Reduced oxygen concentration (hypoxia) is the principal human safety risk for inert gases except for carbon dioxide which has serious human health effects at progressive severity as its concentration increases above 4 vol %. Inert gas agents mixed with air lead to flame extinguishment by

[5] Inert gas agent IG-541 contains 8 vol % carbon dioxide.

physical mechanisms only. The inert gas agents commercialized since 1990 consist of nitrogen, argon, and blends of nitrogen and argon. One blend contains 8 % carbon dioxide. The features of the commercialized inert gas agents are summarized in Tables 2.8 and 2.9.
These agents are electrically non-conductive, clean fire suppressants. The inert gas agents containing nitrogen or argon differ from halogenated gaseous agents in the following ways:

- Inert gases can be supplied from high pressure cylinders, from low pressure cryogenic cylinders, or from pyrotechnic solids. High pressure systems use pressure reducing devices at or near the discharge manifold. This reduces the pipe thickness requirements and alleviates concerns regarding high pressure discharges.
- High pressure system discharge times are on the order of one to two minutes. This may limit some applications involving very rapidly developing fires.
- Inert gas agents are not subject to thermal decomposition and hence form no hazardous by-products.

The table below summarizes key attributes of inert gas agents.

Table 2.8: Inert gas agents

Agent	IG-01	IG-100	IG-55	IG-541
Efficacy	For use in occupied spaces MDC(A) = 41.9 vol% MDC(B) = 51 vol %	For use in occupied spaces MDC(A) = 40.3 vol% MDC(B) = 43.7 vol %	For use in occupied spaces MDC(A) = 40.3 vol% MDC(B) = 47.5 vol %	For use in occupied spaces MDC(A) = 39.9 vol% MDC(B) = 41.2 vol %
Toxicity	Discharge of an inert gas system results in a significant reduction in the oxygen concentration within the protected area. See Table 2.10 regarding concentration and exposure limits for inert gas systems in normally occupied areas.			
Safety Characteristics	High-pressure compressed gas up to 300 bar			
Environmental Characteristics	No adverse characteristics			
Cost-Effectiveness, avg. for 500 to 5000 m^3 volume (2003 data)	~1.8	~1.8	~1.8	~1.8

The table below summarises the main characteristics of inert gas agents including composition, environmental factors, physical properties, and minimum extinguishing concentrations for Class A and Class B fires.

Table 2.9: Properties of inert gas agents for fixed systems

ISO Designation	IG-01	IG-100	IG-55	IG-541
ISO 14520 Part	14520-12	14520-13	14520-14	14520-15
Agent composition				
Nitrogen		100 %	50 %	52 %
Argon	100 %		50 %	40 %
Carbon dioxide				8 %

Inerting design conc., Methane/Air, vol %	61.4	-	-	47.3
Oxygen conc. at min. inerting design conc., vol %	8.1	-	-	11.0

Note 1: Agent vapour specific volume = $k_1 + k_2 \cdot t$, m^3/kg at an atmospheric pressure of 1.013 bar where t is the vapour temperature in °C. Vapour density = 1/s.
Note 2: Extinguishing and design concentration values from ISO 14520 (2015).

2.2.1.1 Physiological effects of inert gas agents

The primary health concern relative to the use of the inert gas agents containing nitrogen or argon is the effect of reduced oxygen concentration on the occupants of a space. The use of reduced oxygen environments has been extensively researched and studied. Many countries have granted health and safety approval for use of inert gases in occupied areas in the workplace. One product contains 8 vol % carbon dioxide[6], which is included to increase blood oxygenation and cerebral blood flow in low-oxygen (hypoxic) atmospheres.

The table below contains exposure guidelines for non-liquefied inert gas agents that are described in detail in ISO 14520-1 (2015), Annex G.

Table 2.10: Exposure limits for inert gas agents

Inert Gas Concentration	Concentration Residual Oxygen Concentration	Permitted Occupancy	Exposure Time Limit
< 43 vol %	> 12 vol %	Normally occupied	5 min
43 to 52 vol %	10 to 12 vol %	Normally occupied	3 min
52 to 62 vol %	8 to 10 vol %	Normally occupied	30 sec
> 62 vol %	< 8 vol %	Normally unoccupied	-

2.2.1.2 Agent exposure limits and system features for inert gas agents

The table below summarises the maximum agent concentration limits for personnel exposure up to 5 minutes, agent requirements for Class A and Class B fires, and some common system features.

[6] Inert gas agent IG-541 contains 8% carbon dioxide and is approved by the U.S. EPA SNAP rules as a safe alternative to halon 1301 in total flooding fire protection systems. At elevated concentrations, however, carbon dioxide is not safe for human exposure and is lethal at fire extinguishing concentrations.

Table 2.11: Inert gas agents - fixed system features

ISO Designation	IG-01	IG-100	IG-541	IG-55
Agent exposure limits				
Max agent concentration where exposure is less than 5 min., vol % (1)	43	43	43	43
Max agent concentration where exposure is less than 3 min, vol % (2)	52	52	52	52
System requirements per m^3 of protected volume				
Class A hazard				
Agent gas volume, m^3 (3)	0.407	0.387	0.381	0.387
Cylinder storage volume, litre (4)	3.01	2.87	3.38	3.44
Cylinder volume relative to halon 1301 (5)	9.90	9.40	11.1	11.2
Class B hazard				
Agent gas volume, m^3 (3)	0.712	0.575	0.577	0.644
Cylinder storage volume, litre (4)	3.95	3.19	3.84	4.30
Cylinder volume relative to halon 1301 (5)	13.0	10.4	12.6	14.0
System Features				
Available cylinder sizes (typical), litre	16;67;80	16;67;80	16;67;80	16;67;80
Available cylinder pressures, bar	150 to 300	150 to 300	150 to 300	150 to 300
Nominal Discharge Time, seconds	60	60	60	60

Note 1: Corresponds to a residual oxygen concentration of 12 vol %.
Note 2: Corresponds to a residual oxygen concentration of 10 vol %.
Note 3: Based on minimum design concentrations in ISO14520, Parts 12 to 15 (2015).
Note 4: Approximate, for the 200 bar cylinder pressure.
Note 5: Halon 1301 cylinder volume per m^3 hazard. See Note 4 of Table 2.6.

2.3 Carbon dioxide

Carbon dioxide was used widely for fire protection prior to the introduction of halons. Due to its toxicity, use of carbon dioxide in occupied or occupiable spaces requires the implementation of significant safety measures. Nonetheless, carbon dioxide has seen a resurgence in use subsequent to the halon production phase-out, particularly in new commercial ship construction where halon 1301 once had a significant role. Minimum design concentrations for carbon dioxide are specified in national and international standards such as NFPA 12 and ISO 6183. The minimum design concentration for carbon dioxide systems is, typically, 35 vol % for Class B fuels and 34 vol % for Class A applications.

2.3.1 Carbon dioxide toxicity

Carbon dioxide is essentially chemically inert as a fire extinguishing gas. Carbon dioxide does, however, have significant adverse physiological effects when inhaled at concentrations above 4 vol %. The severity of physiological effects increases as the concentration of carbon dioxide in air increases. Exposure to carbon dioxide at concentrations exceeding 10 vol % poses severe health risks including risk of death. As such, atmospheres containing carbon dioxide at fire extinguishing concentrations are always lethal to humans. Precautions must always be taken to ensure that occupied spaces are not put at risk by ingress of carbon dioxide from a space into which the agent has been discharged.

The use of carbon dioxide is not recommended for total flooding of normally occupied spaces. NFPA 12 (2018) includes new restrictions on the use of carbon dioxide in normally occupied spaces. Safety precautions related to the use of carbon dioxide may also be found in ISO 6183 (2009).

2.3.2 Environmental effects of carbon dioxide

The carbon dioxide used in fire protection applications is not produced for this use. Instead, it is captured from an otherwise emissive use temporarily sequestering it until it is released. Thus, carbon dioxide from fire protection uses has no net effect on the climate. The table below summarizes key attributes of carbon dioxide.

Table 2.12: Carbon dioxide

Agent	Carbon dioxide, CO_2
Efficacy	For use in unoccupied spaces Basic design concentration = 34 vol% for a "material factor" of 1. Design concentrations for specific combustible materials are determined by multiplying the basic design concentration by an applicable material factor. (1)
Toxicity	Progressively more severe physiological effects as exposure concentration increases, especially above 10 vol%. Carbon dioxide concentrations that exceed 17 vol% present an immediate risk to life. (2) Pre-discharge alarm and discharge time delay required.
Safety Characteristics	Liquefied compressed gas Storage pressure: High-pressure cylinder: 55.8 bar at 20 °C Low-pressure tanks (refrigerated): 21 bar at -18 °C Sublimes at -78.5 °C at atmospheric pressure; cold exposure hazard. Vapours are denser than air and can accumulate in low-lying spaces.
Environmental Characteristics	GWP = 1
Cost-Effectiveness, avg. for 500 to 5000 m^3 volume (2003 data)	1

Note 1: See ISO 6183:2009
Note 2: See U.S. Environmental Protection Agency, "Carbon Dioxide as a Fire Suppressant: Examining the Risks," February 2000.

2.4 Water mist technology

Water mist fire suppression technologies are described in national and international standards such as NFPA 750 *Standard on Water Mist Fire Protection Systems* and the FM Approvals Standard No. 5560 *Water Mist Systems.*

Water mist system technologies strive to generate and distribute within a protected space very small water mist droplets which serve to extinguish flames by the combined effects of cooling and oxygen dilution by steam generated upon water evaporation. Technologies used to generate fine water mists include:

- Low pressure single fluid atomization
- High pressure single fluid atomization
- Dual-fluid atomization
- Hot water steam generation

Briefly, fine water mist relies on sprays of relatively small diameter droplets (less than 200 μm) to extinguish fires. The mechanisms of extinguishment include the following:

- Gas phase cooling
- Oxygen dilution by steam formation
- Wetting and cooling of surfaces, and
- Turbulence effects

The table below summarizes key attributes of water mist technology.

Table 2.13: Water mist technology

Agent	Water mist
Efficacy	For use in occupied spaces. Uses approximately 10 % of the total water quantity discharged by traditional sprinkler system to suppress fires, where tested.
Toxicity	None
Safety Characteristics	No adverse safety characteristics
Environmental Characteristics	No adverse characteristics
Cost-Effectiveness, avg. for a 3 000 m^3 application space	~2

Water mist systems offer some advantages due to their low environmental impact, ability to suppress three-dimensional flammable liquid fires under defined conditions, and reduced water application rates relative to automatic sprinklers in certain applications. More recent innovations include use of nitrogen with water mist to achieve inert gas extinguishing effects and use of bi-fluid (air-water) nozzles to achieve ultrafine droplets and adjustable spray patterns (by varying the air-water ratio). The use of relatively small (10-100 μm) diameter water droplets as a gas phase extinguishing agent has been established for at least 40 years. Advances in nozzle design and improved theoretical understanding of fire suppression processes has led to the development of at least nine technologies for use in water mist fire suppression systems. Several systems have been approved by national authorities for use in relatively narrow application areas. To date, these applications include shipboard machinery spaces, combustion turbine enclosures, flammable and combustible liquid storage spaces as well as light and ordinary hazard sprinkler application areas.

Theoretical analysis of water droplet suppression efficiencies has indicated that a liquid water volume concentration on the order of 0.1 litre of water per cubic meter of protected space is sufficient to extinguish fires. This represents a potential of two orders of magnitude efficiency improvement over application rates typically used in conventional sprinklers. The most important aspect of water mist technology is the extent to which the mist spray can be mixed and distributed throughout a compartment versus the loss rate by water coalescence, surface deposition, and gravity dropout. The suppression mechanism of water mist is primarily cooling of the flame reaction zone below the limiting flame temperature. Other mechanisms are important in certain applications; for example, oxygen dilution by steam has been shown to be important for suppression of enclosed 3-D flammable liquid spray fires.

The performance of a particular water mist system is strongly dependent on its ability to generate sufficiently small droplet sizes and distribute adequate quantities of water throughout the compartment. Factors that affect the ability of achieving that goal include droplet size and velocity, distribution, and spray pattern geometry, as well as the momentum and mixing characteristics of the spray jet and test enclosure effects. Hence, the required application rate varies by manufacturer for the same hazard. Therefore, water mist must be evaluated in the combined context of a suppression system and the risk it protects and not just an extinguishing agent.

There is no current theoretical basis for designing the optimum droplet size and velocity distribution, spray momentum, distribution pattern, and other important system parameters. This is quite analogous to the lack of a theoretical basis for nozzle design for total flooding, gaseous systems, or even conventional sprinkler and water spray systems. Hence, much of the experimental effort conducted to date is full-scale fire testing of particular water mist hardware systems which are designed empirically. This poses special problems for standards making and regulatory authorities.

There are currently two basic types of water mist suppression systems: single and dual fluid systems. Single fluid systems utilize water delivered at 7-200 bar pressure and spray nozzles which deliver droplet sizes in the 10 to 100 μm diameter range. Dual systems use air, nitrogen, or another gas to atomize water at a nozzle. Both types have been shown to be promising fire suppression systems. The major difficulties with water mist systems are those associated with design and engineering. These problems arise from the need to distribute and maintain an adequate concentration of mist throughout the space while momentum of hot fire gases, ventilation, gravity and water deposition loss on surfaces deplete the concentration. Engineering analysis and experimental programmes for specific mist products (with unique droplet distribution and concentration) are employed to minimize the uncertainty.

2.4.1 Physiological Effects of water mist.

At the request of the US EPA, manufacturers of water mist systems and other industry partners convened a medical panel to address questions concerning the potential physiological effects of inhaling very small water droplets in fire and non-fire scenarios. Disciplines represented on the Panel included inhalation toxicology, pulmonary medicine, physiology, aerosol physics, fire toxicity, smoke dynamics, and chemistry, with members coming from commercial, university, and military sectors. The Executive Summary (draft “Water Mist Fire Suppression Systems Health Hazard Evaluation;” Halon Alternatives Research Corporation (HARC), U.S. Army, NFPA; March 1995) states the following: “The overall conclusion of the Health Panel’s review is that...water mist systems using pure water do not present a toxicological or physiological hazard and are safe for use in occupied areas. Thus, EPA is listing water mist systems composed of potable water and natural sea water as acceptable without restriction. However, water mist systems comprized of mixtures in solution must be submitted to EPA for review on a case-by-case basis”.

2.4.2 Environmental factors of water mist.

Water mist does not contribute to stratospheric ozone depletion or to greenhouse warming of the atmosphere. Water containing additives may, however, have other environmental contamination risks, e.g., foams, antifreeze and other additives.

2.5 Inert gas generators

Inert gas generators are pyrotechnic devices that utilize a solid material which oxidises rapidly, producing large quantities of carbon dioxide and/or nitrogen. Recent innovations include generators that produce high purity nitrogen or nitrogen and water vapour with little particulate content. The use of this technology to date has been limited to specialized applications such as dry bays on military aircraft. This technology has demonstrated excellent performance in these applications with space and weight requirements equivalent to those of halon 1301 and is currently being utilized in some US Navy aircraft applications. The table below summarizes key attributes of inert-gas generator agents.

Table 2.14: Inert gas generators

Agent	Inert gas by pyrotechnic generator
Efficacy	For use in occupied or unoccupied spaces depending on properties of emitted agent.
Toxicity	Toxicity depends on the type of gas generator. Guidance related to oxygen concentration reduction applicable to inert gas systems must be followed. Additional safety considerations required where discharged gas contains carbon dioxide.
Safety Characteristics	Potentially hot-gas discharge; potential hot surfaces of generator body. Insulating consideration required by generator manufacturer. Discharge of inert gases into an enclosure will cause a rise in pressure to a level that depends on enclosure venting characteristics.
Environmental Characteristics	No adverse characteristics
Cost-Effectiveness	Not available

Physiological effects of inert gas generator agents. The precise composition and properties of the gas produced will affect the response of exposed persons and are determinant factors regarding application in occupied or unoccupied areas. US EPA SNAP has listed as acceptable a gas generator that produces relatively pure nitrogen for use in normally occupied spaces.

Environmental effects of inert gas generator agents. Gases emitted by these products do not contribute to stratospheric ozone depletion or to greenhouse warming of the atmosphere except to the extent that they emit carbon dioxide, if any.

2.6 Fine solid particulate technology

Another category of technologies being developed and introduced are those related to fine solid particulates and aerosols. These take advantage of the well-established fire suppression capability of solid particulates, with potentially reduced collateral damage associated with traditional dry chemicals. This technology is being pursued independently by several groups and is proprietary. To date, a number of aerosol generating extinguishing compositions and aerosol extinguishing means have been developed in several countries. They are in production and are used to protect a range of hazards. The table below summarizes key attributes of fine solid particle agents (powders).

Table 2.15: Fine solid particles (powders)

Agent	Fine solid particles
Efficacy	For use in normally unoccupied spaces on Class B fires.
Toxicity	Precautions require evacuation of spaces before discharge.
Safety Characteristics	For establishments manufacturing the agent or filling, installing, or servicing containers or systems to be used in total flooding applications, U.S. EPA recommends the following: - adequate ventilation should be in place to reduce airborne exposure to constituents of agent; - an eye wash fountain and quick drench facility should be close to the production area; - training for safe handling procedures should be provided to all employees that would be likely to handle containers of the agent or extinguishing units filled with the agent; - workers responsible for clean-up should allow for maximum settling of all particulates before re-entering area and wear appropriate protective equipment Discharge of associated inert gases into an enclosure will cause a rise in pressure to a level that depends on enclosure venting characteristics.
Environmental Characteristics	No adverse characteristics
Cost-Effectiveness	Not available

One principle of these aerosol extinguishants is in generating solid aerosol particles and inert gases in the concentration required and distributing them uniformly in the protected volume. Aerosol and inert gases are formed through a burning reaction of the pyrotechnic charge having a specially proportioned composition. An insight into an extinguishing effect of aerosol compositions has shown that extinguishment is achieved by combined action of two factors such as flame cooling due to aerosol particles heating and vaporizing in the flame front as well as a chemical action on the radical level. Solid aerosols must act directly upon the flame. Gases serve as a mechanism for delivering the aerosol towards the seat of a fire.

A number of enterprises have commercialized the production of aerosol generators for extinguishing systems that are installed at stationary and mobile industrial applications such as nuclear power station control rooms, automotive engine compartments, defence premises, engine compartments of ships, telecommunications/electronics cabinets, and aircraft nacelles.

Fine particulate aerosols have also been delivered in HFC/HCFC carrier gases. A wide range of research into aerosol generating compositions has been carried out to define their extinguishing properties, corrosion activity, toxicity, and effect upon the ozone layer as well as electronics equipment.

Solid particulates and chemicals have very high effectiveness/weight ratios. They also have the advantage of reduced wall and surface losses relative to water mist, and the particle size distribution is easier to control and optimize. However, there is concern of potential collateral damage to electronics, engines, and other sensitive equipment. Condensed aerosol generators, which produce solid particulates through combustion of a pyrotechnic material, are unsuitable for explosion suppression or inerting since pyrotechnic/combustion ignited aerosols can be re-ignition sources. These agents also have low extinguishing efficiency on smouldering materials. Technical problems including high temperature, high energy output of combustion generated aerosols and the inability to produce a uniform mixture of aerosol throughout a complex geometry remain to be solved.

Additional information on fine solid particulate technologies may be found in NFPA 2010 *Standard for Fixed Aerosol Fire Extinguishing Systems*.

2.6.1 Physiological effects of fine particle agents

There are several potential problems associated with the use of these agents. These effects include inhalation of particulate, blockage of airways, elevated pH, reduced visibility, and the products of combustion from combustion generated aerosols, such as HCl, CO, and NO_x. For these reasons, the majority of these technologies are limited to use in only unoccupied spaces.

2.6.2 Environmental effects of fine particle agents

Fine particulate aerosols themselves and associated inert gases from generators do not contribute to stratospheric ozone depletion or to greenhouse warming of the atmosphere. There may be ozone depletion or greenhouse gas effects, however, where aerosols are delivered with carrier gases that are halogenated gaseous agents.

2.7 System design considerations for total flooding agents

Care must be taken throughout the design process to ensure satisfactory system performance. Hazard definition, nozzle location and design concentration must be specified within carefully defined limits. Further, a high degree of enclosure integrity is required. Design requirements are provided by national and international standards such as NFPA 2001 and ISO 14520. An outline of factors to be taken into consideration is given below:

2.7.1 Definition of the hazard

- Fuel type(s)
- Fuel loading
- Room integrity (openings, ventilation, false ceilings, subfloors)
- Dimensions and Net Volume of the room
- Temperature extremes
- Barometric pressure (altitude above sea level for gas systems)

2.7.2 Agent selection

- Statutory approvals
- Personnel safety
- Minimum concentration required (cup burner/full scale tests)
- Design concentration required with factor of safety
- NOAEL/LOAEL or limiting oxygen concentration. Is the agent design concentration within safe exposure limits over the range of feasible hazard temperatures and net volumes?
- Decomposition characteristics
- Replenishment availability

2.7.3 System selection

- System intended for use with the agent selected
  - Pressures, elastomers, gauges, labels
- System has appropriate approvals as the result of third party testing
  - Strength tests (containers, valves, gauges, hoses, etc.)
  - Leakage tests
  - Cycle testing of all actuating components
  - Corrosion tests
  - Cylinder mounting device tests
  - Aging tests for elastomers
  - Flow tests (software verification, balance limitations)
  - Fire tests (nozzle area coverage, nozzle height limitations)
- System has documented design, installation, maintenance procedures

2.7.4 System design

- Automatic detection and control
  - Type of detection (smoke, heat, flame, etc.)
  - Logic (cross zoned, priority designated)
  - Control system features
  - Local and remote annunciation
  - Start up and shut down of auxiliary systems
  - Primary and back-up power supply
  - Manual backup and discharge abort controls
- Central agent storage, distributed or modular
- Electrical, pneumatic or electrical/pneumatic actuation
- Detector location
- Alarm and control devices location
- Electrical signal and power cable specifications
- Nozzle selection and location
- Piping distribution network with control devices
- Piping and other component hangers and supports
- Agent hold time and leakage
- Selection of an appropriate design concentration
- Agent quantity calculations
- Flow calculations
- Pipe size and nozzle orifice determination

2.7.5 System installation

- Installed per design
- System recalculated to confirm "as built" installation
- Correct piping
  - Size
  - Routing
  - Number and placement of fittings
  - Pipe supports
  - Correct type, style, orifice size nozzle in each location
- Fan test to confirm tightness of protected volume and adequacy of pressure relief venting
- Acceptance functional test of full system without discharge
  - Test each detector's operation

  - Test system logic with detection operation
  - Test operation of auxiliary controls
  - Test local and remote annunciation
  - Test signal received at system valve actuators
  - Test system manual operators
- Test system abort discharge abilities

2.7.6 Post-installation follow up

- Integrity of the protected space does not change
  - Walls, ceiling and floor intact
  - Any new openings sealed properly
- Net volume and temperature range of the space does not change
- Regular maintenance for detection, control, alarm and actuation system
- Regular verification of the agent containers' charged weight
- Regular cleaning of the detection devices
- Confirmation of back-up battery condition

3 Local application (streaming) agents

3.1 General

Local application agents, also referred to as streaming agents, are used in portable fire extinguishers and fixed extinguisher units designed to protect specific hazards. The tables below summarize commercially available, technically proven agents for local application fire protection using portable or fixed systems. Cost effectiveness is represented by an index benchmarked against the approximate cost of a portable carbon dioxide extinguisher unit that has a UL 10B rating. Acceptability of substitutes for halons, HCFCs and HFCs as streaming fire extinguishing agents is also regulated by national agencies.

The US EPA, under the SNAP program, has reviewed a number of materials as substitutes for halons as streaming fire extinguishing agents. The approval status in the US of a number of such alternatives for use in total flooding systems may be found Annex B.

3.2 Carbon dioxide

Carbon dioxide extinguishers use CO_2 stored as a liquefied compressed gas. Carbon dioxide is most suitable for use on fires involving flammable liquids. Carbon dioxide does not conduct electricity and can be used safely on fires involving live electrical circuits. In general, carbon dioxide extinguishers are less effective for extinguishing fires of ordinary combustibles such as wood, paper and fabrics. The table below summarizes key attributes of carbon dioxide as a streaming agent.

Table 3.1: Carbon dioxide streaming agent

Agent	Carbon dioxide, CO_2
Efficacy	For use on Class B fires Can be used on most electrically energized equipment fires.
Toxicity	High exposure risk where carbon dioxide gas accumulates in confined spaces that may be entered by personnel.
Safety Characteristics	Liquefied compressed gas Storage pressure: 55.8 bar at 20 °C Solid CO_2 (“dry ice”) sublimes at -78.5 °C at atmospheric pressure. Presents a cold-exposure hazard. Vapours usually flow to floor level so personnel exposure risk is normally low.
Environmental Characteristics	GWP = 1
Cost-Effectiveness	1 (baseline)

3.3 Halogenated gaseous agents

Halogenated gaseous streaming agents can be used to effectively extinguish fires of ordinary combustibles (wood, paper, plastic) and combustible liquids, and agent vapours permeate well thereby avoiding secondary damage. However, in general, they are more expensive than traditional fire protection agents and, generally, more agent is required than would be for halon 1211. The table below summarises type, composition, and environmental properties of halogenated gaseous streaming agents, also included for reference, for use as local application agents.

Table 3.2: Halogenated gaseous streaming agents - type, composition, and environmental properties

Generic Name	Group	Storage State	Chemical Composition		Environmental Factors		
			Weight %	Species	ODP	100-year GWP (1)	Atmospheric Lifetime yr.
Halon 1211	Halon	LCG	100 %	CF_2ClBr	3	1,750	16
HFC-236fa	HFC	LCG	100 %	$CF_3CH_2CF_3$	0	8,060	242
HFC-227ea	HFC	LCG	100 %	CF_3CHFCF_3	0	3,350	38.9
FK-5-1-12	FK	Liquid	100 %	$C_6F_{12}O$	0	< 1	7 days
FIC-13I1	FIC (2)	LCG	100 %	CF_3I	.0001	0.4	0.005
HCFC Blend B	HCFC & PFC blend	CGS	> 96 %	HCFC-123	0.02	79	1.3
			< 4 %	Ar	0	0	n/a
			< 2 %	CF_4	0	6,630	> 50,000

LCG - Liquefied Compressed Gas; ODP - Ozone Depletion Potential; GWP - 100-year Global Warming Potential; CGS - Compressed Gas in Solution
Note 1: Source: IPCC 5th WGI Assessment Report http://www.climatechange2013.org/
Note 2: FIC-13I1 has B.P. = -23 °C.

3.3.1 Toxicity of halogenated gaseous streaming agents

The toxicity of streaming agents is assessed based on the likely exposure of the person using the extinguisher. This is sometimes measured using breathing zone samples. All of the streaming agents in Table 18 are considered safe for normal use in non-residential and unoccupied applications. Use of some of these agents in confined spaces may be a cause for concern. In particular, FIC-13I1 has a NOAEL of 0.2 vol % and a LOAEL of 0.4 vol % and, as such, poses risks to personnel in confined spaces.

3.3.2 Environmental factors of halocarbon streaming agents

The environmental factors for halogenated gaseous streaming agents are the same as those discussed for halogenated gaseous total flooding agents. Information on ODP, GWP and atmospheric lifetime are presented in the table below. Traditional streaming agents (e.g., water, aqueous salt solutions, dry chemical, and foam) do not present environmental concerns in the areas of ODP, GWP, or atmospheric lifetime but may offer other environmental risks associated with the use of additives, e.g., fluorosurfactants. The table below summarizes main performance attributes of halogenated gaseous chemical streaming agents.

Table 3.3: Halocarbon streaming agents - main performance attributes

Agent	HCFC Blend B 96% HCFC-123 < 2% CF_4 < 4% Argon	HFC-236fa	HFC-227ea	FK-5-1-12	FIC-13I1[7]
Efficacy	For use on Class A fires For use on Class B fires For use on fires involving electrified equipment				
Toxicity	Vapour toxicity low to moderate.				Vapour toxicity moderate to high.
	Vapour exposure risk usually low. Some halogen acids form upon application to a fire. Dense vapour can accumulate in low spaces				
Safety Characteristics	Pressurized hand-held container.				
Environmental Characteristics (1)	ODP / GWP HCFC-123: 0.02 / 79 CF_4: 0 / 6,630 Argon: 0 / 0	ODP: 0 GWP: 8,060	ODP: 0 GWP: 3,350	ODP: 0 GWP: <10	ODP: 0.4 GWP: 0.0001
Cost-Effectiveness	Varies from about 1 to about 2				

Note 1: Source: IPCC 5th WGI Assessment Report http://www.climatechange2013.org/

3.4 Dry chemical agents

Dry chemical extinguishers are of two types. “Ordinary” dry chemicals, usually formulations based on sodium or potassium bicarbonate, are suitable for fires involving flammable liquids and gases. “Multipurpose” dry chemicals, usually formulations of monoammonium phosphate (MAP), are suitable for use on fires of ordinary combustibles such as wood, paper and fabrics and fires involving flammable liquids and gases. Both ordinary and multipurpose dry chemicals may be safely used on fires where electrical circuits are present; however, after application dry chemical residue should be removed because in the presence of moisture it could provide an electrical path that would reduce insulation effectiveness.

One important aspect is that the two types of dry chemicals must never be mixed (e.g. during filling or re-charge) as they react liberating water and CO_2. This can cause corrosion of the cylinder, and the resultant increase in pressure can then become a safety hazard.

[7] Principal known use of FIC-13I1 is used for fire protection of rim seals on floating roof petroleum tanks.

The table below summarizes key attributes of dry chemical streaming agents.

Table 3.4: Dry chemical streaming agents - main performance attributes

Agent	Dry chemicals
Efficacy	For use on Class A fires: Multipurpose dry chemical For use on Class B fires: Ordinary dry chemical or multipurpose dry chemical For use on fires involving electrified equipment Dry chemical applied to some electrical or sensitive equipment may cause damage otherwise not caused by a fire.
Toxicity	Low. Precautions required to avoid inhalation of agent particles.
Safety Characteristics	Pressurized containers
Environmental Characteristics	Low environmental risk
Cost-Effectiveness	~ 0.2

3.5 Water, straight stream

Straight stream water is suitable for use on fires of ordinary combustibles such as wood, paper and fabrics only. This type of extinguisher is unsuitable for use in extinguishing fires involving liquids or gases and in fact could spread a flammable liquid fuel. Straight stream water extinguishers are unsafe for use on fires where energized electrical circuits are present. The table below summarizes key attributes of straight-stream water as a streaming agent.

Table 3.5: Water, straight stream

Agent	Water, straight-stream, ~9 litre
Efficacy	For use on Class A fires not involving electrified equipment or materials that are reactive with water (e.g. metals). Not suitable for Class B fires. Water applied to some electrical or sensitive equipment may cause damage otherwise not caused by a fire.
Toxicity	Non-toxic
Safety Characteristics	No adverse characteristics. Not suitable for use on electrified equipment.
Environmental Characteristics	No significant risk
Cost-Effectiveness	~0.5

3.6 Water mist (spray)

Water spray extinguishers are most suitable for use on fires of ordinary combustibles such as wood, paper and fabrics. This type of extinguisher may be less effective on deep-seated fires. The spray stream is generally more effective on burning embers and may provide a limited capability for fires involving combustible liquid fuels. Some water spray extinguishers can be used on fires where live electrical circuits are present. Users should ensure that the extinguisher has been tested and certified before use on live electrical circuits. Some manufacturers have introduced "water mist" fire extinguishers into commerce. The table below summarizes key attributes of water mist or spray as a streaming agent.

Table 3.6: Fine water spray as a streaming agent

Agent	Water, fine spray
Efficacy	For use on Class A fires including use on electrified equipment up to 10 kV. Not suitable for use on materials that are reactive with water (e.g. metals). Not suitable for Class B fires. Water applied to some electrical or sensitive equipment may cause damage otherwise not caused by a localized fire.
Toxicity	Non-toxic
Safety Characteristics	No adverse characteristics
Environmental Characteristics	No significant risk
Cost-Effectiveness	~ 0.6 (~ 9 litre extinguisher unit; cost index compared to a 10B-rated CO_2 unit)

3.7 Aqueous salt solutions

Aqueous solutions of certain salts are used in fire protection for certain types of hazards. Water containing certain dissolved salts has been found to be more effective than water alone in the extinguishment of fires. Potassium salts are usually employed. Examples include potassium acetate, potassium citrate, potassium formate, potassium lactate, and others, sometimes in combination, and with additives to inhibit corrosion, promote aqueous film-forming action to suppress vapor evolution from flammable liquids, and solution stability. Applications for aqueous salt solutions include fire protection for commercial cooking equipment and industrial vehicles. Some attributes of aqueous salt solution agents are summarized in the table below.

Table 3.7: Aqueous salt solutions streaming agents

Agent	Aqueous salt solutions, fine spray
Efficacy	For use on Class A fires not involving electrified equipment or materials that are reactive with water (e.g., metals). Suitability for use on Class B fires depends on formulation and means of delivery. Used on cooking oil fires where nozzle design limits splatter of hot oil. Salt solutions may cause damage to some electrical equipment not otherwise damaged by fire.
Toxicity	Varies from low to moderate.
Safety Characteristics	pH is usually basic, varying from 8 to 13. Possible short-exposure skin irritation depending on duration of exposure if wetted with agent.
Environmental Characteristics	No significant risk
Cost-Effectiveness	~0.7 to 1 (~9 litre extinguisher unit; cost index compared to a 10B-rated CO_2 unit)

3.8 Aqueous film-forming foam (AFFF)

Extinguishers using water and AFFF additives may be more effective than those using water alone on fires of ordinary combustibles such as wood, paper and fabrics. Additionally, water with AFFF additives will have improved ability, over water alone, to extinguish fires involving flammable or combustible liquids. Also, this agent has the ability to reduce the likelihood of ignition when applied to the liquid surface of an unignited spill. The AFFF reduces vapour propagation from the flammable liquid.

Depending upon the stream pattern, this type of extinguisher may not be safe for use on fires where live electrical circuits are present.

The table below summarizes key attributes of streaming agents employing AFFF. It should be noted that some currently-available AFFF agents contain surfactants consisting of perfluorinated eight-carbon (C8) molecular chains that are known to be bio-persistent and bio-accumulative once released to the environment. The environmental impact of using AFFF agents containing C8 fluorosurfactants must be weighed against the potential gain in efficacy when selecting a portable extinguisher for each specific application. A number of manufacturers ceased production in 2015 of fluorosurfactants containing the problematic C8 species. The performance properties of AFFF agents using reformulated fluorosurfactants should be verified.

Table 3.8: Aqueous film-forming foam as a streaming agent

Agent	Aqueous film-forming foam (AFFF)
Efficacy	For use on Class A fires not involving electrified equipment or materials that are reactive with water (e.g. metals). For use on Class B fires.
Toxicity	Moderate.
Safety Characteristics	pH is approximately neutral, varying between about 6.5 and 8.
Environmental Characteristics	Uncontained run-off of agent poses risks of contamination of soil, streams, and rivers.
Cost-Effectiveness	~0.6 (~9 litre extinguisher unit; cost index compared to a 10B-rated CO_2 unit)

3.9 Streaming agents for residential use

Distinctions are often made by national bodies as to the acceptability of certain agent types in commercial and residential applications. Agents that have the potential of forming toxic byproducts in a fire are usually deemed unsuitable for residential use.[8] Based on this premise the suitability of agents for residential use is summarized in the table below.

[8] For example, the US EPA defines residential use to mean use by a private individual of a chemical substance or any product containing the chemical substance in or around a permanent or temporary household, during recreation, or for any personal use or enjoyment. Use within a household for commercial or medical applications is not included in this definition, nor is use in automobiles, watercraft, or aircraft.

Table 3.9: Suitability of fire extinguishing agent alternatives for use in local application fire protection in residential applications

Substitute	Constituents	Suitable for Residential Use?
Surfactant Blend A	Mixture of organic surfactants and water	Yes
Carbon dioxide (1)	CO_2	Yes
Water	H_2O	Yes
Water Mist Systems	H_2O	Yes
Foam	Aqueous film-forming foam (AFFF)	Yes
Dry Chemical	Formulations based on either monoammonium phosphate (MAP) or sodium bicarbonate	Yes
Gelled Halocarbon/Dry Chemical Suspension	Halocarbon plus dry chemical plus gelling agent	Yes
HFC-227ea	CF_3CHFCF_3	No
HFC-236fa	$CF_3CH_2CF_3$	No
FK-5-1-12	$CF_3CF_2C(O)CF(CF_3)_2$	No
Hydrofluoro-polyethers	Hydrofluoro-polyethers	No
HCFC Blend B	HCFC-123, 95 mol% min; argon, 0.2 mol% min; CF_4, 0.4 mol% min	No

Note 1: Avoid use in confined spaces.

3.8.1 Assessment of alternative streaming agents

The important features of streaming agent alternatives, manually applied fire extinguishing agents, are described below. In general, portable extinguishers are only used on actual fires and can be readily directed at the burning material.

3.8.2 Effectiveness on ordinary combustibles

This parameter considers the ability of the agent to extinguish fires in ordinary solid combustibles, including cellulosic materials. These are called Class A fires and the extinguisher should carry a rating categorising its Class A performance.

3.8.3 Effectiveness on liquid fuel fires

This parameter considers the ability of the agent to extinguish liquid fuel fires (Class B). The extinguisher should carry a Class B rating.

3.8.4 Electrical conductivity

Minimal conductivity is important in fighting fires where electricity is involved.

3.8.5 Ability to permeate

This parameter reflects the ability of the agent to extinguish fires in locations where direct application to the fuel surface or flame reaction zone is not possible, for example, in the hidden void space in a commercial airliner.

3.8.6 Range

This parameter reflects the ability of the agent to maintain a coherent effective stream over a distance.

3.8.7 Effectiveness to weight ratio

This parameter considers the relative fire suppression capability across all fuels per unit weight of agent.

3.8.8 Secondary damage

This category refers to the “clean agent” aspects of the agents, i.e., secondary damage caused by the suppressant agent itself.

3.8.9 Selection of an alternative streaming agent

The relative ratings for each parameter have not been rigorously derived and final selection depends on detailed knowledge of the risk to be protected. Some characteristics of several types of streaming agents are summarized in the table below.

Table 3.10: Portable fire extinguisher capability comparison

Agent Type	Class A Materials	Class B Flammable Liquids	Suitable for Energized Electrical Hazards	Ability to Permeate	Stream Range	Effective Weight	Secondary Damage
CO_2	Poor	Fair	Yes	Good	Fair	Poor	Good
Multi-purpose Dry Chemical	Good	Good	Yes	Fair	Good	Good	Poor
AFFF	Good	Fair	No	Poor	Good	Poor	Poor
Water Stream	Good	Poor	No	Poor	Good	Poor	Poor
Water Mist	Good	Fair	Yes	Fair	Fair	Fair	Fair
Halocarbon	Good	Good	Yes	Good	Good	Good	Good
Halon 1211	Good	Good	Yes	Good	Good	Good	Good
Sodium Bicarbonate Dry Chemical	Poor	Good	Yes	Fair	Good	Good	Poor
Potassium Bicarbonate Dry Chemical	Poor	Good	Yes	Fair	Good	Good	Poor

4 New and emerging technologies

Manufacturers of fire extinguishing agents and systems continue to develop and offer innovative products to serve for total flooding and local application uses.

4.1 HCFO-1233zd(E)

In 2016, Honeywell, a chemical manufacturer, made an application to ISO TC 21 / SC 8 for recognition of HCFO-1233zd(E), as a new total flooding agent. Its chemical name is trans-1-chloro-3,3,3-trifluoropropene and has CAS number 102687-65-0. The chemical received US EPA SNAP approval for this use in October 2016.[9] The manufacturer subsequently suspended support of this chemical as a single-component total flooding agent.

4.2 Halocarbon Blend 55

In September 2018, Honeywell, a chemical manufacturer, made an application to ISO TC 21/SC 8 for recognition of a new agent designated "Halocarbon Blend 55." The agent is a 50 / 50 weight % mixture of FK-5-1-12 and HFO-1233zd(E). The agent was reported to have the following characteristics:

M.W. = 184.7 g/mol B.P. = 20.7 °C NOAEL = 10 %

GWP (100 years) = 1 ODP = 0.000

Class A Minimum Extinguishing Concentration = 4.4 vol %

Class B Minimum Extinguishing Concentration = 6.0 vol %

ISO TC 21/SC 8 has agreed to register the project as preliminary work item (PWI) pending satisfactory completion of an administrative requirements.

4.3 Trifluoroiodomethane

Trifluoroiodomethane, or CF_3I, (CAS Number 2314-97-8), has a Class B minimum extinguishing concentration similar to halon 1301. Due to its LOAEL value of 0.4 vol % it is approved for non-occupied areas only and thus has found limited acceptance in extinguishing applications. However, there has been a resurgence in interest in use of this chemical as an extinguishing agent for use in aircraft engine nacelles and auxiliary power units (APUs). For more information on this agent refer to Volume 2 of the Report of the Halons Technical Options Committee, Supplementary Report #1, Civil Aviation, December 2018, HTOC (2018).

4.4 Updates from 2014 report

4.4.1 2-BTP

The chemical 2-bromo-3,3,3-trifluoro-prop-1-ene, CAS 1514-82-5 has been the subject of study as a fire extinguishant since before 2000. For brevity this chemical is referred to as "2-BTP." The

[9] See https://www.gpo.gov/fdsys/pkg/FR-2016-10-11/pdf/2016-24381.pdf . Note: SNAP approval of substitutes for halons are reviewed on the basis of environmental and health risks, including factors such as ozone depletion potential, global warming potential, toxicity, flammability, and exposure potential. Fire extinguishing effectiveness is not an element of a SNAP review.

agent has received regulatory approval in both the EU and the US EPA SNAP program for use as a streaming agent. While 2-BTP does contain bromine, as do halons, this chemical has a very short atmospheric lifetime (about 7 days), an ODP of 0.0028 and a GWP of 0.26. As such, this chemical is not deemed as a potentially significant contributor to ozone depletion or global warming. This product has been the subject of study for use as a streaming agent in aircraft portable extinguishers. As of 2017, 2-BTP has been approved for use in commercial aircraft handheld fire extinguishers and at least two aircraft manufacturers are fitting 2-BTP extinguishers to new-build aircraft.

4.4.2 C7 Fluoroketone, FK-6-1-14

There is no new information since the 4th edition of this document.

This substitute is a blend of two C7 isomers: 55 – 65% of 3-pentanone, 1,1,1,2,4,5,5,5-octafluoro-2,4-bis(trifluoromethyl), CAS 813-44-5, with balance consisting of 3-hexanone, 1,1,1,2,4,4,5,5,6,6,6-undecafluoro-2-(trifluoromethyl), CAS 813-45-6. This product has been found acceptable under the U.S. EPA SNAP program for use as a streaming agent subject to narrow use limits that require that C7 fluoroketone be used only in non-residential applications.

4.4.3 Low GWP Chemicals

There is no new information since the 4th edition of this document.

One manufacturer announced development of three low-GWP chemicals for possible use as fire extinguishants. The manufacturer has not announced the chemical identities of these products but has disclosed some information summarized in Table 4.1. There is no new information since the 4th edition of this document.

Table 4.1: Properties of developmental halogenated gaseous agents with low GWP

Product	Flooding agent	Streaming agent #1	Streaming agent #2
Boiling point, °C	31	31	18
Liquid density, kg/m^3	1300	1380	1300
MDC, Class A, vol %	5.6	6.1	4.8
MDC, Class B, vol %	6.9	6.9	6.2
NOAEL, vol %	10	1.25	2.5
LOAEL, vol %	12.5	2.5	> 2.5
ODP	0	0	0
100 yr. GWP (est.)	< 2	< 20	< 20

4.4.4 Phosphorous tribromide

There is no new information since the 4^{th} edition of this document.

PBr_3 is a clear liquid with a boiling point of 173 °C. It reacts vigorously with water liberating HBr and phosphoric acid and is, therefore, a highly toxic substance at ambient conditions.

Though the agent contains bromine, it poses little risk to stratospheric ozone. The agent decomposes rapidly in the atmosphere and the HBr formed is quickly eliminated by precipitation. PBr_3 is an effective fire extinguishant due to its high bromine content. Given its high boiling point, and low volatility, this agent must be delivered as a spray or mist into the fire zone in order to be effective. It has been commercialized for use as a fire extinguishant in one small aircraft engine application.

4.4.5 Water mist technologies

Water mist technologies continue to evolve. Recently commercialized innovations include:

- New atomization technology using two-fluid system (air and water) to create ultrafine mist with spray features that are adjustable by changing the flow ratio of water to air or nitrogen.
- Water mist combined with nitrogen to gain extinguishing benefits of both inert gas and water mist

Each approach to generating fine water mists has its own advantages and drawbacks. Additional comments on water mist systems are given in Sections 2.4 and 3.6.

5 Conclusions

There are several in-kind alternatives to halons. These started with HCFCs and PFCs, followed closely by HFCs and inert gases, and more recently by an FK. The HCFCs and PFCs are no longer used in new total flooding fire extinguishing systems and their use is limited to supporting existing systems. Today, for all practical purposes, there are three types of in-kind alternatives to the ozone-depleting fire extinguishants (halons and HCFCs) used in new fire extinguishing systems - these are HFCs, inert gases and an FK. The FK and inert gases also represent low-GWP and no-GWP alternatives to the halons, PFC's, HCFCs and high-GWP HFCs.

Alternative extinguishing agents and technologies are available for nearly all new fire protection applications that previously employed halons, albeit for some applications the only alternatives are the original halon or a high-GWP HFC. A current exception is the fire protection in cargo bays of civil aviation, where no halogenated agents have passed the International Aircraft Systems Fire Protection Working Group Minimum Performance Standard (MPS) for cargo bays. Additionally, some legacy systems (used by the military and in oil and gas production facilities) still require halon as retrofit with current alternatives is not technically or economically feasible at this time.

Annex A U.S. EPA Significant New Alternatives Policy (SNAP) Substitutes in Total Flooding Agents

Substitutes are reviewed on the basis of environmental and health risks, including factors such as ozone depletion potential, global warming potential, toxicity, flammability, and exposure potential. Lists of **Acceptable** and **Unacceptable** substitutes are updated several times each year. The list of substitutes is shown below.

Note: SNAP-related information published in the Federal Register takes precedence over all information on this page.

The SNAP Listing Dates shown in https://www.epa.gov/snap/substitutes-total-flooding-agents contain hyperlinks to U.S. Federal Register publications.

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
2-bromo-3,3,3-trifluoropropene (2-BTP)	0.0028	0.23-0.26	1-Dec-16	**Acceptable with Use Conditions:** For use only in engine nacelles and auxiliary power units (APUs) on aircraft.	
[HCFC Blend] A (NAF S-III)	0.048	1,546	18-Mar-94	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 3, 4, 5.
ATK OS-10	0	<1	2-Jan-09	**Acceptable**	EPA recommends that users consult Section VIII of the Occupational Safety & Health Administration (OSHA) Technical Manual for information on selecting the appropriate types of Personal Protective Equipment (PPE). EPA recommends that use of this system should be in accordance with the safe exposure guidelines for inert gas systems in the latest edition of NFPA 2001, specifically the requirements for residual oxygen levels, and should be in accordance with the relevant operational requirements in NFPA Standard 2010 for Aerosol

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
					Extinguishing Systems. See additional comments 1 and 5.
C3F8 (PFC-218, CEA-308)	0	8,830	13-Jun-95; 28-Apr-99	**Acceptable with Narrowed Use Limits:** Acceptable for non-residential uses where other alternatives are not technically feasible due to performance or safety requirements: (a) because of their physical or chemical properties, or (b) where human exposure to the extinguishing agents may result in failure to meet safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Extinguishing Systems. See rule for detailed conditions.	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. The comparative design concentration based on cup burner values is approximately 8.8%. Users should observe the limitations on PFC acceptability by taking the following measures: - conduct an evaluation of foreseeable conditions of end use; - determine that the physical or chemical properties or other technical constraints of the other available agents preclude their use; - determine that human exposure to the other alternative extinguishing agents may result in failure to meet applicable use conditions; Documentation of such measures should be available for review upon request. The principal environmental characteristic of concern for PFCs is that they have high GWPs and long atmospheric lifetimes. Actual contributions to global warming depend upon the quantities of PFCs emitted. For additional guidance regarding applications in which PFCs may be appropriate, users should consult the description of potential uses which is included in the March 18, 1994, final rule (59 FR 13044). See additional comments 1, 2, 3, 4, 5.
C4F10 (PFC-410, CEA-410)	0	8,860	28-Apr-99; 20-Dec-02	**Acceptable with Narrowed Use Limits:** Acceptable for non-residential uses where other alternatives are not technically feasible due to performance or safety requirements: (a) because of their physical or chemical properties, or (b) where human exposure to the extinguishing agents may result in failure to meet safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Extinguishing Systems. See rule for detailed	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. The comparative design concentration based on cup burner values is approximately 6.6%. Users should observe the limitations on PFC acceptability by taking the following measures:

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
				conditions.	- conduct an evaluation of foreseeable conditions of end use; - determine that the physical or chemical properties or other technical constraints of the other available agents preclude their use; - determine that human exposure to the other alternative extinguishing agents may result in failure to meet applicable use conditions; - Documentation of such measures should be available for review upon request. The principal environmental characteristic of concern for PFCs is that they have high GWPs and long atmospheric lifetimes. Actual contributions to global warming depend upon the quantities of PFCs emitted. For additional guidance regarding applications in which PFCs may be appropriate, users should consult the description of potential uses which is included in the March 18, 1994, final rule (59 FR 13044). See additional comments 1, 2, 3, 4, 5.
C6-perfluoroketone [1,1,1,2,2,4,5,5,5-nonafluoro-4-(trifluoromethyl)-3-pentanone] (Novec 1230)	0	6 to 100	20-Dec-02	**Acceptable**	Use of the agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. For operations that install and maintain total flooding systems using this agent, EPA recommends the following: - install and use adequate ventilation; clean up all spills immediately in accordance with good industrial hygiene practices; and provide training for safe handling procedures to all employees that would be likely to handle containers of the agent or extinguishing units filled with the agent. See additional comments 1, 2, 3, 4, 5.

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
Carbon Dioxide	0	1	18-Mar-94	**Acceptable**	System design must adhere to OSHA 1910.162(b)(5) and NFPA Standard 12
CF3I	0.008	0.4	13-Jun-95; 29-Jan-02	**Acceptable with Narrowed Use Limits:** For use in normally unoccupied areas only.	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 3, 4, 5.
Chlorobromomethane (Halon 1011)	0.07 to 0.15	N/A	28-Apr-99	**Unacceptable**	Other alternatives exist with zero or lower ODP; OSHA regulations prohibit its use as extinguishing agent in fixed extinguishing systems where employees may be exposed. See 29 CFR 1910.160(b)(11).
Firebane® 1179	0	0	4-Oct-11	**Acceptable**	Follow the manufacturer's guidelines in the MSDS.
Foam A [formerly Water Mist / Surfactant Blend A] (Phirex+)	N/A	N/A	5-Sep-96	**Acceptable**	This agent is not a clean agent, but is a low-density, short duration foam.
Gelled Halocarbon /Dry Chemical Suspension (Envirogel) with any additive other than ammonium polyphosphate or sodium bicarbonate	N/A	N/A	29-Jan-02	**Acceptable with Narrowed Use Limits:** For use in normally unoccupied areas only.	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems, for whichever hydrofluorocarbon gas is employed. See additional comments 1, 2, 3, 4, 5.
Gelled Halocarbon /Dry Chemical Suspension with sodium bicarbonate (Envirogel B25 + 36)	N/A	N/A	27-Sep-06	**Acceptable with Use Conditions:** Use of whichever hydrofluorocarbon gas (HFC-125, HFC-227ea, or HFC-236fa) is employed in the formulation must be in accordance with all requirements for acceptability (i.e., narrowed use limits) of that HFC under EPA's SNAP program.	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems, for whichever hydrofluorocarbon gas is employed, and the latest edition of the NFPA 2010 standard for Aerosol Extinguishing Systems. Sodium bicarbonate release in all settings should be targeted so that increased blood pH level would not adversely affect exposed individuals. Users should provide special training, including the potential hazards associated with the use of the HFC agent and sodium bicarbonate, to individuals required to be in environments protected by Envirogel with sodium bicarbonate additive extinguishing systems. Each

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
					extinguisher should be clearly labeled with the potential hazards from use and safe handling procedures. See additional comments 1, 2, 3, 4, 5.
HBFC-22B1 (FM-100)	N/A	N/A		**UnAcceptable**	HBFC-22B1 is a Class I ozone-depleting substance with an ozone depletion potential of 0.74. The manufacturer of this agent terminated production of this agent January 1, 1996, except for critical uses, and removed it from the market because it is a fetal toxin.
HCFC-124 (FE-241)	0.022	609	18-Mar-94	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 3, 4, 5.
HCFC-22	0.055	1,810	18-Mar-94; 20-Jul-15	**UnAcceptable** as of September 18, 2015.	
HFC Blend B (Halotron II®)	0	1,598	29-Jan-02	**Acceptable with Narrowed Use Limits:** For use in normally unoccupied areas only.	See additional comments 1, 2, 3, 4, 5.
HFC-125 (FE 25)	0	3,500	18-Mar-94	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 3, 4, 5.
HFC-125 with 0.1% d-limonene (NAF S-125)	0	3,500 (HFC-125); 10 (d-limonene)	21-Aug-03	**Acceptable**	Use of the agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. Extinguisher bottles should be clearly labeled with the potential hazards associated with the use of HFC-125 and d-limonene, as well as handling procedures to reduce risk resulting from these hazards. See additional comments 1, 2, 3, 4, 5.
HFC-134a	0	1,430	18-Mar-94	**Acceptable**	Use of blends containing this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. The NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems gives guidelines

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
					for blends that contain HFC-134a or HCFC-22 and other **Acceptable** total flooding agents, rather than referring to HFC-134a or HCFC-22 alone. See additional comments 1, 2, 3, 4, 5.
HFC-227ea (FM-200, FE-227)	0	3,220	18-Mar-94	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 3, 4, 5.
HFC-227ea with 0.1% d-limonene (NAF S 227)	0	3,220 (HFC-227ea); 10 (d-limonene)	1-Oct-04	**Acceptable**	Use of the agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. Extinguisher bottles should be clearly labeled with the potential hazards associated with the use of HFC-227ea and d-limonene, as well as handling procedures to reduce risk resulting from these hazards. See additional comments 1, 2, 3, 4, 5.
HFC-23 (FE-13)	0	14,800	18-Mar-94	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 3, 4, 5.
HFC-236fa (FE-36)	0	9,810	28-Apr-99; 29-Jan-02	**Acceptable with Narrowed Use Limits:** Acceptable when manufactured using any process that does not convert perfluoroiso-butylene (PFIB) directly to HFC–236fa in a single step:—for use in explosion suppression and explosion inertion applications, and —for use in fire suppression applications where other non-PFC agents or alternatives are not technically feasible due to performance or safety requirements: (a) because of their physical or chemical properties, or (b) where human exposure to the extinguishing agents may result in failure to meet applicable use conditions.	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. The comparative design concentration based on cup burner values is approximately 6.4%. Users should observe the limitations on HFC-236fa acceptability by taking the following measures: - conduct an evaluation of foreseeable conditions of end use; - determine that the physical or chemical properties or other technical constraints of the other available agents preclude their use; - determine that human exposure to the other alternative

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
					extinguishing agents may result in failure to meet applicable use conditions; - Documentation of such measures should be available for review upon request. Feasible for use in a normally occupied area. The principal environmental characteristic of concern for HFC-236fa is its high GWP of 9400 and long atmospheric lifetime of 226 years. Actual contributions to global warming depend upon the quantities emitted. See additional comments 1, 2, 3, 4, 5.
HFC-32	0	675		**UnAcceptable**	This agent is flammable.
HFC227-BC	0	3,800	27-Jan-03	**Acceptable with Use Conditions:** Sodium bicarbonate release in all settings should be targeted so that increased pH level would not adversely affect exposed individuals. Users should provide special training to individuals required to be in environments protected by HFC227–BC extinguishing systems. Each HFC227–BC extinguisher should be clearly labeled with the potential hazards from use and safe handling procedures.	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 3, 4, 5.
IG-01 (Argotec; formally Inert Gas Blend C)	0	0	28-Jul-95	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 5.
IG-100 (NN 100)	0	0	26-Apr-00	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 5.
IG-541 (Inergen)	0	0	18-Mar-94	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
					for Clean Agent Fire Extinguishing Systems. This agent contains CO2, which is intended to increase blood oxygenation and cerebral blood flow in low oxygen atmospheres. The design concentration should result in no more than 5% CO2. See additional comments 1, 2, 5.
IG-55 (Argonite; formally Inert Gas Blend B)	0	0	28-Jul-95	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems. See additional comments 1, 2, 5.
Inert Gas/Powdered Aerosol Blend (FS 0140)	0	1	13-Jun-95	**Acceptable with Use Conditions:** For use in normally unoccupied areas only. Any employee who could possibly be in the area must be able to escape within 30 seconds. The employer shall assure that no unprotected employees enter the area during discharge.	The manufacturer's SNAP application requested listing for use in unoccupied areas only. See additional comment 2.
N2 Towers® System	0	<1	4-Oct-11	**Acceptable**	EPA recommends that use of this system should be in accordance with the safe exposure guidelines for inert gas systems in the latest edition of NFPA 2001 Standard on Clean Agent Fire Extinguishing Systems, specifically the requirements for residual oxygen levels, and use should be in accordance with the NFPA Standard 2010 for Aerosol Extinguishing Systems.
Phosphorus tribromide (PhostrEx)	0.01 - 0.08	0	27-Sep-06	**Acceptable with Use Conditions:** For use only in aircraft engine nacelles.	For establishments manufacturing the agent or filling, installing, or servicing containers or systems, EPA recommends the following: adequate ventilation should be in place and/or positive pressure, self-contained breathing apparatus (SCBA) should be worn; training for safe handling procedures should be provided to all employees that would be likely to handle containers of the agent or extinguishing units filled with the agent; and all spills should be cleaned up immediately in accordance with good industrial hygiene practices. See additional comments 1, 2, 3, 4, 5.
Powdered Aerosol A (SFE)	N/A	N/A	18-Mar-94	**Acceptable**: For use in normally unoccupied areas only.	

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
Powdered Aerosol C (PyroGen, Soyuz)	N/A	N/A	8-Feb-96	**Acceptable**: For use in normally unoccupied areas only.	
Powdered Aerosol D (Aero K/Stat X)	0	N/A	27-Sep-06; 21-Oct-14; 1-Dec-16	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2010 standard for Aerosol Extinguishing Systems. For establishments manufacturing the agent or filling, installing, or servicing containers or systems to be used in total flooding applications, EPA recommends the following: adequate ventilation should be in place to reduce airborne exposure to constituents of agent; an eye wash fountain and quick drench facility should be close to the production area; training for safe handling procedures should be provided to all employees that would be likely to handle containers of the agent or extinguishing units filled with the agent; workers responsible for clean up should allow for maximum settling of all particulates before reentering area and wear appropriate protective equipment; and - all spills should be cleaned up immediately in accordance with good industrial hygiene practices. See additional comments 1, 2, 3, 4, 5.
Powdered Aerosol E (Fire Pro)	0	N/A	27-Sep-06	**Acceptable with Use Conditions:** For use in normally unoccupied areas only.	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2010 standard for Aerosol Extinguishing Systems. For establishments manufacturing the agent or filling, installing, or servicing containers or systems to be used in total flooding applications, EPA recommends the following: adequate ventilation should be in place to reduce airborne exposure to constituents of agent; an eye wash fountain and quick drench facility should be close to the production area; training for safe handling procedures should be provided to all employees that would be likely to handle containers of the agent or extinguishing units filled with the agent; workers responsible for clean up should allow for maximum settling of all particulates before reentering area and wear appropriate protective equipment; and - all spills should be cleaned up immediately in accordance with good industrial hygiene practices. See additional comments 1, 2, 3, 4, 5.

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
Powdered Aerosol F (KSA®)	0	0	19-Sep-12	**Acceptable with Use Conditions:** For use in normally unoccupied areas only.	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2010 standard for Aerosol Extinguishing Systems. For establishments filling, installing, servicing, using, or disposing of containers or systems to be used in total flooding applications, EPA recommends the following: appropriate protective clothing (e.g., goggles, particulate removing respirators, and gloves) should be worn during the installation and maintenance of the extinguishing units filled with the agent or during clean up and disposal of this agent; training should be provided to all employees that would be likely to handle containers of the agent or extinguishing units filled with the agent, required to clean up after discharge or required to work near spaces protected by Powdered Aerosol F. Releases in all settings should be limited to an appropriate design concentration for the protected space so that increased blood pH level would not adversely affect exposed individuals. Exposed individuals should be given an electrolyte solution to drink afterwards to restore the pH within the appropriate range. Each extinguisher should be clearly labeled with the potential hazards from use and safe handling procedures. In the case of an accidental spill, the area should be well-ventilated, and workers should wear protective equipment while following good industrial hygiene practices for clean-up and disposal. See additional comments 1, 2, 4, 5.
Powdered Aerosol G (Dry Sprinkler Powdered Aerosol (DSPA) Fixed Generators)	0	<1	19-Sep-12	**Acceptable with Use Conditions:** For use in normally unoccupied areas only.	Use of this agent should be in accordance with the safety guidelines in the latest edition of the NFPA 2010 standard for Aerosol Extinguishing Systems. DSPA generators produce combustion byproducts (micron-sized dry particles and a gaseous mixture), that mix together into a uniform fire-extinguishing aerosol before being released into the protected area. The propellant components of the system generates inert gases, which function to physically extinguish the fire by the combined effects of straining the burning flame front and reducing the heat of the combustion sources. The small aerosol particles have a

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
					high surface area-to-volume ratio, which increases their ability to rapidly distribute throughout enclosed areas and to act as heat sinks. For establishments filling, installing, servicing, using or disposing of generator units or systems in total flooding applications, EPA recommends the appropriate protective clothing (e.g., goggles, particulate removing respirators, and gloves) should be worn during the installation and maintenance of the extinguishing units filled with the agent or during clean up and disposal of this agent. Powdered Aerosol G should be collected by hand (e.g., with a dustpan and duster or a vacuum cleaner); waste should be collected in suitable drums for disposal and the area should be washed clean with sufficient quantities of water; and training should be provided to all employees that would be likely to handle the agent or generator units filled containing the agent, required to clean up after discharge or required to work near spaces protected by Powdered Aerosol G fixed generator total flooding systems. In accordance with Department of Health and Human Services regulations (42 CFR Part 84), safety glasses and a NIOSH/CDC-approved N99 respirator are required for individuals installing Powdered Aerosol G fixed systems. Each generator unit should be clearly labeled with the potential hazards from use and safe handling procedures. In the case of an accidental discharge, the area should be well-ventilated, and workers should wear protective equipment while following good industrial hygiene practices for clean-up and disposal. See additional comments 1, 2, 4, 5, 6.
SF6	0	22,800	29-Jan-02	**Acceptable with Narrowed Use Limits:** Only for use as a discharge agent in military applications and in civilian aircraft.	Users should limit testing only to that which is essential to meet safety or performance requirements. This agent is used only to test new Halon 1301 systems.
Solution of 50% potassium acetate and 50% water (K-Ace)	0	0	17-May-13	**Acceptable**	EPA recommends that use of this system should be in accordance with the manufacturer's MSDS. EPA recommends that users consult Section VIII of the OSHA Technical Manual for information on selecting the appropriate types of personal protective equipment for all

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
					listed fire suppression agents. EPA has no intention of duplicating or displacing OSHA coverage related to the use of personal protective equipment (e.g., respiratory protection), fire protection, hazard communication, worker training or any other occupational safety and health standard with respect to EPA's regulation of halon substitutes. Use must conform to relevant OSHA requirements, including 29 CFR Part 1910, subpart L, sections 1910.160 and 1910.162.
Surfactant Blend A (Cold Fire®)	0	0	10-Aug-12	**Acceptable**	Observe recommendations in the manufacturer's MSDS and guidance for using this substitute.
Trans-1-chloro-3,3,3-trifluoroprop-1-ene (Solstice® FS)	0.00024 – 0.001512	4.7-7	11-Oct-16	**Acceptable**	Use of this agent should be in accordance with the safety guidelines in the latest edition of the National Fire Protection Association (NFPA) 2001 Standard on Clean Agent Fire Extinguishing Systems. Safety features that are typical of total flooding systems such as pre-discharge alarms, time delays, and system abort switches should be provided, as directed by applicable OSHA regulations and NFPA standards. See additional comments 1, 2, 3, 4, 5.
Uni-light Advanced Fire Fighting Foam 1% water mist system (Uni-light AFFF 1%)	0	Negligible	29-Mar-06	**Acceptable**	This agent is intended for use onboard ships and in off-shore installations. It may be used both in normally occupied and unoccupied areas. Appropriate personal protective equipment should be worn during manufacture or in the event of a release. Personal protective equipment should include safety goggles, protective gloves, and a self-contained breathing apparatus. Supply bottles for the foam should be clearly labeled with the potential hazards associated with the use of the chemicals in the foam, as well as handling procedures to reduce risk resulting from these hazards. Use should conform with relevant OSHA requirements, including 29 CFR1910, Subpart L, Sections 1910.160
Victaulic Vortex Systems	0	0	2-Jan-09	**Acceptable**	EPA recommends that users consult Section VIII of the Occupational Safety & Health Administration (OSHA) Technical Manual for information on selecting the appropriate types of Personal Protective Equipment (PPE). EPA recommends that use of this system should be

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
					in accordance with the safe exposure guidelines for inert gas systems in the latest edition of NFPA 2001, specifically the requirements for residual oxygen levels, and should be in accordance with the relevant operational requirements in NFPA 750 Standard on Water Mist Fire Protection Systems.
Water	0	0	18-Mar-94	**Acceptable**	

Additional Comments

1. Must conform with OSHA 29 CFR 1910 Subpart L Sections 1910.160 and 1910.162.
2. Per OSHA requirements, protective gear (SCBA) must be available in the event personnel must reenter the area.
3. Discharge testing should be strictly limited only to that which is essential to meet safety or performance requirements.
4. The agent should be recovered from the fire protection system in conjunction with testing or servicing, and recycled for later use or destroyed.
5. EPA recommends that users consult Section VIII of the OSHA Technical Manual for information on selecting the appropriate types of personal protective equipment for all listed fire suppression agents. EPA has no intention of duplicating or displacing OSHA coverage related to the use of personal protective equipment (e.g., respiratory protection), fire protection, hazard communication, worker training or any other occupational safety and health standard with respect to EPAs regulation of halon substitutes.
6. The NFPA 2001 Standard for Clean Agent Fire Extinguishing Systems gives guidelines for blends that contain HFC-134a or HCFC-22 and other **Acceptable** total flooding agents, rather than referring to HFC-134a or HCFC-22 alone.

Annex B U.S. EPA Significant New Alternatives Policy (SNAP) Substitutes in Streaming Agents

Substitutes are reviewed on the basis of environmental and health risks, including factors such as ozone depletion potential, global warming potential, toxicity, flammability, and exposure potential. Lists of acceptable and Unacceptable substitutes are updated several times each year. The list of substitutes is shown below.

Note**:** SNAP-related information published in the Federal Register takes precedence over all information on this page.

The SNAP Listing Dates shown in https://www.epa.gov/snap/substitutes-streaming-agents contain hyperlinks to U.S. Federal Register publications.

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
2-bromo-3,3,3-trifluoropropene (2-BTP)	0.0028	0.23-0.26	1-Dec-16	**Acceptable with Use Conditions:** For use only in handheld extinguishers in aircraft.	
[HCFC Blend] B (Halotron 1)	0.0098	77	March 18, 1994	**Acceptable:** For non-residential uses only.	
[HCFC Blend] C (NAF P-III)	N/A	N/A	August 26, 1994	**Acceptable:** For non-residential uses only.	
[HCFC Blend] D (Blitz III)	N/A	N/A	August 26, 1994	**Acceptable:** For non-residential uses only.	
[HCFC Blend] E (NAF P-IV)	0.02	N/A	April 26, 2000	**Acceptable with Narrowed Use Limits:** For non-residential uses only.	As with other streaming agents, EPA recommends that potential risks of combustion byproducts be labeled on the extinguisher (see UL 2129). Discharge testing and training should be strictly limited only to that which is essential to meet safety or performance requirements. The agent should be recovered from the fire protection system in conjunction with testing or servicing, and recycled for later use or destroyed.
[HCFC Blend] B (Halotron 1)	0.0098	77	March 18, 1994	**Acceptable:** For non-residential uses only.	

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
[HCFC Blend] C (NAF P-III)	N/A	N/A	August 26, 1994	**Acceptable:** For non-residential uses only.	
[HCFC Blend] D (Blitz III)	N/A	N/A	August 26, 1994	**Acceptable:** For non-residential uses only.	
[HCFC Blend] E (NAF P-IV)	0.02	N/A	April 26, 2000	**Acceptable with Narrowed Use Limits:** For non-residential uses only.	As with other streaming agents, EPA recommends that potential risks of combustion byproducts be labeled on the extinguisher (see UL 2129). Discharge testing and training should be strictly limited only to that which is essential to meet safety or performance requirements. The agent should be recovered from the fire protection system in conjunction with testing or servicing, and recycled for later use or destroyed.
Surfactant Blend] A [Cold Fire, FlameOut, Fire Strike]	N/A	N/A	March 18, 1994	**Acceptable**	
C_6-perfluoroketone [1,1,1,2,2,4,5,5,5-nonafluoro-4-(trifluoromethyl)-3-pentanone] (Novec 1230)	0	6 to 100	January 27, 2003	**Acceptable with Narrowed Use Limits:** For non-residential uses only.	For operations that fill canisters to be used in streaming applications, EPA recommends the following**:** - install and use adequate ventilation ; - clean up all spills immediately in accordance with good industrial hygiene practices; and - provide training for safe handling procedures to all employees that would be likely to handle containers of the agent or extinguishing units filled with the agent. Discharge testing and training should be strictly limited only to that which is essential to meet safety or performance requirements. The agent should be recovered from the fire protection system in conjunction with testing or servicing, and recycled for later use or destroyed. As with other streaming agents, EPA recommends that potential risks of combustion by-products be labeled on the extinguisher (see UL 2129). EPA has no intention of duplicating or displacing OSHA coverage related to the use of personal protective equipment (e.g., respiratory protection), fire protection, hazard communication, worker training or any other occupational safety and health standard with respect to halon substitutes.

Substitute	ODP	GWP	SNAP Listing Date	Listing Status	Further Information
C_6F_{14} (PFC-614, CEA-614)	0	9,300	April 28, 1999	**Acceptable with Narrowed Use Limits:** For non-residential uses where other alternatives are not technically feasible due to performance or safety requirements**:** a. because of their physical or chemical properties, or b. where human exposure to the extinguishing agents may result in failure to meet applicable narrowed use limits.	Users should observe the limitations on PFC acceptability by making reasonable effort to undertake the following measures**:** - conduct an evaluation of foreseeable conditions of end use; - determine that the physical or chemical properties or other technical constraints of the other available agents preclude their use; and - determine that human exposure to the other alternative extinguishing agents may result in failure to meet applicable narrowed use limits; Documentation of such measures should be available for review upon request. The principal environmental characteristic of concern for PFCs is that they have high GWPs and long atmospheric lifetimes. Actual contributions to global warming depend upon the quantities of PFCs emitted. For additional guidance regarding applications in which PFCs may be appropriate, users should consult the description of potential uses which is included in the March 18, 1994, Final Rule (59 FR 13044). Discharge testing and training should be strictly limited only to that which is essential to meet safety or performance requirements. The agent should be recovered from the fire protection system in conjunction with testing or servicing, and recycled for later use or destroyed.
C_7 Fluoroketone	0	1	September 19, 2012	**Acceptable with Narrowed Use Limits:** For non-residential uses only.	Use of this agent should be in accordance with the latest edition of NFPA Standard 10 for Portable Fire Extinguishers. For operations that fill canisters to be used in streaming applications, EPA recommends the following**:** –Adequate ventilation should be in place; –All spills should be cleaned up immediately in accordance with good industrial hygiene practices; and –Training for safe handling procedures should be provided to all employees that would be likely to handle

PCB PIEZOTRONICS
AN AMPHENOL COMPANY

ENDEVCO
AN AMPHENOL COMPANY

PFAS Current Unavoidable Uses
For PCB Piezotronics, Inc. and its Subsidiaries

Exemptions needed for PFAS applications necessary for PCB Piezotronics Companies' without effective substitutes

Submission Date: February 29, 2024

This submission is in response to Minnesota session Law on PFAS and Currently Unavoidable Uses proposed for a restriction pursuant to 2023, Chapter 60, H.F. No. 2310.It is respectfully submitted on behalf of PCB Piezotronics, Inc. ("PCB") and its subsidiaries set forth on Exhibit A attached hereto (collectively, PCB and its subsidiaries are referred to herein as the "PCB Companies"). This document is in submission for all Schedule B numbers in Exhibit B. which PCB Companies considers testing electronics as a product group. The PCB Companies are committed to continuously improving the environmental performance and safety of all products they place on the market.

In this document we expect to answer the submission requirements of the following:

1. Provide a brief description of the type of product including, if applicable, the Global Product Classification (GPC) brick category and code, or if GPC is not applicable then the Harmonized Tariff System (HTS) code.
2. Describe the intended use of the product and explain how it is essential for health, safety or the functioning of society.
3. Describe how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, provide citations to that requirement.
4. Describe whether there are alternatives for this specific use of PFAS which are reasonably available.
5. Provide contact information for the submission.

1. Provide a brief description of the type of product including, if applicable, the Global Product Classification (GPC) brick category and code, or if GPC is not applicable then the Harmonized Tariff System (HTS) code.

PCB products are filled with a potting or an epoxy agent that encapsulates our components that creates a protected environment which makes break down very slow or impossible. These are commercial products that are mainly used in business sectors and generally not available to consumers. PCB uses an exhaustive list of HTS codes. Our most popular categories (the first four digits) are listed below. An addendum of our exact exhaustive list of HTS codes that have used in the past as of this document are provided in a supplemental document labeled Exhibit B.

- 9031 (Measuring or checking instruments, appliances and machines, not specified or included elsewhere in this chapter; profile projectors; parts and accessories thereof)
- 9026 (Instruments and apparatus for measuring or checking the flow, level, pressure or other variables of liquids or gases (for example, flow meters, level gauges, manometers, heat meters),

- 8504 (Electrical transformers, static converters (for example, rectifiers) and inductors; parts thereof)

- 8518 (Microphones and stands therefor; loudspeakers, whether or not mounted in their enclosures; headphones and earphones, whether or not combined with a microphone, and sets consisting of a microphone and one or more loudspeakers; audio-frequency electric amplifiers; electric sound amplifier sets; parts thereof)

- 9024 (Machines and appliances for testing the hardness, strength, compressibility, elasticity or other mechanical properties of materials (for example, metals, wood, textiles, paper, plastics), and parts and accessories thereof)

- 8544 (Insulated (including enameled or anodized) wire, cable (including coaxial cable) and other insulated electric conductors, whether or not fitted with connectors; optical fiber cables, made up of individually sheathed fibers, whether or not assembled with electric conductors or fitted with connectors)

2. Describe the intended use of the product and explain how it is essential for health, safety or the functioning of society.

Sensors and equipment manufactured by PCB Companies play a crucial role in enhancing safety testing and condition monitoring across various sectors, including consumer products, automotive, aerospace, infrastructure, industrial, and military applications. When used for consumer product testing, PCB sensors find extensive use in both the development and testing phases of a broad spectrum of products, from everyday household appliances to specialized sports equipment our units test it all. In the automotive industry, they are indispensable in crash testing to improve vehicle safety, as well as informing electric vehicle design to enhance fuel efficiency. In the aerospace and energy sectors, PCB sensors ensure gas turbines run more efficiently, to cut down on greenhouse gas emissions. In the sports industry, PCB sensors play a critical role providing force impact data that contributes to the design of personal protective gear. PCB acoustic sensors are employed to mitigate noise pollution in heavy noise areas including around airports.

Sensors for condition monitoring are pivotal in preventing catastrophic equipment failures, unplanned downtime, and costly repairs particularly in the energy and industrial sectors. This proactive approach not only safeguards machinery but also ensures industrial workers operate in a safe environment. Within military applications, such as ballistics testing and ground vehicle development, PCB sensors provide critical data for optimizing performance and ensuring the safety and effectiveness of defense systems.

Given the widespread application of PCB's sensors in vital areas such as safety enhancement, environmental protection, and the safeguarding of human life, the company should qualify for an exemption.

The below table answers 3. and 4. are together.

3. Describe how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, provide citations to that requirement.

4. Describe whether there are alternatives for this specific use of PFAS which are reasonably available.

Products of the PCB Companies are considered complex products (articles) and have anywhere from 10 to 500 components in each individual product. Further, the PCB Companies have thousands of active model numbers, each with separate bills of material. This submission is based on a detailed review of our products and supply chain, including internal review by the PCB Companies, review by an independent outside expert, Claigan Environmental Inc. ("Claigan Environmental"), and a review of our supply chain. The complexity of the supply chain, and the intermediate and final products manufactured by PCB Companies does not easily lend itself to gathering credible and accurate information on all essential chemicals and materials embedded in electronics manufacturing processes and products. Claigan Environmental was able to do a full analysis of our industry as found in Exhibit C.

Current Unavoidable Use CUU	**Example Articles in our Products**	**Essential Use of PFAS**	**Comparison of Alternatives**
Fluoroacrylic and PFA coatings (and solvents) for encapsulation of capacitors or semiconductor components.	Capacitors and integrated circuits used in computers, servers, Industrial, Machinery, and laboratory equipment	Very thin fluoroacrylic and PFA coatings provide water resistance at high temperature to sensitive electronics.	**Alternative non-fluorinated materials do not have adequate chemical, water, and heat resistance in a high density / thin film application.**
Lubricants: threads, O-rings, plungers, hammer shaft (assembly and maintenance)	Gaskets, O-rings, and molded rubber parts in electronics, pumps,	Release agents are required to release rubber parts from their molds	**Superior to other release agents. May be replaceable in the future by silicone. Wide verification and validation required.** **Silicone has higher friction and adhesion than fluoropolymer based**
PTFE used as an additive drip agent in plastics to meet flammability safety requirements	Widespread use. Including plastic components, fans, processing equipment ect. Used in the vast majority of complex electronics on the market.	Provide required anti-drip flame retardancy required by fire regulation and standards. currently no effective replacements for PTFE as an anti-drip additive. Virtually all electronics use PTFE anti-drip agents in one or more parts. Restriction of PTFE anti-drip agents would create a significant safety risk for electronics and require the redesign and re-qualification of safety of virtually every electronic product on the US market	**Only additive widely approved for use to meet strict anti-drip flame retardancy requirements in plastics**
PTFE, ETFE, PFA, PVDF, and FEP as a wire insulator.	Wires	Provide temperature resistance with electrical insulation	**Other materials do not have sufficient temperature resistance, feasibility in dense electronics (too thick), and electrical insulation**
Fluoropolymers (PTFE, ETFE, FEP, and PFA) used for electrical insulation purposes except wiring.	Coaxial cables, ports, hoses, and antennas	Fluoropolymers have the best in class dielectric constants / electrical insulation while maintaining flexibility.	**Other polymers do not provide sufficient electrical insulation (poorer dielectric constants).** **Ceramics can provide sufficient**

		This includes both electrical isolation but also in static dissipation and related safety activities.	**dielectric constant for some RF applications, but do not have the flexibility required for most applications.**
Fluoroelastomers (including perfluoroelastomers), fluorosilicone, and amorphous fluoro resins as a sealing and packing material in situations requiring chemical resistance, oil resistance, oxidation resistance, decompression resistance, high temperature (over 150C), or low temperature (<-20C).	Rubbers, Seals, Aerospace, equipment for extreme environments	Products using fluoroelastomer seals can be found in virtually every industrial or machinery application worldwide. Without fluoroelastomer seals, virtually all industrial applications would no longer be viable.	**No other rubbers have equivalent hydrophobic and oleophobic properties, oxidation resistance, and chemical safety over a range of low and high temperatures as fluoroelastomers. Fluoroelastomers are also very resistant to explosive decompression.** **Fluoroelastomer use can extend product life/service intervals thereby reducing potential chemical releases/exposures. Alternative materials would need to be replaced monthly, as they begin to leak.** **PTFE has similar environmental properties, but is a plastic and is not suitable for applications requiring the conformity of a 'rubber' seal. Fluoroelastomers also have a higher coefficient of friction than PTFE and create a superior 'seal' in most applications.**
PTFE tape for moisture insulation, or joining of fluid or gas components.	Widespread use. PTFE tape for plumbing, Industrial, Machinery with fluids or gasses, and other equipment requiring piping to be sealed together.	PTFE rubber tape has best in class water and oil resistance in a thin applicable tape.	**Alternative materials do not provide the same water or oil seal in a thin tape.**
PTFE tape for reduction of friction.	Self-adhesive tape, PTFE tape provide a thin coating to reduce friction between moving parts.	PTFE rubber tape has very low friction reduce the wear and extending the lifetime of moving parts.	**No other tape materials have as low friction as PTFE tape and the ability to conform to uneven surfaces.** **Replacement of PTFE tape in a low friction application will affect product performance issues and reduced lifetime of the product - causing earlier disposal or replacement of the product using the PTFE tape.**

Fluorocoating of rubber, metal, and plastic seals in high temperature, professional, or industrial applications where chemical resistance is required	Rubber components in contact with chemicals	Most standard rubbers are high friction (nitrile rubber, styrene rubber, EPDM) and require a fluorocoating for low friction. This is necessary for rubber parts likely to encounter friction in operation.	**Alternative materials do not sufficiently reduce the friction of rubber to allow for the necessary movement of the rubber part.** **No other coating material provides the same environmental protection to rubber and metal seals.**
PTFE, ETFE, and PFA coating of metal for environmental or temperature resistance not in contact with food or drinking water	Coatings on parts to resist harsh or outdoor environments	Fluoropolymer coatings provide environmental resistant to metal parts. Resistance to water, acids, and oils extends the lifetime of the parts in outdoor and harsh environments.	**No other coating materials provide the same environmental (water, oil, acid, and chemical) protection to metals.** **Replacement PTFE and PFA environmental coatings for metals will reduce the corrosion resistance (in particular over temperature) of many metals resulting in failure of these metals and/or reduced product lifetime (resulting in more products entering end of life disposal sooner).**
Fluorocoatings on labels on products (excluding textiles) necessary for environmental resistance	Labels	Clear labels that do not degrade over time are required for safety and regulatory reasons on most electronic, professional, and industrial products. A thin fluorocoating protects the label from the environment, maintaining the legibility of the label..	**Alternative coatings do not have equivalent water or oil resistance.** **Or, in the case of nitrile or EPDM rubber, do not have the required transparency to read the label's writing.** **PVC has nearly equivalent water and oil resistance, but has risks of other regulated substances (such as phthalates) and does not withstand temperature ranges as well as fluoropolymers.**
PTFE, PFA, FEP, PVDF, ETFE, and fluoroelastomer (including perfluoroelastomer) tubing not in contact with drinking water.	Tubing	Fluoropolymers have flexibility, biocompatibility (low chemical reactivity), optical transparency, and high temperature resistance. For electronics, the flexibility and high temperature resistance is critical for power applications such as the leads in transformers. For medical devices, the flexibility, transparency, and low chemical reactivity are critical for human or laboratory processes.	**Alternative polymers do not have equivalent low chemical reactivity, optical transparency, flexibility, and temperature resistance.** **Polyurethane and PVC tubing can be used in some applications, but have poor resistance to acids and bases, can release chemicals (isocyanates or phthalates) into the fluid, and both have poor temperature stability.**

PVDF and PTFE as the cathode binder in lithium batteries	Batteries in electronics including for Wi-Fi models used in applications like windmills	Fluoropolymer binders have high heat resistance and excellent electrical insulation - improving performance lithium batteries and reducing delamination of the electrodes in the battery.	**Alternative polymers do not have as good temperature resistance and/or electrical insulation, reducing the performance and lifetime of lithium batteries.** **Other polymers could not maintain the rigorous performance requirements of a binder in a high-density lithium battery.** **Pb acid batteries have similar performance to lithium batteries, but can release Pb at the end of life and have a weight that makes them unusable for mobile applications including electrical vehicles.**
PVDF, PTFE, TFE, and sulfonated PTFE as a binder or spacer in capacitors	Capacitors, Electronics, Vehicles, Industrial, Machinery	Fluoropolmer binders and spacers provide the electrical insulation and temperature resistance needed in high capacitance capacitors.	**Alternative polymers do not have as good temperature resistance and/or electrical insulation, reducing or preventing the performance of the high-performance capacitors**
PTFE, PCTFE, PVDF, FEP, ePTFE, PFA, and TFE (including copolymers) as a sealing or spacer material.	Plastic seals, Building Products, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	Fluoropolymers have the acid, heat, water, and oil resistance needs for industrial sealing applications.	**Alternatives do not provide sufficient resistance to acid, chemicals, water, oils, and temperature.** **In most of the applications listed in this entry, alternative sealing materials were tested, and no materials and closure systems showed positive results.**
PTFE in coatings of labels for security or tamper evidence.	Tamper proof labels	PTFE coatings provide tamper proof protection for labels. PTFE cannot be modified chemicals and shows physical wear if tampered.	**For security - no other polymer provides the same tamper proof properties (chemical resistance) as PTFE as a coating. Use of another polymer would reduce the security of devices especially those for financial transactions or personal identification.** **For tamper evidence - PTFE material film (plus an adhesive) is used in the label in order to provide evidence. Other plastics do not have the combination of chemical resistance and visibility of tampering than irradiated (soft) PTFE.**
Fluoroacrylic and PFA coatings (and solvents) for encapsulation of capacitors or semiconductor components.	Capacitors and integrated circuits used in computers, servers, Industrial, and Machinery	Very thin fluoroacrylic and PFA coatings provide water resistance at high temperature to sensitive electronics.	**Alternative non-fluorinated materials do not have adequate chemical, water, and heat resistance in a high density / thin film application.**

Ionic fluoro fluids as electrolytes in capacitors or batteries	Super Capacitors in electronics, portable electronic equipment	Fluoro ionic fluids provide a great surfactant power, chemical/biological inertness, easy recovery and recyclability, low surface tension, extreme surface activity, no flammability, and high thermal stability. The surface active and high thermal stability are excellent for high performance lithium batteries and super capacitors.	**Other ionic fluids can be used, but these fluids do not exhibit either/or the performance or flammability resistance of FILs.**
PVDF polymers and PVDF terpolymers for ferroelectric films.	Films, electronics	PVDF and similar films are fundamental to the specialize use of ferro electric films. Without PVDF, ferroelectric films would not be possible.	**Specialized PVDF films have the highest dielectric constant of polymers, are new innovations, and are not replaceable with other materials.**
Fluorosilicone used as a surfactant or anti-foaming agent in semiconductor materials	Integrated circuits used in computers, servers, Industrial, Machinery, and laboratory equipment	The fluorosilicone surfactants are used in a manufacturing step for a microscopic material internal to a semiconductor device. The resulting chemical is only used in the manufacturing of the product and will not be present above 50 ppm organic fluorine in the final product.	**Other surfactants are not as effective for this high precision application or as inert. In semiconductor manufacturing this surfactant cannot react without other materials.**
F2 gas fluorinated plastics in capacitors and microchips	Integrated circuits used in computers, servers, Industrial, Machinery, and laboratory equipment	A microlayer of fluorinated material is created in capacitors and semiconductor devices by F2 gas fluorination (usually plasma fluorination) of a plastic such as polyethylene or polyphenylene sulfide The thin layer has amorphous fluorinated alkane molecules. This very thin internal fluorinated layer provides specialized capacitance curves and is useful in specialized applications.	**Thin fluorinated plastics provide capacitance performance advantages not available in other materials.**
PTFE filled die attach material for semiconductor devices	Integrated circuits used in computers, servers, Industrial, Machinery, and laboratory equipment	PTFE provides a chemical inertness and temperature resistance to microchip die attach material.	**No other polymer powder is as chemically inert and have as high temperature resistance as PTFE powder.**
PFBS (Perfluorobutane sulfonate) and its salts - for the purposes of optical clarity in flame retarded polymers.	Refrigerator, computer display, kiosk terminal. Optically clear and flame retarded displays are important for displays used by consumers.	Flame retarded clear plastic tends to be slightly cloudy, reducing the transparency of the screen. By adding <0.01% PFBS, the plastic of the displays is 'clarified', and can be used easily and safety.	**No information is available on a potential replacement for PFBS. Currently is it the only material effective for its specialized application.**

PTFE as an additive up to 25% in plastics for the purposes reduced friction and wear	Plastics and electronics	PTFE additive provides greatly reduced friction and wear in plastic parts. This properly greatly extends their lifetime and time before replacement.	**Alternatives do not have equivalent low friction or compatibility as an additive.** **No other additives are as effective to safely reduce the coefficient of friction of plastics. Restriction of PTFE additives in plastics for friction reduction would reduce the lifetime of many products, resulting in products going to waste or landfall sooner and more often.** **In addition, PTFE added plastics extend product life/service intervals thereby reducing potential fluid and gas releases/exposures. They also reduce power consumption compared to non-PTFE added counterparts.**
PTFE, ETFE, and PCTFE for professional, industrial, or high temperature applications (>150C) requiring reduced friction, or chemical inertness.	Electronics, Oil and gas, Industrial applications	Fluoropolymers have tremendous chemical and temperature resistance combined with low friction. All three are essential of operation and safety in industrial environments.	**No other materials have the same low friction and chemical inertness properties as PTFE, ETFE and PCTFE at regular temperatures and at high temperature (150C).** **PTFE and PCTFE extend product life/service intervals thereby reducing potential chemical releases/exposures. They also can reduce power consumption compared to non-PTFE/PCTFE counterparts.**
Fluorosilicone and nano-fluorocoatings for anti-smudge and antireflective coatings for plastics and glass.	LCD screens and windows.	Anti-smudge and anti-reflective coatings are necessary to maintain optical clarity in products that are touched by humans or are exposed to the environment. Fluorinated coatings provide hydrophobic (water repellant) and oleophobic (oil repellant) properties to glass and plastics while maintaining optical transparency. Without anti-smudge and anti-reflective coatings, safety and functionality could be compromised by lack of visibility.	**Alternative materials do not have equivalent water or oil resistance with the necessary optical clarity. In particular, oil (fingerprint) repellency of other materials are not equivalent.** **Other anti-fingerprint coatings exist, such as perylene, but they do not adhere to plastic substrates as effectively as fluoropolymer side chain polymers and have lower thermal stability.**

The PCB Companies are committed to replacing PFAS in products and processes where feasible and in a responsible manner. Due to the widespread and varied nature of PFAS used in electronics in performance materials, broad generalizations on alternatives are not reasonable or valuable to eliminating these substances in products. Replacement of these substances must be undertaken on a case-by-case basis as they are selected for their specific properties that ensure product reliability, safety, and efficiency. For most uses of PFAS in PCB Company products, there are no drop-in solutions which provide the same properties as PFAS-containing materials. Because of this, more research must be conducted on alternatives based on use case and industry must have more time to investigate alternatives. The use of PFAS in electronics materials is currently necessary for the key functionalities and properties it provides.

The PCB Companies respectfully request an exemption for the above PFAS products. Differentiating specific uses and exploring non-PFAS options is our ongoing plan. As noted above, many individual parts go into our thousands of products, and PFAS currently is an unavoidable substance to making our products function properly. Our products do not easily break down and are not a risk to the water systems as such. We request an exemption to mitigate unintended consequences and will continue to aim for the removal of all PFAS in our products as substitutes become available.

5. Provide contact information for the submission.

Industry PFAS CUU Project

PFAS Currently Unavoidable Uses (CUU)

Submission by Industry

The Industry PFAS CUU project is made up of ~50 companies that span consumer, professional, medical, industrial, and laboratory uses of PFAS. The CUUs listed here are based on very detailed work by each member of the project combined with tens of thousands of parts tested by Claigan Environmental in 2023 and 2024.

This submission should be the most comprehensive list of Currently Unavoidable Uses in physical products (articles) with detailed justifications and comparisons of alternatives.

The full justifications are available in detail in the accompanying spreadsheet PFAS Currently Unavoidable Uses - Feb 2024.xls.

Table of Contents

Exhibit C

1. Summary

This report is a submission by Claigan Environmental Inc. (Claigan) on behalf of the Industry PFAS Submission Project ("PFAS Submission Project"). The PFAS submission project is made up of 50+ companies from a wide range of industries (consumer, professional, industrial, medical, oil and gas, laboratory equipment, textiles, electronic components, and retail sales.)

The PFAS Submission Project is focused primarily on the needs of complex products (articles). Claigan is both a restricted materials consultancy and a high-volume restricted materials testing laboratory. Each of the PFAS Submission Project submissions are based on contributions from all major sectors of industry, and 2023 and 2024 PFAS testing data from tens of thousands of parts.

The detailed justification of each CUU is covered in the accompanying spreadsheet PFAS Currently Unavoidable Uses - Feb 2024.xls.

Each CUU entry includes

- A brief description of the Currently Unavoidable Use of PFAS.
- A brief description of the type of product including industries and example products with HTS codes.
- A description of the intended use of the product and explanations on how it is essential for health, safety, or the functioning of society.
- A description of how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, citations will be provided for that requirement.
- A description of whether there are reasonably available alternatives for this specific use of PFAS.
- Plus
    - Whether the PFAS use includes PFOA or Long Chain Perfluoroalkyl Carboxylic Acids (LC-PFCA). Many of these PFAS uses do not include (nor degrade into) any PFAS found in drinking water and humans.
    - PFOA / LC-PFCA presence is based on tens of thousands of parts tested in 2023 and 2024.

Exhibit C

Important note 1 - due to the short timeline for the PFAS Currently Unavoidable Use consultation, each justification is only in brief with a detailed comparison of alternatives. Each justification can be further elaborated upon if needed.

Important note 2 - the regulation of chemical substances in medical devices is governed by the FDA. It is generally assumed that this preempts restrictions of PFAS in medical devices under state regulation, "A product for which federal law governs the presence of PFAS in the product in a manner that preempts state authority". However, for completeness and until this question is fully solved, currently unavoidable uses of PFAS in medical devices are also included in this submission.

Important note 3 - The States of Maine and Minnesota adopted a broad definition for PFAS substances. The vast majority of PFAS substances, as defined by Maine and Minnesota, that are found in products are not found in the environment. The broad definition impacts PFAS use in multiple categories of products and equipment needed to make products. PFAS substances are used in these applications because they have unique properties that impart specific performance characteristics making them essential to a product's function. The accompanying spreadsheet provides a detailed comparison of fluoropolymer, fluoroelastomer, and alternative materials for each application. The reason for the use of the fluoropolymer or fluoroelastomer is generally fairly obvious when you look at the application and the alternatives.

2. Related documents

2.1. PFAS Currently Unavoidable Uses spreadsheet - Industry PFAS Submission Project

2.1.1. PFAS Currently Unavoidable Uses - Feb 2024.xls

3. Definitions

3.1. ***Currently Unavoidable Use of PFAS (CUU)*** - a use of PFAS that is essential for the health, safety, or functioning of society and for which alternatives are not reasonably available.

3.2. ***Widespread Use*** -

Exhibit C

3.2.1. For essential uses of a PFAS-containing product, uses that are very high volume with widespread use are identified.

3.2.1.1. For example - fluoroelastomers and perfluoroelastomers have very widespread use in professional/industrial products (> 10M products per year sold in the US).

3.2.2. **For consumer uses** - Over 100 Million products sold in the US each year use this Currently Unavoidable Use of PFAS, or

3.2.3. **For industrial uses (including professional uses)** - Over 10 Million products sold in the US each year use this Currently Unavoidable Use of PFAS.

3.3. ***vPvB*** - Very persistent and very bioaccumulative

3.4. ***PBT*** - Persistent, bioaccumulative, and toxic

4. Key notes

4.1. Importance of PFAS

4.1.1. > 500 million products containing PFAS are sold in the US each year

4.1.2. Banning PFAS would eliminate

4.1.2.1. Laptops

4.1.2.2. The internet (unless servers are moved offshore)

4.1.2.3. Food processing

4.1.2.4. Water processing and treatment

4.1.2.5. Oil and gas industry

4.1.2.6. Heart surgeries and biopsies

4.1.3. Banning PFAS without exception for Currently Unavoidable Uses would likely create the largest recession in the history of the United States.

4.2. PFAS in Drinking Water and Humans

4.2.1. From this project and related testing data

4.2.1.1. ~99% of PFAS found in drinking water and humans is from <0.1% of products (primarily legacy fire extinguisher fluid and legacy foundation/concealer (C9-C15 fluoroalkyl phosphate in personal care products)).

4.2.1.2. ~99.99% of PFAS found in drinking water and humans is from <1% of products (a slight additional contribution from washing of waterproof fabrics contain fluoroacrylates).

4.2.1.3. The average silicone part has 100X more forever chemicals than the worst fluoropolymer (ePTFE). 200 ppm vs 2 ppm.

4.2.1.4. Based on ISO 10993-18 medical biocompatibility testing: Silicone, ABS, polystyrene, PVC, nylon, and polyurethane leak more dangerous chemicals into humans than fluoropolymers

4.2.1.5. Fluoropolymers are used because they are safer and more effective than their alternatives.

4.3. PFAS and Drinking Water - Kentucky 2023 PFAS testing of all drinking water sites

4.3.1. Kentucky 2023 drinking water sites testing

4.3.1.1. https://eec.ky.gov/Environmental-Protection/Water/Reports/Reports/2023-PFASFinishedDrinkingWaterResults.pdf

4.3.1.2. Kentucky was chosen because

4.3.1.2.1. Modern data (2023)

4.3.1.2.2. Comprehensive PFAS testing of each drinking water site

4.3.2. Sources of PFAS in drinking water

4.3.2.1. Based on the comparison of drinking water testing results and laboratory testing results of products

4.3.2.2. Legacy fire fighting foam

4.3.2.2.1. Fire fighting foam that uses C8 fluoro surfactants

Exhibit C

Exhibit C

4.3.2.2.2. Generally phased out of products a decade ago

4.3.2.2.3. Testing characteristic

4.3.2.2.3.1. Always - PFOS

4.3.2.2.3.2. Majority of situations - PFOA

4.3.2.2.3.3. Would not have - PFNA or PFDA (higher-length PFOA substances)

4.3.2.3. Modern fire fighting foam

4.3.2.3.1. Fire fighting foam that uses C4 or C6 fluoro surfactants

4.3.2.3.2. Common in modern fire fighting foam

4.3.2.3.3. Testing characteristic

4.3.2.3.3.1. Always - at least one of 6:2 FTS, PFHxS, PFBS

4.3.2.3.3.2. Majority of situations - PFHxA, PFBA

4.3.2.3.3.3. Would not have - PFOS, PFOA, PFNA, or PFDA

4.3.2.4. Cosmetics (Foundation and Concealer)

4.3.2.4.1. Foundation and concealer using C9-C15 Fluoroalkylphospate

4.3.2.4.1.1. Degrades over time into high concentration of PFOA, PFNA, and PFDA

4.3.2.4.2. Phased out in 2021/2022

4.3.2.4.3. Testing characteristic

4.3.2.4.3.1. Always - PFNA and PFDA (PFDA not included in Kentucky testing)

4.3.2.4.3.2. Majority of situations - PFOA

4.3.2.4.3.3. Would not have - PFOS or any sulphonate, or short-length fluoro carboxylates (PFBA, PFPeA, PFHxA).

Exhibit C

4.3.2.5. Physical products

4.3.2.5.1. Primarily fluoroacrylate coatings of water-resistant fabric

4.3.2.5.1.1. Would release all lengths of perfluorocarboxylic acids during washing in detergent.

4.3.2.5.2. Common today

4.3.2.5.3. Testing characteristic

4.3.2.5.3.1. Always - All lengths of perfluorocarboxylates from PFBA to PFDA.

4.3.2.5.3.2. Would not have - PFOS or any sulphonate.

4.3.2.6. Unknown

4.3.2.6.1. Testing results from water are not consistent with any known product.

4.3.3. Chart of Projected Sources of PFAS in 2023 Kentucky drinking water site testing

4.3.3.1. 113 sites tested in Kentucky in 2023

4.3.3.2. Note - some sites could be listed under more than one source. The total should be above 100%

5. PFAS Currently Unavoidable Uses

5.1. The full details are contained in the accompanying spreadsheet PFAS Currently Unavoidable Uses - Feb 2024.xls.

5.1.1. The comparisons are too large and detailed for a Word document and are instead summarized in an Excel file.

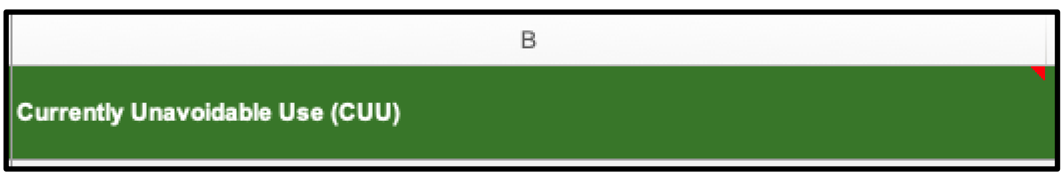
5.2. This document features several tabs with tables containing details about ***CUU's***.

5.2.1. The CUU tab provides details about the specific ***CUU's*** as well as where and why they are specifically used.

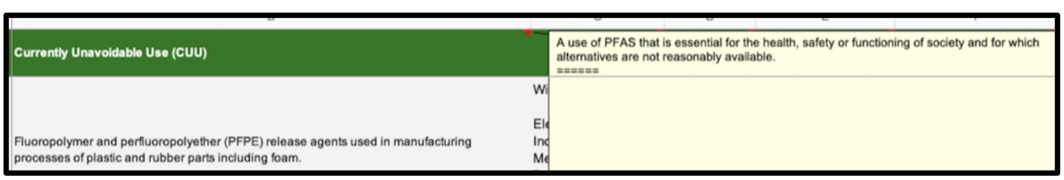
5.2.2. The remaining tabs are the Alternative tabs. They provide the evaluation of alternative materials across a range of criteria applicable to the relevant use, which is labelled on the tab at the bottom of the document.

5.3. The core data is found within the tables, while further explanatory notes are found in the applicable column and row headers.

5.4. Cells with a red triangle in the top right corner have additional information pertinent to their respective row or column. They are found in Row 1 of the CUU tab and Column A of the Alternatives tabs. For example:



5.5. Additional details are revealed by hovering the mouse cursor over the cell (without clicking it). For example:



5.6. Additionally, this same information is captured in the document below.

Exhibit C

6. CUU Tab

6.1. Columns A and B (CUU Number and Description) provide the numbering and descriptions for each ***CUU***.

6.2. Column C (Products) provides an overview of the applicable product families that require the listed Currently Unavoidable Use.

6.3. Column D (HS Codes) provides a list of HS Codes of products that require the listed ***CUU***. Some uses are so pervasive that the entire HS Code (Customs Code) chapters are listed.

6.4. Column E (Example Products) details a list of example products that require the applicable ***CUU.*** This list is representative and is not intended to be exhaustive.

6.5. Column F (Essential Use of Product) describes the intended use of the product and explains how it is essential for health, safety, or the functioning of society. It also describes if products using this CUU are ***Widespread*** or ***Industrial***.

6.6. Column G (Essential Use of PFAS) describes how the specific use of PFAS in the product is essential to the function of the product.

6.7. Column H (Comparison of Alternatives) describes reasonably available alternatives for this specific use of PFAS and compares them to the applicable ***CUU***. For further details, refer to the relevant Alternatives tab.

6.8. Column I (PFOA) identifies if this CUU contains any PFOA or Long Chain Perfluoroalkylcarboxylates (LCPFCAs). This column is based on 2023 and 2024 testing data of hundreds of representative parts for PFOA and LC-PFCAs.

6.9. Column J (Alternatives Tab) provides a direct link within the document to the identified tab comparing the performance of PFAS materials and alternative materials.

7. Alternatives Tabs

7.1. Row 1 (Comparison) identifies the alternative materials being evaluated.

7.2. Low Friction

7.2.1. Excellent - The material has a low coefficient of static friction. It is nearly frictionless.

Exhibit C

7.2.2. Decent - The material has a lower coefficient of static friction but has some friction in use.

7.2.3. Poor - The material has a high coefficient of static friction. It displays strong friction during use and is not suitable for applications requiring low friction.

7.3. ***Chemical Resistance*** - the resistance to acids or bases may not be uniform for a material. The rating reflects the general potential applications of the material

7.3.1. Excellent - The material has superior resistance to acids and bases. Acid and bases have no discernible effect on the material.

7.3.2. Decent - The material is resistant to acids and bases but does exhibit some degradation. It should not be in extended contact with, or subject to, high concentrations of acids or bases.

7.3.3. Poor - The material is not resistant to acids and/or bases.

7.4. Water Resistance

7.4.1. Excellent - The material is hydrophobic (*i.e.* it is impermeable to water even as a coating).

7.4.2. Decent - The material is resistant to water, but not completely hydrophobic or waterproof.

7.4.3. Poor - The material is permeable to water.

7.5. Oil Resistance

7.5.1. Excellent - The material is oleophobic (*i.e.* it is impermeable to oil even as a coating).

7.5.2. Decent - The material is resistant to oil, but not completely oleophobic, oil-proof, or stain-resistant.

7.5.3. Poor - The material is permeable to oil.

7.6. Temperature Resistance

7.6.1. Excellent - The material can withstand temperatures above 150°C.

7.6.2. Decent - The material can withstand temperatures above 100°C, but is impacted by temperatures above 150°C.

Exhibit C

7.6.3. Poor - The material is impacted by temperatures above 100°C.

7.7. Fire Resistance

7.7.1. Excellent - The material meets stringent fire/flame resistance standards.

7.7.2. Decent - The material has fire/flame resistance but does not meet the most stringent standards.

7.7.3. Poor - The material is not fire/flame resistant.

7.8. Flexibility

7.8.1. Excellent - The material exhibits good flexibility and is useful in most applications requiring flexibility.

7.8.2. Decent - The material has some rigidity, but still exhibits some flexibility.

7.8.3. Poor - The material is rigid and is not suitable for applications requiring flexibility.

7.9. Forever Chemicals (Initial)

7.9.1. Excellent - The material does not contain any substances with an EU harmonized classification of vPvB or PBT after manufacturing.

7.9.2. Decent - The material contains trace amounts (<1 ppm) of substances with an EU harmonized classification of vPvB or PBT after manufacturing.

7.9.3. Poor - The material contains amounts (> 1ppm) of substances with an EU harmonized classification of vPvB or PBT after manufacturing

7.10. Forever Chemicals (Over Time)

7.10.1. Excellent - The material does not degrade into substances with an EU harmonized classification of vPvB or PBT.

7.10.2. Decent - The material degrades lightly into substances (<1 ppm) with an EU harmonized classification of vPvB or PBT over time.

7.10.3. Poor - The material degrades into substances (> 1ppm) with an EU harmonized classification of vPvB or PBT over time.

7.11. Bio-compatibility

Exhibit C

7.11.1. Excellent - The material passes US FDA and EU MDR biocompatibility testing and does not normally require toxicological justification.

7.11.2. Decent - The material passes US FDA and EU MDR biocompatibility testing but often requires toxicological justification.

7.11.3. Poor - The material does not generally pass US FDA or EU MDR biocompatibility testing or it requires significant toxicological justification.

7.12. Insulation

7.12.1. Excellent - The material has a low dielectric constant and is suitable for most insulating or electronics purposes.

7.12.2. Decent - The material has a medium dielectric constant and is only suitable for some insulating or electronics purposes.

7.12.3. Poor - The material has a high dielectric constant and is not normally suitable as an insulating material in electronics.

7.13. High-Density Applications

7.13.1. Excellent - The material is usable in applications requiring thin layers or high density.

7.13.2. Decent - The material is usable in applications that do not require thin materials, but it is not suitable for very fine or dense applications.

7.13.3. Poor - The material is not feasible as a thin film or in high-density applications.

7.14. Polymer Additive

7.14.1. Excellent - The material can be added to a wide range of polymers to provide additional properties.

7.14.2. Decent - The material can be added to some polymers to provide some level of additional properties.

7.14.3. Poor - The material is not suitable as a polymer additive.

7.15. Porous

7.15.1. Excellent - The material is permeable to air.

Exhibit C

7.15.2. Decent - The material is partially permeable to air but is resistant to airflow.

7.15.3. Poor - The material is not permeable to air.

7.16. Durability

7.16.1. Excellent - The material has superior resistance to wear.

7.16.2. Decent - The material is partially resistant to wear but is not suitable for high-wear situations.

7.16.3. Poor - The material is not suitable for situations where wear resistance is required.

7.17. Optical Transparency

7.17.1. Excellent - The material is optically transparent.

7.17.2. Decent - This material has some optical transparency but is not suitable for applications requiring clarity and high transparency.

7.17.3. Poor - This material is not normally optically transparent

7.18. Structural

7.18.1. Excellent - The material is rigid with the ability to support its weight and any weight of the fluid it is transporting. It also has superior fatigue resistance.

7.18.2. Decent - The material can support its weight, but it is not as reliable for additional weight or fatigue.

7.18.3. Poor - The material cannot rigidly support its weight.

7.19. Radiation Resistance

7.19.1. Excellent - The material has superior resistance to gamma and e-beam radiation and does not exhibit degradation due to radiation.

7.19.2. Decent - The material has some resistance to gamma and e-beam radiation but exhibits degradation with repeat or high dosage exposure.

7.19.3. Poor - The material degrades in gamma or e-beam radiation.

7.20. Acceptable

Exhibit C

7.20.1. A material is deemed acceptable if it receives an excellent or decent rating in non-critical properties. The material must receive an excellent rating in critical properties to be deemed acceptable.

7.20.1.1. Critical properties are identified where ratings (excellent, decent, poor) are shown in bold.

8. Acknowledgements

Special thank you to Nials Everett, Chris Scully, Julie Van Moorsel, Dr Tim Holt, and the entire Claigan Environmental staff and students for their contributions. And thank you to all of our industry members who contributed so much in such little time.

Exhibit C

CUU	Currently Unavoidable Use (CUU)	Products	HS Codes	Example Products	Essential Use of Product	Essential Use of PFAS	Comparison of Alternatives	PFOA	Alternatives Tab
1	Fluoropolymer and perfluoropolyether (PFPE) release agents used in manufacturing processes of plastic, rubber, and pressed wooden parts including foam.	Widespread use Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory, Building Products, and Security & Defense	HS Code Chapters - 32, 39, 40, 56 83, 84, 85, 86, 87, 88, 89, and 90	Gaskets (401693), o-rings (401693), and molded rubber parts in electronics (40), pumps (841381), medical devices (9018), door locks (830140), pressed wood pallets (441520)	Widespread use. Used in the majority of manufactured products on the market.	Release agents are required to release rubber parts from their molds	Superior to other release agents. May be replaceable in the future by silicone. Wide verification and validation required. Silicone has higher friction and adhesion than fluoropolymer based release agents.	None	Release agent
2	PTFE used as an additive drip agent in plastics to meet flammability safety requirements	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 39, 40, 48, 49, 76 83, 84, 85, 86, 87, 88, 89, and 90	Electronics with plastic components (85). Examples- vacuum cleaners (850860), computers (847130), fans (841490), food processing equipment (843880), and electric cars (870380).	Widespread use. Used in the vast majority of complex electronics on the market to meet flame retardancy standards such as UL 94 and IEC 60695-11.	Provide required anti-drip flame retardancy required by fire regulation and standards. Currently no effective replacements for PTFE as an anti-drip additive. Virtually all electronics use PTFE anti-drip agents in one or more parts. Restriction of PTFE anti-drip agents would create a significant safety risk for electronics and require the redesign and re-qualification of safety of virtually every electronic product on the US market	Only additive widely approved for use to meet strict anti-drip flame retardancy requirements in plastics	None	Anti-Drip
3	PTFE, ETFE, PFA, PVDF, and FEP as a wire insulator.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90	Laptops (847130), medical endoscopes (901890), mass spectrometers (902781), car ignition (8708), tablets (847160), Pumps (8414), Data Machines (8517), Printers (8544), Analytical Instruments (9026), Photometers/Instruments (9027)	Widespread use. >100M products per year Used in the majority of complex higher performance electronics on the market.	Provide temperature and chemical resistance in combination with electrical insulation	Other materials do not have sufficient temperature and corrosive resistance, feasibility in dense electronics (too thick), and electrical insulation	None except PFA. PFA can be manufactured without residual PFOA but time will be required for conversion.	Wiring
4	Fluoropolymers (PTFE, ETFE, FEP, and PFA) used for electrical insulation purposes except wiring.	Hoses, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90	Coaxial cables (854420), audio ports (853669), chemical hoses (3917), antennas (852910), electrical transformers (850431), electric switches (853630)	Widespread use. >10M products per year. Common in most RF applications. Necessary for many radio frequency applications Also common to general electrical insulation, static dissipative hoses, and fire suppression.	Fluoropolymers have the best in class dielectric constants / electrical insulation while maintaining flexibility. This includes both electrical isolation but also in static dissipation and related safety activities.	Other polymers do not provide sufficient electrical insulation (poorer dielectric constants). Ceramics can provide sufficient dielectric constants for some RF applications, but do not have the flexibility required for most applications.	None except PFA. PFA can be manufactured without residual PFOA but time will be required for conversion.	Dielectric
5	Fluorosilicone, amorphous fluoro resins, and fluoroelastomers (including perfluoroelastomers) for electrical insulation purposes except wiring.	Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90; and HS Code 3917.	High voltage cables (854460), electric vehicles (870380), hoses (3917), (853340) electrical resistors (including rheostats and potentiometers) and industrial machinery (843890).	High voltage applications would be difficult without fluoroelastomers	Specialized uses requiring electrical isolation in a rubber	No other material has equivalent dielectric constant / electrical insulation capability with flexibility Fluoroelastomer use is more specialized and lower volume than PTFE and ETFE for the same purpose.	None	Insulator
6	Fluoropolymers in invasive, implantable, fluid, and gas contacting applications in medical devices.	Medical	HS Code Chapter - 90	Endoscopes (901890), surgical instruments (9018), surgical tubing, and pacemakers (902150), electrical components (854370)	Widespread medical use. Necessary for most invasive procedures	Low friction, flexibility, and high biocompatibility are essential for internal procedures	Alternatives do not have equivalent low friction, flexibility, and/or biocompatibility. Some polymers, such as silicone and polyurethane, have applications in invasive medical devices but not in situations requiring low friction or thin material. Silicone also contains over 100X higher concentrations of forever chemicals (D4, D5, and D6) than PFA fluoropolymer.	Yes. However PFOA presence is strongly linked to flexibility and will take time and validation to phase out.	Medical
7	PTFE as an additive up to 25% in plastics for the purpose of reduced friction and wear	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 28, 32, 38, 39, 40, 49, 73, 74, 82, 83, 84, 85, 86, 87, 88, 89, and 90	Bearings (848210), medical devices, drills (846721), manufacturing equipment, food processing equipment (820830), industrial vehicles and instruments for analysis (9027).	Widespread use. Very common in longer life products with moving parts. Without these products, there would be no more automation or automated assistance.	PTFE additive provides greatly reduced friction and wear in plastic parts. This property greatly extends their lifetime and time before replacement.	Alternatives do not have equivalent low friction or compatibility as an additive. No other additives are as effective in safely reducing the coefficient of friction of plastics. Restriction of PTFE additives in plastics for friction reduction would reduce the lifetime of many products, resulting in products going to waste or landfall sooner and more often. In addition, PTFE added plastics extend product life/service intervals thereby reducing potential fluid and gas releases/exposures. They also reduce power consumption compared to non-PTFE added counterparts.	No	Friction
8	PTFE, ETFE, and PCTFE for professional, industrial, or high temperature applications (>150C) requiring reduced friction, or chemical inertness.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 32, 39, 40, 83, 84, 85, 86, 87, 88, 89, and 90.	Chemical reactors (841989), breathing appliances (9020), chemical processing, oil and gas (847989), laboratory equipment, engines, electrical transformers (850450), and industrial equipment.	Widespread professional and industrial use. Requirement for industrial and laboratory machinery. Working at high temperatures or harsh environments would no longer be possible.	Fluoropolymers have tremendous chemical and temperature resistance combined with low friction. All three are essential for the operation and safety in industrial environments.	No other materials have the same low friction and chemical inertness properties as PTFE, ETFE and PCTFE at regular temperatures and at high temperature (150C). PTFE and PCTFE extend product life/service intervals thereby reducing potential chemical releases/exposures. They also can reduce power consumption compared to non-PTFE/PCTFE counterparts.	No	Harsh Env.
9	Fluoroacrylic coatings necessary for chemical or fire safety for fabrics including applications requiring extreme water repellancy for professional use.	Textiles	HS Code Chapters - 39, 42, 56, 62, and 63	Chemical aprons (6210), Splash shields (392690), motorcycle racing jacket (420310), and hazardous environment clothing (621010)	Safety clothing is necessary for worker safety in hazardous environments.	Fluoroacrylics provide adhesion to the fabric and protection from acid, water, and oil.	Alternatives do not have the combination of acid, water, temperature, and oil resistance sufficient for hazardous environments while maintaining permeability to air (breathability).	Yes from the fracturing of the C-O-C bond in the fluoroacrylic coatings. But in low concentration.	Fabric Coating
10	Fluoroacrylic coatings on fabrics necessary for the protection or storage of portable medical devices or laboratory equipment.	Textiles, Medical, Laboratory	HS Code Chapter - 84 and 90	Water resistance cases for pumps (841370), dialysis equipment (901890), CPAPs and other sensitive medical or laboratory devices (901920).	Water resistance provided by the carrying case is necessary for sensitive medical and laboratory requirement.	Fluoroacrylics provide adhesion to the fabric and significant protection from acid, water, and oil. The safety of the laboratory or medical device is dependant on their proper care from the environment.	Alternatives do not have the combination of acid, water, and oil resistance sufficient for complete protection of the sensitive equipment or medical devices.	Yes from the fracturing of the C-O-C bond in the fluoroacrylic coatings. But in low concentration.	Fabric Coating

11	PTFE, PFA, FKM, and PVDF membranes for gas and aqueous filtration, or particle retention.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 38, 39, 73, 84, 85, 86, 87, 88, 89, and 90.	Medical filtration membrane (901819), laboratory filtration membranes (8414), water purification / food processing equipment filtration membranes (842121), and drinking water filtration and laboratory membranes (9020)	PTFE, PVDF, FPA, and FKM membranes are hydro- (water) and oleo- (oil) phobic while still allowing air to pass. These membranes provide the ability to extract air components from liquids and solids in specialized environments. Fluoropolymer membranes perform well under pressure and are stable over time and resistant to corrosive cleaning reagents.	PTFE, PVDF, PFA, and FKM membranes are the only material with best in class air porousness and resistance to water and oils.	No other material has the same gas permeability while being hydrophobic, oleophobic, acid resistant, and alkali resistant. Fluoropolymer membranes also have the advantage of maintaining their performance characteristics even at elevated temperatures. Although it is theoretically possible to develop a porous gas permeable polyethylene frit for some applications, this would be a long project and is risky regarding tightness and reproducibility of the gas transfer. Safety and accuracy would degrade in these specialized medical, laboratory, or industrial applications.	Yes. From the fracturing ('rubberizing') of the fluoropolymer to create the membrane fibre. Low concentration: 1 to 4 ppm	Membranes
12	PTFE as a lubricant additive under 30% concentration not in contact with drinking water.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 34, 84, 85, 86, 87, 88, 89, and 90	Widespread use. Mineral or silicone oil with PTFE powder added. Used in a wide range of consumer, professional, and industrial machinery to maintain low friction. PTFE added oil lubricants are both found inside machinery and are sold independently for use on moving parts.	The PTFE added lubricants significantly decrease the wear and increase the lifetime of machinery parts.	PTFE powder added to oils safely provides lubrication in a large range of environments necessary for proper function and lifetime of machinery.	No other material has the same impact as a low friction additive to mineral or silicone oil than PTFE.	No	Lubricant
13	PTFE as a fused coating on cookware	Cookware	HS Code Chapters 73, 76 and 84	Frying pans, electric griddles, electric waffle machines. (7323, 761510)	Cooking appliances and frying pans are essential to the continued functioning of society. Non-stick cookware is necessary to reduce cooking and cleaning time for consumers and professionals.	Fused PTFE powder to create anti-stick coating on cooking surface	No polymer provides the same low friction at high temperature. Ceramic cookware can provide sufficient non-stick (low friction) but is not as durable as PTFE coated cookware, reducing the lifetime of the fry pan or cooking appliance.	No	Cookware
14	PTFE as a coating for chemical containers	Containers	HS Code Chapters - 39, 73, 84, and 86	Chemical containers (for storage or industrial machinery) for hazardous chemicals (7309-7311) (841989, 8609)	PTFE has the necessary acid, water, oil, and temperature resistance to handle some of the most hazardous chemicals.	PTFE provides excellent resistance to chemicals, acids, water, and oils - and temperatures.	Alternatives do not provide sufficient resistance to acid, water, oils, and temperature for all harsh chemicals. Ceramics have similar performance characteristics but could only be used to coat metal vessels. Ceramic coatings are more difficult to coat completely without gaps in larger containers, creating leakage or degradation risk.	No	Harsh Env.
15	Fluoroelastomers (including perfluoroelastomers), fluorosilicone, and amorphous fluoro resins as a sealing and packing material in situations requiring chemical resistance, oil resistance, oxidation resistance, decompression resistance, elasticity, high temperature (over 150C), and/or low temperature (<-20C).	Rubbers, Building Products, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 32, 34, 39, 40, 49, 59, 68, 72, 73, 83, 84, 85, 86, 87, 88, 89, and 90.	Widespread use. Pumps, oil and gas (848790), industrial machinery (848420), chemical tanks (7309), food processing, medical devices, laboratory equipment, aerospace, chemical processing, pharmaceutical and cosmetic processing equipment, and equipment for extreme environments	Products using fluoroelastomer seals can be found in virtually every industrial or machinery application world wide. Without fluoroelastomer seals, virtually all industrial applications would no longer be viable.	Fluoroelastomers (including perfluoroelastomers and amorphous fluoro resins) are the necessary sealing material for applications requiring temperature resistance, chemical resistance, flexibility, and water/oil resistance. Without fluoroelastomers, sealing on machinery would not be viable in many applications.	No other rubbers have equivalent hydrophobic and oleophobic properties, oxidation resistance, and chemical safety over a range of low and high temperatures as fluoroelastomers. Fluoroelastomers are also very resistant to explosive decompression. Fluoroelastomer use can extend product life/service intervals thereby reducing potential chemical releases/exposures. Alternative materials would need to be replaced monthly, as they begin to leak. PTFE has similar environmental properties, but is a plastic and is not suitable for applications requiring the conformity of a 'rubber' seal. Fluoroelastomers also have a higher coefficient of friction than PTFE and create a superior 'seal' in most applications.	No	Seals
16	Fluoroelastomers (including perfluoroelastomers), fluorosilicone, and amorphous fluoro resins as a sealing and packing material for drinking water or food contact if compliant with NSF, FDA, and State food and/or drinking water regulations.	Rubbers, Industrial, Machinery	HS Code Chapters - 40, and 84.	Widespread use. Seals in water purification facilities and laboratory equipment. Very common material in drinking water contact. (842121, 842199)	Water purification is essential to the functioning of society.	Fluoroelastomers provide flexibility, biocompatibility, temperature resistance, and water resistance.	No other rubbers have equivalent hydrophobic and oleophobic properties, UV resistance, and chemical safety over a range of temperatures as fluoroelastomers. The most common alternatives are not chemically compatible for direct contact for long exposure time (years). PTFE has similar environmental properties, but is a plastic and is not suitable for applications requiring the conformity of a 'rubber' seal. Fluoroelastomers also have a higher coefficient of friction than PTFE and create a superior 'seal' in most applications. Additionally, silicone has reduced biocompatibility and high forever chemicals due to its normal high concentration of residual D4, D5, and D6 forever chemicals.	No. However, fluoroelastomers can contain 6:2 fluorotelomer from their emulsion surfactant. Any presence of 6:2 fluorotelomer (and related short chain perfluorocarboxylate degradation products) must conform to drinking water standards.	Water Seals
17	PTFE tape for moisture insulation, or joining of fluid or gas components.	Self adhesive tape, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 40, 84, 85, 86, 87, 88, 89, 90, and HS Code 3919.	Widespread use. PTFE tape for home and professional use, plumbing, machinery with fluids or gasses, drinking water equipment, food production equipment, industry water processes, medical endoscopes, analytical instruments, and any other equipment requiring piping to be sealed together. (3919)	PTFE tape is the most effective joining materials in a fluid environment. Alternative materials do not have equivalent water and oil sealing in a thin coating.	PTFE rubber tape has the best in class water and oil resistance in a thin applicable tape.	Alternative materials do not provide the same water or oil seal in a thin tape.	Yes. The fracturing of the PTFE polymer chain to produce PTFE rubber commonly produces PFOA and LC-PFCA. Manufacturing of PTFE tape without PFOA is possible and PFOA containing PTFE can be phased out.	PTFE Tape
18	PTFE tape for reduction of friction.	Self adhesive tape, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 39, 40, 84, 85, 86, 87, 88, 89, 90, and HS Code 3919.	Industrial machinery or equipment with moving parts. (3919). Printing equipment (3215)	PTFE tape provides a thin coating to reduce friction between moving parts.	PTFE rubber tape has very low friction, reducing the wear, and extends the lifetime of moving parts.	No other tape materials has as low friction as PTFE tape and the ability to conform to uneven surfaces. Replacement of PTFE tape in a low friction application will negatively affect product performance and reduce lifetime of the product - causing earlier disposal or replacement of the product using the PTFE tape.	Yes. The fracturing of the PTFE polymer chain to produce PTFE rubber commonly produces PFOA and LC-PFCA. Manufacturing of PTFE tape without PFOA is possible and PFOA containing PTFE can be phased out.	PTFE Tape
19	Fluorocoating of rubber, metal, carbon, and plastic seals in high temperature, professional, or industrial applications where chemical resistance is required.	Rubbers, Building Products, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory, Aerospace	HS Code Chapters - 40, 83, 84, 85, 86, 87, 88, 89, and 90	Plunger in a syringe (901831), rubber plunger in industrial equipment (841319), rubber component in contact with chemicals.	Most standard rubbers are high friction (nitrile rubber, styrene rubber, EPDM) and require a fluorocoating for low friction. This is necessary for plungers and other rubber parts likely to encounter friction in operation.	Fluorocoating of standard rubber such as nitrile or butadiene rubber provides low friction to a standard rubber.	Alternative materials do not sufficiently reduce the friction of rubber to allow for the necessary movement of the rubber part. No other coating material provides the same environmental protection to rubber and metal seals.	No	Rubber coating

Exhibit C

20	PTFE, ETFE, and PFA coating of metal for environmental or temperature resistance not in contact with food or drinking water.	Metal, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory, Aerospace	HS Code Chapters - 72, 84, 85, 86, 87, 88, 89, and 90	Widespread use. Outdoor machinery, construction vehicles, oil and gas platforms, industrial equipment (3208) (721070)	Metals and machinery used in harsh or outdoor environment need chemical, water, and oil resistant coatings to protect from the conditions.	Fluoropolymer coatings provide environmental resistant to metal parts. Resistance to water, acids, and oils extends the lifetime of the parts in outdoor and harsh environments.	No other coating materials provide the same environmental (water, oil, acid, and chemical) protection to metals. Replacement PTFE and PFA environmental coatings for metals will reduce the corrosion resistance (in particular over temperature) of many metals resulting in failure of these metals and/or reduced product lifetime (resulting in more products entering end of life disposal sooner).	No	Outdoor
21	PTFE, FEP, and PFA coating of metal for low friction, improved wetting, and/or wear resistance in machinery or tools	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Machinery or equipment with moving parts. Wood saw blade, pumps, and other moving components in contact with other materials. (721070). Machines and mechanical appliances (847989), pumps (8413), laboratory or plant machinery (841989), spectrometers (902730). Includes paint, anodization, and other coatings on metals.	Cutting, drilling, grinding, milling, and other activities with metal in contact with other materials requires low friction, high wear resistance and high temperature resistance.	Fluoropolymers coatings are nearly frictionless, have excellent wetting properties, and can withstand high temperature and wear.	Alternative materials do not have equivalent low friction, wetting, and/or temperature resistance. PEEK provides similar durability but not equivalent low friction. PFA does not have as low friction as PTFE, but is lower friction than PEEK. Replacement PTFE, FEP, and PFA environmental coatings will greatly reduce the performance of some machinery, increase wear, and reduce lifetimes on metal components. Liquid lubricants can be used, but they are temporary in nature, and the most effective lubricants for low friction in metal parts contain PTFE powder and are covered by another derogation request.	None except PFA. PFA can be manufactured without residual PFOA but time will be required for conversion.	Machinery
22	PTFE, PFA, FEP, and TFE copolymers in hoses in chemical, pump, or valve applications.	Tubing, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 3917.	Widespread use. Pump hoses, chemical plants, gasoline hose, fuel lines, and oil and gas. (4009)	Transport of chemical or petroleum fluids requires specialized materials.	Fluoropolymers have excellent chemical, acid, and oil resistance - the requirements for transportation of many petroleum and chemical fluids. Fluoropolymers also have the flexibility necessary for hose (as opposed to rigid tube) applications.	No other polymer that can be formed into hoses or braided to transport chemicals has the equivalent acid, chemical, oil, fire, and temperature resistance with the necessary flexibility required for hoses.	None except PFA. PFA can be manufactured without residual PFOA but time will be required for conversion.	Hoses
23	Fluorocoatings on labels on products (excluding textiles) necessary for environmental resistance	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory, Personal Protective Equipment (PPE), Consumer	HS Code Chapters - 65, 84, 85, 86, 87, 88, and 90	Widespread use. Safety label on product, product serial number label, battery capacity and composition label, and other labels with indelibility and lifetime requirements. (482110)	Clear labels that do not degrade over time are required for safety and regulatory reasons on most electronic, personal protective equipment, professional, and industrial products. A thin fluorocoating protects the label from the environment, maintaining the legibility of the label and meet standards such as UL 969.	Fluoropolymer coatings provide water and oil resistance to labels - reducing, if not preventing legibility issues with the label's writing.	Alternative coatings do not have the equivalent water or oil resistance. Or, in the case of nitrile or EPDM rubber, do not have the required transparency to read the label's writing. PVC has nearly equivalent water and oil resistance, but has risks of other regulated substances (such as phthalates) and does not withstand temperature ranges as well as fluoropolymers.	No	Labels
24	PTFE, PFA, FEP, PVDF, ETFE, and fluoroelastomer (including perfluoroelastomer) tubing not in contact with drinking water.	Tubing, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, 90; and HS Code 3917.	Widespread Use. (391739) Transformers, power suppliers, laboratory equipment, medical devices (901839), accelerometers (903180), and servers	Electrical transformers are reliant on PTFE tubing to protect their wiring. Medical devices and laboratory equipment use fluoropolymer tubing for transport of fluids in situations where non-reactive materials are critical. Tubing and bellows are used in articulating joints in machinery and vehicles. Without which, the joints would be inflexible and would wear.	Fluoropolymers have flexibility, biocompatibility (low chemical reactivity), optical transparency, and high temperature resistance. For electronics, the flexibility and high temperature resistance is critical for power applications such as the leads in transformers. For medical devices, the flexibility, transparency, and low chemical reactivity are critical for human or laboratory processes.	Alternative polymers do not have equivalent low chemical reactivity, optical transparency, flexibility, and temperature resistance. Polyurethane and PVC tubing can be used in some applications, but have poor resistance to acids and bases, can release chemicals (isocyanates or phthalates) into the fluid, and both have poor temperature stability.	No	Tubes
25	Heat transfer fluids for industrial applications	Heat transfer fluids, Electronics, Vehicles, Industrial, Machinery, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, and 89; and HS Code 3824.	Servers, semiconductor manufacturing equipment, radar equipment, and large power supplies.	Specialized high performance products that require fast and efficient transfer of heat from the heat generation source.	Fluorinated fluids have best in class heat transfer properties.	No other fluids have equivalent heat capacity to transfer heat sufficiently in machinery. Replacement with other fluids would create safety and performance issues in industrial applications such as semiconductor manufacturing, data centers, and military/aerospace.	Unknown	N/A
26	PVDF and PTFE as the cathode binder in lithium batteries	Lithium batteries, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8507.	Lithium batteries in electronics, vehicles, medical devices, servers, power drills (846721), analysis equipment for water, and portable electronic equipment. (850760)	Lithium batteries are fundamental to electric vehicles, servers, and portable electronics / tools.	Fluoropolymer binders have high heat resistance and excellent electrical insulation - improving performance of lithium batteries and reducing delamination of the electrodes in the battery.	Alternative polymers do not have as good of temperature resistance and/or electrical insulation, reducing the performance and lifetime of lithium batteries. Other polymers could not maintain the rigorous performance requirements of a binder in a high density lithium battery. Lead acid batteries have similar performance to lithium batteries, but can release lead at the end of life and have a weight that makes them unusable for mobile applications including electrical vehicles.	No	Batteries/Cap
27	PVDF, PTFE, TFE, and sulfonated PTFE as a binder, separator, or spacer in capacitors (including copolymers)	Capacitors, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8532.	supercapacitors and other high capacitance capacitors have a broad use in electronics, electrical distribution, and industrial equipment. (8532)	Fluorinated binders in capacitors are fundamental to high performance / capacitance capacitors. The fluoropolymers fill a similar role in a capacitor as they do in a lithium battery.	Fluoropolymer binders, separators, and spacers provide the electrical insulation and temperature resistance needed in high capacitance capacitors.	Alternative polymers do not have as good temperature resistance and/or electrical insulation, reducing or preventing the performance of the high performance capacitors	No	Batteries/Cap
28	Surfactants in emulsion based bio-assays and dry-chemistry assays	Medical, Laboratory	HS Code Chapter 90	Specialized low volume use in laboratory assays. Research and development, and medical applications.	Surfactants are commonly needed in laboratory and medical assays. These assays are necessary for measurement of biological, human, and chemical properties.	Fluorinated surfactants have the best surfactant performance. High performance and critical measurements using bio and dry chemistry assays often have to use fluorinated surfactants for measurement accuracy.	Fluoro based surfactants are commonly used as the surfactants in specialized bio-assays and dry chemistry assays. Fluoro based surfactants are useful for membrane protein stabilization in subsequent purification steps as they do not strip natural lipids and other co-factors from the proteins. In addition, the bulky fluorinated tails can not penetrate into the interior and disrupt the structure. Fluorinated surfactants often decrease non-specific aggregation and are thought to result in improved distribution. Without fluoro based surfactants, many specialized laboratory or medical measurements would not be possible or, at least, not with the same accuracy.	Yes. The very small amount present is very low volume, specialized use, and has controlled disposal. No risk of impact to humans or drinking water.	N/A
29	PTFE foil coating of rubber for biotechnology or chromatography purposes.	Medical, Laboratory	HS Code Chapter 90	Specialized very low volume use in laboratory and medical testing. Research and development, and medical applications. (902720)	PTFE foil is a specialized use in gas (and other) chromatography. This is a low volume application necessary for very specialized tests.	By enclosing the gas / fluid path with PTFE, higher precision chromatography is possible due to the reduced friction and low chemical reactivity of the tubing.	No other polymer has as low reactivity and low friction as PTFE. Specialized biotechnology or chromatography applications require the highest possible performance for measurement accuracy and consistency.	No	N/A

Exhibit C

Exhibit C

30	Fluorinated polyethylene for chemical storage and handling.	Industrial, Machinery, Laboratory	HS Code 3904	Fluorinated polyethylene containers for hazardous or laboratory chemicals.	Certain laboratory and hazardous chemicals will dissolve standard polyethylene or other polymer containers. Fluorinated polyethylene containers are needed for transport and storage of these chemicals (pesticides, optical personal care products, and industrial cleaners).	Fluorinated polyethylene provides the chemical resistance to standard polyethylene containers necessary to contain and transport certain chemicals.	Alternative non-fluorinated polymers do not have the chemical resistance to safely contain or transport pesticides and industrial cleaners. PFA fluoropolymer has similar performance as fluorinated polyethylene, but is more flexible and not suitable for most applications of fluorinated polyethylene.	Yes. Small concentration of PFOA and LC-PFCA are created by the fluorination of polyethylene.	N/A
31	Fluorosilicone and nano-fluorocoatings for antismudge and antireflective coatings for plastics and glass.	Electronics, Building Products, Vehicles, Industrial, Machinery, Medical, Laboratory, Eyewear	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90.	LCD screens (852859), ski goggles (900490), sunglasses and eyewear (900410), refrigerator shelves (841899), and windows (761010).	Anti-smudge and anti-reflective coatings are necessary to maintain optical clarity in products that are touched by humans or are exposed to the environment. Without anti-smudge and anti-reflective coatings, safety and functionality could be compromised by lack of visibility.	Fluorinated coatings provide hydrophobic (water repellant) and oleophobic (oil repellant) properties to glass and plastics while maintaining optical transparency.	Alternative materials do not have equivalent water or oil resistance with the necessary optical clarity. In particular, oil (fingerprint) repellency of other materials are not equivalent. Other anti-fingerprint coatings exist, such as parylene, but they do not adhere to plastic substrates as effectively as fluoropolymer side chain polymers and have lower thermal stability.	No	Anti-smudge
32	PTFE, PCTFE, PVDF, FEP, ePTFE, PFA, and TFE (including copolymers) as a sealing or spacer material.	Seals (plastic, rubber, or metal), Building Products, Electronics, Vehicles, Industrial, Machinery, Pumps, Medical, Laboratory	HS Code Chapters - 28, 32, 38, 39, 40, 49, 59, 72, 73, 74, 82, 83, 84, 85, 86, 87, 88, 89, and 90	Widespread use. Pumps, oil and gas, industrial machinery, food processing, pharmaceutical and cosmetic processing equipment, medical devices, laboratory equipment, aerospace, chemical processing, electronic components, and equipment for extreme environments.	Products using fluoropolymer seals can be found in a wide range of industrial or machinery applications. Fluoropolymer seals are used in situations requiring a solid or vacuum seal versus the rubber seal of a fluoroelastomer, or added / impregnated into sealing material to provide the necessary performance properties.	Fluoropolymers have the acid, alkali, temperature, heat, water, and oil resistance needed for industrial sealing applications.	Alternatives do not provide sufficient resistance to acid, chemicals, water, oils, and temperature. In most of the applications listed in this entry, alternative sealing materials were tested, and no materials and closure systems showed positive results.	No Except PFA and ePTFE. They often contain PFOA and LCPFCA from the fracturing of the C-O-C bond of PFA, and the crosslinking of the polymer in ePTFE. Both can be designed without PFOA or LC-PFCA.	Seals
33	PVDF and ETFE as a component in fluid or gas systems	Plumbing, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90 - HS Code 3917	Pumps (841381), water circulation systems (842121), water purification system (842121), laboratory equipment (8419), and water heaters (8419).	Fluid and gas transportation is critical for a wide range of industries. Society cannot function without the ability to transport fluids and gases.	PVDF and ETFE provide significant performance advantages as components in a fluid or gas transportation system as either part of the tubing or as connector pieces in the system.	Alternatives do not have sufficient resistance to water, oil, and chemicals; and with the necessary durability and biocompatibility. The only other polymer with similar properties is PTFE. PTFE is higher density and has less abrasion resistance than PVDF. PVDF is preferred in industrial or heating applications for piping. ETFE has higher tensile strength than PTFE and can be used under harsher conditions that PTFE. The exception is the PEEK polymer. PEEK is technically a viable alternative to PVDF. Validation work needs to be completed to ensure replacement is viable in all circumstances.	No	Fluid/Gas Comp.
34	PTFE in coatings of labels for security or tamper evidence.	Tamper proof labels	HS Code Chapters - 84, 85, 90 HS Code 3923	Food packaging (3923), smart cards (8523.52), secure forms delivery, passports, self-adhesive plates, sheets, film, foil, tape (3919)	Abrasion and tamper proof labelling is needed for the security of personal information and product safety.	PTFE coatings provide abrasion and tamper proof protection for labels. PTFE cannot be modified by chemicals and shows physical wear if tampered, such as leaving a "Void" marking when the tamper evident label is pulled away/off.	For security - no other polymer provides the same tamper proof properties (chemical resistance) as PTFE as a coating. Use of another polymer would reduce the security of devices especially those for financial transactions or personal identification. For tamper evidence - PTFE material film (plus an adhesive) is used in the label in order to provide evidence. Other plastics do not have the combination of chemical resistance and visibility of tampering than irradiated (soft) PTFE.	No	Labels
35	Fluoroacrylic and PFA coatings (and PFPE solvents) for encapsulation of capacitors or semiconductor components.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8532 and 8542	Capacitors and integrated circuits used in computers, servers, machinery, and laboratory equipment	Electronics with advanced capacitors and integrated circuits are necessary for the continued functioning of society.	Very thin fluoroacrylic and PFA coatings provide water resistance at high temperature to sensitive electronics. There will be a very small amount of residual perfluoropolyether (PFPE) from application of the coatings	Alternative non-fluorinated materials do not have adequate chemical, water, and heat resistance in a high density / thin film application.	Below measurable levels due to small size of application	IC Coating
36	PTFE and fluorosilicone sprays for maintaining lubrication in industrial equipment.	Lubricants, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 34, 84, 85, 86, 87, 88, 89, and 90	Widespread use. Pumps (841381), oil and gas, industrial machinery, food processing, medical devices, laboratory equipment, aerospace, chemical processing, and equipment for extreme environments.	Widespread use. Very common in longer life products with moving parts. Without these products, there would be no more automation or automated assistance.	PTFE and fluorosilicone sprays provides lubrication in a large range of environments necessary for proper function and lifetime of industrial machinery, metal parts, and wire/cable.	No other spray is as effective in low concentrations and thickness in achieving reduced friction. Silicone spray is less effective than fluoro sprays and often contains D4, D5, and D6 forever chemicals (also regulated in the EU with further restriction expected). Silicone lubricants stay 'wet', apply thicker, do not have good high temperature resistance, and are less effective on moving parts.	No	Lubricant
37	Ionic fluoro fluids as electrolytes in capacitors or batteries	Lithium batteries, Capacitors, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8507 and 8532.	Lithium batteries and supercapacitors in electronics (8507), vehicles (870380, medical devices, servers, power drills (8467), and portable electronic equipment.	Lithium batteries, capacitors, and supercapacitors are fundamental to electric vehicles, servers, industrial equipment, and portable electronics / tools.	Fluoro ionic fluids provide great surfactant power, chemical/biological inertness, easy recovery and recyclability, low surface tension, extreme surface activity, no flammability, and high thermal stability. The surface activity and high thermal stability are excellent for high performance lithium batteries and supercapacitors.	Other ionic fluids can be used, but these fluids do not exhibit either/or the performance or flammability resistance of FILs.	No	N/A
38	Perfluorinated polyether (PFPE) as a lubricant for harsh (very low or high temperature) environments	Building Products, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90.	Industrial machinery, components, and equipment uses at low and high temperatures.	Industrial machinery is required to work in low and high temperatures in laboratory and outdoor environments.	PFPE provides lubrication at very low temperatures which is not available for other materials. PTFE can offer high temperature lubrication equivalent to PFPE.	Silicone oil does not have the temperature range of PFPE and is not suitable for contact with some plastics. PFPE can handle a higher temperature range and is compatible with a wider range of rubbers.	No	N/A
39	PVDF polymers and PVDF terpolymers for ferroelectric films.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Specialized use of ferroelectric films in micromachines and memory devices. Use of PVDF terpolymer films in actuators for medical devices (e.g. catheters or other implantable devices).	Micromachines and memory devices are specialized use, but are necessary for miniature applications and memory storage. Medical devices such as catheters and other implantable devices have an essential medical use.	PVDF and similar films are fundamental to the specialized use of ferroelectric films. Without PVDF, ferroelectric films would not be possible. PVDF terpolymer ferroelectric films enable the construction of flexible actuators that assist medical devices in their function. Without PVDF films, flexible actuators would not be possible in medical uses.	Specialized PVDF films have the highest dielectric constant of polymers, are new innovations, and are not replaceable with other materials. Given the electroactivity, strength and flexibility of PVDF terpolymer films, they enable the construction of flexible actuators for which there is currently no alternative.	No	N/A

Exhibit C

40	Fluoroethers for degreasing applications	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Metal components for electronics, medical, industrial, or laboratory equipment are commonly degreased with fluoroethers.	Clean high precision metal components are needed for electronics, laboratory, medical, and high precision applications.	Fluoroethers provide degreasing cleanliness necessary for metals in high precision applications.	Chlorinated and brominated solvents can be used to degrease metal parts, they have higher greenhouse gas and environmental emissions; and reduced solvency power - resulting in most environmental hazards and would reduce part quality.	No	N/A
41	Residual hydrofluoroolefins used as blowing agents for insulating foam internal to products	Polyurethane foam, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90, and HS Code 392690	Blown foam for refrigerators, centrifuges, buildings, and shipping of fragile products.	Blow foam is necessary for thermal insulation for food safety and for transportation of valuable / fragile products.	Hydrofluorolefins used as a blowing agent for insulated foam leaves residual hydrofluorolefins.	HFOs (hydrofluorolefins) are the environmentally friendly replacements for hydrofluorocarbons (HFCs). To meet greenhouse gas emissions targets, companies need to continue to use and convert to HFOs.	No	N/A
42	PTFE as a manufacturing aid or tool for high temperature (> 150C) applications	Tools for manufacturing	HS Code Chapter 84.	Tools includes tools, jigs, and molds for high temperature manufacturing.	Industrial manufacturing processes often involve high temperatures which require tools that can withstand high temperature with strong chemical resistance.	PTFE withstands high temperatures and has very good chemical resistance.	Metals are too thermally conductive for most high temperature manufacturing processes. Other polymers either do not have the temperature resistance of PTFE (example - polyethylene) or are difficult to machine into custom tools (example - PEEK).	No	Harsh Env.
43	Fluorocoatings on laser fibers, laser fiber components, and fibers for optical purposes including light guidance.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Fibre optics in communication systems (854470), medical endoscopes (901890), industrial vehicles (8708), aerospace, and laboratory equipment.	UV curable coatings based on fluorinated polymers (amorphous fluoropolymers) are used in connecting optical fibres or fiber based components to maintain light guidance along a chain of fiber and fiber based components when making a device. For optical components, light guidance needs to be maintained with high reliability and precise optical matching to avoid losses and transmitting light between beam forming components.	Fluoropolymers have optical transparency, excellent optical matching properties, and can be used in thin or dense environments.	Alternative materials are not as transparent to visible light and have poorer optical matching properties.	None expected. The amount of amorphous fluoropolymer is not sufficient for measurable perfluorocarboxylates in the final device even for a potential degradation product.	Optical Coating
44	Fluorosilicone used as a surfactant or anti-foaming agent in semiconductor materials	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8532 and 8542	Integrated circuits used in computers, resistors, servers, industrial machinery, and laboratory equipment	Precision semiconductor products are fundamental to virtually all modern electronic applications.	The fluorosilicone surfactants are used in a manufacturing step for a microscopic material internal to a semiconductor device. The resulting chemical is only used in the manufacturing of the product and will not be present above 50 ppm organic fluorine in the final product.	Other surfactants are not as effective for this high precision application or as inert. In semiconductor manufacturing this surfactant cannot react without other materials.	No	N/A
45	F2 gas and PFA fluorinated plastics in capacitors and microchips	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 34, 39, 40, 48, 49, 73, 84, 85, 86, 87, 88, 89, and 90; and HS Code 8532 and 8542	Integrated circuits used in computers, servers, industrial machinery, and laboratory equipment	Precision semiconductor products are fundamental to virtually all modern electronic applications.	A microlayer of fluorinated material is created in capacitors and semiconductor devices by F2 gas fluorination (usually plasma fluorination) of a plastic such as polyethylene or polyphenylene sulfide The thin layer has amorphous fluorinated alkane molecules. This very thin internal fluorinated layer provides specialized capacitance curves and is useful in specialized applications. Capacitors and microchips require extreme chemical resistance or flexibility advantages.	Thin fluorinated plastics provide capacitance performance advantages plus environmental resistance not available in other materials, and temperature resistance necessary for dense electronics	No	N/A
46	PTFE filled die attach material for semiconductor devices	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8532 and 8542	Integrated circuits and semiconductor devices (854110) used in computers, servers, industrial machinery, and laboratory equipment	Precision semiconductor products are fundamental to virtually all modern electronic applications.	PTFE provides a chemical inertness and temperature resistance to microchip die attach material.	No other polymer powder is as chemically inert and has as high temperature resistance as PTFE powder.	No	N/A
47	PFBS (Perfluorobutane sulfonate) and its salts - for the purposes of optical clarity in flame retarded polymers.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Refrigerator, computer display, kiosk terminal	Optically clear and flame retarded displays are important for displays used by consumers.	Flame retarded clear plastic tends to be slightly cloudy, reducing the transparency of the screen. By adding <0.01% PFBS, the plastic of the displays is 'clarified', and can be used easily and safety.	No information is available on a potential replacement for PFBS. Currently is it the only material effective for its specialized application.	No	N/A
48	PVDF, PTFE, PCTFE, FKM, ETFE, PFA, PVDF in chemical and pharmaceutical packaging	Diagnostic / laboratory reagents, Pharmaceuticals	HS Code Chapters - 38, 39, and 90.	Reagents (3822), chemical analysis instruments and apparatus (9027), plastic articles and materials (3926), pharmaceutical packaging	Pharmaceutical and chemical packaging has to be very chemical resistance, high purity, and have high biocompatibility (low leaching).	Fluoropolymers including PVDF, PTFE and other fluorinated polyethylenes, provide chemical resistance for corrosive and solvent chemicals. Heat or UV resistance needed during some uses. Fluoropolymers incorporated into liners and seals in chemical packaging, and through fluorinations of inner container surfaces maintains integrity of the containers, preventing potentially hazardous leaks and protecting human health and the environment.	No alternatives to fluorinated chemical containers currently exist. Replacement with non-fluorinated materials would create a safety hazard for workers. Non-fluorinated polymers such as polyethylene lack resistance to corrosive and solvent chemicals and harsh conditions.	No Except PFA. PFA often contains PFOA and LCPFCA from the fracturing of the C-O-C bond of PFA. Both can be designed without PFOA or LC-PFCA.	Chemical packaging
49	PTFE, PFA coated tubing to prevent clogging if compliant to applicable NSF, FDA, or State requirements	Analyzer reagent tubing, wastewater tubing, printer tubing	HS Code Chapters - 39, 40, 49, 73, 84, 85, 90	Printer system tubing & spigots, pumps (841381), water circulation systems (842121), water purification system (842121), laboratory equipment (8419), and water heaters (8419).	Water quality tubing, analyzers, printers.	Parts that require either low friction or have a role in hostile chemical environments. PTFE required to reduce friction to prevent clogs within a hostile environment.	No alternative material with required resistance to hostile environments.	No Except PFA. PFA often contains PFOA and LCPFCA from the fracturing of the C-O-C bond of PFA. Both can be designed without PFOA or LC-PFCA.	Tubes
50	Conductivity agent in continuous ink jet for coding and marking	Printing ink, ink cartridges	HS Code Chapters - 32 and 84.	Printer inks (321511, 844399)	Essential marking of information, tracing and tracking of product. Sell by dates for food, pharmaceuticals, bottling and packaging.	Lithium trifluoromethanesulfonate is used as a conductivity agent in the ink formulation	No non-PFAS conductivity agents compatible with these formulations have been identified. Lithium trifluoromethanesulfonate is only used when other approaches are unsuccessful.	No	N/A
51	High temperature greases containing perfluoropolyether (PFPE)	Lubricating preparations	HS Code Chapter 34.	Fluorinated greases and oils (340399)	Assembly aid in production	Lubricant with high fluid resistance	No alternative material with required resistance to fluids	No	N/A

52	PTFE fibers and filtration disks used in corrosive gas filtration	Machinery, Electronics, Industrial	HS Code Chapter - 90 HS Code - 8421	Chemical analyzers, filtering or purifying machinery and apparatus for gases, others (8421)	These types of instruments are used to test if the water is safe for consumption or discharge in to the environment.The filtration allows successful conversion of these gases back to harmless forms that will not damage the environment or affect human health.	For filtration of corrosive or oxidizing gases the material is required to be very chemical resistant. The material must be able to separate particles from gas flow without damaging the filter.	Other polymers and filter material will react by dissolving and do not have the wide range of environmental resistance.	Yes. From the fracturing ('rubberizing') of the fluoropolymer to create the membrane fibre. Low concentration: 1 to 4 ppm	Membranes
53	PTFE Impregnated fabric for high temperature insulation	Electronics, Vehicles, Industrial, Machinery, Laboratory, Cooking Appliances	HS Code Chapters - 32, 39, 40, 83, 84, 85, 86, 87, 88, 89, and 90.	Insulation blankets in appliances, kilns, chemical reactors, conveyor belts	PTFE impregnated glass fabric is used as a heat insulating materials in high temperature professional and consumer products. The insulation fabric prevents heat from impacting other components including human contact surfaces.	PTFE provides additional insulation over glass fibre alone.	Silicone impregnated glass fibre does not have the temperature or chemical resistance of PTFE impregnated glass fibre.	No	Harsh Env.

Letter of Support

John Crane stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.

In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Maine and Minnesota. This proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders. By engaging experts from various industries, Claigan Environmental has adopted a collaborative approach to address this complex issue.

John Crane actively participated in the consultation process and supports Claigan Environmental's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

Sincerely,

Denise S. Lee

Industry PFAS CUU Project

PFAS Currently Unavoidable Uses Proposals (CUU)
Fifty-three (53) Proposals

Submission by Industry

This document is the guidance document to fifty-three (53) PFAS Currently Unavoidable Uses proposals being submitted by industry. Each CUU proposal is separate, but listed together in an orderly fashion for clarity and the convenience of regulators. Most of the proposals are for widespread uses of PFAS. These uses span across all industry segments and were included together. If required, they can be separated, but they would create between 300 and 400 separate proposals for regulators to review (for the 53 fundamental uses).

The Industry PFAS CUU project is made up of >50 companies that span consumer, professional, medical, industrial, and laboratory uses of PFAS. The CUUs listed here are based on very detailed work by each member of the project combined with tens of thousands of parts tested by Claigan Environmental in 2023 and 2024.

This submission should be the most comprehensive list of Currently Unavoidable Uses in physical products (articles), with detailed justifications and comparisons of alternatives.

The full CUU proposals and justifications are listed in detail in the accompanying spreadsheet PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx.

Table of Contents

1. Summary

This report is a submission by Claigan Environmental Inc. (Claigan) on behalf of the Industry PFAS Submission Project (“PFAS Submission Project”). The PFAS submission project is made up of 50+ companies from a wide range of industries (consumer, professional, industrial, medical, oil and gas, laboratory equipment, textiles, electronic components, and retail sales.)

The PFAS Submission Project is focused primarily on the needs of complex products (articles). Claigan is both a restricted materials consultancy and a high-volume restricted materials testing laboratory. Each of the PFAS Submission Project submissions are based on contributions from all major sectors of industry, and 2023 and 2024 PFAS testing data from tens of thousands of parts.

The detailed justification of each CUU is covered in the accompanying spreadsheet PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx.

Each CUU entry includes

- A brief description of the Currently Unavoidable Use of PFAS
- A brief description of the type of product including industries and example products with HTS codes.
- A description of the intended use of the product and explanations on how it is essential for health, safety, or the functioning of society.
- A description of how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, citations will be provided for that requirement.
- A description of whether there are reasonably available alternatives for this specific use of PFAS.
- Plus
    - Whether the PFAS use includes PFOA or Long Chain Perfluoroalkyl Carboxylic Acids (LC-PFCA). Many of these PFAS uses do not include (nor degrade into) any PFAS found in drinking water and humans.

- PFOA / LC-PFCA presence is based on tens of thousands of parts tested in 2023 and 2024.

Important note 1 - due to the short timeline for the PFAS Currently Unavoidable Use consultation, each justification is only in brief with a detailed comparison of alternatives. Each justification can be further elaborated upon if needed.

Important note 2 - the regulation of chemical substances in medical devices is governed by the FDA. It is generally assumed that this preempts restrictions of PFAS in medical devices under state regulation, "A product for which federal law governs the presence of PFAS in the product in a manner that preempts state authority". However, for completeness and until this question is fully solved, currently unavoidable uses of PFAS in medical devices are also included in this submission.

Important note 3 - The States of Maine and Minnesota adopted a broad definition for PFAS substances. The vast majority of PFAS substances, as defined by Maine and Minnesota, that are found in products are not found in the environment. The broad definition impacts PFAS use in multiple categories of products and equipment needed to make products. PFAS substances are used in these applications because they have unique properties that impart specific performance characteristics making them essential to a product's function. The accompanying spreadsheet provides a detailed comparison of fluoropolymer, fluoroelastomer, and alternative materials for each application. The reason for the use of the fluoropolymer or fluoroelastomer is generally fairly obvious when you look at the application and the alternatives.

2. Related documents

2.1. PFAS Currently Unavoidable Uses Proposals spreadsheet - Industry PFAS Submission Project

2.1.1. PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx

3. Definitions

3.1. ***Currently Unavoidable Use of PFAS (CUU)*** - a use of PFAS that is essential for the health, safety, or functioning of society and for which alternatives are not reasonably available.

3.2. ***Widespread Use*** -

3.2.1. For essential uses of a PFAS-containing product, uses that are very high volume with widespread use are identified.

3.2.1.1. For example - fluoroelastomers and perfluoroelastomers have very widespread use in professional/industrial products (> 10M products per year sold in the US).

3.2.2. **For consumer uses** - Over 100 Million products sold in the US each year use this Currently Unavoidable Use of PFAS, or

3.2.3. **For industrial uses (including professional uses)** - Over 10 Million products sold in the US each year use this Currently Unavoidable Use of PFAS.

3.3. ***Forever chemicals***

3.3.1. *Substances that are either*

3.3.1.1. ***vPvB*** - Very persistent and very bioaccumulative

3.3.1.2. ***PBT*** - Persistent, bioaccumulative, and toxic

3.4. ***Machinery***

3.4.1. *Machinery includes all aspects of machinery including (but not limited to) manufacturing, construction, clean energy, water treatment, and forestry*

3.5. ***Laboratory***

3.5.1. *Laboratory includes all aspects of laboratory equipment including (but not limited to) water testing, life sciences, research and development, and medical testing.*

4. Key notes

4.1. Importance of PFAS

4.1.1. > 500 million products containing PFAS are sold in the US each year

4.1.2. Banning PFAS would eliminate

4.1.2.1. Laptops

4.1.2.2. The internet (unless servers are moved offshore)

4.1.2.3. Food processing

4.1.2.4. Water processing and treatment

4.1.2.5. Forestry

4.1.2.6. Life sciences

4.1.2.7. Oil and gas industry

4.1.2.8. Heart surgeries and biopsies

4.1.3. Banning PFAS without exception for Currently Unavoidable Uses would likely create the largest recession in the history of the United States.

4.2. Sources PFOA / LC-PFCA in Products

4.2.1. Most fluoropolymers and virtually all fluoroelastomers do not contain PFOA or LC-PFCA

4.2.2. The follow sections are based on 2022 - 2024 testing of products for PFOA / LC-PFCA and include explanation of how these substances are formed in very specific situations.

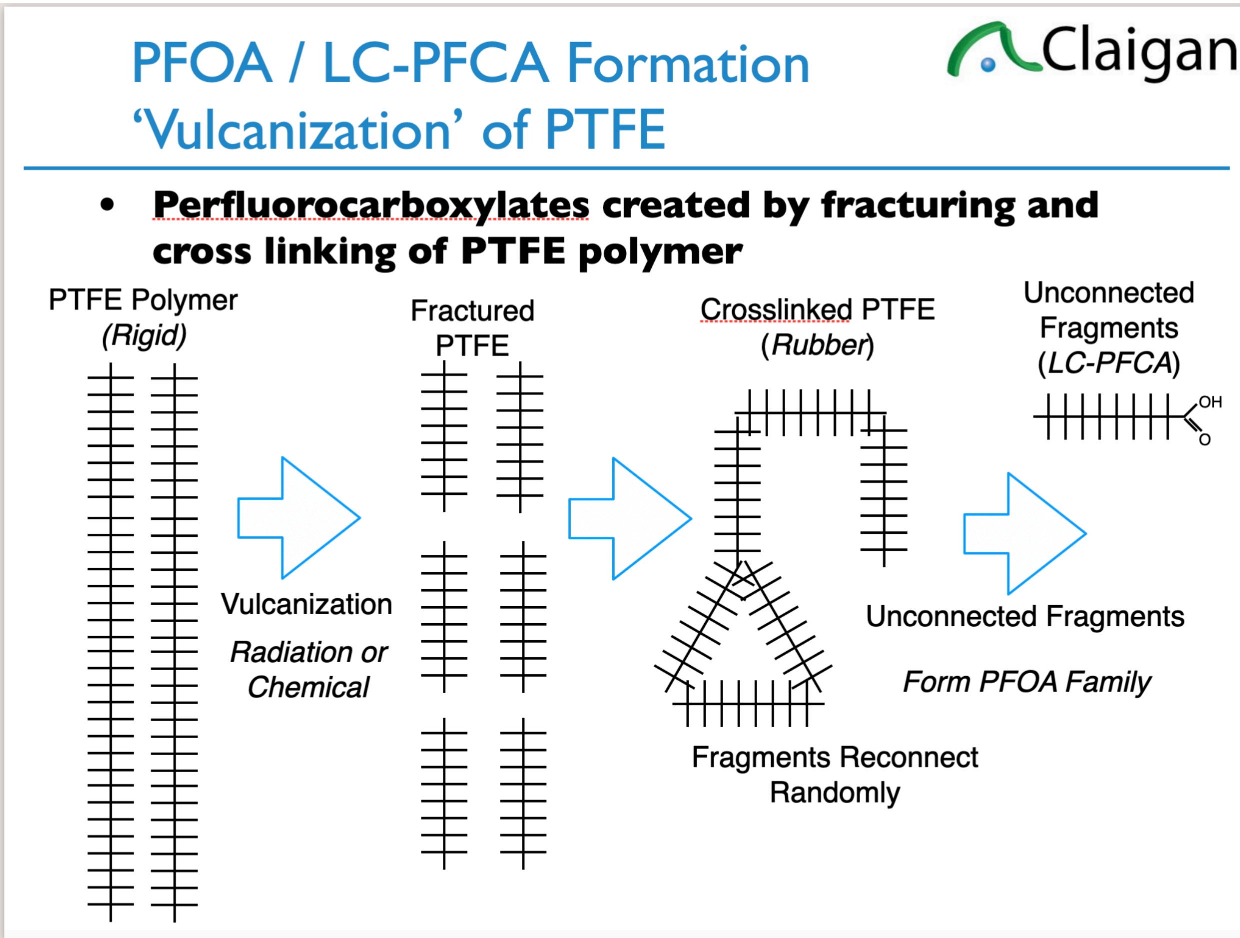
4.2.3. **Cause #1** of unintentional PFOA / LC-PFCA - Formation of LC-PFCA during vulcanization of rigid PTFE (or PVDF) into cross-linked rubber

4.2.3.1. Vulcanization / crosslinking of PTFE involves

4.2.3.1.1. Fracturing of long rigid PTFE polymer through radiation or chemical means

4.2.3.1.2. Reconnecting of fragments of PTFE in random directions (creating rubber instead of rigid polymer)

4.2.3.1.3. Some fragments react instead with air and create random sizes of perfluorocarboxylates.



4.3. **Cause #2** of unintentional PFOA / LC-PFCA - PFAS polymers (such as PFA or fluoroacrylates) that have a fluoromonomer side chain with a fragile C-O-C (carbon-oxygen-carbon) bond.

4.3.1. Formation of perflluorocarboxylates

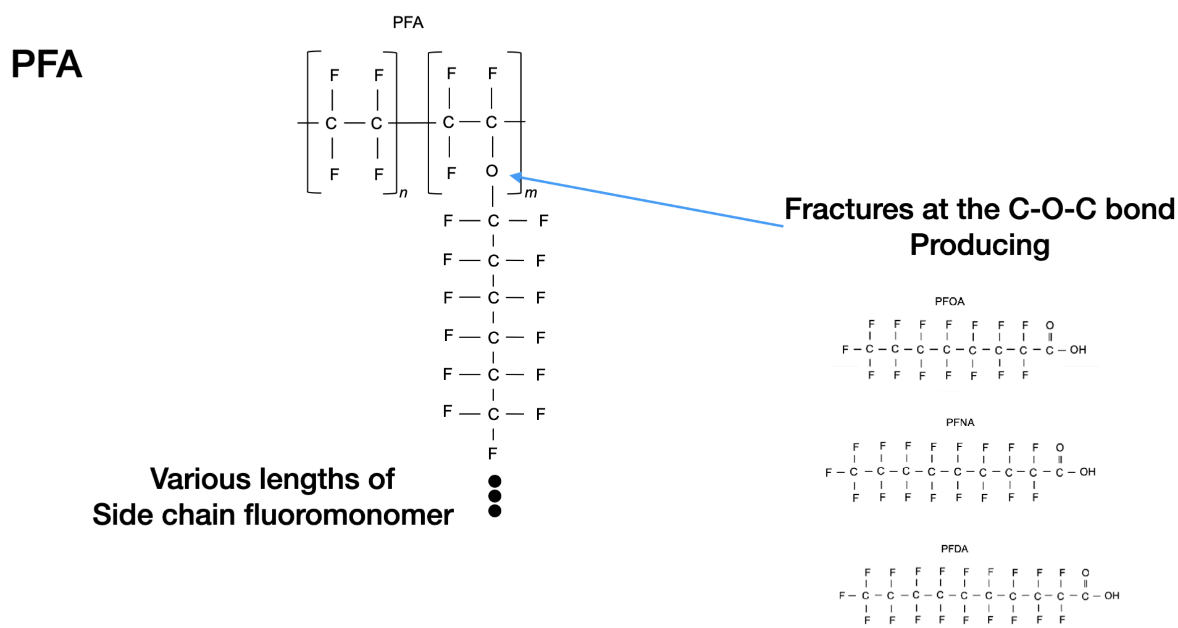
4.3.1.1. Fragile C-O-C bonds fracture during initial manufacturing and over time.

4.3.1.2. Fluoromonomer fragments are ‘fluorotelomers’, PFOA-like molecules with an extra 2 carbon hydrogens (such as 8:2 FTOH).

4.3.1.3. The fluorotelomer fragments react with air and water to slowly form perfluorocarboxylates

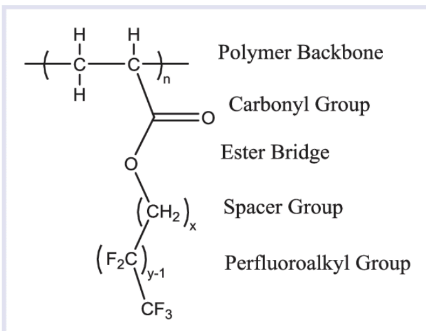
4.3.1.4. The lengths of eventual perfluorocarboxylates depend on the lengths of side chain monomers on the original PFA or fluoroacrylate polymer.

Formation of PFOA / LC-PFCA
PFA (Perfluoroalkoxy Alkane Polymer)



PFOA / LC-PFCA Formation Fluoroacrylates

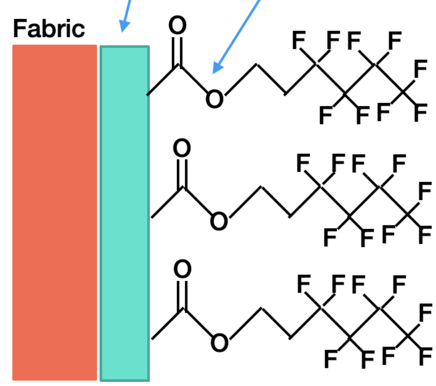
- Fluoroacrylates have a 'side chain polymer'
  - Acrylic or other polymer
    - With chains of PFAS extending from polymer
    - *PFOA may be present as an impurity from PFAS side chain*
  - Example - water repellant coatings



Side chain PFAS

Fragile C-O-C Bond

Acrylic polymer



Side Chain PFAS

4.4. Perfluorocarboxylates and Perfluorosulfonates Found in Fluoropolymers and Fluoroelastomers

4.4.1. Presence of perfluorocarboxylates and perfluorosulfonates

4.4.2. 2022 to 2024 testing data by Claigan Environmental

Comparison	PTFE	PVDF	ETFE	Crosslinked PTFE	ePTFE	PFA	Fluoroelastomers	Fluoroacrylates	Fluorophosphates
Short Chain Perfluorocarboxylates (C4-C7)	Never	Never	Never	Commonly	Commonly	Commonly	Commonly	Commonly	Commonly

Long Chain Perfluorocarboxylates (C8-C14)	Never	Never	Never	Commonly	Commonly	Commonly	Never	Commonly	Commonly
Short Chain Fluorotelomers (C4-C7)	Never	Never	Never	Never	Never	Never	Never	Commonly	Commonly
Long Chain Fluorotelomers (C8-C14)	Never	Never	Never	Never	Never	Never	Never	Commonly	Commonly
Short Chain Fluoroacrylates (C4-C7)	Never	Never	Never	Never	Never	Never	Never	Commonly	Never
Long Chain Fluoroacrylates (C8-C14)	Never	Never	Never	Never	Never	Never	Never	Commonly	Never
Short Chain Fluorosulphonates (C4-C7)	Never	Never	Never	Never	Never	Never	Never	Never	Never

Long Chain Fluorotelomers Sulphonates	Never	Never	Never	Never	Never	Never	Never	Never	Never

4.5. PFAS in Drinking Water and Humans

4.5.1. From this project and related testing data

4.5.1.1. ~99% of PFAS found in drinking water and humans is from <0.1% of products (primarily legacy fire extinguisher fluid and legacy foundation/concealer (C9-C15 fluoroalkyl phosphate in personal care products)).

4.5.1.2. ~99.99% of PFAS found in drinking water and humans is from <1% of products (a slight additional contribution from washing of waterproof fabrics contain fluoroacrylates).

4.5.1.3. The average silicone part has 100X more forever chemicals than the worst fluoropolymer (ePTFE). 200 ppm vs 2 ppm.

4.5.1.4. Based on ISO 10993-18 medical biocompatibility testing: Silicone, ABS, polystyrene, PVC, nylon, and polyurethane leak more dangerous chemicals into humans than fluoropolymers

4.5.1.5. Fluoropolymers are used because they are safer and more effective than their alternatives.

4.6. PFAS and Drinking Water - Kentucky 2023 PFAS testing of all drinking water sites

4.6.1. Kentucky 2023 drinking water sites testing

4.6.1.1. https://eec.ky.gov/Environmental-Protection/Water/Reports/Reports/2023-PFASFinishedDrinkingWaterResults.pdf

4.6.1.2. Kentucky was chosen because

4.6.1.2.1. Modern data (2023)

4.6.1.2.2. Comprehensive PFAS testing of each drinking water site

4.6.2. Sources of PFAS in drinking water

4.6.2.1. Based on the comparison of drinking water testing results and laboratory testing results of products

4.6.2.2. Legacy fire fighting foam

4.6.2.2.1. Fire fighting foam that uses C8 fluoro surfactants

4.6.2.2.2. Generally phased out of products a decade ago

4.6.2.2.3. Testing characteristic

4.6.2.2.3.1. Always - PFOS

4.6.2.2.3.2. Majority of situations - PFOA

4.6.2.2.3.3. Would not have - PFNA or PFDA (higher-length PFOA substances)

4.6.2.3. Modern fire fighting foam

4.6.2.3.1. Fire fighting foam that uses C4 or C6 fluoro surfactants

4.6.2.3.2. Common in modern fire fighting foam

4.6.2.3.3. Testing characteristic

4.6.2.3.3.1. Always - at least one of 6:2 FTS, PFHxS, PFBS

4.6.2.3.3.2. Majority of situations - PFHxA, PFBA

4.6.2.3.3.3. Would not have - PFOS, PFOA, PFNA, or PFDA

4.6.2.4. Cosmetics (Foundation and Concealer)

4.6.2.4.1. Foundation and concealer using C9-C15 Fluoroalkylphospate

4.6.2.4.1.1. Degrades over time into high concentration of PFOA, PFNA, and PFDA

4.6.2.4.2. Phased out in 2021/2022

4.6.2.4.3. Testing characteristic

4.6.2.4.3.1. Always - PFNA and PFDA (PFDA not included in Kentucky testing)

4.6.2.4.3.2. Majority of situations - PFOA

4.6.2.4.3.3. Would not have - PFOS or any sulphonate, or short-length fluoro carboxylates (PFBA, PFPeA, PFHxA).

4.6.2.5. Physical products

4.6.2.5.1. Primarily fluoroacrylate coatings of water-resistant fabric

4.6.2.5.1.1. Would release all lengths of perfluorocarboxylic acids during washing in detergent.

4.6.2.5.2. Common today

4.6.2.5.3. Testing characteristic

4.6.2.5.3.1. Always - All lengths of perfluorocarboxylates from PFBA to PFDA.

4.6.2.5.3.2. Would not have - PFOS or any sulphonate.

4.6.2.6. Unknown

4.6.2.6.1. Testing results from water are not consistent with any known product.

4.6.3. Chart of Projected Sources of PFAS in 2023 Kentucky drinking water site testing

4.6.3.1. 113 sites tested in Kentucky in 2023

4.6.3.2. Note - some sites could be listed under more than one source. The total should be above 100%

5. PFAS Currently Unavoidable Uses

5.1. The full details are contained in the accompanying spreadsheet PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx.

5.1.1. The comparisons are too large and detailed for a Word document and are instead summarized in an Excel file.

5.2. This document features several tabs with tables containing details about ***CUU's***.

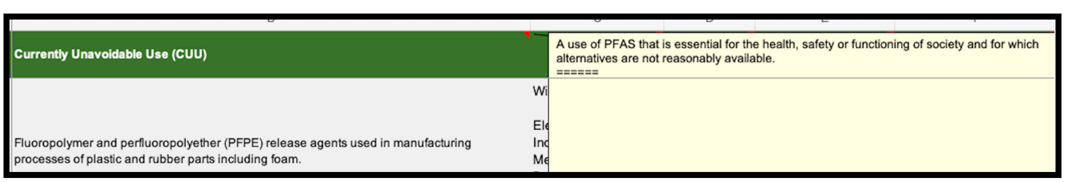
5.2.1. The CUU tab provides details about the specific ***CUU's*** as well as where and why they are specifically used.

5.2.2. The remaining tabs are the Alternative tabs. They provide the evaluation of alternative materials across a range of criteria applicable to the relevant use, which is labelled on the tab at the bottom of the document.

5.3. The core data is found within the tables, while further explanatory notes are found in the applicable column and row headers.

5.4. Cells with a red triangle in the top right corner have additional information pertinent to their respective row or column. They are found in Row 1 of the CUU tab and Column A of the Alternatives tabs. For example:

5.5. Additional details are revealed by hovering the mouse cursor over the cell (without clicking it). For example:



5.6. Additionally, this same information is captured in the document below.

6. Explanation of Currently Unavoidable Use (CUU) Proposal Tab

6.1. Columns A and B (CUU Number and Description) provide the numbering and descriptions for each ***CUU***.

6.2. Column C (Products) provides an overview of the applicable product families that require the listed Currently Unavoidable Use.

6.3. Column D (HS Codes) provides a list of HS Codes of products that require the listed ***CUU***. Some uses are so pervasive that the entire HS Code (Customs Code) chapters are listed.

6.4. Column E (Example Products) details a list of example products that require the applicable ***CUU.*** This list is representative and is not intended to be exhaustive.

6.5. Column F (Essential Use of Product) describes the intended use of the product and explains how it is essential for health, safety, or the functioning of society. It also describes if products using this CUU are ***Widespread*** or ***Industrial***.

6.6. Column G (Essential Use of PFAS) describes how the specific use of PFAS in the product is essential to the function of the product.

6.7. Column H (Comparison of Alternatives) describes reasonably available alternatives for this specific use of PFAS and compares them to the applicable ***CUU***. For further details, refer to the relevant Alternatives tab.

6.8. Column I (PFOA) identifies if this CUU contains any PFOA or Long Chain Perfluoroalkylcarboxylates (LCPFCAs). This column is based on 2023 and 2024 testing data of hundreds of representative parts for PFOA and LC-PFCAs.

6.9. Column J (Alternatives Tab) provides a direct link within the document to the identified tab comparing the performance of PFAS materials and alternative materials.

7. Alternatives Tabs

7.1. Row 1 (Comparison) identifies the alternative materials being evaluated.

7.2. Low Friction

7.2.1. Excellent - The material has a low coefficient of static friction. It is nearly frictionless.

7.2.2. Decent - The material has a lower coefficient of static friction but has some friction in use.

7.2.3. Poor - The material has a high coefficient of static friction. It displays strong friction during use and is not suitable for applications requiring low friction.

7.3. ***Chemical Resistance*** - the resistance to acids or bases may not be uniform for a material. The rating reflects the general potential applications of the material

7.3.1. Excellent - The material has superior resistance to acids and bases. Acid and bases have no discernible effect on the material.

7.3.2. Decent - The material is resistant to acids and bases but does exhibit some degradation. It should not be in extended contact with, or subject to, high concentrations of acids or bases.

7.3.3. Poor - The material is not resistant to acids and/or bases.

7.4. Water Resistance

7.4.1. Excellent - The material is hydrophobic (*i.e.* it is impermeable to water even as a coating).

7.4.2. Decent - The material is resistant to water, but not completely hydrophobic or waterproof.

7.4.3. Poor - The material is permeable to water.

7.5. Oil Resistance

7.5.1. Excellent - The material is oleophobic (*i.e.* it is impermeable to oil even as a coating).

7.5.2. Decent - The material is resistant to oil, but not completely oleophobic, oil-proof, or stain-resistant.

7.5.3. Poor - The material is permeable to oil.

7.6. Temperature Resistance

7.6.1. Excellent - The material can withstand temperatures above 150°C.

7.6.2. Decent - The material can withstand temperatures above 100°C, but is impacted by temperatures above 150°C.

7.6.3. Poor - The material is impacted by temperatures above 100°C.

7.7. Fire Resistance

7.7.1. Excellent - The material meets stringent fire/flame resistance standards.

7.7.2. Decent - The material has fire/flame resistance but does not meet the most stringent standards.

7.7.3. Poor - The material is not fire/flame resistant.

7.8. Flexibility

7.8.1. Excellent - The material exhibits good flexibility and is useful in most applications requiring flexibility.

7.8.2. Decent - The material has some rigidity, but still exhibits some flexibility.

7.8.3. Poor - The material is rigid and is not suitable for applications requiring flexibility.

7.9. Forever Chemicals (Initial)

7.9.1. Excellent - The material does not contain any substances with an EU harmonized classification of vPvB or PBT after manufacturing.

7.9.2. Decent - The material contains trace amounts (<1 ppm) of substances with an EU harmonized classification of vPvB or PBT after manufacturing.

7.9.3. Poor - The material contains amounts (> 1ppm) of substances with an EU harmonized classification of vPvB or PBT after manufacturing

7.10. Forever Chemicals (Over Time)

7.10.1. Excellent - The material does not degrade into substances with an EU harmonized classification of vPvB or PBT.

7.10.2. Decent - The material degrades lightly into substances (<1 ppm) with an EU harmonized classification of vPvB or PBT over time.

7.10.3. Poor - The material degrades into substances (> 1ppm) with an EU harmonized classification of vPvB or PBT over time.

7.11. Bio-compatibility

7.11.1. Excellent - The material passes US FDA and EU MDR biocompatibility testing and does not normally require toxicological justification.

7.11.2. Decent - The material passes US FDA and EU MDR biocompatibility testing but often requires toxicological justification.

7.11.3. Poor - The material does not generally pass US FDA or EU MDR biocompatibility testing or it requires significant toxicological justification.

7.12. Insulation

7.12.1. Excellent - The material has a low dielectric constant and is suitable for most insulating or electronics purposes.

7.12.2. Decent - The material has a medium dielectric constant and is only suitable for some insulating or electronics purposes.

7.12.3. Poor - The material has a high dielectric constant and is not normally suitable as an insulating material in electronics.

7.13. High-Density Applications

7.13.1. Excellent - The material is usable in applications requiring thin layers or high density.

7.13.2. Decent - The material is usable in applications that do not require thin materials, but it is not suitable for very fine or dense applications.

7.13.3. Poor - The material is not feasible as a thin film or in high-density applications.

7.14. Polymer Additive

7.14.1. Excellent - The material can be added to a wide range of polymers to provide additional properties.

7.14.2. Decent - The material can be added to some polymers to provide some level of additional properties.

7.14.3. Poor - The material is not suitable as a polymer additive.

7.15. Porous

7.15.1. Excellent - The material is permeable to air.

7.15.2. Decent - The material is partially permeable to air but is resistant to airflow.

7.15.3. Poor - The material is not permeable to air.

7.16. Durability

7.16.1. Excellent - The material has superior resistance to wear.

7.16.2. Decent - The material is partially resistant to wear but is not suitable for high-wear situations.

7.16.3. Poor - The material is not suitable for situations where wear resistance is required.

7.17. Optical Transparency

7.17.1. Excellent - The material is optically transparent.

7.17.2. Decent - This material has some optical transparency but is not suitable for applications requiring clarity and high transparency.

7.17.3. Poor - This material is not normally optically transparent

7.18. Structural

7.18.1. Excellent - The material is rigid with the ability to support its weight and any weight of the fluid it is transporting. It also has superior fatigue resistance.

7.18.2. Decent - The material can support its weight, but it is not as reliable for additional weight or fatigue.

7.18.3. Poor - The material cannot rigidly support its weight.

7.19. Radiation Resistance

7.19.1. Excellent - The material has superior resistance to gamma and e-beam radiation and does not exhibit degradation due to radiation.

7.19.2. Decent - The material has some resistance to gamma and e-beam radiation but exhibits degradation with repeat or high dosage exposure.

7.19.3. Poor - The material degrades in gamma or e-beam radiation.

7.20. Acceptable

7.20.1. A material is deemed acceptable if it receives an excellent or decent rating in non-critical properties. The material must receive an excellent rating in critical properties to be deemed acceptable.

7.20.1.1. Critical properties are identified where ratings (excellent, decent, poor) are shown in bold.

8. Acknowledgements

Special thank you to Nials Everett, Chris Scully, Julie Van Moorsel, Dr Tim Holt, and the entire Claigan Environmental staff and students for their contributions. And thank you to all of our industry members who contributed so much in such little time.

PFAS EDUCATION

PART 1: COOKWARE, PFAS, AND PTFE

The CBA is a not-for-profit trade association owned by its membership: manufacturers of cookware, bakeware and kitchenware with substantial operations and headquarters in the United States. The CBA began in the early 1920s as the Aluminum Wares Association, became the Metal Cookware Manufacturers Association in the 1960s, and in the 1970s changed its name to the Cookware Manufacturers Association in recognition of its representation of all types of cookware and bakeware materials. The CBA's mission is to inform and promote the industry to its members, their customers and to the general public.

The members of The Cookware & Bakeware Alliance (CBA) develop standards to promote the welfare of the cookware industry and improve its service to the public. The CBA Engineering Standards are continually updated to reflect changes in materials and technology and include test methods for nonstick finishes on cookware that when followed ensure coating performance and durability.

Nonstick cookware and bakeware manufactured according to CBA Standards use only US FDA food contact compliant materials for surfaces. CBA supports the responsible manufacturing and safe uses of PTFE and other fluoropolymers, and a science-based approach to regulations that benefit human health and the environment. CBA supports labeling provisions to alert consumers to the presence of PFAS, but based on current science, considers it unnecessary to prohibit sales and eliminate consumer choice.

Your cookware and bakeware industry resource.

Knowledge is powerful. This is a key element in why The Cookware & Bakeware Alliance was formed back in 1922, to collect and share important information and create safe consumer products.

For years we have answered questions and shared resources on important topics facing our industry. Many times, only part of the answer is shared, or one viewpoint. The Good Science site has been created to help provide resources and access to more information on important topics. We now bring all of this information to our website to share and promote Good Science. Visit the Good Science webpage to explore.

For questions, please contact Fran Groesbeck, Managing Director (fran@cookware.org).

Thank you for your interest in Good Science!

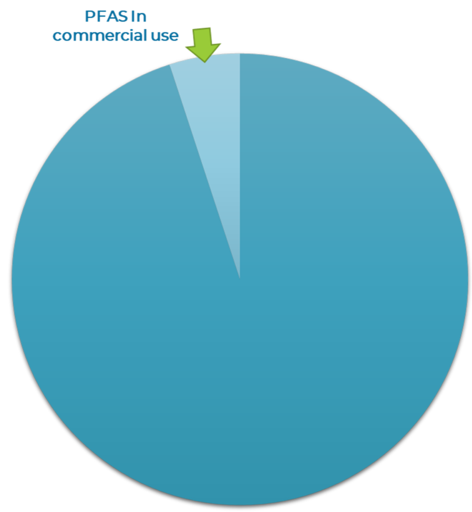
PART 1: Cookware, PFAS, and PTFE



Per- and polyfluoroalkyl substances (PFAS) are a diverse group of chemistries that contain carbon-fluorine bonds, the strongest chemical bonds in organic chemistry. Due to their unique and useful properties, PFAS are widely used and critical to enabling numerous technologies.

The term PFAS encompasses in some instances as many as 12,000+ substances. However, it is estimated that roughly 5% of all PFAS substances are in commercial use today. Further, not all PFAS are the same. The chemistries currently in commercial use have very different physical and chemical properties, health, and environmental profiles, uses, and benefits.

- Large family of substances
- Significantly varied properties
- Subgroups have unique and specific differences

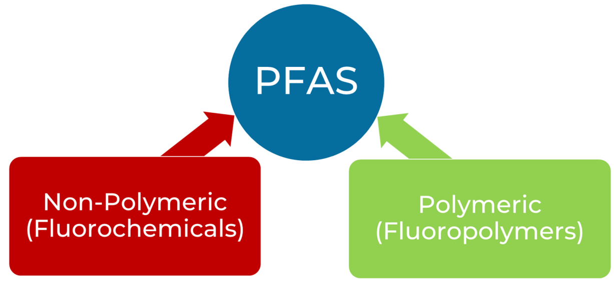
They can be considered part of a universe of fluorinated organic substances with varying physical, chemical, and biological properties including polymers and non-polymers; solids, liquids, and gases.[1]

A subgroup of PFAS having specific characteristics and properties is called fluoropolymers. The discovery of the first fluoropolymer, polytetrafluoroethylene (PTFE), occurred in 1938 [2], and it led to its use in the most critical and demanding applications known. Aerospace and military applications were first to use fluoropolymers to insulate cables or create impermeable seals because it can withstand the harshest conditions and it replaces materials that have a high risk of failure due to a deterioration of properties. Uses in conditions where other materials fail due to corrosion and extreme temperature are the hallmark of fluoropolymers, often making them irreplaceable.

The first nonstick cookware appeared in the US in 1961.[3] Fluoropolymers are used in cookware, for their non-stick and barrier properties. To ensure food contact substances are safe for their intended use, the FDA conducts a rigorous scientific review before they are authorized for the market.[4]

DISCLAIMER: The Information compiled here Is not to be considered legal advice. This Information Is Intended to help understand Important Industry news and provide what the Alliance and/or affiliated experts understand of the situation. We recommend that all follow up on this or other Industry news be discussed with your legal teams.

PFAS can be divided into two distinct groups: non-polymeric and polymeric PFAS. Furthermore, the non-polymeric, ie fluorochemicals, are water soluble, versus the polymeric, ie fluoropolymers, are not.



The non-polymeric PFAS (fluorochemicals) are typically used for food contact materials (FCM), such as fast-food packaging and microwave popcorn bags, as well as a number of other applications and industries. The FCM examples referenced can indirectly contribute to dietary exposure through the migration of PFAS into food, which can be a food safety concern [5]. Because they are water soluble, consumers have the potential to be exposed through foods and/or drinking water.

Whereas the polymeric PFAS (fluoropolymers), such as PTFE, which are used in nonstick cookware and bakeware coatings, are not water soluble, and have documented safety profiles. They are thermally, biologically, and chemically stable. They are also nonmobile, non bioavailable, non bioaccumulative, nontoxic, and most importantly they are not soluble in water. Although fluoropolymers fit the current PFAS structural definition, they have very different physical, chemical, environmental, and toxicological properties when compared with other PFAS.[6]

Fluorochemicals	Characteristic	Fluoropolymer *(used in cookware)*
Yes	Water Soluble	No
Yes	PFAS of Concern	No
Yes	Transported in Air	No
Yes	Toxicity	No
Yes	Persistence/ Non-Degradable	Yes

PFAS EDUCATION

COOKWARE & BAKEWARE ALLIANCE
CBA
EST. 1922

PART 2: FLUOROPOLYMERS AND HUMAN HEALTH

PFAS Education Series

PART 2: Fluoropolymers and Human Health

Definition of Fluoropolymers:

Fluoropolymers are defined according to Buck et a.l[1] as a distinct subset of fluorinated polymers, based on a carbon-only polymer backbone with fluorine atoms directly attached to it, e.g., polytetrafluoroethylene (PTFE), fluorinated ethylene propylene (FEP) and perfluoroalkoxy polymer (PFA). Many fluoropolymers have been approved for food contact applications by regulators, including the US FDA (21 CFR 175.1550), the European Union through Regulation (EU) 10/2011 and also through specific national regulations such as German BfR recommendation LI.

Fluoropolymers do not present an unacceptable risk to human health.

The current OECD definition of PFAS includes thousands of substances with wide ranges of properties, including classes such as fluoropolymers which have traditionally been differentiated from legacy non-polymeric PFAS (PFOA or PFOS). In 2021, the OECD wrote, "The term "PFASs" is a broad, general, non-specific term, which does not inform whether a compound is harmful or not, but only communicates that the compounds under this term share the same trait for having a fully fluorinated methyl or methylene carbon moiety".[2]

A typical restriction on a substance or material requires the demonstration of "unacceptable risk", and fluoropolymers do not meet this standard, as demonstrated by years of research:

- The OECD is a central source of definitions for global chemical regulation (including the definition of PFAS) and classifies polymers with "insignificant environmental and human health impacts" as polymers of low concern.[3]

- PTFE is not soluble in water (or any other common solvents) and is not mobile in the environment.[4]

- Fluoropolymers have been repeatedly found to meet all of the OECD characteristics of polymers of low concern,[5] based on their stability, lack of bioavailability, lack of bioaccumulation, and general absence of observed ill effects.

DISCLAIMER: The Information compiled here Is not to be considered legal advice. This Information Is Intended to help understand Important Industry news and provide what the Alliance and/or affiliated experts understand of the situation. We recommend that all follow up on this or other Industry news be discussed with your legal teams.

- In a scientific opinion published in 2016 relating to the risk analysis of chemical products in food, the scientific committee of the European Food Safety Authority (EFSA) specified that the risk analysis of polymers used in food additives must consider the molar mass of the polymer in question. For fluorinated polymers, EFSA proposed a threshold of 1,500 Daltons. Beyond this threshold, EFSA indicated that it is unlikely that the polymers will be absorbed through the gastrointestinal barrier and therefore considered that they do not present a health hazard.(6) By comparison, PTFE for food contact applications is characterized by sizes ranging from hundreds of thousands to several million Daltons. This recent opinion from EFSA shows that fluorinated polymers and in particular PTFE used for food contact materials like nonstick coated cookware do not pose a concern for health authorities.

Studies have consistently shown that fluoropolymers do not pose a risk to human health, largely due to their inertness, insolubility, and lack of reactive functional groups.

- A 2016 study by Naftalovich et al. shows that PTFE ingestion to increase satiety was both successful and safe. They also reviewed the biological safety of PTFE.(7)

- A 2022 study by Lee et al. shows that fluoropolymers such as PTFE are safe when ingested. For example, no toxic effects were observed from PTFE exposure in mice. No traces of PTFE were observed in the blood of mice even though they were exposed to very large amounts of PTFE.(8)

- The International Agency for Research on Cancer (IARC) has repeatedly investigated the carcinogenicity and toxicity of PTFE, finding it has no toxicological impact, and cannot be classified according to its carcinogenicity (IARC Group 3).(9)

Use of fluoropolymers in cookware and bakeware does not lead to negative health impacts.

The evidence does not indicate that use of fluoropolymer-coated cookware exposes users to non-polymeric PFAS.

- In a study on articles in the Korean market, Choi et al show that only a very limited number of articles (3 out of 139 fry pans) show migration of low molecular weight PFAS and only in the first migration experiment with no detection in later experiments. All detected quantities were significantly below the level of concern.(10)

- Studies of PTFE-coated cookware have detected no or for some products only traces of low molecular weight PFAS in the first migration experiment. The French consumer association 60 millions de consommateurs (n°579, April 2022), published a study on 9 non-stick coated articles. Despite detecting very low levels of low molecular weight PFAS, the author conceded that these substances “were probably not used in the manufacturing of the pans

DISCLAIMER: The Information compiled here Is not to be considered legal advice. We recommend that all follow up on this or other Industry news be discussed with your legal teams.

but could have been introduced in an accidental manner during manufacturing, packaging or transport".[11]

- PTFE is known to start to deteriorate at an extremely slow rate above 260 °C (500°F). Above 360 °C (680°F), the degradation of PTFE starts to be measurable. However, according to the German Federal Office for Risk Assessment (BfR), the concentration of these emissions while normally using PTFE-coated cookware is so low that there is no health risk for the user.[12]

- It should be noted that degradation temperatures for fats and oils are typically lower than 200 °C (392°F), consequently at a much lower temperature than when fluoropolymers would begin to degrade. For instance, emission of volatiles, such as aldehydes, from coconut, safflower, canola, or extra virgin olive oil are measured by Katragada et al. from 180 °C (356°F).[13] This suggests that regular usage of fluoropolymer-coated cookware would not result in sufficient temperatures for fluoropolymer degradation.

Studies and expert reports consistently evaluate PTFE coated cookware as safe for users.

- The European Food Safety Authority (EFSA) published a 2020 report assessing the safety of PFAS in food contact materials, primarily focusing on non-polymeric legacy PFAS (PFOA and PFOS).[14] The study assessed the use of PTFE in cookware, saying it may contribute to human exposure on the scale of micrograms per kilogram, a level far below background exposure from eating fish, meat, eggs, and fruit (among the most common sources of exposure to PFAS).

- The American Cancer Society considers the use of fluoropolymer-coated cookware safe, saying "there are no proven risks to humans from using these products. While PFAS can be used in making some of these coatings, it is not present (or is present in extremely small amounts) in the final products".[15]

Fluoropolymers, including PTFE, are widely used in other applications with no evidence of negative health effects.

PTFE is widely used in medical devices, including implanted devices, which are highly regulated and thoroughly studied for any negative health impacts. Evidence demonstrates the use of PTFE in these devices is safe, suggesting it does not pose a health risk for humans in other uses such as in cookware.

- The US-based independent research and innovation organization ECRI (Emergency Care Research Institute) was tasked by the US Food and Drug Administration (FDA) to carry out a review of the scientific literature and produce a report on the state of knowledge of the biocompatibility of PTFE-based (medical devices in terms of local and systemic host

We recommend that all follow up on this or other Industry news be discussed with your legal teams.

response. The analysis covered a total of 52 studies. The analysis found no local response to PTFE in implanted devices, and no exaggerated or fatal systemic responses.[16]

The general consensus of researchers is that PTFE and fluoropolymers do not present a health risk to humans.

- Their suitability for direct use in the human body is a central reason for their role in medical devices, and many researchers have argued that PTFE should be considered a polymer of low concern by meeting or exceeding all OECD criteria. This view is reinforced by regulatory agencies in the EU and the United States in multiple reviews and meta-analyses.

- The scientific literature on the health impacts of fluoropolymers, PTFE particularly as used in cookware, suggests that the use phase does not pose a risk to human health, as the fluoropolymers themselves are not absorbed by the body (not biologically available) and have no indicated harmful effects, and other non-polymeric PFAS are not present in meaningful quantities in the final products.

Beyond fluoropolymers, exposure to non-polymeric PFAS in other applications nonetheless presents a risk to health.

- According to the European Chemicals Agency (ECHA), the largest sources of PFAS contamination in the environment come from non-polymeric applications such as fluorinated refrigerants or waterproof coatings [e.g., treatments and finishes], which then raise concerns for exposure to humans through the food and water supply.[17] Regulatory solutions for PFAS exposure should be guided by the scientific consensus, while considering categories like fluoropolymers which have been consistently shown to be safe and result in minimal exposure.

Where or why does nonstick cookware come into all this?

PTFE, or polytetrafluoroethylene, is the PFAS material that makes nonstick coatings non-stick. As we discussed in Part 1 – PTFE is a fluoropolymer: it is non-water soluble, it is non-toxic, and it is not mobile or bio-accumulative. It has a certain level of persistence, but as with other fluoropolymers, it is this trait that makes it beneficial in so many applications.

Fluoropolymers do not fit any of the new classifications such as:

PBT : Persistent, Bioaccumulative, Toxic
vPvB : very Persistent, very Bioaccumulative
PMT : Persistent, Mobile, Toxic
vPvM : very Persistent, very Mobile

DISCLAIMER: The Information compiled here Is not to be considered legal advice. This Information Is Intended to help understand Important Industry news and provide what the Alliance and/or affiliated experts understand of the situation. We recommend that all follow up on this or other Industry news be discussed with your legal teams.

Looking at PTFE from a high level, it offers many benefits to the products that use it. It is an insulator, so it reduces heat transfer. It reduces friction, which is what allows it to aid products from cookware to cars. Also, we must remember this is one of the non-water soluble PFAS types, so water contamination is not possible.

Fluoropolymers, like PTFE, are stable under normal, foreseeable use conditions. Stability is resistance to physical, chemical, or biological breakdown. Fluoropolymers, in general, have very good chemical and thermal stability due to the strength of the Carbon to Fluorine bond. (Henry et al: 2018).[5]

PTFE is the most stable fluoropolymer and has a continuous use temperature of 500°F (260°C). (Plastics Safe Handling Guide 2018).[18] This temperature is well above temperatures realized during normal cooking and baking activities when a nonstick housewares article is used per the manufacturers' use and care instructions.

Consumer Nonstick Housewares Products

Fluoropolymers, mainly PTFE, are the principal ingredients in traditional nonstick coatings for housewares. In most cases, these coatings are water-based, liquid coatings. The PTFE has to be stable in this liquid mixture in order to be applied to a product like a piece of cookware. PTFE, as helpful as it is, is extremely stubborn when it comes to mixing with water. In order to get PTFE to be stable in a water mixture, a surfactant is needed as a dispersing aid. Historically, the surfactant used to make PTFE stable in water was a fluorinated surfactant (i.e. fluorochemical).

You don't need a lot of the fluorochemical to make this work. A good analogy is if you had an Olympic size swimming pool, you would need to add a thimble-sized amount of the fluorosurfactant to make the PTFE stable. To put this small amount into another perspective, it translates to just over a minute in a century, or 0.000000025%

Aqueous film forming foams (AFFF) used to fight petroleum-based fires can often contain as much as 3.0% of fluorochemicals which are PFAS of true concern. To contrast these amounts, it would require 2 million years of cookware production to equal the environmental exposure caused by 1 year's use of AFFF.[19]

There are PTFE manufacturers that are committed to the reduction of emissions from polymerization aid/surfactant technology used in the fluoropolymer manufacturing process, the adoption of state-of-the-art emission reduction technologies, and informing downstream users of fluoropolymers about their safe handling, use, and prevention of environmental release.[20]

DISCLAIMER: The Information compiled here Is not to be considered legal advice. This Information Is Intended to help understand Important Industry news and provide what the Alliance and/or affiliated experts understand of the situation. We recommend that all follow up on this or other Industry news be discussed with your legal teams.

Conclusion:

There is no scientific basis that PTFE-coated cookware and bakeware poses a hazard or risk to humans or the environment when used under normal conditions. Therefore, in our opinion it is safe to use and should not be restricted.

More from the PFAS Education Series

In the other parts in this series by CBA, we discussed several topics around PFAS and Cookware & Bakeware.

Part 1: Cookware, PFAS, and PTFE, the definition of PFAS involving a large family of substances with significantly varied properties and uses, was discussed. PFAS was divided into two distinct groups: non-polymeric and polymeric. The polymeric PFAS (fluoropolymers) are neither water soluble, nor mobile, nor bioavailable, nor bio accumulative.

Next in the series:

Part 3: A Closer Look at PFAS in Cookware & Bakeware: other contested issues with fluoropolymers were discussed such as, Environmental Emissions of PFAS, End of Life of Nonstick Cookware, Feasibility of Alternatives to PTFE.

Visit the Good Science webpage to explore.

The Cookware and Bakeware Alliance

The CBA is a not-for-profit trade association owned by its membership: manufacturers of cookware, bakeware and kitchenware with substantial operations and headquarters in the United States. The CBA began in the early 1920s as the Aluminum Wares Association, became the Metal Cookware Manufacturers Association in the 1960s, and in the 1970s changed its name to the Cookware Manufacturers Association in recognition of its representation of all types of cookware and bakeware materials. The CBA's mission is to inform and promote the industry to its members, their customers and to the general public.

The members of The Cookware & Bakeware Alliance (CBA) develop standards to promote the welfare of the cookware industry and improve its service to the public. The CBA Engineering Standards are continually updated to reflect changes in materials and technology and include test methods for nonstick finishes on cookware that when followed ensure coating performance and durability.

Nonstick cookware and bakeware manufactured according to CBA Standards use only US FDA food contact compliant materials for surfaces. CBA supports the responsible manufacturing and safe

THE COOKWARE & BAKEWARE ALLIANCE

Building industry excellence through engineering, engagement, education and expertise.

PFAS Education Series

PART 3: A Closer Look at PFAS and Cookware & Bakeware

In previous parts of this series by CBA, we discussed several topics around PFAS and Cookware & Bakeware.

1. In Part 1 the large group of PFAS was divided into **non-polymeric fluorochemicals** and **polymeric fluoropolymers**. Fluoropolymers such as PTFE, which is used in nonstick coatings of cookware and bakeware, have very different properties compared to fluorochemicals. Existing legal restrictions of legacy fluorochemicals such as PFOA or PFOS should not be extended to fluoropolymers without scientific justification.
2. In Part 2, it was shown that fluoropolymers do not present an unacceptable risk to human health and are classified as polymers of low concern. PTFE coated cookware and bakeware are assessed by authorities in the US and Europe as safe for the user. In addition, the emissions of PFAS into the environment during the production of PTFE coated cookware is negligible.
3. In Part 3 we will have a closer look at the complete lifecycle of PTFE coated cookware and bakeware and current alternatives.

Lifecycle Assessment

Any lifecycle of consumer goods can be separated into four different sections: 1. Manufacturing of raw materials, 2. manufacturing of the product, 3. use of the product and 4. end-of-life.

It is important to point out that in the case of PTFE coated cookware phases 1, 2 and 4 are carried out by professionals with clear and elaborate OSHA safety and EPA environmental regulations.

Only phase 3 is carried out by non-professional consumers.

In Part 2 it was shown that PTFE coated cookware is of no or negligible concern during phases 2 and 3. Using existing best-available technologies emissions of these PTFE coated products are insignificant and will even be reduced in the coming years.

In phase 1 chemical manufacturers produce fluorinated monomers such as TFE (tetrafluoroethylene) and transform them into fluoropolymers using both fluorinated and non-fluorinated polymerization aids. There are technical and scientific indications that either of these production steps can be done without any non-polymeric PFAS emissions to the environment. A fluoropolymer industry-led initiative includes a platform to promote the adoption of commercially available state of the art technologies to minimize non-polymeric PFAS emissions during manufacturing.[(1)]

DISCLAIMER: The Information compiled here Is not to be considered legal advice. This Information Is Intended to help understand Important Industry news and provide what the Alliance and/or affiliated experts understand of the situation. We recommend that all follow up on this or other Industry news be discussed with your legal teams.

It can be summarized that based on phases 1 – 3 of the full lifecycle PTFE-coated cookware should not be restricted.

End-of-Life

Landfill, incineration or recycling are viable options for PTFE-coated cookware and bakeware used by consumers or professionals at the end-of-life.

A RIVM (Dutch National Institute for Public Health and the Environment) incineration review states that PTFE is stable at 260 °C without loss of mass. A PTFE coated article in **landfill** would therefore not decompose at the temperatures found in this environment (https://rivm.openrepository.com/handle/10029/625409). In addition, fluoropolymers such as PTFE are not soluble in water, not mobile, stable to most chemicals (https://setac.onlinelibrary.wiley.com/doi/10.1002/etc.5182) and UV radiation.

Therefore, it can be expected that there are negligible emissions of non-polymeric fluorochemicals in landfill due to PTFE-coated cookware.

Incineration and recycling can be discussed together because in both cases the fluoropolymer is thermally treated. Several studies have shown that it is possible to destroy or mineralize the fluoropolymers including undesired decomposition products such as problematic fluorochemicals (Utah 2023 https://www.wastedive.com/news/clean-harbors-incinerator-pfas-forever-chemicals/640829/, Dutch RIVM https://rivm.openrepository.com/handle/10029/625409, Karlsruhe Institute of Technology 2019 and 2023 https://doi.org/10.1016/j.chemosphere.2019.03.191).

Therefore, using the best-available technology and appropriate temperatures, PTFE and other fluoropolymers are of no concern for emissions of PFAS into the environment.

Due to the significant reduction of carbon footprint using recycled aluminum and stainless steel compared to their primary materials, it is strongly recommended to use an existing collection scheme or to implement a new scheme for PTFE-coated cookware at its end-of-life. Based on a rough estimate by FEC (European Federation for Cookware, Cutlery and Houseware Industry) more than 100 Mio. pieces of coated cookware is sold in Europa annually. The recycling of PTFE-coated aluminum cookware at end-of-life would reduce the carbon footprint by more than 250’000 tons $CO_{2\ eq.}$ per year.

Conclusion

PTFE-coated cookware and bakeware has throughout its full lifecycle a negligible risk for PFAS emissions into the environment and is safe-to-use for the consumer. Therefore, **in our opinion,** there is no foundation to restrict the manufacture, usage or recycling of products made with fluoropolymers.

DISCLAIMER: The Information compiled here Is not to be considered legal advice. This Information Is Intended to help understand Important Industry news and provide what the Alliance and/or affiliated experts understand of the situation. We recommend that all follow up on this or other Industry news be discussed with your legal teams.

Alternatives to PTFE-coated cookware

There are alternatives to PTFE-coated cookware and bakeware. The options can be split into two sub-groups: with and without nonstick coating. According to the 2023 Consumer Outlook Report, published by HomePage News, 72% of consumers indicated that they have a preference for products with nonstick coatings[(2)]. Therefore, stainless steel, cast iron or enameled cookware are not an equivalent alternative because they possess no nonstick property.

Nonstick is not only a function that simplifies the life of the user, it also reduces the risk of burning food with undesirable by-products that might be unhealthy. In turn, this also reduces the potential of food waste. It is an obvious feature of nonstick cookware that the cleaning is easier, and less cleaning agents and water is needed. Overall, nonstick cookware has a lower environmental footprint during its usage compared to alternatives without this property.

An example of nonstick alternatives are silicone-based coatings which are mainly used for bakeware. They are a low performance alternative to fluoropolymer systems, both in terms of temperature and damage resistance and nonstick performance. To avoid deterioration of silicones, temperatures of 230°C/446°F should not be exceeded during use [BfR recommendation, https://www.bfr.bund.de/cm/349/LI-Temperature-Resistant-Polymer-Coating-Systems-for-Frying--Cooking-and-Baking-Utensils.pdf].

The best-known nonstick alternative to PTFE based nonstick coatings are ceramic or sol-gel coatings. Ceramic refers to the material from which the coating is made of and sol-gel to the production technique being used. Today, there are two points in assessing this alternative:

- PTFE is a 100% defined material (polytetrafluoroethylene), but ceramic nonstick coatings can be made with a variety of materials. Thereby, the final ceramic coating and its composition varies from manufacturer to manufacturer.
- The ceramic coating itself has usually no nonstick performance and needs additional additives such as silicone oils.

To avoid any regretful substitution of PTFE-coated nonstick cookware, it is mandatory to carry out a study of the full lifecycle of ceramic coatings. To our best knowledge, no such analysis exists, and these coatings have been studied a lot less due to their limited applications compared to PTFE.

DISCLAIMER: The Information compiled here Is not to be considered legal advice. This Information Is Intended to help understand Important Industry news and provide what the Alliance and/or affiliated experts understand of the situation. We recommend that all follow up on this or other Industry news be discussed with your legal teams.

Important points regarding PTFE-based nonstick coatings:

1. PTFE-based nonstick coatings will retain their nonstick properties for as long as the coating is present on the coated article. This is due to the inherent nonstick properties of PTFE, a fluoropolymer. Alternative nonstick coating technologies will lose the nonstick characteristics over time.
2. PTFE-based nonstick coatings are unaffected by household dishwashers.
3. PTFE-based nonstick coatings emit very low levels of volatile organic compounds (VOCs) during the coating application process.
4. The risk of PTFE-based nonstick coatings releasing low molecular weight PFAS substances of concern or any other substance that might adulterate food during normal use is very low.[3]

Conclusion

Not enough is scientifically known about the full lifecycle of ceramic or sol-gel coated cookware to declare this a valuable alternative to PTFE coated cookware and bakeware. The risk of a regretful substitution is significant.

YAGEO Group
YAGEO KEMET Pulse

February 23, 2024

Letter of Support

YAGEO Group stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.

In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Maine and Minnesota. This proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders. By engaging experts from various industries, Claigan Environmental has adopted a collaborative approach to address this complex issue.

YAGEO Group actively participated in the consultation process and supports Claigan Environmental's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

Re: Request for Comments: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

We respectfully submit our comments on the following questions posed by MPCA:

1. **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**

MN law states "(j) *"Currently unavoidable use" means a use of PFAS that the commissioner has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available,"* with no further description of "essential for the health, safety, or functioning of society" or "alternatives". "Essential for the health, safety, or functioning of society" is encompassed within "currently unavoidable use," and we suggest that it is more productive to focus on the broader term and delineate what constitutes a "currently unavoidable use" instead of trying to categorize them under the two prongs of the definition.

We recommend that MPCA find that the use of PFAS in a product category is currently unavoidable only if all the following criteria are met:
(1) There are no safer alternatives to PFAS that are reasonably available.
(2) The function provided by PFAS in the product is necessary for the product to work.
(3) The use of PFAS in the product is critical for health, safety, or the functioning of society.

The second proposed criteria could easily fit under both prongs of the definition of "unavoidable use." If PFAS is not necessary for the product to work, that is a safer alternative to the use of the PFAS. It also means that the use of PFAS in the product is not necessary for the health, safety, or functioning of society. It is not important to delineate which prong the criteria falls under.

However, it is important to specifically articulate the criteria so that it is considered in every analysis and is not overlooked.

In order to implement these three criteria, additional terms are critical to define. Specifically, we recommend including the following definitions:

- "Safer alternative" means an alternative that, in comparison with another product or product manufacturing process, has reduced potential adverse impacts and/or potential exposures associated with PFAS. Alternatives include materials, processes, designs, products, or chemicals that achieve the desired result. For example, a safer alternative to stain resistant sprays for avoiding stains could be the use of detergents or the use of fibers that are inherently stain resistant.
- "Necessary of the product to work" means required for the product to perform its core function, as determined by the department. For example, the core function of a couch is for people to sit on.
- "Product" means an item manufactured, assembled, packaged, or otherwise prepared for sale in Minnesota, including but not limited to, its components, sold or distributed for personal, residential, commercial, or industrial use, including for use in making other products.

The proposed criteria above add critical detail to inform considerations of safer alternatives and necessity. Additional considerations of necessity beyond these criteria will rely on the discretion of the agency to account for information that comes before the MPCA.

2. **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

Firstly, if alternatives are already being used or if PFAS in an application has already been banned in another jurisdiction and that ban is in effect, then the alternative should be determined to be reasonably available. In addition, if the findings of an available study or evaluation of alternatives by an authoritative body shows the viability of safer alternatives to PFAS in the product category under review, then those alternatives should also be considered reasonably available.

Secondly, a cost threshold is not appropriate in this context, because the cost implications can vary dramatically from product to product. Rather the focus should be on assessing what is "reasonably available." We believe that inquiry could involve considerations of adequate supply of the alternatives and potentially the cost to the public. Costs to manufacturers are variable and subject to market pressures, including MPCA action. An alternative may initially start out significantly more expensive than the PFAS it is intended to replace, but as demand increases, the cost can fall rapidly, and a mandated switch away from PFAS could be the catalyst for demand for the alternative to increase. This is why it is important for cost considerations to not be determinative (and to have determinations of "currently unavoidable use" be time bound, as the availability of alternatives can change over time).

The need for any consideration of costs to be more focused on the impact to the public rather than the manufacturer is reinforced by the nature of alternatives that should be covered. As we propose above, MPCA should adopt definitions that make clear that alternatives can include materials, processes, designs, products, or chemicals that achieve the desired result. For example, a safer alternative to stain resistant sprays for avoiding stains on upholstery could be the use of detergents or the use of fibers that are inherently stain resistant. In the example where detergents are a viable alternative to PFAS treated upholstery, there would be little to no direct costs to the public, but there might be economic impacts for the manufacturer of the PFAS treated upholstery. Thus, the cost to the manufacturer should not be the relevant cost for MPCA's analysis.

There should also be some consideration of the significance of additional cost to the public. However, minor costs should not influence the analysis. Even when considering costs to the public, a set threshold in absolute dollars should not be used as product categories may vary significantly in scale of cost. Nor is a percentage-based threshold appropriate because the significance of a certain percentage cost difference depends on the context–a high percentage could still amount to mere cents. In addition, any cost should be considered alongside societal costs of PFAS exposure and clean up.

3. **Should unique considerations be made for small businesses with regards to economic feasibility?**

For reporting requirements, it makes sense to consider economic feasibility for small businesses based on a combination of the number of employees and revenue. For example, Maine has exempted from reporting manufacturers that have 100 or fewer employees. However, there may be cases where a business has fewer than 100 employees, but makes substantial revenue to which reporting would not be a financial hardship. Furthermore in the case of franchises or businesses with contractors, the franchisor or the number of contractors (so that we are not creating perverse incentives to hire contractors instead of employees) should be considered in the analysis of economic feasibility of reporting.

However, these considerations should not be made when restricting the avoidable use of PFAS. Regardless of size, businesses should not be permitted to use PFAS unnecessarily because of the significant harms that may follow for human health and the environment.

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

As mentioned above, safer alternatives should include materials, processes, designs, products, or chemicals that achieve the desired result. For example, a safer alternative to stain resistant sprays for avoiding stains could be the use of detergents or the use of fibers that are inherently stain resistant.

A safer alternative should be an alternative that, in comparison with another product or product manufacturing process, has reduced potential adverse impacts and/or potential exposures associated with PFAS. There are tools such as Greenscreen or Chemforward to compare potential adverse impacts of alternatives, but as the proposed definition above suggests, non-chemical alternatives that achieve the desired end result should be considered.

The Washington Safer Products program has developed detailed criteria for "safer alternatives," which are available in [Phase 3 Working Draft Criteria for Safer.](#) If you have questions about these criteria or about the Safer Products for Washington program, we recommend contacting SaferProductsWA@ecy.wa.gov. The WA Department of Ecology has already shown great success in applying these criteria for identifying safer alternatives to PFAS in a number of product categories.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

A currently unavoidable use determination should be reevaluated at least every five years. This length of time provides a degree of certainty for businesses while taking into account often quickly changing market conditions. Furthermore, when a manufacturer applies for a renewal of a currently avoidable use determination, they should not only have to show that their use still meets the criteria outlined in question 1, but they should also provide evidence of significant efforts to develop a safer alternative to the continued use of PFAS in the product or product category, including, but not limited to, published peer-reviewed papers and funding of third-party research with no financial conflict of interest. Without such a requirement, there is little incentive for businesses to make efforts to find alternatives to PFAS.

If significant changes in available information about alternatives becomes available the MPCA should review any relevant currently unavoidable use determinations and revoke any determinations where the use no longer meets the criteria for a currently unavoidable use. Furthermore, a public petition process should be put in place to allow for petitions to review a determination based on a significant change of information.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

A petition process should be put in place for requests for a currently unavoidable use determination. In submitting a petition, a manufacturer should be required to provide evidence that their use of PFAS meets *all* of the following criteria:
(1) There are no safer alternatives to PFAS that are reasonably available.
(2) The function provided by PFAS in the product is necessary for the product to work.
(3) The use of PFAS in the product is critical for health, safety, or the functioning of society.

When evaluating the above suggested criteria for an unavoidable use, MPCA does not need to evaluate all the criteria if the determination can be made on fewer criteria since all criteria must be met for an exemption. In other words, if a use is found not to meet one of the three criteria, the use is avoidable.

When reviewing this evidence MPCA should also consider the relevance and significance of the information provided for the product category, other available reliable information, and bans on the sale or use of PFAS in the product or product category in another state or other countries. If the sale or use of PFAS in the product or product category has already been banned in another state or other countries, and if the ban is in effect, then that should demonstrate that the use of PFAS is not a currently unavoidable use. Finally, MPCA should provide an opportunity for public comment, where other stakeholders could provide relevant information.

In the case that a currently unavoidable use determination has already been granted for a product or product category, there should also be a petition process in which the public or other stakeholders can provide information showing that the use is now no longer currently unavoidable. (See our response to question 5.)

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

8. **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

MPCA should not *a priori* determine that any PFAS use is currently unavoidable. This would bypass a petition process where manufacturers must provide evidence to MPCA that a use is currently unavoidable. It also removes any incentives to develop or implement safer alternatives for these uses.

Rather, MPCA should make additional determinations that the following are avoidable uses before the 2032 phase out:

1) Expanded textiles category: California has passed a law that bans the sale of PFAS containing textile articles starting January 1, 2025 (with a limited set of products provided an extension until 2028) and has defined "textile articles" broadly as "textile goods of a type customarily and ordinarily used in households and businesses, and include, but are not limited to, apparel, accessories, handbags, backpacks, draperies, shower curtains, furnishings, upholstery, beddings, towels, napkins, and tablecloths." Therefore textile articles beyond upholstered furniture and textile furnishings (already listed to be avoidable uses in Minnesota law) should also be determined to be avoidable, including apparel, accessories, handbags, backpacks, footwear, and other products. MPCA should expand the restrictions on PFAS in textiles to be consistent with the scope of California's law (AB 1817).

   Similarly, Washington Department of Ecology, under the Safer Products for Washington law, has taken action on the use of PFAS in apparel and gear, including: athletic wear, rain wear, reusable diapers, menstrual underwear, school uniforms, dresses, hats, scarves, gloves, shoes, extended use products, backpacks, sleeping bags, umbrellas, camping furniture, and climbing rope. In this case, Ecology made the draft regulatory determinations that PFAS uses must be reported for: apparel intended for extended use by experts or professionals that are not marketed to the general public, shoes, and gear. Ecology further made a draft regulatory determination to restrict the use of PFAS in all other types of apparel.

2) Pesticides: Maine passed a law (H.P. 1501 - L.D. 2019) prohibiting the distribution of pesticides that are contaminated by perfluoroalkyl and polyfluoroalkyl substances; or that contain intentionally added PFAS beginning in 2030. “Pesticides” include any substance or mixture of substances intended for preventing, destroying, repelling or mitigating any pests; any substance or mixture of substances intended for use as a plant regulator, defoliant or desiccant; and any substance or mixture of substances intended to be used as a spray adjuvant. "Pesticide" includes a highly toxic pesticide.

3) Oil and gas products: Colorado passed a law (HB22-1345) that bans the sale or distribution of multiple product categories with PFAS, including oil and gas products, starting January 1, 2024. "Oil and gas products” include hydraulic fracturing fluids, drilling fluids and proppants.

4) Coatings, paints and varnishes: The Organisation for Economic Co-operation and Development (OECD), an intergovernmental organization with representatives from 38 industrialized countries, as well as the European Commission, produced a report on coatings, paints and varnishes (CPVs). They conclude that “for the most closely examined uses in CPVs, non-fluorinated alternatives account for a large majority of market share. It is more cost-effective to use the nonfluorinated alternatives and therefore FPs [fluoropolymers] and SC [short-chain] PFASs are typically used only where specific high- performance attributes are sought.” The information in this report and in the European Union’s Universal PFAS Restriction Proposal (see below) show that most if not all PFAS uses in coatings, paints and varnishes are avoidable.

The European Union has proposed an economy wide ban on PFAS, known as the Universal PFAS Restriction Proposal. In Table 9 of Annex XV many product/use categories have received no derogations to the proposed ban, meaning that alternatives have already been identified and the use of PFAS in those products is avoidable. Here we have listed a few examples that are not already included in MN law: metal plating, sterilization gases, PTFE thread sealing tape, window frames, various types of coatings, paints and sealants, and various packaging applications.

9. Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination?

In order to reduce administrative burdens and delay tactics, MPCA should use the broadest reasonable product category in making currently unavoidable use determinations and rely on the determination for the category for any product in the product category. This requires a definition of a “product category”, and we propose the following:

> "Product category" means a group of similar products that are used for a similar purpose and that could functionally replace each other for that purpose, as determined by the department, and does not mean a specific variation within a product. For example, pants, insulation, and cookware are each a product category whereas stain resistant pants, spray insulation, and nonstick cookware are specific variations of products within those product categories.

In using the broadest reasonable product category in making its determination, the department need not be overly limited by exceptions. Instead, the department could identify exclusions from a product category, if appropriate.

We would be happy to discuss any of the information provided in our comments. For further details, please contact:

RE: Request for Comments: Planned new Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID number R-4837.

Dear Minnesota Pollution Control Agency:

PSG® writes to express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. PSG therefore seeks Currently Unavoidable Uses consideration from the Minnesota Pollution Control Agency. It's important to acknowledge that certain PFAS play a vital role in ensuring product functionality in critical applications in order to meet stringent safety standards.

PSG is the global pump, metering and dispensing-solution expert, enabling the safe and efficient transfer of critical and valuable fluids that require optimal performance and reliability in applications where it matters most. Additionally, PSG is a leading provider of flow meters designed to reduce waste and downtime while accurately measuring, monitoring and controlling the distribution of fluids. Headquartered in Oakbrook Terrace, IL, USA, PSG is comprised of several world-class brands, including Abaque®, All-Flo™, Almatec®, Blackmer®, Ebsray®, em-tec®, Griswold®, Hydro™, Malema™, Mouvex®, Neptune®, PSG® Biotech, Quantex™, Quattroflow®, and Wilden®. PSG products are manufactured on three continents – North America, Europe and Asia – in state-of-the-art facilities that practice lean manufacturing and are ISO-certified.

PSG manufactures and provides pumps, flows meters, and flow control devices that use certain fluoropolymer PFAS, primarily due to the fact that these materials are suitable to function in a broad temperature range (from very cold to very hot), are chemically compatible with a wide range of substances that are caustic and hazardous, provide seals to prevent hazardous or caustic materials from escaping into the environment while they are being produced, transferred, and used, are wear and gall resistant, are used for cleanliness and reduced particle generation, and are able to provide process critical lubrication. Uses are ubiquitous and are vital to the essential needs of society. Some example applications include:

1. The transfer of fuels (such as gasoline, diesel, home heating oil, etc...) at various stages of the supply chain: transfer from the refinery to the storage facility to the truck to the end customer tank. Critical to transportation of people and goods, and the heating of homes.
2. The transfer of liquid propane from tank to truck to customer's tank to provide propane for heating of homes and spaces, and for cooking.
3. The transfer, handling, and dosing of fertilizer and pesticides for agriculture to support the food supply.
4. The transfer of solvents in the chemical industry for the production of paints and coatings, as well as inks for the printing industry.
5. Handling, measuring, and transferring caustic materials used in semiconductor production. Semiconductors are critical elements that enable the miniaturization and functionality of electronic items.
    a. The original cell phones were called "bricks" due to their size and weight, and all they did was make phone calls. Now phones are smaller and more functional, and their multi-functional nature is an underpinning of modern-day society.
    b. Before integrated circuits and semiconductors, computers were the size of multistory buildings and were only found in the military, on university campuses, and at major companies. Now computers are small with exceptional processing power and applied to many daily devices we use.
    c. Electronics are in our cell phones, computers, televisions, automobiles, home appliances, etc., and at the core of home, work, communication, and travel...
6. Handling, measuring, and transferring caustic materials used in Battery manufacturing, which are used to power electric vehicles and other electronic devices.
7. Handling, measuring, dosing management of water, wastewater, and agriculture.
8. Various military applications whose requirements are so stringent that the use of PFAS is the only feasible solution to meet the specifications.

The examples above are compelling, and we are unaware of any materials that are readily available alternatives to the fluoropolymer PFAS used in these applications, among others. Exhibit A, attached, while not exhaustive, provides additional details about the broad range of product and applications.

In line with our commitment to finding balanced solutions, we have worked through our industry associations: Hydraulic Institute, Fluid Sealing Association, Valve Manufacturers Association, the Water and Wastewater Manufacturers Association (a.k.a. Flow Control Coalition) which have developed a comprehensive Currently Unavoidable Uses (CUU) proposal, that is being submitted to the states of Maine and Minnesota. Their proposal, which is separate from this one, is founded upon expert knowledge of the design of critical processes, and incorporates valuable insights gathered from diverse stakeholders including design engineers, end-users and manufacturers of critical system components.

By engaging engineers and experts from the various segments of the fluid handling industry, the Associations have applied a collaborative, systems level approach to this complex issue. Highly corrosive materials, high temperatures, harsh environments, accessibility and life-cycle considerations all are part of the design criteria of the industrial and other process systems which currently require certain PFAS as there are no viable alternatives to handle toxic substances, prevent hazardous leaks and fugitive emissions, ensure clean air and water, etc.

In closing, PSG is respectfully requesting your consideration for our products as you establish Currently Unavoidable Uses for certain PFAS. Please feel free to reach out to me for any additional information that you may require through my contact information below.

Thanks and regards,

Christopher Walsh

Identification of Currently Unavoidable Uses for PFAS

Product Description	GPC/HTS Code	Use of PFAS	Alternatives
Backflow Preventer Parts / Accessories	10005865	Fluoroelastomer seals	
Backflow Preventers	10005866	Fluoroelastomer seals	
Backflow Test Kits	10005863	Fluoroelastomer seals	
Vacuum Breakers	10005864	Fluoroelastomer seals	
Screw Pumps	10008345	Fluoroelastomer seals Bearing components Flame resistant plastics used in Wiring. Motors and Controllers required to meet UL safety standards.	
Peristaltic/Roller Pumps	10008346	Fluoroelastomer seals Bearing components Flame resistant plastics used in Wiring. Motors and Controllers required to meet UL safety standards.	
Vane Pumps	10008347	Fluoroelastomer seals Bearing components, wear disc, valve coating, magnetic couplings, vanes, push rods Flame resistant plastics used in wiring, Motors and Controllers required to meet UL safety standards.	
Progressive Cavity Pumps	10008348	Fluoroelastomer seals Bearings, stators, joint sealing Flame resistant plastics used in wiring. Motors and Controllers required to meet UL safety standards.	
Gear Pumps	10008349	Fluoroelastomer seals Bearing components Flame resistant plastics used in Wiring. Motors and Controllers required to meet UL safety standards.	
Lobe Pumps	10008350	Fluoroelastomer seals Bearing components Flame resistant plastics used in Wiring. Motors and Controllers required to meet UL safety standards.	
Piston Pumps	10008351	Fluoroelastomer seals Bearing components Flame resistant plastics used in Wiring. Motors and Controllers required to meet UL safety standards.	
Plunger Pumps	10008352	Fluoroelastomer seals Bearing components Flame resistant plastics used in Wiring. Motors and Controllers required to meet UL safety standards.	
Diaphragm Pumps	10008353	Fluoroelastomer seals, valve seats, check valves, diaphrams, pump head components, tubing, valving, pistons, Flame resistant plastics used in cables, wiring, Motors and Controllers required to meet UL safety standards.	
Pneumatics Pumps	10008354	Fluoroelastomer seals Bearing components Flame resistant plastics used in Wiring. Motors and Controllers required to meet UL safety standards.	
Industrial Pumps - Electric Engines	10008355	Fluoroelastomer seals Bearing components Flame resistant plastics used in Wiring. Motors and Controllers required to meet UL safety standards.	
Industrial Pumps – Replacement Parts / Accessories	10008364	Replacement parts would use various PFAS for repair of pumps (seals, components, etc)	
Industrial Pumps - Engines	11030100	Fluoroelastomer seals Bearing components Flame resistant plastics used in Wiring. Motors and Controllers required to meet UL safety standards.	
Industrial Pumps – Replacement Parts / Accessories	11050100	Replacement parts would use various PFAS for repair of pumps (seals, components, etc)	
Pumps	10004055	Fluoroelastomer seals, bearing components, moulded plastic components, Tribologic components, coatings Flame resistant plastics used in cables, wiring, Motors and Controllers required to meet UL safety standards.	
Valves/Fittings - Water and Gas	10004024	Fluoroelastomer seals, valve liners	
Valves/Fittings Accessories/Replacement Parts - Water and Gas	10008011	Includes multiple PFAS materials for replacement/repair. (e.g. bearings, gaskets, compression packings, seals, seats, linings)	
Gaskets - Polymer	3920.10.00.00	Fluoroelastomer seals	
Thread Sealant (Paste)	3403.19.00.00	Fluoropolymer friction reducer critical to NPC piping systems and system sealing	
Thread Sealant (Tape)	3403.19.00.00	Fluoropolymer friction reducer critical to piping systems and system sealing	
EPS (Plastic) Seals	3296.90.45.10	Fluoroelastomer seals	
PTFE Expansion Joints	3917.40.00.90	Temperature and chemical resistance	

PTFE lined Hoses	3917.39.00.10 3917.21.00.00 4009.42.00.50 3917.33.00.00 3917.29.00.90 3917.39.00.50	Temperature and chemical resistance	
ETFE Lined Pipes Valves and Fittings	7306.19.10.50 8481.80.90.50 7307.99.10.00	Temperature and chemical resistance	
PFA Lined Pipes Valves and Fittings	7306.19.10.10 8481.30.20.90 8481.80.30.65 8481.80.30.20 7307.19.90.80 8481.80.90.50	Temperature and chemical resistance	
PVDF lined Pipes Valves and Fittings	7306.19.10.10 8481.30.20.90 7307.19.90.80 8481.80.90.50	Temperature and chemical resistance	
PTFE lined Pipes Valves and Fittings	7306.19.10.10 8481.80.10.90 8481.80.30.30 8481.80.30.75 7307.19.90.80	Temperature and chemical resistance	
Sealants	10003204	Chemical resistance, Gas permeability, Diffusion coefficient	
Adhesives		Chemical resistance, Gas permeability, Diffusion coefficient	
Lubricating Greases	10005268	Long period operation, High temperatures, Low friction/low wear, Good gliding properties, Resistant to aggressive chemicals and reagents	
Lubricating Oils/Fluids	10005267	Long period operation, High temperatures, Low friction/low wear, Good gliding properties, Resistant to aggressive chemicals and reagents	
Lubricating Products Variety Packs	10005270	Long period operation, High temperatures, Low friction/low wear, Good gliding properties, Resistant to aggressive chemicals and reagents	
Lubricating Waxes	10005269	Long period operation, High temperatures, Low friction/low wear, Good gliding properties, Resistant to aggressive chemicals and reagents

St. Paul, Minnesota, 55155-4194

RE: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Dear Ms. Lynn,

The American Chemistry Council's Center for the Polyurethanes Industry[1] (CPI) thanks the Minnesota Pollution Control Agency (MCPA) for engaging stakeholders during the rulemaking regarding Products Containing Per-and polyfluoroalkyl substances (PFAS). The Notice of the Request for Comment (Notice) specifically asks for information related to currently unavoidable uses.

Polyurethanes manufacturers and chemical producers have been investing in the transition to low-global warming potential (GWP) foam blowing agents for decades. Since the early 2010s, polyurethanes manufacturers have had access to hydrofluoroolefin (HFO) foam blowing agents. HFO blowing agents provide a significant GWP reduction as compared to earlier generations of blowing agents and have a short atmospheric lifetime. The three primary HFO foam blowing agents used in the polyurethanes sector have ultra-low GWPs using the 100-year basis[2], which is approximately 200-1400 times lower than the substances previously used in the industry. In October 2023, the U.S. Environmental Protection Agency (EPA) published a final rule outlining the federal phaseout of HFC blowing agents with a GWP of over 150.[3] For polyurethane end uses, this phaseout date is January 1, 2025. The only currently available alternative to high-GWP blowing agents like HFCs is HFOs.

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Rather than defining by exact criteria, CPI recommends that the following guiding principles be used to help determine what is a currently unavoidable use:

- **Essential functionality:** Do the products provide critical or essential function in daily lives, society, infrastructure, and critical operations?
- **Lack of Alternatives:** Are there alternatives available that meet technical readiness to fill the gaps from a performance, regulatory, or demand standpoint? Are there reliability or performance concerns that may cause customers to be hesitant to switch?
- **Cost-effectiveness:** Are the benefits of transitioning to alternatives higher than the cost?

[1] The Center for the Polyurethanes Industry's (CPI) mission is to promote the growth of the North American polyurethanes industry through effective advocacy, delivery of compelling benefits messages demonstrating how polyurethanes deliver sustainable outcomes, and creation of robust safety education and product stewardship programs.
[2] Fifth Assessment Report, Intergovernmental Panel on Climate Change
[3] 88 FR 88825

- **Compatibility:** Where products are integrated into existing systems or processes, would transitioning or obsolescence require substantial capital investment, disruption, socioeconomic or other issues?
- **Regulatory Compliance:** Are these products necessary to meet legal or regulatory compliance obligations?
- **Safety and Security:** Are these products crucial for ensuring safety or security?

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Costs of PFAS alternatives should be considered in the definition of "reasonably available." As mentioned earlier, the benefits of transitioning to an alternative should outweigh the costs associated with the transition. MPCA should look at not only the performance benefits of transitioning to alternatives, but the safety benefits as well. MPCA should weigh the tradeoffs in performance and safety, in addition to the monetary costs associated with transitioning to alternatives to ensure that necessary products remain in commerce in the state of Minnesota.

3.) Should unique considerations be made for small businesses with regards to economic feasibility?

Yes, considerations should be made for small businesses with regards to economic feasibility. Changing to alternatives can increase the cost of products that can impact small businesses' ability to conduct business in an affordable manner. For example, changes in the blowing agents used in spray foam can impact the price of spray foam. Applicators of spray foam are generally small businesses, and changes in price stemming from changes to the formula could impact their ability to remain in business.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

Instead of creating new criteria for PFAS alternatives, MPCA should look to federal programs that are already in place. For example, EPA's Significant New Alternatives Policy (SNAP) Program has reviewed environmental fate data on HFO foam blowing agents for acceptability as approved alternatives to previous generation materials. By deeming HFO foam blowing agents "acceptable," EPA has determined that HFO foam blowing agents "reduce overall risk to human health and the environment compared to other substitutes for the particular end-use."[4] Additionally, HFO foam blowing agents are not classified as persistent, bioaccumulative, or toxic (PBT). The HFOs used as foam blowing agents have atmospheric lifetimes measured in days and are designed to readily breakdown in the atmosphere if released, forming compounds that occur naturally in the environment.[5]

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

Currently unavoidable use determinations should last indefinitely, until there is an alternative that is proven to be cost-effective, safe, and provides similar performance to the original product and, if applicable, deemed an acceptable alternative by federal regulatory programs already in place.

---

[4] Final Rule, Protection of Stratospheric Ozone: Listing of Substitutes Under the Significant New Alternatives Policy Program in Refrigeration, Air Conditioning, and Fire Suppression, 88 Fed. Reg. 26382, 26414 (Apr. 28, 2023).

[5] ECHA PBT Assessment List. Available at: https://echa.europa.eu/fi/pbt

As previously mentioned, MPCA should reference EPA's SNAP Program for alternatives to blowing agents. Many of these federal programs go through years-long, thorough, and rigorous regulatory processes to determine the performance and safety of new alternatives. Another example is the Federal Trade Commission's (FTC) R-Value rule. The FTC only reopens the R-Value rule every 10 years.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

As mentioned above, products that are already governed by existing federal and state regulations should qualify as being designated currently unavoidable uses. Stakeholders whose products are already governed should not need to be considered for currently unavoidable use, as they are already considered a currently unavoidable use by existing regulations. A technical advisory committee should be established to determine currently unavoidable uses if the products are not already governed by existing regulations.

To the second question, conversely, no, stakeholders should not be able to request a PFAS use not be determined as a currently unavoidable use.

To the third question, information to be considered when submitting a request should address the guiding principles mentioned in response to question 1.

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Blowing agents like HFOs and HFC blends with a GWP under 150 should be considered currently unavoidable uses. These products have already been evaluated by EPA's SNAP Program, which has deemed HFO blowing agents as an acceptable alternative to high-GWP blowing agents.

Additionally, these blowing agents are used in spray foam insulation, which provide copious economic and environmental benefits by reducing the energy needed to heat and cool buildings. This, in turn, reduces the greenhouse gas emissions associated with heating and cooling and reduces utility costs.

Intended Use of Spray Foam

Spray polyurethane foam is used to insulate and air seal residential and commercial buildings, as well as provides a moisture barrier. The air barrier provided by spray foam prevents unwanted air flow caused by cracks and gaps. This keeps the internal temperature of the building envelope more consistent and reduces the energy needed to heat and cool. This reduces energy costs, carbon emissions, and HVAC load. These qualities make spray foam integral to helping Minnesota achieve its climate goals.[6,7,8]

---

6 https://www.revisor.mn.gov/laws/2007/0/Session+Law/Chapter/136/?keyword_type=exact&keyword=The+Next+Generation+Energy+Act

7 https://climate.state.mn.us/sites/climate-action/files/Climate%20Action%20Framework.pdf

8 https://www.pca.state.mn.us/air-water-land-climate/climate-change-initiatives

As much as 40% of a building's energy is lost due to air infiltration. Gaps, holes and air leaks—which can all be prevented—can make energy bills unnecessarily high and let valuable resources go to waste. Spray foam offers a solution: it weatherizes homes acting as both insulation and an air sealant, or air barrier, closing those nooks and crannies that let air escape and increase monthly energy bills. EPA's Energy Star program estimates that by adding insulation and sealing air leaks, homeowners could save up to 20% on their monthly energy bills.[9]

Essentiality of HFOs to Spray Foam

Blowing agents are necessary for polyurethane foam to expand and develop a cellular structure. HFO blowing agents, specifically, are integral to spray polyurethane foam, as they provide thermal resistance and are affordable. Additionally, HFO foam blowing agents are not classified as PBT. The HFOs used as foam blowing agents have atmospheric lifetimes measured in days and are designed to readily breakdown in the atmosphere if released, forming compounds that occur naturally in the environment.[10]

Environmental fate data on the HFO foam blowing agents were reviewed under Section 612 of the Clean Air Act (CAA) – EPA's SNAP Program – for acceptability as approved alternatives to previous generation materials. By deeming HFO foam blowing agents "acceptable," EPA has determined that HFO foam blowing agents "reduce overall risk to human health and the environment compared to other substitutes for the particular end-use."

Additionally, in the preamble of the final rule regarding HFOs in refrigerant end uses, EPA stated:

> Regardless of what definition of PFAS is used, not all PFAS are the same in terms of toxicity or any other risk. Some PFAS have been shown to have extremely low toxicity, for example. If a chemical has been found to present lower overall risk to human health or the environment, it might be found acceptable under SNAP regardless of whether or not it falls under a particular definition of PFAS. Likewise, SNAP might not find a potential alternative acceptable if it presented greater overall risk, regardless of whether or not it falls under a particular definition of PFAS. As described in the risk screens for alternatives found in the docket for this rulemaking, potential risk to human health or the environment has been considered directly for each chemical, and the risks are not assumed to follow from a chemical falling into any particular category of substances.[11]

The American Innovation and Manufacturing (AIM) Act, which was signed into law at the end of 2020, implements the phasedown of HFC blowing agents. HFO blowing agents are a preferred alternative to HFCs and are already playing an important role in supporting EPA's climate goals under the AIM Act. By requiring the reporting and eventually banning of HFO blowing agents, per the overly broad PFAS definition in the Minnesota's PFAS in Products legislation, Minnesota PCA is restricting the use of an alternative to high-GWP blowing agents and undermining EPA's climate goals in the AIM Act.

[10] ECHA PBT Assessment List. Available at: https://echa.europa.eu/fi/pbt
[11] 88 Fed. Reg. 26382 at 26414

Alternatives to HFOs

As of now, there are currently no alternatives to HFOs on the market. HFCs would be the closest alternative; but, as mentioned above, are currently being phased out under the AIM Act's Technology Transition rule. Other potential alternatives to HFOs, like pentane, have flammability risks associated with them and are deemed unacceptable by the United Nations Foam Technical Options Committee (UN FTOC)[12] [13].

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

As previously stated, MPCA should rely heavily on existing regulations to make these determinations. Ultra-low GWP blowing agents like HFOs have already been extensively studied by EPA's SNAP Program to determine the overall risk to human health and the environment and have been determined as an acceptable alternative. Taking into consideration determinations made at a federal level will greatly assist MPCA in determining actual chemicals of concern instead of overly broad approaches to regulating chemical families.

Conclusion

MPCA should develop a set of guiding principles to determine if a product is a currently unavoidable use. Additionally, MPCA should heavily consider the environmental, health and safety, performance, and monetary cost of an alternative compared to its benefits when determining whether or not a product meets the definition of a currently unavoidable use. MPCA should rely on current federal regulations and programs to assist with making these determinations.

If you have any questions or need additional information, please contact me at Ian_Choiniere@americanchemistry.com or (202) 249-6424.

Sincerely,

Ian Choiniere

Industry PFAS CUU Project

PFAS Currently Unavoidable Uses Proposals (CUU) Fifty-three (53) Proposals

Submission by Industry

This document is the guidance document to fifty-three (53) PFAS Currently Unavoidable Uses proposals being submitted by industry. Each CUU proposal is separate, but listed together in an orderly fashion for clarity and the convenience of regulators. Most of the proposals are for widespread uses of PFAS. These uses span across all industry segments and were included together. If required, they can be separated, but they would create between 300 and 400 separate proposals for regulators to review (for the 53 fundamental uses).

The Industry PFAS CUU project is made up of >50 companies that span consumer, professional, medical, industrial, and laboratory uses of PFAS. The CUUs listed here are based on very detailed work by each member of the project combined with tens of thousands of parts tested by Claigan Environmental in 2023 and 2024.

This submission should be the most comprehensive list of Currently Unavoidable Uses in physical products (articles), with detailed justifications and comparisons of alternatives.

The full CUU proposals and justifications are listed in detail in the accompanying spreadsheet PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx.

Claigan Environmental Inc.

Table of Contents

1. Summary

This report is a submission by Claigan Environmental Inc. (Claigan) on behalf of the Industry PFAS Submission Project ("PFAS Submission Project"). The PFAS submission project is made up of 50+ companies from a wide range of industries (consumer, professional, industrial, medical, oil and gas, laboratory equipment, textiles, electronic components, and retail sales.)

The PFAS Submission Project is focused primarily on the needs of complex products (articles). Claigan is both a restricted materials consultancy and a high-volume restricted materials testing laboratory. Each of the PFAS Submission Project submissions are based on contributions from all major sectors of industry, and 2023 and 2024 PFAS testing data from tens of thousands of parts.

The detailed justification of each CUU is covered in the accompanying spreadsheet PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx.

Each CUU entry includes

- A brief description of the Currently Unavoidable Use of PFAS
- A brief description of the type of product including industries and example products with HTS codes.
- A description of the intended use of the product and explanations on how it is essential for health, safety, or the functioning of society.
- A description of how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, citations will be provided for that requirement.
- A description of whether there are reasonably available alternatives for this specific use of PFAS.
- Plus
    - Whether the PFAS use includes PFOA or Long Chain Perfluoroalkyl Carboxylic Acids (LC-PFCA). Many of these PFAS uses do not include (nor degrade into) any PFAS found in drinking water and humans.

- PFOA / LC-PFCA presence is based on tens of thousands of parts tested in 2023 and 2024.

Important note 1 - due to the short timeline for the PFAS Currently Unavoidable Use consultation, each justification is only in brief with a detailed comparison of alternatives. Each justification can be further elaborated upon if needed.

Important note 2 - the regulation of chemical substances in medical devices is governed by the FDA. It is generally assumed that this preempts restrictions of PFAS in medical devices under state regulation, "A product for which federal law governs the presence of PFAS in the product in a manner that preempts state authority". However, for completeness and until this question is fully solved, currently unavoidable uses of PFAS in medical devices are also included in this submission.

Important note 3 - The States of Maine and Minnesota adopted a broad definition for PFAS substances. The vast majority of PFAS substances, as defined by Maine and Minnesota, that are found in products are not found in the environment. The broad definition impacts PFAS use in multiple categories of products and equipment needed to make products. PFAS substances are used in these applications because they have unique properties that impart specific performance characteristics making them essential to a product's function. The accompanying spreadsheet provides a detailed comparison of fluoropolymer, fluoroelastomer, and alternative materials for each application. The reason for the use of the fluoropolymer or fluoroelastomer is generally fairly obvious when you look at the application and the alternatives.

2. Related documents

2.1. PFAS Currently Unavoidable Uses Proposals spreadsheet - Industry PFAS Submission Project

2.1.1. PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx

3. Definitions

3.1. ***Currently Unavoidable Use of PFAS (CUU)*** - a use of PFAS that is essential for the health, safety, or functioning of society and for which alternatives are not reasonably available.

3.2. ***Widespread Use*** -

3.2.1. For essential uses of a PFAS-containing product, uses that are very high volume with widespread use are identified.

3.2.1.1. For example - fluoroelastomers and perfluoroelastomers have very widespread use in professional/industrial products (> 10M products per year sold in the US).

3.2.2. **For consumer uses** - Over 100 Million products sold in the US each year use this Currently Unavoidable Use of PFAS, or

3.2.3. **For industrial uses (including professional uses)** - Over 10 Million products sold in the US each year use this Currently Unavoidable Use of PFAS.

3.3. ***Forever chemicals***

3.3.1. *Substances that are either*

3.3.1.1. ***vPvB*** - Very persistent and very bioaccumulative

3.3.1.2. ***PBT*** - Persistent, bioaccumulative, and toxic

3.4. ***Machinery***

3.4.1. *Machinery includes all aspects of machinery including (but not limited to) manufacturing, construction, clean energy, water treatment, and forestry*

3.5. ***Laboratory***

3.5.1. *Laboratory includes all aspects of laboratory equipment including (but not limited to) water testing, life sciences, research and development, and medical testing.*

4. Key notes

4.1. Importance of PFAS

4.1.1. > 500 million products containing PFAS are sold in the US each year

4.1.2. Banning PFAS would eliminate

4.1.2.1. Laptops

4.1.2.2. The internet (unless servers are moved offshore)

4.1.2.3. Food processing

4.1.2.4. Water processing and treatment

4.1.2.5. Forestry

4.1.2.6. Life sciences

4.1.2.7. Oil and gas industry

4.1.2.8. Heart surgeries and biopsies

4.1.3. Banning PFAS without exception for Currently Unavoidable Uses would likely create the largest recession in the history of the United States.

4.2. Sources PFOA / LC-PFCA in Products

4.2.1. Most fluoropolymers and virtually all fluoroelastomers do not contain PFOA or LC-PFCA

4.2.2. The follow sections are based on 2022 - 2024 testing of products for PFOA / LC-PFCA and include explanation of how these substances are formed in very specific situations.

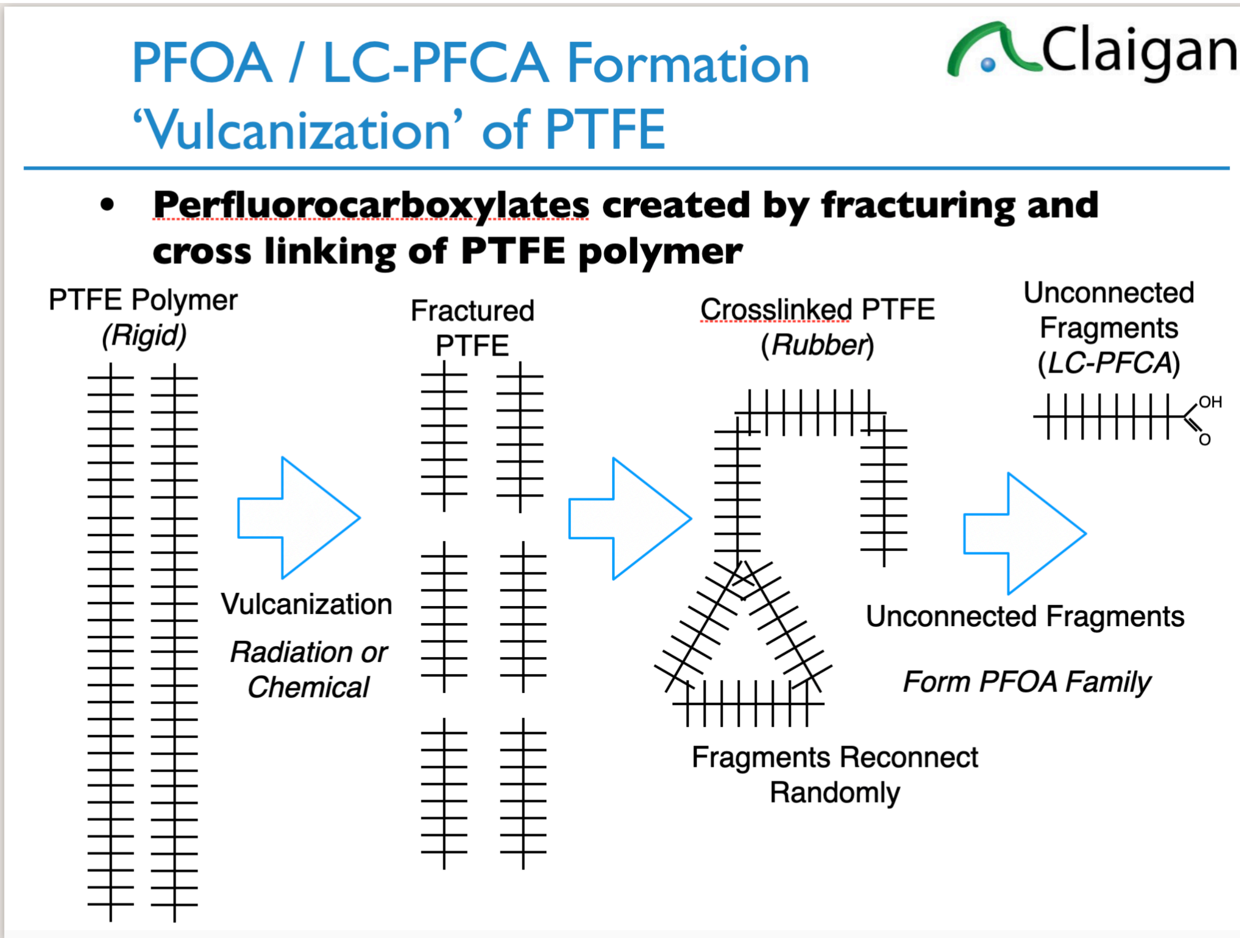
4.2.3. **Cause #1** of unintentional PFOA / LC-PFCA - Formation of LC-PFCA during vulcanization of rigid PTFE (or PVDF) into cross-linked rubber

4.2.3.1. Vulcanization / crosslinking of PTFE involves

4.2.3.1.1. Fracturing of long rigid PTFE polymer through radiation or chemical means

4.2.3.1.2. Reconnecting of fragments of PTFE in random directions (creating rubber instead of rigid polymer)

4.2.3.1.3. Some fragments react instead with air and create random sizes of perfluorocarboxylates.



4.3. **Cause #2** of unintentional PFOA / LC-PFCA - PFAS polymers (such as PFA or fluoroacrylates) that have a fluoromonomer side chain with a fragile C-O-C (carbon-oxygen-carbon) bond.

4.3.1. Formation of perflluorocarboxylates

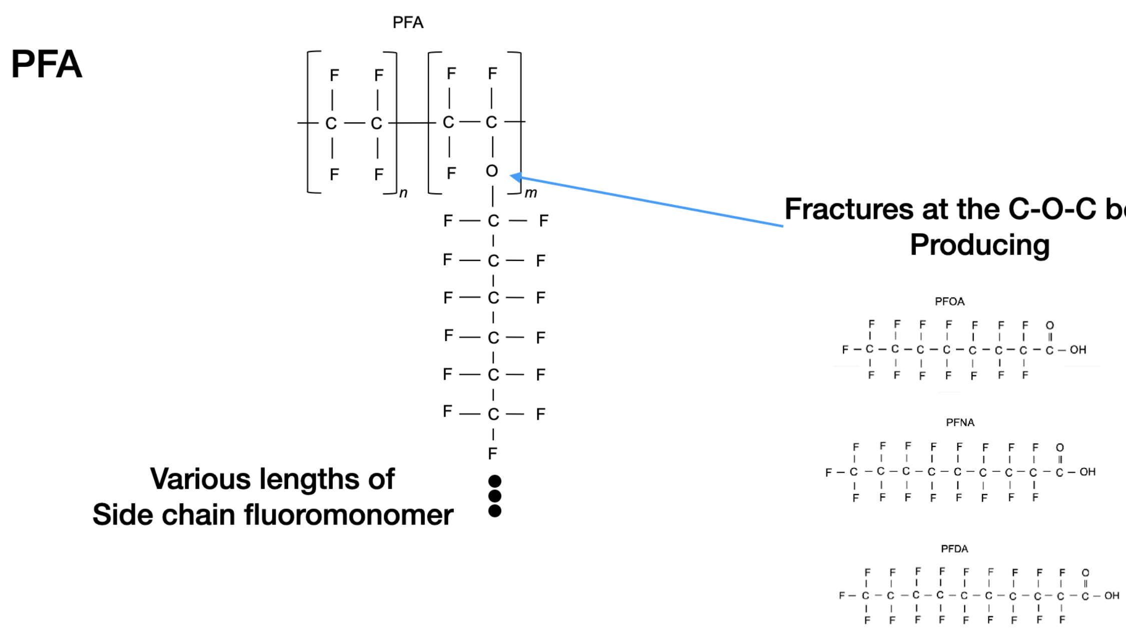
4.3.1.1. Fragile C-O-C bonds fracture during initial manufacturing and over time.

4.3.1.2. Fluoromonomer fragments are ‘fluorotelomers’, PFOA-like molecules with an extra 2 carbon hydrogens (such as 8:2 FTOH).

4.3.1.3. The fluorotelomer fragments react with air and water to slowly form perfluorocarboxylates

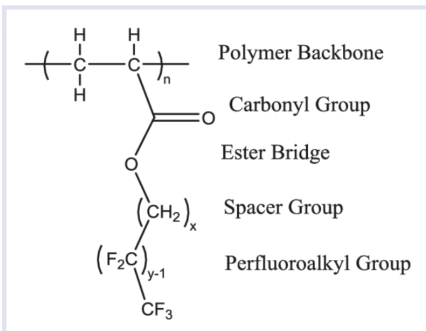
4.3.1.4. The lengths of eventual perfluorocarboxylates depend on the lengths of side chain monomers on the original PFA or fluoroacrylate polymer.

Formation of PFOA / LC-PFCA
PFA (Perfluoroalkoxy Alkane Polymer)

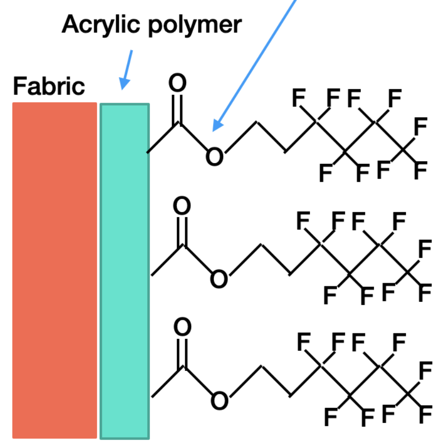


PFOA / LC-PFCA Formation Fluoroacrylates

- Fluoroacrylates have a 'side chain polymer'
  - Acrylic or other polymer
    - With chains of PFAS extending from polymer
    - *PFOA may be present as an impurity from PFAS side chain*
  - Example - water repellant coatings



Side chain PFAS



Side Chain PFAS

4.4. Perfluorocarboxylates and Perfluorosulfonates Found in Fluoropolymers and Fluoroelastomers

4.4.1. Presence of perfluorocarboxylates and perfluorosulfonates

4.4.2. 2022 to 2024 testing data by Claigan Environmental

Comparison	PTFE	PVDF	ETFE	Crosslinked PTFE	ePTFE	PFA	Fluoroelastomers	Fluoroacrylates	Fluorophosphates
Short Chain Perfluorocarboxylates (C4-C7)	Never	Never	Never	Commonly	Commonly	Commonly	Commonly	Commonly	Commonly

Long Chain Perfluorocarboxylates (C8-C14)	Never	Never	Never	Commonly	Commonly	Commonly	Never	Commonly	Commonly
Short Chain Fluorotelomers (C4-C7)	Never	Never	Never	Never	Never	Never	Never	Commonly	Commonly

Long Chain Fluorotelomers Sulphonates	Never	Never	Never	Never	Never	Never	Never	Never	Never

4.5. PFAS in Drinking Water and Humans

4.5.1. From this project and related testing data

4.5.1.1. ~99% of PFAS found in drinking water and humans is from <0.1% of products (primarily legacy fire extinguisher fluid and legacy foundation/concealer (C9-C15 fluoroalkyl phosphate in personal care products)).

4.5.1.2. ~99.99% of PFAS found in drinking water and humans is from <1% of products (a slight additional contribution from washing of waterproof fabrics contain fluoroacrylates).

4.5.1.3. The average silicone part has 100X more forever chemicals than the worst fluoropolymer (ePTFE). 200 ppm vs 2 ppm.

4.5.1.4. Based on ISO 10993-18 medical biocompatibility testing: Silicone, ABS, polystyrene, PVC, nylon, and polyurethane leak more dangerous chemicals into humans than fluoropolymers

4.5.1.5. Fluoropolymers are used because they are safer and more effective than their alternatives.

4.6. PFAS and Drinking Water - Kentucky 2023 PFAS testing of all drinking water sites

4.6.1. Kentucky 2023 drinking water sites testing

4.6.1.1. https://eec.ky.gov/Environmental-Protection/Water/Reports/Reports/2023-PFASFinishedDrinkingWaterResults.pdf

4.6.1.2. Kentucky was chosen because

4.6.1.2.1. Modern data (2023)

4.6.1.2.2. Comprehensive PFAS testing of each drinking water site

4.6.2. Sources of PFAS in drinking water

4.6.2.1. Based on the comparison of drinking water testing results and laboratory testing results of products

4.6.2.2. Legacy fire fighting foam

4.6.2.2.1. Fire fighting foam that uses C8 fluoro surfactants

4.6.2.2.2. Generally phased out of products a decade ago

4.6.2.2.3. Testing characteristic

4.6.2.2.3.1. Always - PFOS

4.6.2.2.3.2. Majority of situations - PFOA

4.6.2.2.3.3. Would not have - PFNA or PFDA (higher-length PFOA substances)

4.6.2.3. Modern fire fighting foam

4.6.2.3.1. Fire fighting foam that uses C4 or C6 fluoro surfactants

4.6.2.3.2. Common in modern fire fighting foam

4.6.2.3.3. Testing characteristic

4.6.2.3.3.1. Always - at least one of 6:2 FTS, PFHxS, PFBS

4.6.2.3.3.2. Majority of situations - PFHxA, PFBA

4.6.2.3.3.3. Would not have - PFOS, PFOA, PFNA, or PFDA

4.6.2.4. Cosmetics (Foundation and Concealer)

4.6.2.4.1. Foundation and concealer using C9-C15 Fluoroalkylphospate

4.6.2.4.1.1. Degrades over time into high concentration of PFOA, PFNA, and PFDA

4.6.2.4.2. Phased out in 2021/2022

4.6.2.4.3. Testing characteristic

4.6.2.4.3.1. Always - PFNA and PFDA (PFDA not included in Kentucky testing)

4.6.2.4.3.2. Majority of situations - PFOA

4.6.2.4.3.3. Would not have - PFOS or any sulphonate, or short-length fluoro carboxylates (PFBA, PFPeA, PFHxA).

4.6.2.5. Physical products

4.6.2.5.1. Primarily fluoroacrylate coatings of water-resistant fabric

4.6.2.5.1.1. Would release all lengths of perfluorocarboxylic acids during washing in detergent.

4.6.2.5.2. Common today

4.6.2.5.3. Testing characteristic

4.6.2.5.3.1. Always - All lengths of perfluorocarboxylates from PFBA to PFDA.

4.6.2.5.3.2. Would not have - PFOS or any sulphonate.

4.6.2.6. Unknown

4.6.2.6.1. Testing results from water are not consistent with any known product.

4.6.3. Chart of Projected Sources of PFAS in 2023 Kentucky drinking water site testing

4.6.3.1. 113 sites tested in Kentucky in 2023

4.6.3.2. Note - some sites could be listed under more than one source. The total should be above 100%

5. PFAS Currently Unavoidable Uses

5.1. The full details are contained in the accompanying spreadsheet PFAS Currently Unavoidable Uses Proposals - Feb 2024.xlsx.

5.1.1. The comparisons are too large and detailed for a Word document and are instead summarized in an Excel file.

5.2. This document features several tabs with tables containing details about ***CUU's***.

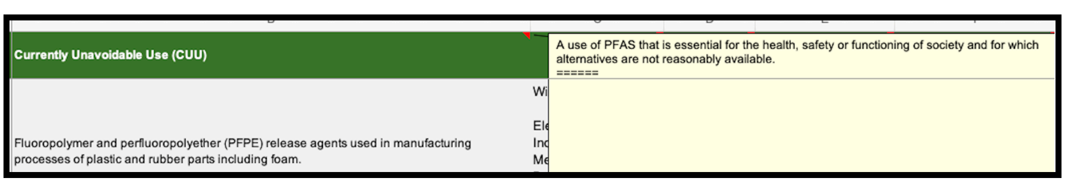
5.2.1. The CUU tab provides details about the specific ***CUU's*** as well as where and why they are specifically used.

5.2.2. The remaining tabs are the Alternative tabs. They provide the evaluation of alternative materials across a range of criteria applicable to the relevant use, which is labelled on the tab at the bottom of the document.

5.3. The core data is found within the tables, while further explanatory notes are found in the applicable column and row headers.

5.4. Cells with a red triangle in the top right corner have additional information pertinent to their respective row or column. They are found in Row 1 of the CUU tab and Column A of the Alternatives tabs. For example:

5.5. Additional details are revealed by hovering the mouse cursor over the cell (without clicking it). For example:



5.6. Additionally, this same information is captured in the document below.

6. Explanation of Currently Unavoidable Use (CUU) Proposal Tab

6.1. Columns A and B (CUU Number and Description) provide the numbering and descriptions for each ***CUU***.

6.2. Column C (Products) provides an overview of the applicable product families that require the listed Currently Unavoidable Use.

6.3. Column D (HS Codes) provides a list of HS Codes of products that require the listed ***CUU***. Some uses are so pervasive that the entire HS Code (Customs Code) chapters are listed.

6.4. Column E (Example Products) details a list of example products that require the applicable ***CUU.*** This list is representative and is not intended to be exhaustive.

6.5. Column F (Essential Use of Product) describes the intended use of the product and explains how it is essential for health, safety, or the functioning of society. It also describes if products using this CUU are ***Widespread*** or ***Industrial***.

6.6. Column G (Essential Use of PFAS) describes how the specific use of PFAS in the product is essential to the function of the product.

6.7. Column H (Comparison of Alternatives) describes reasonably available alternatives for this specific use of PFAS and compares them to the applicable ***CUU***. For further details, refer to the relevant Alternatives tab.

6.8. Column I (PFOA) identifies if this CUU contains any PFOA or Long Chain Perfluoroalkylcarboxylates (LCPFCAs). This column is based on 2023 and 2024 testing data of hundreds of representative parts for PFOA and LC-PFCAs.

6.9. Column J (Alternatives Tab) provides a direct link within the document to the identified tab comparing the performance of PFAS materials and alternative materials.

7. Alternatives Tabs

7.1. Row 1 (Comparison) identifies the alternative materials being evaluated.

7.2. Low Friction

7.2.1. Excellent - The material has a low coefficient of static friction. It is nearly frictionless.

7.2.2. Decent - The material has a lower coefficient of static friction but has some friction in use.

7.2.3. Poor - The material has a high coefficient of static friction. It displays strong friction during use and is not suitable for applications requiring low friction.

7.3. ***Chemical Resistance*** - the resistance to acids or bases may not be uniform for a material. The rating reflects the general potential applications of the material

7.3.1. Excellent - The material has superior resistance to acids and bases. Acid and bases have no discernible effect on the material.

7.3.2. Decent - The material is resistant to acids and bases but does exhibit some degradation. It should not be in extended contact with, or subject to, high concentrations of acids or bases.

7.3.3. Poor - The material is not resistant to acids and/or bases.

7.4. Water Resistance

7.4.1. Excellent - The material is hydrophobic (*i.e.* it is impermeable to water even as a coating).

7.4.2. Decent - The material is resistant to water, but not completely hydrophobic or waterproof.

7.4.3. Poor - The material is permeable to water.

7.5. Oil Resistance

7.5.1. Excellent - The material is oleophobic (*i.e.* it is impermeable to oil even as a coating).

7.5.2. Decent - The material is resistant to oil, but not completely oleophobic, oil-proof, or stain-resistant.

7.5.3. Poor - The material is permeable to oil.

7.6. Temperature Resistance

7.6.1. Excellent - The material can withstand temperatures above 150°C.

7.6.2. Decent - The material can withstand temperatures above 100°C, but is impacted by temperatures above 150°C.

7.6.3. Poor - The material is impacted by temperatures above 100°C.

7.7. Fire Resistance

7.7.1. Excellent - The material meets stringent fire/flame resistance standards.

7.7.2. Decent - The material has fire/flame resistance but does not meet the most stringent standards.

7.7.3. Poor - The material is not fire/flame resistant.

7.8. Flexibility

7.8.1. Excellent - The material exhibits good flexibility and is useful in most applications requiring flexibility.

7.8.2. Decent - The material has some rigidity, but still exhibits some flexibility.

7.8.3. Poor - The material is rigid and is not suitable for applications requiring flexibility.

7.9. Forever Chemicals (Initial)

7.9.1. Excellent - The material does not contain any substances with an EU harmonized classification of vPvB or PBT after manufacturing.

7.9.2. Decent - The material contains trace amounts (<1 ppm) of substances with an EU harmonized classification of vPvB or PBT after manufacturing.

7.9.3. Poor - The material contains amounts (> 1ppm) of substances with an EU harmonized classification of vPvB or PBT after manufacturing

7.10. Forever Chemicals (Over Time)

7.10.1. Excellent - The material does not degrade into substances with an EU harmonized classification of vPvB or PBT.

7.10.2. Decent - The material degrades lightly into substances (<1 ppm) with an EU harmonized classification of vPvB or PBT over time.

7.10.3. Poor - The material degrades into substances (> 1ppm) with an EU harmonized classification of vPvB or PBT over time.

7.11. Bio-compatibility

7.11.1. Excellent - The material passes US FDA and EU MDR biocompatibility testing and does not normally require toxicological justification.

7.11.2. Decent - The material passes US FDA and EU MDR biocompatibility testing but often requires toxicological justification.

7.11.3. Poor - The material does not generally pass US FDA or EU MDR biocompatibility testing or it requires significant toxicological justification.

7.12. Insulation

7.12.1. Excellent - The material has a low dielectric constant and is suitable for most insulating or electronics purposes.

7.12.2. Decent - The material has a medium dielectric constant and is only suitable for some insulating or electronics purposes.

7.12.3. Poor - The material has a high dielectric constant and is not normally suitable as an insulating material in electronics.

7.13. High-Density Applications

7.13.1. Excellent - The material is usable in applications requiring thin layers or high density.

7.13.2. Decent - The material is usable in applications that do not require thin materials, but it is not suitable for very fine or dense applications.

7.13.3. Poor - The material is not feasible as a thin film or in high-density applications.

7.14. Polymer Additive

7.14.1. Excellent - The material can be added to a wide range of polymers to provide additional properties.

7.14.2. Decent - The material can be added to some polymers to provide some level of additional properties.

7.14.3. Poor - The material is not suitable as a polymer additive.

7.15. Porous

7.15.1. Excellent - The material is permeable to air.

7.15.2. Decent - The material is partially permeable to air but is resistant to airflow.

7.15.3. Poor - The material is not permeable to air.

7.16. Durability

7.16.1. Excellent - The material has superior resistance to wear.

7.16.2. Decent - The material is partially resistant to wear but is not suitable for high-wear situations.

7.16.3. Poor - The material is not suitable for situations where wear resistance is required.

7.17. Optical Transparency

7.17.1. Excellent - The material is optically transparent.

7.17.2. Decent - This material has some optical transparency but is not suitable for applications requiring clarity and high transparency.

7.17.3. Poor - This material is not normally optically transparent

7.18. Structural

7.18.1. Excellent - The material is rigid with the ability to support its weight and any weight of the fluid it is transporting. It also has superior fatigue resistance.

7.18.2. Decent - The material can support its weight, but it is not as reliable for additional weight or fatigue.

7.18.3. Poor - The material cannot rigidly support its weight.

7.19. Radiation Resistance

7.19.1. Excellent - The material has superior resistance to gamma and e-beam radiation and does not exhibit degradation due to radiation.

7.19.2. Decent - The material has some resistance to gamma and e-beam radiation but exhibits degradation with repeat or high dosage exposure.

7.19.3. Poor - The material degrades in gamma or e-beam radiation.

7.20. Acceptable

7.20.1. A material is deemed acceptable if it receives an excellent or decent rating in non-critical properties. The material must receive an excellent rating in critical properties to be deemed acceptable.

7.20.1.1. Critical properties are identified where ratings (excellent, decent, poor) are shown in bold.

8. Acknowledgements

Special thank you to Nials Everett, Chris Scully, Julie Van Moorsel, Dr Tim Holt, and the entire Claigan Environmental staff and students for their contributions. And thank you to all of our industry members who contributed so much in such little time.

JFMDA Input for Request for Comments on Currently Unavoidable Uses under Minnesota Session Law – 2023, Chapter 60, H.F. No.2310

We, Japanese Federation of Medical Devices Association (JFMDA), would like to express the gratitude of having the opportunity of stating our opinion to Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837.
https://www.pca.state.mn.us/get-engaged/pfas-in-products-currently-unavoidable-use

JFMDA answers to the questions from the MPCA.

1) ***Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?***

Yes, criteria should be defined.
First, medical devices are essential to health, safety or the functioning of society.
Like pharmaceuticals, medical devices are invariably used in the treatment and diagnosis of diseases and other medical procedures, supporting our lives. Medical devices are constantly evolving, incorporating the latest technologies and combining various techniques. This evolution has made it possible to diagnose previously undetectable diseases at an early stage and to cure diseases and injuries that could not be cured in the past. It has also contributed to improving people's quality of life by reducing the burden on patients.

In addition, the following criteria could be considered.
- their elimination or substitution via design changes or materials and components which do not require any of the materials or substances listed in Annex II is scientifically or technically impracticable,
- the reliability of substitutes is not ensured,
- the total negative environmental, health and consumer safety impacts caused by substitution are likely to outweigh the total environmental, health and consumer safety benefits thereof.

2) Should costs of PFAS alternatives be considered in the definition of “reasonably available”? What is a “reasonable” cost threshold?

Yes.

For example, fluoropolymers are the only materials that combine excellent properties such as biocompatibility, persistence (stability), chemical resistance, repellency from water and oil , low-friction, heat resistance, electric insulation, flame resistance and durability, and are known as essential materials that support social infrastructure functions such as medical devices and their progress.

Even if there are alternatives that can replace some of the functions of fluoropolymers, other costs must be considered in the cost of material substitution. For example, the use of an alternative material may shorten the life of the product and require more resources for maintenance, thus increasing the cost of substitution.

In addition, in the case of medical devices, the following socio-economic impacts are expected due to substitution, which may increase social costs.

- The use of alternative materials may reduce product functionality and increase risks to patients, such as medical accidents
- Shortage of supply of medical devices will occur because it will take considerable time to change the design of medical devices that have already been developed.
- Medical device manufacturers will be forced to concentrate their human, financial, and other resources on design changes, which will affect the technological development of medical devices. The launch of medical devices with the latest technology in Minnesota will be delayed, resulting in lost opportunities for Minnesotans to receive the latest technology in medical care.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

Some consideration may be needed, but we do not have any concrete information on this issue.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

With regard to safety as an alternative to PFAS, it is essential that no hazardous properties be identified.

In addition, for medical devices, it is essential to guarantee safety as a medical device by PFAS alternative. Medical devices require not only clinical efficacy but also high safety and quality. To achieve them, PFAS is widely used in medical devices because of its biocompatibility, persistence (stability), chemical resistance, repellency from water and oil, low-friction, heat resistance, electric insulation, flame resistance, durability, flexibility and other characteristics. (Details of PFAS applications in medical devices are described in Appendix 1.)

Medical devices have the following characteristics

1) Clinical efficacy and safety

- Third-party certification is required.
- Sevier requirements for safety than consumer products are required and it takes long period to evaluate biocompatibility and long-term reliability.
- It also needs to assess whether the design change will have any impact on clinical efficacy.

2) Long supply chain

Time-consuming to identify PFAS-containing parts

3) High-mix low-volume production

Evaluation by substitution is necessary for each product type, and reliability evaluation is time-consuming. In addition, the low volume of parts purchased makes it difficult for parts suppliers to recover their investment, resulting in a low priority for alternative technology development and time-consuming development of alternative technologies.

4) Long product development cycle

Many products are used for long period while undergoing repairs

Based on the characteristics of medical devices described above, we will discuss the time period required to become PFAS-free for medical devices.

<Identification of parts containing PFAS>

Due to the extremely long supply chain of medical devices and the large number of parts, it is expected to take several years to identify parts containing PFAS. Since the proposed regulation would apply not only to the medical device sector but also to products in all sectors, it is easy to imagine that a very large number of survey requests would be concentrated on component suppliers and that it would take a very long time to obtain survey responses.

<Substitution of parts>

For example, in the case of medical electrical equipment, design engineers rarely specify PFAS as a material for parts. In most cases, they present the required specifications such as repellency from water, chemical resistance, flame resistance, and low-friction, etc., to the parts manufacturer, who then selects a material that meets the required specifications. Even if there are a variety of alternative candidates at the material level, each has different physical properties, so the parts manufacturer must develop an alternative technology that satisfies the part's required specifications. Reliability evaluation at the component level is also necessary.

Since the supply of parts for medical equipment is small, parts suppliers tend to give low priority to responding, and it takes time for parts suppliers to develop their own parts.

<Evaluation of alternative components in medical devices>

PFAS-free alternatives developed by parts manufacturers shall be evaluated for adoption in medical devices.

Parts in direct contact with the human body and wetted parts (*) are required to be evaluated for biocompatibility and shall be evaluated based on the EN ISO 10993-1 series standard.

In the case of devices that invade the human body, material changes may require a clinical trial, which requires a study protocol, contract with physicians, approval by the ethics committee of the medical institution, informed consent from the person undergoing the trial, protection of personal information, implementation of the trial, analysis of data, etc., and evaluation over several years.

In the case of medical electrical equipment, if the changed component is an electrical safety critical component, the safety test must be redone.

Even for medical devices for which such evaluations are not required, it is necessary to verify that design changes to alternative components do not affect performance and safety, which requires a much longer evaluation period than for consumer products.

*Wetted parts:

Parts that (re)administered medicines, body fluids or other substances, including gases, to/from the body, or that transport or store such medicines, body fluids or other substances, including gases, to be (re)administered to the body

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

We believe that no time limit should be set for the exclusion of medical devices, and that PFAS restrictions on medical devices should be considered at an appropriate time when other sectors have made some progress in PFAS alternative.

As noted in the comments to question 4), simply changing the design of an existing product to a PFAS-free component would require a considerable number of years of evaluation, and if a sufficient grace period were not set, there would be a shortage of medical devices in Minnesota.

In addition, medical device manufacturers will be forced to concentrate human, financial, and other resources on design changes, which will affect the technological development of medical devices. The launch of medical devices with the latest technology in Minnesota will be delayed, resulting in lost opportunities for Minnesota citizens to receive the latest technological medical care.

Since the amount of PFAS used in medical equipment is small and disposal is properly managed, the need to regulate PFAS content in medical equipment in the same manner as in other sectors is extremely low. Since regulating other sectors first will lead to a switch to PFAS-free in medical devices for general-purpose components even without regulating medical devices, it would be more socio-economically beneficial for medical devices to focus resources on new development and prioritize the introduction of medical devices with the latest technology. We believe that it is more beneficial from a social and economic perspective to focus resources on new development and prioritize the introduction of the latest technology in medical equipment.

6) ***How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA?***

For example, in cases where it is determined that the use of PFAS is necessary to realize products with functions required by medical institutions, which are the users of medical devices.
Cases in which the use of PFAS is determined to be necessary when parts specifications required to realize the specifications of medical devices are requested from parts manufacturers.

Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable?

There is no possibility that it will not be deemed unavoidable due to lack of alternative technology.

What information should be submitted in support of such requests?

Features and benefits of PFAS, safety of PFAS, lack of alternative materials with equivalent performance to PFAS, etc.

7) ***In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.***

Please see Appendix 1 “Uses of PFAS in Medical device” for explanation on functions of PFASs, uses of medical device, and alternative materials.

The majority of PFAS used in the medical device sector are “Fluoropolymers” and “Fluoroelastomers”.

“Fluoropolymers" and "Fluoroelastmers" meet the OECD's "Polymers of Low Concern", and are used as safe and stable materials in many medical devices such as catheters and guidewires, as well as in medical devices implanted in the body, such as artificial blood vessels. For example, PTFE is an excellent medical material with stability and biocompatibility, and has been used implanted in the human body for decades without showing adverse effects. Fluoropolymers are also stable in the environment, and there is limited information on their degradation products, therefore there is no international consensus to conclude that they are "hazardous materials posing an unacceptable risk to human health or the environment”.

Fluoropolymers in medical devices used in medical institutions can be managed at the time of their disposal, therefore they are not discharged into the ocean through sewage or rivers, as is unlike the case with fluorinated polymers used in food wrapping paper and water repellents for clothing. The fluoropolymers used in medical devices are disposed of at waste disposal sites, and are therefore not released into the ocean and are not considered to be a major source of microplastics. In addition, research reports investigating the materials of microplastics show that the chemical composition are mainly polyethylene, polypropylene, polyethylene terephthalate, and polystyrene, and that fluoropolymers are not commonly found in microplastics. (Nature Reviews Materials volume 7, p138-152, 2022: Risk assessment of microplastic particles)

'Fluoropolymers' combine biocompatibility, persistence (stability), chemical resistance, repellency from water and oil , low-friction, heat resistance, electric insulation, flame resistance, durability, etc., while 'fluoroelastomers' also combine high stability, chemical resistance and flexibility. Since these properties derive from the C-F bond, there are currently no equivalent alternative materials. These materials are therefore required as components and coating materials for a wide range of medical devices, such as endovascular treatment devices and radiological diagnostic equipment.

8) ***Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?***

Yes.
Medical device should be determined as currently unavoidable uses because they are essential to the health, safety, or functioning of society

9) ***Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.***

We have strong concerns about the legitimacy and socioeconomic impact of uniformly regulating PFAS by lumping them all together as "common hazards and risks“.   PFAS are lumped together on the basis of their "persistent" nature, however, the chemical structure and physical, chemical and biological properties of each sub-group of PFAS differ greatly, and their toxicity profiles are not identical. In addition, the risk to human health, the environment, and the socioeconomy varies greatly depending on the application. We request to establish appropriate grace measures for essential use, and also request to regulate on a priority basis PFAS subgroups with greater hazards or PFAS application posing higher environmental risks as well.

For example, fluoropolymers are lumped together with PFCAs and are included in the proposed restriction as posing a high risk to humans and the environment, even though they meet the criteria for a "polymer of low concern" as defined by the Organization for Economic Co-operation and Development (OECD). Fluoropolymers are the only materials that combine excellent properties such as biocompatibility, persistence (stability), chemical resistance, repellency from water and oil , low-friction, heat resistance, electric insulation, flame resistance and durability, and are known as essential materials that support social infrastructure functions such as medical devices and their progress.

We believe that it is beneficial to society to establish effective regulations for PFAS after appropriate assessment of health and environmental risks, socioeconomic impacts, risks of exposure to humans throughout the product life cycle, and feasibility of countermeasures for low concern fluoropolymers and fluoroelastmers. In other words, by prioritizing the regulation of PFAS subgroups, including Arrowheads substances, for which there is evidence or strong suspicion of hazards, and applications with severe environmental and health risks, it will be possible to effectively and efficiently reduce risks to human health and the environment with minimal socioeconomic impact.

As an organization supplying medical devices, we request the following in order to contribute to human health and safety and to socio-economic development in Minnesota, and to ensure that healthcare professionals and people in Minnesota do not lose an opportunity to access to the best medical care.

1. Enact effective PFAS regulations in a phased manner based on appropriate risk and socioeconomic assessments
2. Exempt fluoropolymers and fluoroelastomers from the proposed PFAS regulation
3. Medical Devices and In-Vitro Diagnostic Medical Devices shall be exempted as Essential Use

About JFMDA:

We JFMDA (The Japanese Federation of Medical Devices Association) was founded by medical device associations consisting of manufacturers and suppliers of medical and health-care devices, equipment, instruments and materials.

The JFMDA represents 20 medical device associations, consisting of about 4300 companies that together more than 120,000 employees.

Appendix 1

Uses of PFAS in Medical device

This document is the appendix 1 of the Input for Request for Comments on Currently Unavoidable Uses under Minnesota Session Law – 2023, Chapter 60, H.F. No.2310 from the Japanese Federation of Medical Devices Association (JFMDA)

submitted on 1. March 2024

Table of Content

General

PFAS are a very important group of substances for Medical device, which depends on these uses to maintain safety, as they are highly effective in chemical resistance, Repellency from water and oil, and electric insulation.
PFAS polymer resins are two to ten times more expensive than other commodity plastics. There is no use other than where the equipment does not work without the use of PFAS.
General electronics components are not covered in this document. However, since our equipment also uses common electronic circuit parts, we also use parts common to information equipment and general consumer EEE. For usage and non-substitutable information for such parts, please refer to Japan 4EE Input for Request for Comments on Currently Unavoidable Uses under Minnesota Session Law – 2023, Chapter 60, H.F. No.2310. Semiconductors are also used in our products. Many PFASs are used in semiconductors and semiconductor manufacturing equipment. Comments on most of the items in this section have been submitted by industry associations that specialize in the respective items. We hope that dossier submitters consider the manufacturer's opinions.

In this chapter, the use of PFAS in components and materials are explained. Then the some examples of the uses follows. These examples are not exhaustive.

1. Reserver for adding pressure / Ultrasound Probe

In ultrasonic probes, when the acoustic coupling medium expands as a result of temperature changes, the internal pressure of the medium chamber may increase excessively. It results in damage to the sealing part of the medium chamber and possible air bubble contamination.

Resin is used as the material that makes up the media chamber because of its acoustic properties. Even if the media chamber is sufficiently sealed, during long-term use, the pressure inside the media chamber gradually decreases due to elongation caused by the creep phenomenon of the resin.

As a result, the pressure inside the media chamber becomes lower than the external pressure, and air may permeate through the resin that constitutes the media chamber.

If air bubbles are introduced into the media chamber, they become reflectors of ultrasound waves, which inhibits ultrasound transmission and reception. As a result, the ultrasound image is degraded.

In this type of ultrasonic probe, it is necessary to adjust the pressure in the media chamber to suppress the generation of bubbles, and fluorine rubber, which has low permeability to gases and liquids, is used to achieve this objective.

Cross-sectional view of an ultrasonic probe

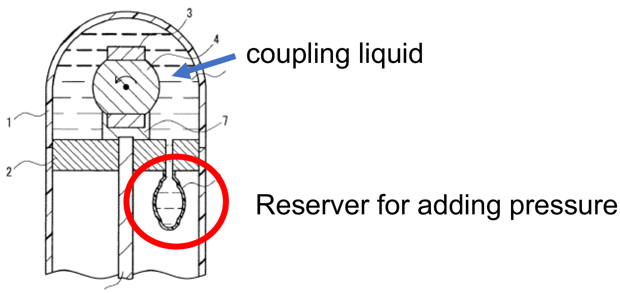

Image of Reserver for adding pressure

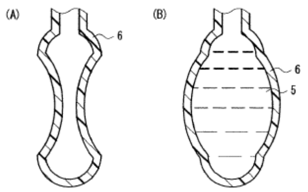

(A)adding pressure (B) unpressurized

Figure 1.3.1.

Period required for replacement: About 1 years, if a non-fluorine material with PFAS-equivalent performance is produced.

2. Medical devices inserted into the living body

Medical devices inserted into the body need to be covered with rubber or resin material to protect the outer surface of the drive unit, and FKM or fluororesin (PVDF, etc.) is used in areas where chemical resistance, biocompatibility, heat resistance, and non-adhesiveness are required. Chemical resistance is necessary for disinfection and cleaning after use to prevent infection. Biocompatibility is necessary for medical devices to be inserted into the body. Heat resistance is necessary for autoclave sterilization at 136 degree Celsius. Non-adhesiveness is necessary to prevent adhesion of mucous membranes and other substances that adhere to the device when it is inserted into the body.

Figure 1.4.1.

Description: Fluoropolymers for use in medical devices Endoscope Applications

PFAS substance(s) used: name and CAS number (If known):

PFAS including but not limited,

fluorocarbon elastomers (FKM)

Fluorocarbon elastomers, such as Fluorocarbon elastomers(FKM) , are the unique elastomers developed, which have been used in medical device such as endoscope with many benefits, including but not limited: i. fluorocarbon elastomers have a wide working temperature range from -26°C to 205°C, which is critical for high temperature sterilization applications, such as steam sterilization, dry heat sterilization, which are current standard sterilization practices in hospital. ii. fluorocarbon elastomers have a wide range of chemical resistance, which is critical for low temperature sterilization applications, such as hydrogen peroxide gas plasma sterilization, high level disinfection, and other liquid chemicals for cleaning. iii. fluorocarbon elastomers have excellent aging characteristics, which is very important for shelf time of medical device products.

Thermoplastic polyurethane (TPU) is an alternative material, but it cannot be substituted because it has poor chemical resistance and heat resistance, so the quality of sterilization, disinfection, and cleaning decreases, and the risk of infection increases.

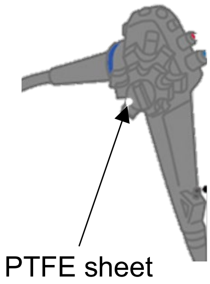

Figure 1.4.2.

Since the fluorine material has excellent low friction and non-adhesion while having chemical resistance, PTFE sheets are used between the sliding parts of the drive unit. Since there is no material other than fluorine having similar properties, change to alternative materials is not possible.

3. Solvent for cleaning and draining endoscope lens component

Figure 1.5.1.

HFE, the fluorinated composite material has good drying properties, no heat resistance, and low surface tension, so it has high particle removal ability. Non-flammable drying technologies include rotational drying and hot air drying using water as a solvent, but dry stains are likely to occur on the lens surface and are insufficient, and if they are incorporated into the product as they are, endoscopic image defects will occur and diagnosis will be hindered.

4. Insulation components for surgical instruments

- **Resectoscopes including electrodes to resect tissue (tumor or BPH)**

PTFE CAS: 9002-84-0

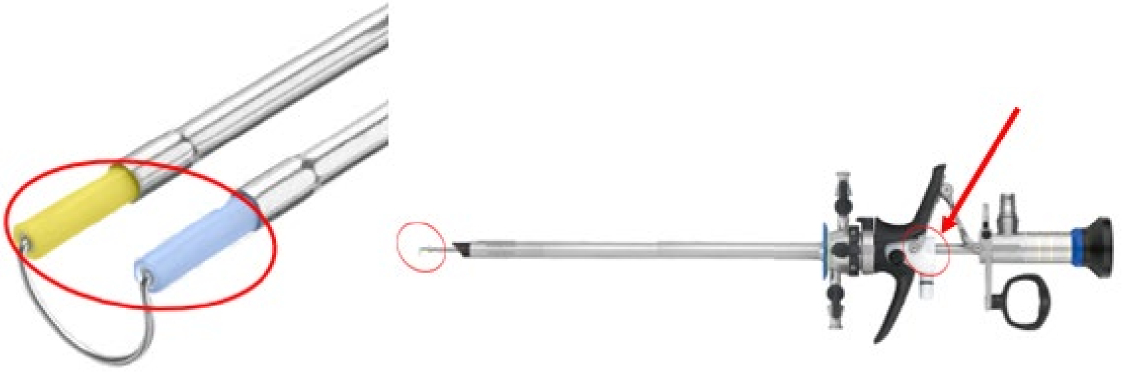

Figure 1.6.1.

Arc resistance to RF- plasma; Cleanability of surfaces; safe dielectric strength at small layer thickness; Non- Slip- Stick effect for movement; low friction for mounting in and on pipes and rods; low friction for moving parts (after cleaning cycles- grease would be removed); high temperature resistance for steam cleaning and disinfection; high chemical resistance for cleaning and disinfection (Peroxide, etc.)

There is no hazard and exposure risk. All materials in contact are controlled via ISO 10993. This product is single used

-PI is not flexible, has high slip- stick behavior

-PEEK will burn down under RF- plasma (arc)

-PET chemical resistance is to low, slip- stick behavior, non sufficient thermal stability

-All Cleaning disinfection tests have to be requalified, since low surface energy of PTFE is unmatched it can be estimated that cleaning procedures have to be harsher in the future.

◆ **Pad for Ultrasonic surgical device**

It is essential for ultrasonic surgical device to have the pad which contacts with ultrasonic probes that are vibrating at high speeds.

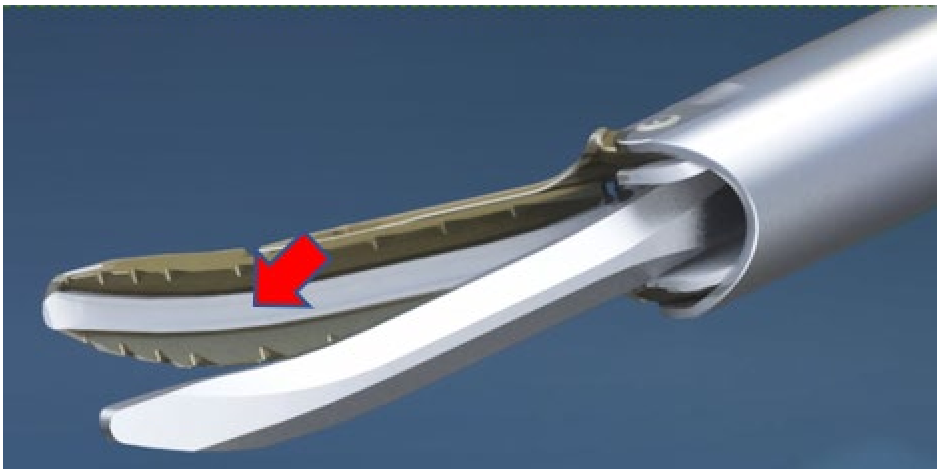

Figure 1.6.2.

During surgery, the tissue is sandwiched between the pad and the ultrasound probe, and the tissue is incised without bleeding due to the frictional heat and friction action caused by ultrasonic friction. During the incision of the tissue and after the incision is completed, the ultrasonic probe and the pad come into contact with the ultrasonic vibrating at high speed. In order to reduce the frictional heat generated at this time, it is necessary that the pad has low friction. In addition, even if the friction is low, the ultrasonic probe vibrates at high speed, so high wear resistance is required. In addition, a large amount of heat is generated due to friction. Since this is a surgical treatment tool, it is essential to have chemical resistance (acid and alkali resistance), heat resistance, and electrical insulation. The PTFE is the only material that can withstand that's friction and heat, so PTFE is indispensable. (If it is another member, it will melt easily and become unusable immediately.) ） In addition to these properties, biocompatibility is required. See "Biocompatibility" in the endoscope section of "Plumbing" for details.

◆ **Probe holder for Ultrasonic surgical device**

Probes Suppress exists to prevent pipe and ultrasonic probe that is vibrating at high speed from being destroyed and forming unintended electrical paths by coming into contact with each other.

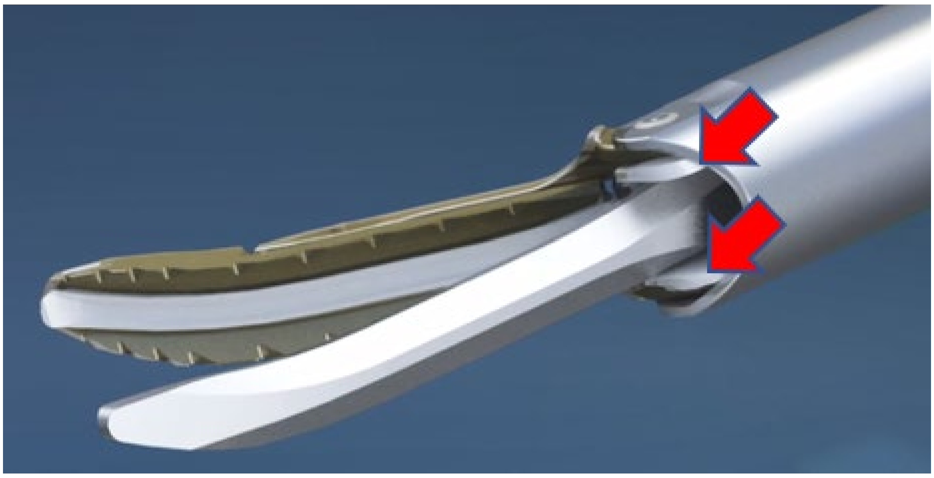

Figure 1.6.3.

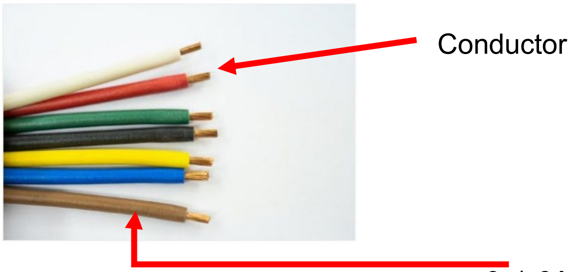
By performing surgery from a small port, it is necessary to reduce the burden on the patient by reducing the wound created on the patient's outer surface during surgery, and it is necessary to make it thin as a surgical treatment tool. As a result of thinning, the rigidity is weakened, so if the equipment is accidentally twisted with the tissue in between, the probe may deflect and come into contact with the pipe. In order to prevent this, it is necessary to be able to withstand wear and heat generation due to contact with a probe that vibrates at high speed, and it is essential to be able to withstand heat resistance, slipperiness, and wear resistance. In addition, the viewpoints of biocompatibility, chemical resistance (acid and alkali resistance), mechanical physical properties, flame retardancy, and electrical insulation required for energy surgical treatment tools are also essential. In particular, moldability is important to maintain the fineness of equipment, and PFA is indispensable. In addition to these properties, biocompatibility is required. See "Biocompatibility" in the endoscope section of "Plumbing" for details.

5. Electric wires and insulation

An electric wire is a linear member for transmitting electricity. Metal, which is a good conductor, is used for the part that transmits electricity, and plastic resin that has electric insulation is used around the wire in order to block the influence on anything other than the transmission destination of electricity.



Sheath

Figure 1.7.1.

Polyvinyl chloride is generally used for covering parts where plastic resin is used, which is called as sheath, but PTFE, PFA, FTPE, etc. are selected depending on the suitability of use and electric insulation requirements. Since these are more expensive than polyvinyl chloride, they are used only when it is difficult to use other materials such as polyvinyl chloride.

PFAS functions required by PFAS wires and availability of alternatives.

Wires using PFAS for coating have high electrical insulation when the coating is thin (100 μm or less). PFAS also has a high heat resistance of 150-200°C. In addition, PFAS wires can be used even when there are chemicals around the device because PFAS has chemical resistance.

Examples of devices equipped with electric wire and insulation

◆ **Medical cables of probe cable for ultrasound diagnostic equipment**

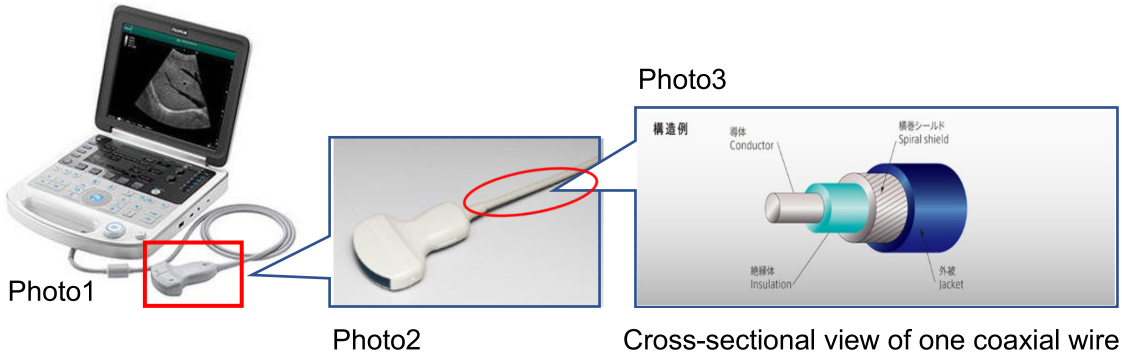


Figure 1.7.2.

The ultrasonic diagnostic device is shown in Photo 1 and consists of an image analysis unit and a cable with a transducer.

The cable with transducer shown in Photo 2 is composed of about 200 coaxial wires in order to transmit and receive about 200 signals.

The inside of the red circle cable in Photo 2 is as shown in Photo 3.

Photo 4 shows a cross-sectional view of one of Photo 3.

The performance required for these coaxial wires is (electric insulation / low dielectric constant), heat resistance, and extrusion suitability. PFA/FEP is used as a material that satisfies these three elements.

Table 15 shows the comparison results with the alternative candidate material PEEK.

In order to obtain a diagnostic image with high accuracy, the attenuation of coaxial wire must be 2 dB / m or less in terms of the size shown in Table 15 , and the required performance is not satisfied unless PFA/FEP is applied.

In order to satisfy the attenuation, it is necessary to reduce the capacitance, and for this purpose, the dielectric constant must be 2.1 or less.

The cross-sectional view of one coaxial wire is shown in Photo 4, and the red arrow part is the insulating layer and the green arrow part is the outer layer.

Both layers require thickness control of 0.05 mmt or less, and PEEK cannot be controlled, especially for the outer layer because it does not stretch.

In order to evenly cover the outer layer without destroying the shield layer, stretching is necessary.

PEEK meets only heat resistance requirements.

		PFA		PEEK		Required characteristics
electrical characteristics	dielectric constant	2.1	○	3.15	×	≦2.1
	Attenuation*1	1.75	○	≧2	×	@10MHz <2 d B/m
heat resistance	Rated temperature	≧200	○	≧200	○	200° C or higher
extrusion suitability	Coating thickness control	GOOD	○	BAD	×	≦0.05mmt
	Non-stop extrusion time	GOOD	○	BAD	×	≧2hr

*1Conductor 48AWG (7/0.012), OD 0.18mmΦ

Table 1.7.1. Comparison with alternative candidate material PEEK

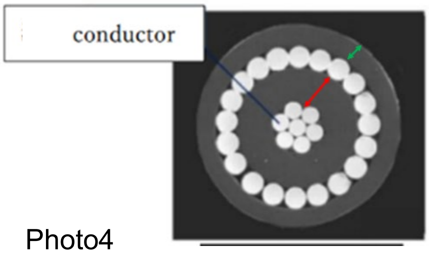

Photo4

Cross-sectional view of one coaxial wire

Figure 1.7.3.

◆ **Cables in MRI**

Magnetic resonance imaging (MRI) diagnostic equipment transmits and receives high-frequency signals in the FM frequency band in a high magnetic field space, so coaxial cables are used to efficiently transmit high-frequency signals.

A coaxial cable is a distributed constant line with a cross-sectional structure consisting of a center conductor, an insulator around it and which is further surrounded by a metal braided outer conductor.

Impedance matching is important in transmission lines for high-frequency signals to suppress reflections, and coaxial cables with a characteristic impedance Z_0 of 50 Ω are used.
The ratio of outer and inner conductor diameters that minimizes transmission loss in coaxial cables is defined as D/d=0.2785. Therefore, if polyethylene with a dielectric constant of 2.3 is used as the insulator, the characteristic impedance is 50Ω, which is used for most coaxial cables. To obtain these characteristics, PFAS (PTFE, FEP, ETFE) is now essential for MRI equipment.

Figure 1.7.4. MRI equipment

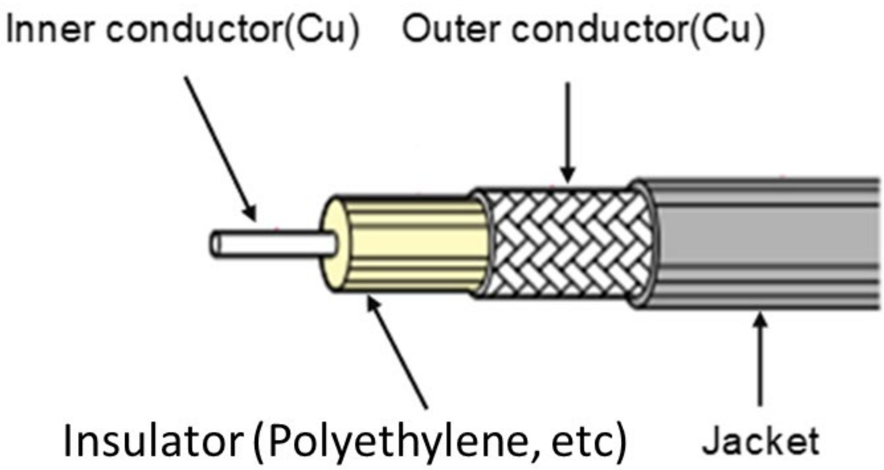

Figure 1.7.5. Structure of Coaxial cable (commercial product)

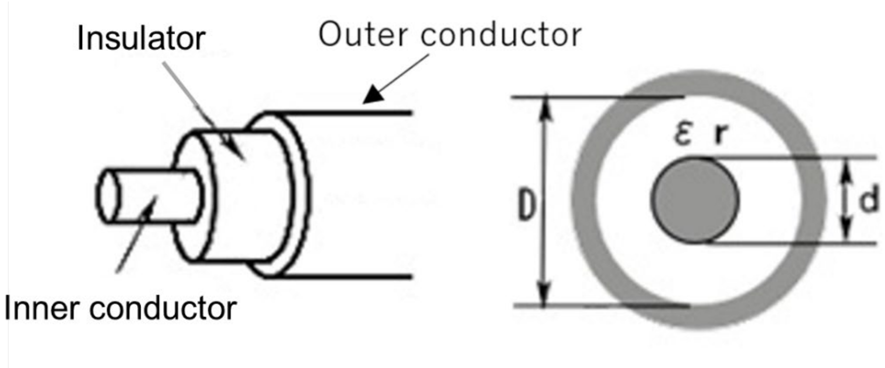

$$Z_0 = \frac{60}{\sqrt{\varepsilon}} \log_e \frac{D}{d} = \frac{138.1}{\sqrt{\varepsilon}} \log \frac{D}{d}$$

ε：Dielectric constant of dielectric

D：Inner diameter of outer conductor
(Outer diameter of insulator)

d：Outer diameter of inner conductor

Figure 1.7.6. Theory of coaxial cable

Technical Explanation of Non-Substitutability, Pictorial photographic data, information on reference websites, etc. are shown below.

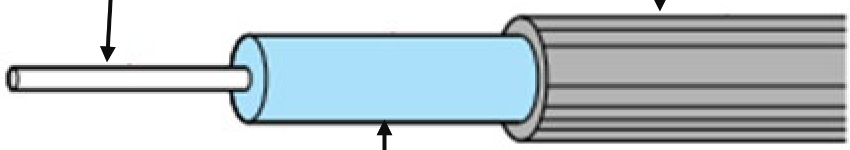

Figure 1.7.7. Semi-Rigid Cables

In contrast to general coaxial cables, shape memory types such as semi-rigid cables with a seamless metal tube as the outer conductor, or semi-flexible cables with a plated coating on the braided conductor, generally use fluoropolymer as the insulator.
The insulator of such cables maintains tight tolerances, the cable structure is highly uniform, and power loss due to reflection is minimized, resulting in superior transmission characteristics at high frequencies compared to general coaxial cables made of polyethylene.
The low loss of the cable provides a higher power capacity than general coaxial cables of the same size. Furthermore, it has excellent temperature characteristics, and stable characteristics can be obtained over a wide temperature range (about -55°C to +200°C).
Particularly in the antenna power feeding system such as MRI equipment, which uses cable assemblies tuned to a specific electrical length (phase), it is critical that the electrical length of the cable little varies due to temperature, deflection, tension or other environmental factors.
Transmitter circuit units in which semi-rigid cables are used transmit high-frequency signals in the rang from several kW to more than 10 kW with high-precision phase control. Therefore, the temperature inside the enclosure covered with noise shielding is expected to be up to 100°C.
Based on the above, the following properties are considered necessary when substituting fluoropolymer.

Dielectric constant is about 2.1 to 2.3.

Dissipation factor is about 0.0002.
Rated temperature is 100°C or higher.
Electrical length (phase) variation is -100 PPM/℃ or less.

The insulator of commercially available coaxial cables is de facto two options of polyethylene and fluoropolymer. Polyethylene has a good dielectric constant and dissipation factor, but has a temperature rating of about 75°C and an electrical length (phase) variations of about -250 PPM/°C, which do not meet the requirements. Therefore, general coaxial cables using polyethylene cannot be used. Other resin materials are also considered difficult to substitute due to the fact that the cable industry has not adopted them for insulator.

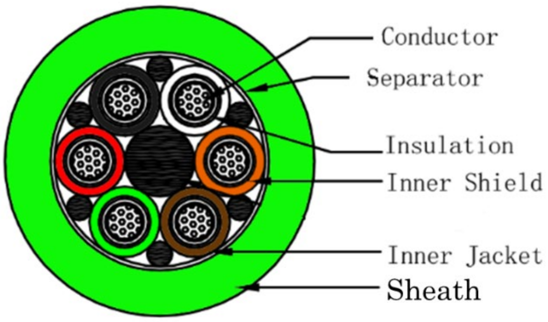

Figure 1.7.8. Composite coaxial cables

Composite coaxial cables consist of multiple small gauge coaxial cables and single core cables, which are bundled together with a common shield and jacket.
In MRI equipment, it is used for the internal wiring of the patient bed, and the cable bears a bending motion in accordance with the bed motion by every patient or every imaging part.
For coaxial cables, fluoropolymer is used for insulator and jacket, and for single core cables, used for jacket.
The following properties are considered necessary when substituting fluoropolymer.
(Coaxial cable)
Dielectric constant is about 2.1 to 2.3.
Dissipation factor is about 0.0002.
Withstands soldering temperatures (lead-free solder melting temp: 217°C).
Coefficient of kinetic friction (jacket) is about 0.1 to 0.2.
(Single core cable)
Withstands soldering temperatures (lead-free solder melting temp: 217°C).

Dynamic coefficient of friction is about 0.1 to 0.2.
Small gauge coaxial and single core cables are as small as 28 AWG to 30 AWG, and require heat resistance to withstand terminal soldering operations and low dynamic friction resistance to withstand bending fatigue up to 100,000 times.

The insulator of commercially available coaxial cables is de facto two options of polyethylene and fluoropolymer. Polyethylene has a good dielectric constant and dissipation factor, but has a temperature rating of about 75°C and does not meet the soldering temperature requirement. Therefore, general coaxial cables using polyethylene cannot be used. Other resin materials are also considered difficult to substitute due to the fact that the cable industry has not adopted them for insulator.
For coaxial and single core cable jackets, polyethylene, for example, has good sliding properties although inferior to fluoropolymer, but it cannot be used because it does not meet the soldering temperature requirements. The jacket must also be flexible when bent. PEEK, for example, satisfies the heat resistance requirement, but cannot be used because of its flexibility and sliding properties.

◆ **Cables in XR and CT**

Radiological equipment such as radiography equipment, CT tomography equipment, and bone densitometry equipment generate X-rays at up to 150 kV. Such high voltage is supplied to the X-ray tube. Electric wires are used to supply high voltages to the X-ray tube, but the wire coating materials that can withstand high voltages are Fluoropolymer is used.
To obtain these characteristics, PFAS (PFA, PTFE) is now essential.

Figure 1.7.9. Example of Radiologocal medical devices

A high voltage generator is used to generate high voltages. In addition to voltage resistance, the wires used in the insulating oil inside the high-voltage generator must have a dielectric constant close to that of the insulating oil for oil resistance and electric field mitigation. For this reason, fluoropolymer is used for the coating of the wires.

Technical Explanation of Non-Substitutability, Pictorial photographic data, information on reference websites, etc. are shown below.

Required Electrical Characteristics
- Dielectric breakdown voltage: 19kV/mm
- Dielectric constant: 2.1 (dielectric constant close to that of insulating oil is required for electric field mitigation)
- Alternative material: silicone rubber
- A dielectric constant of 3.0 or higher makes electrolytic mitigation impossible.

◆ **Surgical power cord**

Figure 1.7.10.

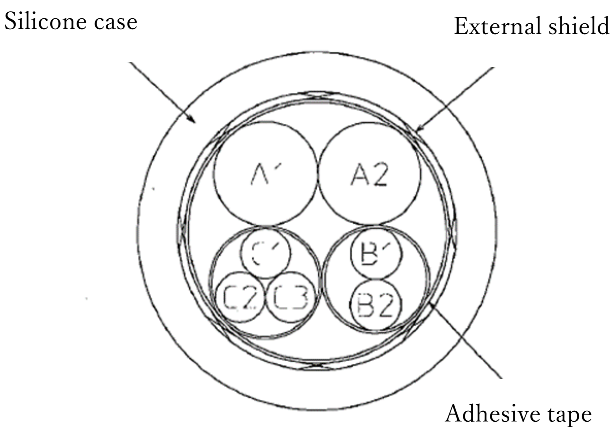

Figure 1.7.11.

The surgical treatment tool shown in the above figure11 has a structure in which the tip of the treatment part can be rotate. The power supply cord twists according to the rotation of the treatment part. Since the resistance and hardness of the rotation of the tip treatment tool due to this twist greatly hinder the operation of the surgeon, it is essential to maintain the flexibility of the cord in surgical treatment tools especially which need delicate operation. It is necessary to maintain electric insulation between each bundled cord, but the flexibility is not maintained when

it becomes thicker. So it is essential that each cord is covered with PFA.
In addition, since surgical devices conduct high-frequency currents, they are affected by the capacitance between each cord. In addition to suppressing changes in capacitance due to changes in the position of the cord internally, the suppression tape for regulating the position of each cord must have flexibility with the function of preventing the increase of capacitance between cords by autoclave, which is a sterilization process, and it is essential to be EPTFE.

- **RF- generators electrical insulation of patient treatment circuit to mains and other electrical circuits**

Figure 1.7.12.

RF- generators electrical insulation of patient treatment circuit to mains and other electrical circuits [RF = radio frequency current]
RF- generators used in the transformer for wire insulation so it is inside the generators . It is used in wire and tubes.Electric insulating and non-adhesion are required. All electrical tests according to IEC 60601-2-2 have to be repeated. It is a high risk that leakage current limits cannot be kept PI and PEEK is not flexible enough. PET chemical resistance is to low, not sufficient heat resistance.
US(Ultra Sonic)- generators also used it.

6. Sealing materials

Parts description

- Packings, gaskets, and O-rings

Packings and gaskets exist to connect and seal by placing/placing them between parts. As an example, they are used in piping and pipe connections. Gases and liquids that pass through pipes leak out through the smallest gaps, and packing gaskets exist to prevent this. Packing in the narrow sense is used for power system parts, and those used for non-moving parts are called

gaskets. Various innovations have been made in molding and realizing functions, such as spiral gaskets made of alternating layers of thin metal strips and PTFE sheets, and wrapped gaskets made of 0.4~0.8 mm hot PTFE, covering gaskets of metal or other materials.
Those with a circular/round cross section are called O-rings.
In addition to PTFE, fluoropolymer rubbers such as FKM and FFKM are also used for this application.

Figure 1.8.1. Packings, gaskets, O-rings

➢ Bearings

A bearing reduces friction between two parts to make movement smoother. Bearings are classified into radial bearings, thrust bearings, and linear bearings, depending on whether rotational or linear motion is involved. A bush is also a type of bearing.
Fluoropolymer bearings such as PTFE have a low coefficient of friction and can maintain a constant torque within various tolerances, while minimizing rattling and noise. In particular, PTFE must be used for bearings near chemical fluids such as acids, alkalis, organic solvents, and ozone, and for food contact applications, where oil is not preferred.

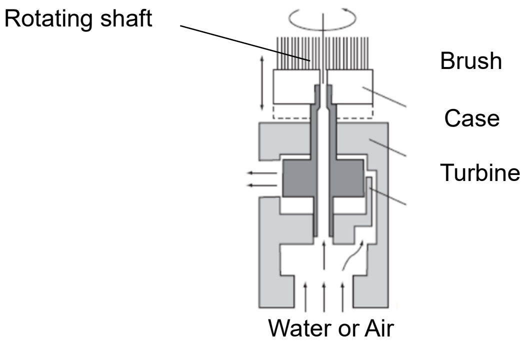

Figure 1.8.2. Bearing used for the rotating shaft sliding part of the sensor cleaning brush

➢ Sealing tape

Sealing tape, made of PTFE material, is an adhesive tape used to secure parts within equipment. It is employed to fasten parts that could pose safety risks if dislodged, as well as to seal mounting parts. Additionally, the tape serves as a filler to address gaps in the joints or connections of pipes for flowing liquids or gases, such as water pipes, air pipes, and hydraulic pipes. Notably, the tape can establish liquid- or gas-tight connections with tapered pipe threads by directly filling the voids between the threads.

Figure 1.8.3.

The functions of sealing materials of PFAS and alternatives

Functions of PFAS Required by Sealing Materials and the Feasibility of Alternatives to PFAS

- Required Functions for Sealing Materials

  Liquids and gases flowing in pipes, or near parts, often consist of strong acids, alkalis, or organic solvents. Therefore, the sealing materials used must be resistant to these chemicals. Fluoropolymer is highly resistant to such chemicals, and additionally, it is ozone-resistant, making it an ideal choice when ozone is present in the piping.

  If the liquid or gas in the piping, or the equipment itself, operates at high temperatures, PTFE or PFA are good options due to their high heat resistance of up to 260°C, a limit higher than other resins. FFKM and FKM rubbers also exhibit high heat resistance, withstanding temperatures up to 250-300°C.

  For applications where sealing materials, such as gaskets, are used on sliding surfaces, where lubricating oil is unsuitable (particularly in contact with food), or where play and noise must be avoided, sealing materials must also possess low friction and self lubrication properties.

  In the restriction report on seal tape, paste-like sealing materials are mentioned as alternative materials. However, if these sealing materials contain hydrocarbon substances, reactive functional groups may decompose. This could pose a risk of contamination in the surrounding area due to the produced decomposition products. For sealing tape used for equipment operating in clean environments, where such contamination is unacceptable, paste-like sealing materials cannot be used as alternatives.

  As a sealing material that combines outstanding chemical resistance, ozone resistance, heat resistance, water and oil repellency, low friction, self-lubrication, and cleanliness, there is no substitute for fluoropolymers. The substitution of fluoropolymers with other materials poses a significant challenge. Non fluorine elastomers might be considered as potential replacements for fluorine rubbers like FKM rubber. However, their heat resistance, low friction, and chemical resistance do not measure up to those of fluorine-rubbers like FKM rubber. Therefore, substituting fluorine -rubbers with non fluorine elastomers is unfeasible.

Examples of the products which uses sealing materials

◆ **Endoscope reprocessor**

The endoscope reprocessors use a variety of chemical solutions such as acids, alkalis, and alcohols to clean and disinfect the endoscopes after use. Some of these solutions may cause health hazards such as chemical burns if they come into direct contact with the human body, and sealing materials in the endoscope reprocessor are required to have chemical resistance to withstand these chemical solutions and prevent leakage.

Therefore, fluoropolymers such as PTFE, FKM, FFKM, and FEPM, which have high chemical resistance to various chemical solutions, are used for sealing materials such as packing, gaskets, O-ring and sealing tape.

Other substances such as EPDM and silicone are not sufficiently resistant to these solutions, especially the peracetic acid used for endoscopes disinfection, because these substances deteriorate in a short period of time. Therefore, it is impossible to substitute other substances.

Endoscope

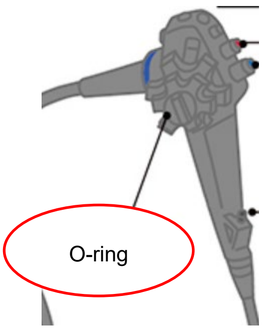

Figure 1.8.4.

A medical device that is inserted into the body through the oral cavity to observe and treat the inside of a lumen. FKM is necessary because the O-ring provided in the sliding part must have chemical resistance and low friction. Chemical resistance is a property necessary for sterilization, disinfection, and cleaning after use to prevent infection. As a sterilization method, there is a method using gas such as EOG or hydrogen peroxide, and the sterilization gas penetrates the interior of the product, so chemical resistance is a necessary characteristic even for internal parts.

The sterilization methods that can be used are limited depending on the region, and it is not enough for a product to be compatible with just one, but it is necessary to have resistance to all sterilization methods. There is no material with chemical resistance equivalent to that of FKM and low friction.

◆ **Computed Radiography (CR)**

CR generates an X-ray image by converting the X-ray information recorded on an imaging plate (IP), a type of X-ray detector used in X-ray photography, into an electrical signal by exciting it with a laser beam.
PTFE is used for the sliding bearings in IP transport unit inside CR.

The durable life of a CR is about 6 years. In order to achieve this, it must be durable enough to withstand 64 million times of IP conveyance (calculated from the assumed frequency of use of CR). In order to achieve this durability, the sliding and wear resistance of PTFE are essential, and there is no material that has the same sliding and wear resistance as PTFE.

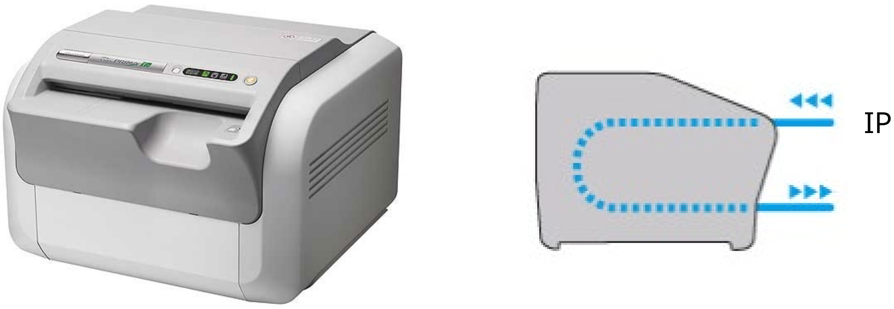

Figure 1.8.5. Computed Radiography

Figure 1.8.6. sliding bearing

7. Valves

Valves are general for equipment with a movable mechanism that can open and close flow paths in order to go through, stop, and control the flow of fluids. They are used in a wide variety of products, from relatively small devices with flow paths and valves to large-scale manufacturing processes and chemical plants. There are many types of valves. Some valves, which are often incorporated in medical device, are discussed. They are not exhaustive.

The functions and alternatives which valves require:
The chemical resistance against acids, alkalis, organic solvents oils, and ozone, which flows through valves, is essentially required. Valves, which opens and close frequently required the property of low friction, repellency from water and oils, non-adhesion. Any failure of valves can cause serious accidents. therefore, the durability of fluoropolymer resin is required for valves PTFE and other fluoropolymer resins are frequently used. Fluoropolymer resins, such as, PTFE are the only materials that can simultaneously provide and express multiple functions required for the proper functioning of valves.

- Solenoid valve

A solenoid valve is electromehanically operated. One of the operations is to open and close a valve using the principle that when an electric current is applied to an electromagnet (solenoid), an iron piece called a plunger is attracted and released when the electric current is cut off. Diaphragms divide into a valve compartment that opens and closes flow paths and a functioning compartment that drives. Fluoropolymer resins, such as, PTFE, FKM, FFKM, and FEPM, are frequently used for flow paths, diaphragms, and sealing materials in solenoid valves. Solenoid valves have wide variety of types, such as, liner action, pilot operated, the combination of liner action and pilot operated.

- Ball valves

A ball valve opens and closes a flow path by rotating a hollow ball. In automatic valves, an electric motor is used to rotate the ball. A large cross-sectional area of the flow path can be obtained, and the resistance of the path can be kept low. Fluoropolymer resins, such as, PTFE, are frequently used

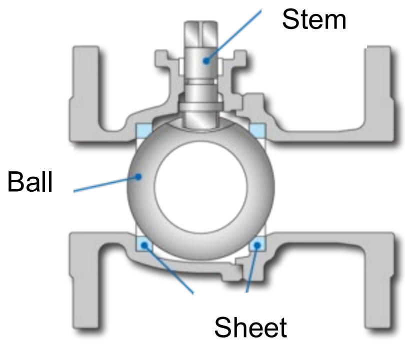

Figure 1.9.1.

- Check valve

A check valve is installed on gas or liquid piping where the fluid back pressure closes the valve plug to prevent reverse flow. A check valve is called as non-return valve, reflux valve, retention valve, foot valve, or one-way valve There are disc check valves that blocks backflow by closing the O-ring valve with a disc and duckbill check valves that uses a valve plug shaped like a duck's beak. Fluorinated materials such as PTFE, FKM, FFKM and FEPM are used for the valve plug and the sealing materials of the housing.

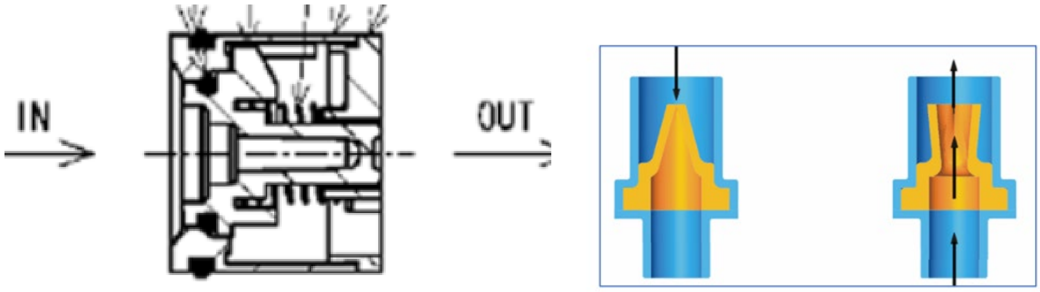

Figure 1.9.2.

- Relief valves/safety valves

A relief valve is a valve that automatically releases pressure when excessive pressure occurs in the pipes. A spring keeps the valve plug such as O-rings or diaphragms closed, and it opens (released) when a pressure exceeding the spring force occurs.

Fluorinated materials such as PTFE, FKM, FFKM and FEPM are used for the valve plug and the sealing materials of the housing.

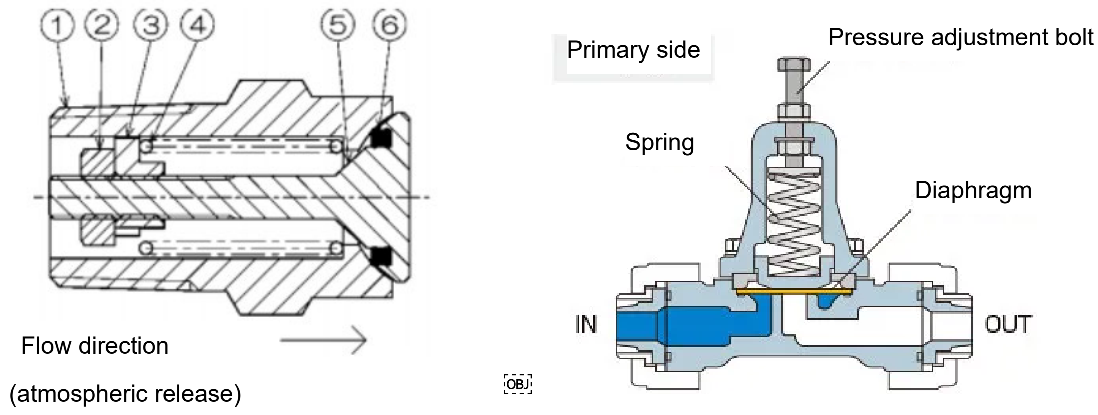

Figure 1.9.3.

Examples of the products which incorporates valves

◆ **Endoscope reprocessor**

The endoscope reprocessors use a variety of chemical solutions such as acids, alkalis, and alcohols to clean and disinfect the endoscopes after use.

Various valves such as solenoid valves, ball valves, check valves, and relief valves are used to switch the solutions and control the flow. If the performance of the valve is degraded or broken, the cleaning and disinfection of the endoscope may be inadequate, leading to cross-infection. Therefore, fluoropolymers such as PTFE, FKM, FFKM, and FEPM, which have high chemical resistance to various chemical solutions, are used for the valve discs, diaphragms, and sealing materials between housings in each valve.

Other substances such as EPDM and silicone are not sufficiently resistant to these solutions, especially the peracetic acid used for endoscopes disinfection, because these substances deteriorate in a short period of time. Therefore, it is impossible to substitute other substances.

8. Pumps

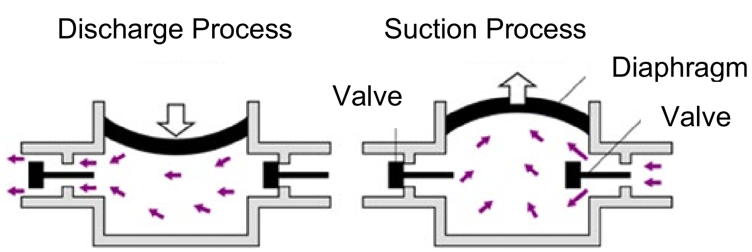

Figure 1.10.1. Explanation on Pumps [1]

[1] https://www.monotaro.com/note/cocomite/525/

A pump is a device that transfers, pumps, and stirs liquids and gases under the action of pressure. It is divided into two types according to the difference in structure: non-positive displacement pumps and positive displacement pumps. Non-positive displacement pumps are pumps that impart energy to liquids by rotating impellers, and include centrifugal pumps, propeller pumps, and viscous pumps. A positive displacement pump is a pump that pressurizes and energizes a liquid that is within a certain volume, and there are plunger pumps, diaphragm pumps, gear pumps, etc. In pumps, fluorine rubber such as FKM, FFKM, and FEPM is used for the sealing members and diaphragms of the housing. PTFE is used for the impeller bearings.

PFAS functions which pumps require and alternatives
Pumps used to transfer fluids such as acids, alkalis, organic solvents, oils, and ozone require high chemical resistance for each member in contact with the fluid. Especially in the case of diaphragms, durability that can withstand repeated bending are also required. Fluorine materials such as FKM, FFKM, and FEPM are used as materials to satisfy these requirements, and it is difficult to replace them with other materials.
In the case of bearings, low friction, self-lubrication, and wear resistance are also required. Fluorine materials such as PTFE are used as materials to satisfy these requirements, and it is difficult to replace them with other materials.

Examples of the products which incorporate pumps

- **Endoscope reprocessor**

The endoscope reprocessors use a variety of chemical solutions such as acids, alkalis, and alcohols to clean and disinfect the endoscopes after use.
And the endoscope reprocessors use internal pumps to deliver these solutions to the outer surfaces and channels of the endoscope.If the performance of the pump deteriorates or breaks down, the cleaning and disinfection of the endoscope may be insufficient, leading to cross-infection. Therefore, fluoropolymers such as PTFE, FKM, FFKM, and FEPM, which have high chemical resistance to various chemical solutions, are used for sealing materials, diaphragms, and bearings in these pumps.
Other substances such as EPDM, silicone and POM don’t have sufficient chemical resistance to these solutions, especially to the peracetic acid solution which used to disinfect endoscopes, because these substances deteriorate in a short period of time. Therefore, it is impossible to substitute other substances.

9. Heat medium

Examples of medical devices with heat medium

MR: A refrigerator is built into the system to maintain superconducting conditions
Biochemistry analyzers: Cooling is required to keep reagents in a low-temperature environment for analytical work.
Medical equipment: Localized cooling is necessary to avoid overheating and equipment malfunction or system shutdown due to prolonged operation.

Refrigerators are used for the units require temperature control, and pretreatment for measurement and analysis. Fluorinated gases are the only materials that can simultaneously provide and express multiple functions required for the proper functioning of refrigerators, such as, thermodynamic efficiency, surface tension, electrical insulation, inactivity, heat conductivity, and a wide range of operating temperature.
HFCs as F-gas will be restricted by the EU F-gas regulation and international treaties. HFCs will be replaced by organic fluorine compounds that their GWP are smaller than carbon dioxide. In that case, the substituted organic fluorine compounds (GWP>1) will be further substituted.
A succession of substitutions in a short period shortens the lifetime of specialist equipment, which is originally long-life. Refrigerators, compressors, centrifuges are used as units of specialist equipment, the derogation as spare parts should be considered. Specialist equipment cannot be repaired, it will be discarded and its lifetime will be shortened.
Refrigerants must not leak from the unit, the units that uses refrigerants such as refrigerators, compressors, and centrifuges requires the sealing materials mentioned in this document.
5(f), (g), and (h) of proposal wordings are written in Annex A of the restriction report. Specialist equipment with a long Lifetime cannot be sufficient grace periods. The grace periods should be examined.

10. Flat panel detector for digital radiography

When performing X-ray photography, the DR panel (GOS type) uses TFT to receive GOS scintillator emitted light proportional to the radiation dose and generates an X-ray diagnostic image. A GOS scintillator is used in the X-ray sensor of the DR panel. GOS scintillators are based on polyethylene terephthalate (PET) material, which has excellent flatness and flexibility, and are coated with a conductive layer and GOS phosphor (Gd_2O_2S:Tb) dispersed in a polymer.

The role of the conductive layer is to prevent image defects due to discharge. If there is a defective image due to discharge during X-ray photography, there is a risk of misdiagnosis. Uniform application of the conductive layer is essential to obtain a defect-free image. In order to improve coating performance, excellent wettability due to the low surface tension and excellent uniform coating properties (leveling properties) of the fluoropolymer due to high surface viscosity are essential.

11. Photographic imaging film for medical purpose

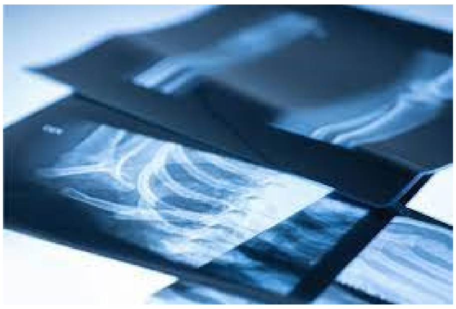

Figure 1.1.1.

The photographic films are still used for medical purposes, i.e., X-ray photography.
The photographic films for medical purposes are divided into two groups: a) for direct X-ray exposure, and b) for digitally outputting captured images.

PFAS is used as a surfactant for the photographic films and provides critical anti-electrostatic properties.

As our previous studies, it was found that fluorine-surfactants with short carbon chains do not show sufficient performance even for the molecules with fluorine atoms. Since chemical stability in the process of neutralizing and deactivating alkaline developing process was also required, designing a materials for photosensitive materials was quite difficult. There is a high possibility that general materials that have been proposed as alternatives in the world could not satisfy the required performance. Longer R&D will be required to design and find alternatives.
Since the restriction proposal on PFHxA was released in December 2019, we have conducted the feasibility study to find alternatives. However, we have not yet found alternative materials besides PFAS. We are not sure whether any non-PFAS alternative materials can be found in the future.
In our experience on the case of switching from PFOS/PFOA in the past, it took a lot of resources and approximately 10 years to find the alternative, prototyping, and develop to the commercial products. We will require extensive lead time extending beyond the 2030 deadline to redesign and revalidate the materials, equipment and production processes.

12. Coating applications for medical devices other than Metered Dose Infalers

Part Description

A surface treatment in which the surface or inner surface of a base material is covered with a fluoropolymer is called a coating or lining. A relatively thick covering is often referred to as a lining, while a thin covering is often referred to as a coating. There are various methods such as molding, bonding a sheet to the base material, bonding powder, or covering with a liquid. Fluoropolymers used include PTFE, PFA, PCTFE, FEP, and ETFE.

Metal plating and surface treatment containing fluoropolymer resins are used to adhere to metals. Coatings and linings are applied to parts in contact with fluids. The parts include the inner surface of the piping and parts in contact with the fluid. Coatings may be applied to areas where water repellency to water and oil, low friction, self lubrication, and non-adhesion are desired.

Examples of coating / lining

Piping inner surface

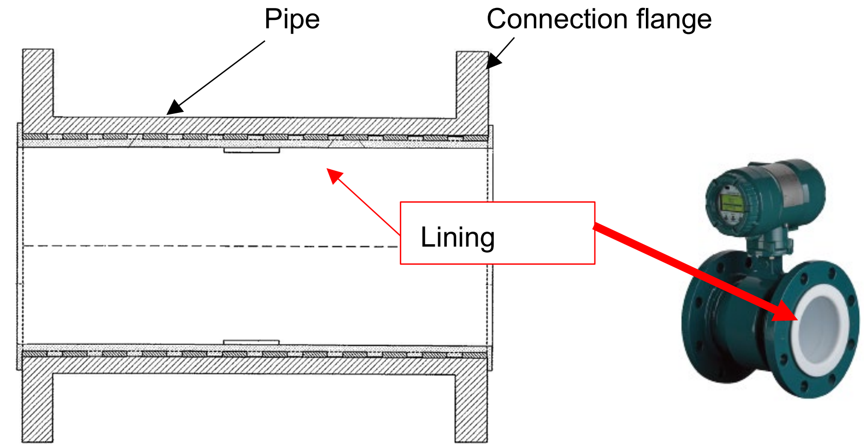

Figure 2.1.1. Coating and lining section of parts (diaphragm) in contact with fluid

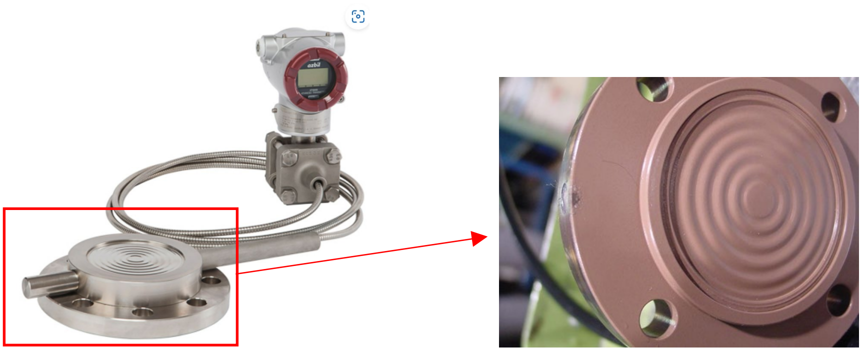

Figure 2.1.2.

PFAS functionality required by coating/lining and possible substitutions

By covering the surface with a fluoropolymer, PFAS gains chemical resistance/cleanliness and mold-releasing properties that the base material does not have. Coatings and linings in contact with fluids can withstand corrosion and operate stably without maintenance for long periods of time (10 years). For example, fluorine coatings and linings on low-hardness rubber materials provide both high flexibility and chemical resistance. When the fluid is a powder, it is difficult for the fluid to adhere to the coating/lining area due to non-adhesion of fluoropolymers.

Optical coating

A water-repellent coating layer which contains Perfluoroalkyl or perfluoropolyether compounds is formed with a thickness of less than tens of nm on the outermost surface of coating layers of the ophthalmic lens surfaces.

The water repellent coating provides superior properties such as water repellency, oil repellency, lubricity, smoothness and chemical resistance to the ophthalmic lens. These properties improve prevention of water discoloration on anti-reflection coatings, scratch resistance, ease of wiping off stains (fingerprints, sebum, etc.) on the lens surface and maintainability. As the results, these high performances enable to extend substantially the product life of lenses.

And the water-repellent coating layer is coated on anti-reflection coating layers to eliminate the ghost and flare phenomena in lens optical systems.

The one of valuable features is having both properties of low refractive index (n<=1.40) and high transparency of the coating layer which composed of perfluoroalkyl or perfluoropolyether compounds.

*1 Ghosting/flare: Reflected light generated on the lens surface is repeatedly reflected in complex ways, resulting in the appearance of light images that are not actually there. The higher the reflectivity of the lens surface, the more likely it is to appear.

*2 Anti-reflection coating: A film with a function to reduce reflected light. In ophthalmic lenses, reflection is reduced by alternately layering materials with different refractive indices to utilize light interference.

*3 Low refractive index: Since the lower the refractive index of the film of the top surface layer of an antireflection coating, the greater the effect of reducing reflections from the lens surface, a film material with a lower refractive index is required. The refractive index of general glass is 1.52, and the refractive index of base materials for eyeglass lenses is 1.50~1.90 (including plastic and glass).

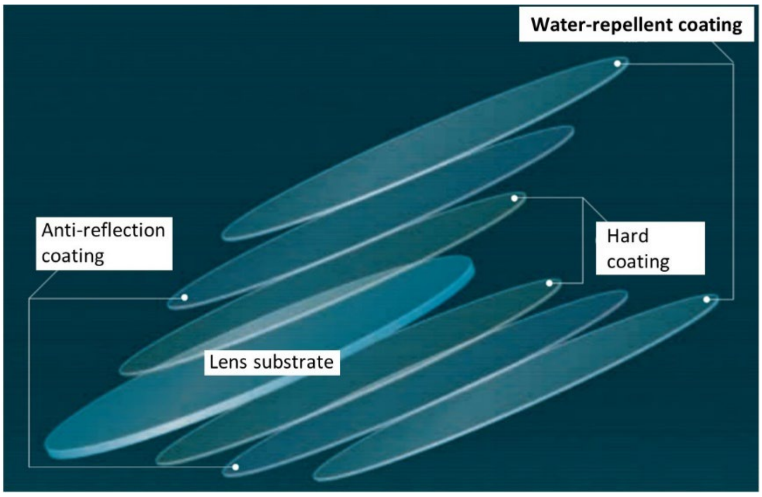

Figure 2.1.3.

Examples of Parts and Equipment Using Lining and Coating

There are a great many devices that coat base materials that come in contact with fluids.

- **Surface coating of the rubber roller (see photo below) that feeds the film in the thermal developing section of the laser imager**

A laser imager is a device that outputs various image data (general radiography, CT, MRI, etc.) taken by an X-ray machine onto DRY film, and doctors use these medical images to diagnose patients. The film with the image data output is fed by rollers. Image data is output by thermal processing (temperature 126°C), so the rollers must be heat resistant. In addition, the material generated during thermal processing adheres to the rollers, causing image defects, feeding failures, and other problems, so releasability is necessary. Therefore, fluoropolymer coated rollers with heat resistance and releasability are required. Defects in the image may result in misdiagnosis or oversight.

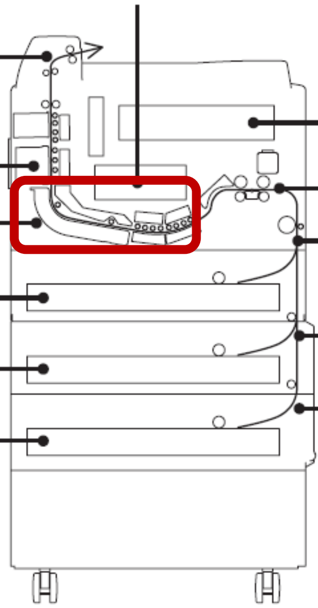

Figure 2.1.4.

◆ **Imaging Plate (IP)**

Imaging plate (IP) is an X-ray image conversion panel used in Computed Radiography (CR). When performing X-ray photography, the radiation that passes through the inspection object is temporarily recorded in the IP in the form of electronic energy distributed over the entire surface in proportion to the dose. The CR reads the X-ray information recorded in the IP and generates an X-ray image. After reading with CR, the X-ray information recorded on the IP is erased by irradiating it with white light, and the IP can be used repeatedly.

The layer structure of the imaging plate (IP) is shown in Figure 2.1.5. A phosphor is coated on a polyethylene terephthalate (PET) base approximately 350μm thick, which has excellent flatness and flexibility.

A transparent "front protective layer" is applied to the surface of the phosphor layer to prevent dirt and scratches from sticking to the phosphor layer.

Fluoropolymer is used for "front protective layer".

The role of the surface protective layer is to prevent dirt and scratches on the IP surface due to repeated transport of the IP within the CR.

Dirt and scratches on the surface of the IP will cause defects in X-ray images, making accurate diagnoses impossible. Therefore, the "front protective layer" on IP surface is required to be antifouling and low-friction.

Fluoropolymer is the only material that satisfies the following property (antifouling, low-friction) and manufacturing suitability for coating.

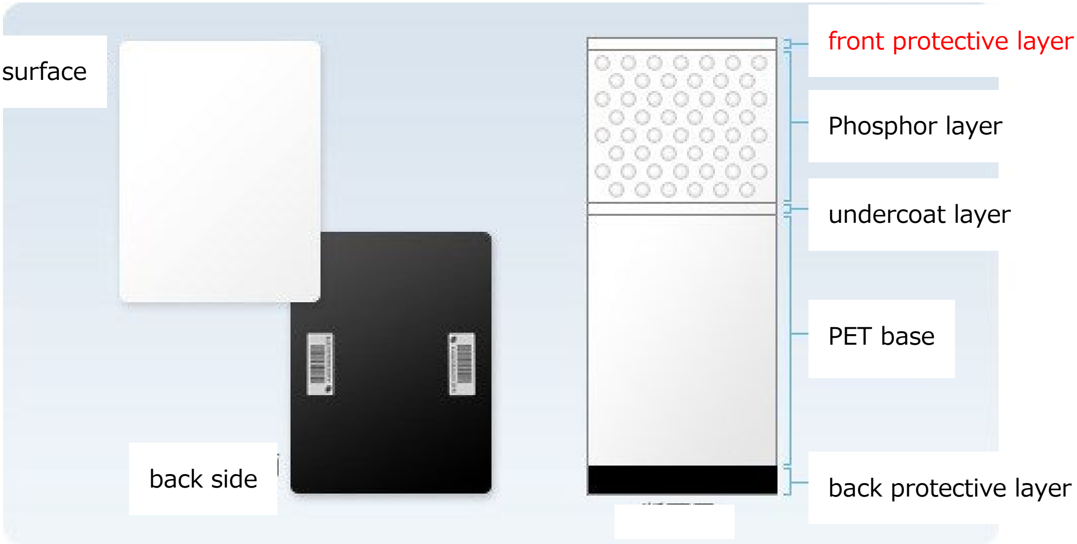

Figure 2.1.5. Imaging Plate

◆ **Computed Radiography (CR)**

PTFE is used to coat the plunger of the solenoid motor and the bobbin pipe in the mechanism that locks the IP cassette that stores IP in CR.

The durable life of CR is about 6 years. In order to achieve this, it must be durable enough to withstand 540,000 times of IP cassette loading from the assumed frequency of use of CR. PTFE's low friction property is essential, and replacing it with nickel plating reduces the durability to about 1/6, reducing the durable life of the equipment from 6 years to 1 year.

Figure 2.1.6. plunger of the solenoid motor and the bobbin pipe

◆ **Endoscope (Coating)**

- **Guidewire**

Figure 2.1.7

A guidewire used to secure the insertion route of the treatment tool when performing procedures for periods that are difficult to approach, such as the pancreatic bile duct. By coating fluoropolymer resin on the surface of a substrate such as metal, it acquires acid resistance, low friction, and non-adhesiveness that cannot be possessed by the base material alone. Biocompatibility and chemical resistance are also important characteristics for use as medical devices.

Chemical resistance is a necessary characteristic for resistance to body fluids such as stomach acid. Low friction is a characteristic necessary for smoothly guiding the treatment tool and inserting the treatment tool into the target site. Non-adhesion is a characteristic necessary for the mucous membrane and the like to not stick when inserted into a living body. There is no coating material other than fluoropolymer resin that satisfies all of these properties. Aliphatic urethane has poor low friction, and the necessary quality cannot be ensured, such as deterioration of treatment performance due to deterioration of insertability.

In addition, there is a method of using a gas such as EOG or hydrogen peroxide as a sterilization method, and since it is exposed to sterile gas, chemical resistance is a necessary characteristic. There is no material that has chemical resistance equivalent to fluoropolymer resin and has low friction.

In addition to these properties, biocompatibility is required. See "Biocompatibility" in the endoscope section of "Plumbing" for details.

- **Endoscope**

A medical device that is inserted into the body from the oral cavity to observe and treat the inside of the lumen.

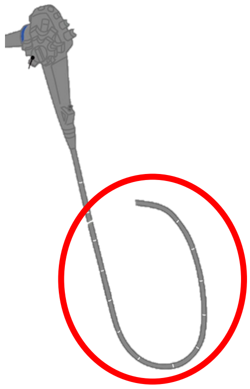

Figure 2.1.8.

By coating fluoropolymer (PTFE etc.) on the surface of base materials such as resin or rubber , chemical resistance, acid resistance, alkali resistance, heat resistance, low friction, and non-adhesiveness that cannot be possessed by the base material alone are acquired. In addition, flexibility is a necessary characteristic for insertion into complex lumens. Chemical resistance, acid and alkali resistance are necessary characteristics for disinfection and cleaning to prevent infection after use. Acid resistance is a characteristic that is also necessary for resistance to body fluids such as stomach acid. Low friction is a characteristic necessary for smooth insertion into the lumen to reduce pain. Heat resistance is a necessary characteristic to perform autoclave sterilization at 136 °C. Non-adhesiveness is a characteristic necessary for the mucous membrane and the like to not stick when inserted into a living body. There is no coating material other than fluoropolymer that satisfies all of these properties. Aliphatic urethane has poor heat resistance, chemical resistance, and low friction, and the quality of sterilization, disinfection, and cleaning decreases, increases the risk of infection, and increases patient pain. For example, in hydrogen peroxide sterilization, which is currently becoming mainstream, it has been confirmed that the coating surface easily deteriorates, and coating peeling occurs in less than half the cases compared to fluorine-based coatings.

As a sterilization method for endoscopes, there is a method of using gases such as EOG and hydrogen peroxide, and since sterile gas also penetrates the inside of the product, chemical resistance is a necessary characteristic even for internal parts. Sterilization methods are limited by the methods that can be used depending on the region, and it is not enough to be able to correspond to any one as a product, but it is necessary to be resistant to all sterilization methods. Furthermore, in metal mechanical parts such as O-rings provided on sliding parts and curved operation wires built-in, in addition to chemical resistance, low friction is required to reduce friction between members, so similarly, coatings containing fluoropolymer such as PTFE and PTFE-Ni plating are required. For example, when the coating of the operation wire is replaced with a non-PFAS member such as boron nitride, carbon, and silicone, which are general coating agents, the frictional resistance between the members increases, and the bending operation of the endoscope requires 2~5 times greater traction force than the fluorinated coating. In addition, there is molybdenum disulfide as another non-PFAS material, but although the lubrication performance is relatively excellent, it is difficult to replace it due to the risk of toxic substances generated in hydrogen peroxide sterilization. As described above, PFAS materials are indispensable because there is no material having chemical resistance equivalent to fluoropolymer and low friction.

In addition to these properties, biocompatibility is required. See "Biocompatibility" in the endoscope section of "Plumbing" for details.

1. Description: Fluoropolymers for use in medical devices Surgical Guidewire Applications

Figure 2.1.9.

2. PFAS substance(s) used: name and CAS number (If known):

PFAS substances, including but not limited,

- Poly(1,1,2,2-tetrafluoroethylene), CAS # 9002-84-0
- Perfluoro-alkoxy polymer, CAS # 26655-00-5
- Copolymer of hexafluoropropylene and tetrafluoroethylene CAS # 25067-11-2

3. It is well known that C-F bonding energy is much higher energy than C-C bonding energy, the unique crystal structure of fluoropolymers. lower surface energy, hydrophobic as well. Due to the unique microstructure structure, and hydrophobic characteristics, fluoropolymers have been used in medical device, such as endoscope with many benefits, including but not limited, i. excellent biocompatibility, biostability, and patient safety history. ii.resistant to chemical, enzyme, and microbiological attacks while eliminating biodegradation issues. iii. low co-efficient of friction allows moving parts to slide with ease, loading device effectively as well. iv. low surface energy or hydrophobic makes it nonstick material combined with its moisture barrier and chemical resistance, makes it a valuable polymer for medical device especially for physician to tackle a surgical procedure with difficulty anatomy conditions.

4. These unique chemical-physical characteristics of fluoropolymers make medical devices

safer to use for patients. However, the unique properties of fluoropolymers make them difficult to replicate with other non-fluoropolymers. For instance, to the best practices in polymer industry, the alternative materials for fluloropolymers are proposed as follows: Chlorotrifluoroethylene (E-CTFE), Ethylene Tetrafluoroethylene (ETFE), and so on and so furth. However, the proposed alternative materials are still under the umbrella of 2021 OECD definition of PFAS “Any substance that contains at least one fully fluorinated methyl (CF3-) or methylene (-CF2-) carbon atom (without any H/Cl/Br/I attached to it)”

- **Coating of surgical instruments**

The tissue gripping part consists of two parts. (Electrode member in contact with tissue and jaw holding electrode member)

Figure 2.1.10.

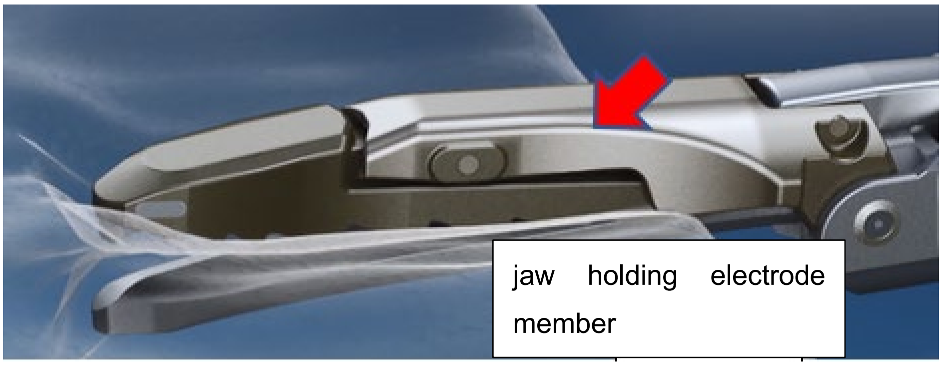

Figure 2.1.11.

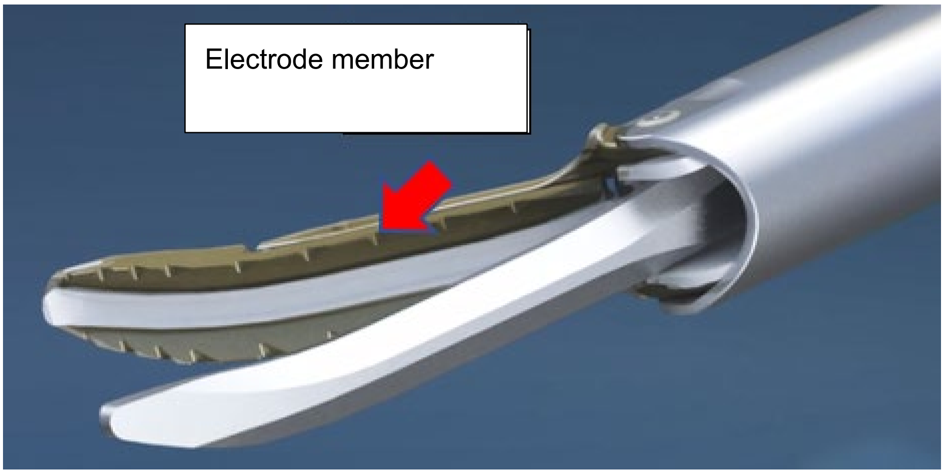

Figure 2.1.12.

Since the tissue gripping surface of the electrode part is a part where burnt tissue tends to stick very easily because of the high-frequency current being passed through it, it is especially essential for gripping surface to be non-sticking. This is because if they don't have the non-stickness, the bleeding that has been stopped will be re-bleeding due to the operation when releasing the adhesion, which is very dangerous. In addition to chemical resistance, heat resistance, electrical insulation, and low friction required for surgical treatment tools, Ni-PTFE plating is essential because mechanical properties that can withstand heat, pressure, and mechanical damage when assembling pads are required at a particularly high level and have electrical conductivity.
In order to prevent unnecessary energy from acting on the living body, the outer surface of the jaw does not conduct electricity (has insulating properties) and becomes hot due to the heat generated during treatment, so it is very important to be non-adhesion like the electrode part. PFA coating is indispensable for biocompatibility, chemical resistance, heat resistance, electrical insulation, and low friction required for surgical treatment tools.
In addition to these properties, biocompatibility is required. See "Biocompatibility" in the endoscope section of "Plumbing" for details.

◆ **Monopolar and bipolar surgical RF instruments with Halar coating**

ECTFE CAS: 25101-45-5

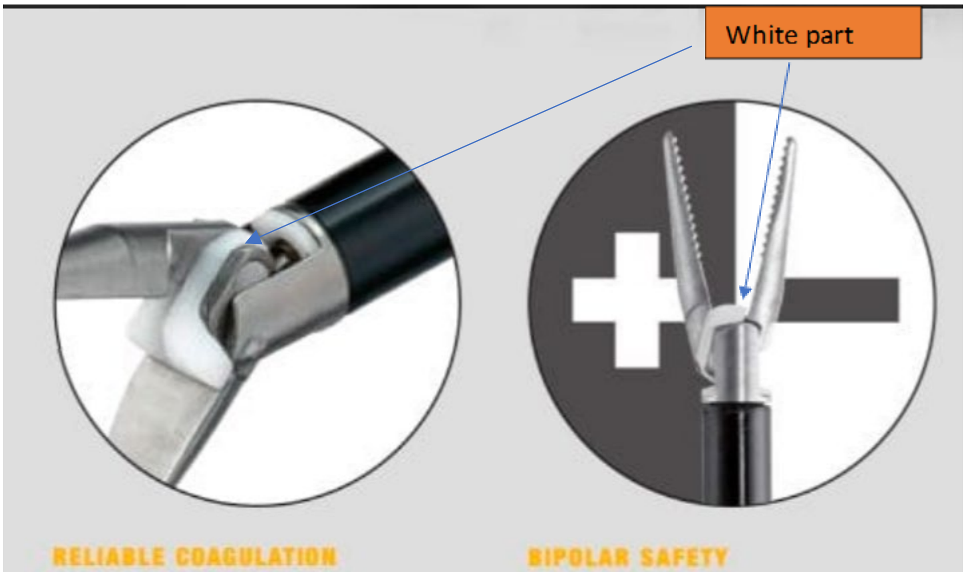

Figure 2.1.13. In below picture PFAS is used for coating for insulation

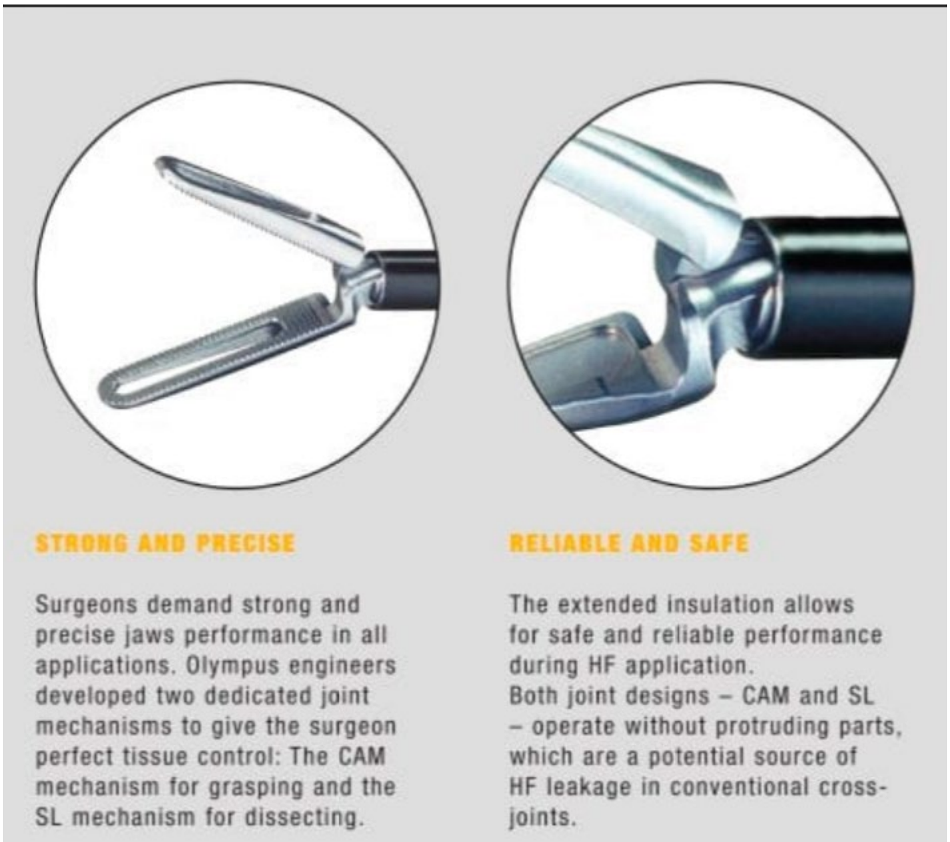

Figure 2.1.14.

Arc resistance to RF- plasma; Cleanability of surfaces; safe dielectric strength at small layer thickness; Non- Slip- Stick effect for movement; low friction for mounting in and on pipes and rods; low friction for moving parts (after cleaning cycles- grease would be removed); high temperature resistance for steam cleaning and disinfection; high chemical resistance for cleaning and disinfection (Peroxide, etc.)

PI is not flexible, has high slip- stick behavior

PEEK will burn down under RF- plasma (arc)

PET chemical resistance is to low, slip- stick behavior, non sufficient thermal stability

All Cleaning disinfection tests have to be requalified, since low surface energy of ECTFE is unmatched it can be estimated that cleaning procedures have to be harsher in the future

◆ **Anti-fog and anti-smudge coating for endoscope tip lenses**

Figure 2.1.15.

Material: Organofluorine compound

It is an organic fluorine compound and has good hydrophilicity and water repellency, so it is highly effective in preventing dirt and water droplet adhesion. Inorganic MgF_2 and SiO_2 are used as lens coatings, but they have insufficient hydrophilicity and repellency from water, and dirt and water droplets stick to the lens during diagnosis, hindering diagnosis.

◆ **Anti-reflective coating material for endoscopes**

Material: 4,5-Difluoro-2,2-bis(trifluoromethyl)-1,3-dioxole,polymer with Tetrafluoroethylene （CAS RNo：37626-13-4）

Since it is a fluorine resin and has good elasticity, it has high chemical resistance and heat resistance even when coated on the WLO resin lens part. Inorganic materials such as MgF2 and SiO2 are used as lens coatings, but their elasticity is insufficient, and in reflow resistance and reusable endoscope resistance tests, coating cracks occur on the WLO resin lens, resulting in defects.

Optical fibers are embedded inside the endoscope to transmit illumination light and images of the inside of the body. As shown in the figure below, an optical fiber consists of a core and cladding made of multi-component glass, with a coating containing PFAS (fluorinated silane coupling agent) on the outside.

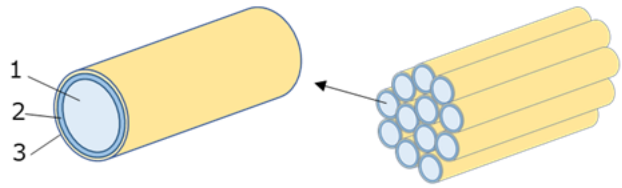

Figure. Optical fiber for endoscope
1_Core, 2_Cladding, 3_PFAS coating

Figure 2.1.16.

A PFAS coating is applied to the fiber surface to ensure chemical resistance to withstand disinfection and sterilization of the endoscope, and sliding to reduce friction between members that occurs during pulling and bending operations. As a substitute, when non-PFAS materials such as boron nitride, carbon, and silicone, which are general lubricants, are used, the frictional resistance between the fibers and other materials increases when the endoscope is repeatedly bent, and more than half of the fibers break. In the worst case, there is a risk that all the fibers break and the illumination light will not reach the body cavity during the use of the endoscope, resulting in a loss of observation, which is extremely dangerous. Molybdenum disulfide is another non-PFAS lubricant, which has relatively good lubrication performance, but it is difficult to replace molybdenum disulfide because of the risk of generating toxic substances in hydrogen peroxide sterilization, which is now becoming mainstream.

◆ **Medical Fiber Optics**

1. Fluoropolymers used in medical optical fibers for medical devices

Applications

Figure 2.1.17.

2. PFAS substance(s) used: name and CAS number (If known):
PFAS substances, including but not limited,
Poly(1,1,2,2-tetrafluoroethylene), CAS # 9002-84-0
Perfluoro-alkoxy polymer, CAS # 26655-00-5
Copolymer of hexafluoropropylene and tetrafluoroethylene CAS # 25067-11-2
Poly(ethene-co-tetrafluoroethene CAS # 25038-71-5
…

3. It is well known that C-F bonding energy is much higher energy than C-C bonding energy, the unique crystal structure of fluoropolymers, lower surface energy, hydrophobic as well. Due to the unique microstructure structure, fluoropolymers have been used in medical device, such as endoscope with many benefits, including but not limited, i. excellent biocompatibility, biostability, and patient safety history. ii.resistant to chemical, enzyme, and microbiological attacks while eliminating biodegradation issues. iii. low co-efficient of friction allows moving parts to slide with ease, loading device effectively as well. iv. low refractive index (RI), 1.3 - 1.4, makes it valuable low refractive index polymer for optical fiber application used in medical device, in which cladding materials have to be lower refractive index than core materials in order to meet total internal reflection specification through Snell's law.

4. These unique chemical-physical characteristics of fluoropolymers make medical devices safer to use for patients. However, the unique properties of fluoropolymers make them difficult to replicate with other non-fluoropolymers. For instance, to the best practices in polymer industry, the alternative materials of fluloropolymers for Polymer Optical Fiber (POF) applications are proposed as follows: Chlorotrifluoroethylene (E-CTFE), Ethylene Tetrafluoroethylene (ETFE), and so on and so furth. However, the proposed alternative materials are still under the umbrella of 2021 OECD definition of PFAS “Any substance that contains at least one fully fluorinated methyl (CF3-) or methylene (-CF2-) carbon atom (without any H/Cl/Br/I attached to it)” Silicone rubber, RI about 1.4 at 819 nm, could be proposed as an alternative substances for limited POF applications but POF need another jacket layer with lower RI materials such as fluoropolymers beyond its limitation mechanical behavior for medical optical fiber applications.

13. Ophthalmic lenses

Ophthalmic lenses are daily exposed to sunlight, rain, sweat, and washed with detergents. So, high level repellency from water and oil are required for the coating of ophthalmic lenses. PFAS-based coatings are widely used because of their excellent weatherability, low friction, and repellency from water and oil. The water-repellent coatings have been developed since the 1980s, but it is still very difficult to achieve the target performances with non-fluorine compounds. Even after more than 30 years effort, no coating without PFAS, which can pass abrasion resistance, chemical resistance, and weather resistance tests assuming everyday use, has been developed yet.

As the proposal alternatives, silicone-based water repellents are representative material, though they can achieve fluorine-based equivalents in terms of contact angle to water, they have not been able to achieve fluorine-based equivalents in terms of contact angle to oil, chemical resistance, and low refractive index.

＜Test results＞
Performance comparison of fluorine-based perfluorinated polyether water-repellent coating and silicone-based polydimethylsiloxane water-repellent coating

		Perfluorinated polyether	Polydimethylsiloxane
Contact angle	To water （H_2O）	108°	104°
	To oil (Oleic acid $C_{18}H_{34}O_2$）	80°	52°
Scratch resistance	Steel wool load 500g 50 round-trip	Good	Bad
Chemical resistance	After 6hr dipping in alkali（NaOH aq. pH:11）	Good	Bad
	After 6hr dipping in acid（HNO_3 aq. pH:1）	Good	Bad

Table 2.2.1.

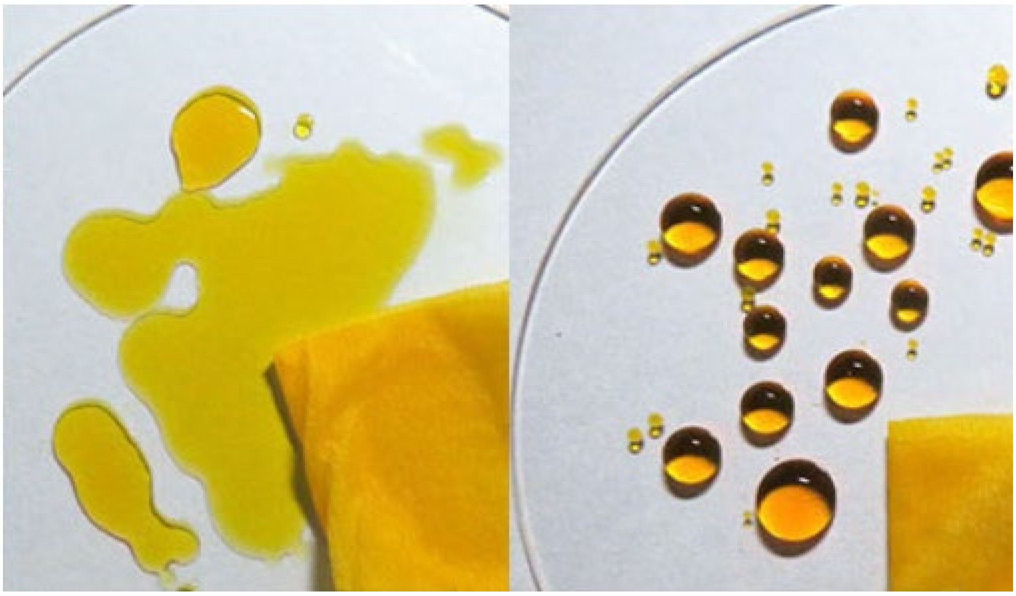
Water repellent effect by coating



Without coating With Coating

Figure 2.2.1. Difference among lens with coating and without coating [2]

[2] Cannon optron https://optron.canon/ja/evaporation/pickup01.html accessed on 31 May 2023.

Period required for replacement: About 1.5 to 2 years, if a non-fluorine material with PFAS-equivalent performance is produced.
Volume of PFAS to be placed on the EU market : car camera 0.32μg/year
Amount of PFAS entering in the EU as water-repellent coating materials on ophthalmic lenses

The amount of PFAS entering the EU as water-repellent coatings on ophthalmic lenses is estimated to be 300 kg/year*1. The amount of PFAS entering the EU through water coating*2 is much smaller (1 ppm to 2 ppm) than the total amount of PFAS entering the EU through all applications (140,000 to 310,000 ton/year).

<Explanation for estimating the amount of PFAS entering the EU as water-repellent coating materials of ophthalmic lenses>.

The amount of PFAS entered in the EU as ophthalmic lenses was calculated from the product of the annual sales volume of eyeglass lenses in the EU and the amount of PFAS coated as hydrophobic coating film per lens.

1. Hypothesis

・Assume that all vision corrective spectacle lenses sold in the EU have a hydrophobic coating on both sides.

2. Estimate

1) Annual sales volume of eyeglass lenses in the EU
200,000,000 pcs/year (200 million pcs/year) *1,*2
2) Amount of PFAS per lens (both sides) **
1.5 x 10-3 g/pcs
3) Amount of PFAS entering the EU through spectacle lenses
1) × 2) = 300 kg/year
4) Total amount of PFAS entering the EU
140,000 to 310,000 tons/year *3
5) PFAS content ratio by spectacle lens
9.7E-07～2.1E-06 (1ppm～2ppm)

**The net PFAS amount a is the solid content coated as the water-repellent coatings on both sides of the lens, excluding the solvent. Assuming that the total amount a is deposited on the total number of lenses b that are put in. The amount of PFAS per lens is calculated as a/b.

Therefore, The PFASs amount entering in EU countries as water-repellent coating materials for ophthalmic lenses is much smaller than that entered in EU as other industrial application.

14. Membrane used for venting of medical devices

◆ **Endoscope (Electrical Contact Unit)**

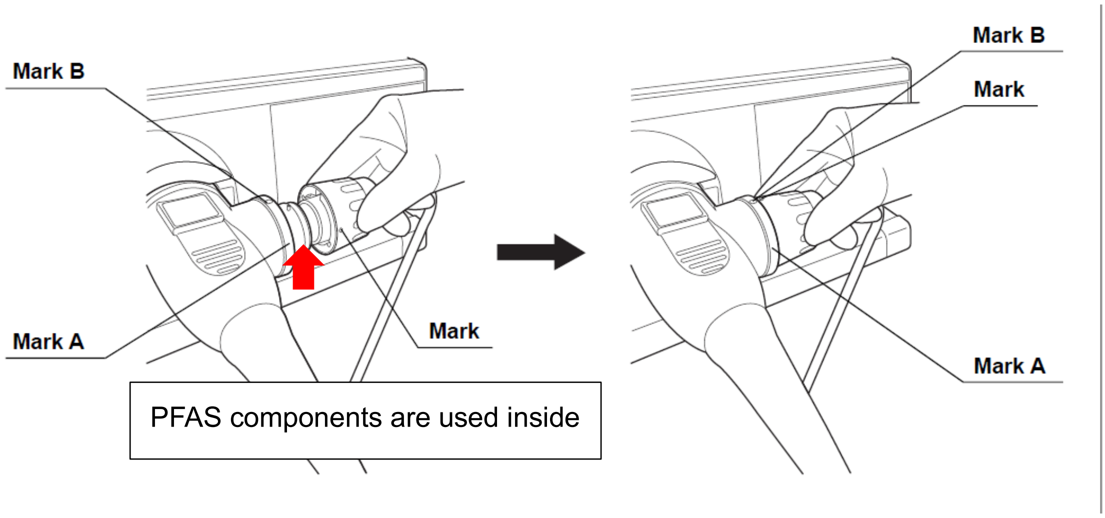

Figure 2.3.1.

In the electrical contact unit of the endoscope, ePTFE sheet is used for parts that require ventilation while waterproofing. When connecting watertight with a plug and receptacle, an air escape path is secured inside. Otherwise, high pressure will occur between the plug and the receptacle, causing poor work or damage. Since the air escape path at this time is connected to the inside of the product, waterproof performance is required as a protection of the electric parts. Therefore, by utilizing the porous structure of ePTFE, it is waterproof and moderately breathable.

There is no substitute material that is resistant to deterioration by chemicals and gases and is both waterproof and breathable.

◆ **Endoscope Reprocessor**

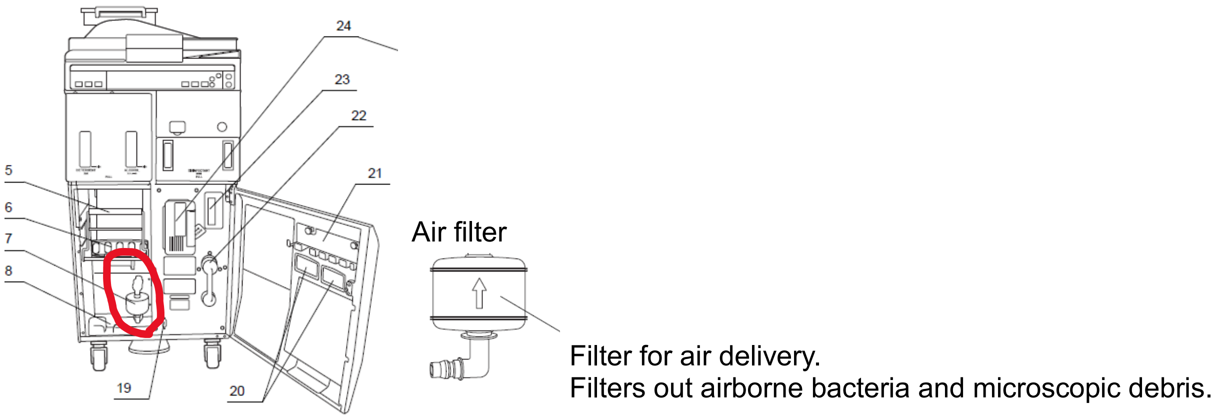

Figure 2.3.2.

After cleaning and disinfection the endoscope, a PTFE membrane filter is used as an air filter for compressed air to remove water from the endoscope channels. The filter must have filter sterilization properties (pore size of 0.2 μm) to prevent recontamination of the endoscope after cleaning and disinfection. It must have biocompatibility so that there is no risk of toxicity if debris remains the endoscope and is used in the patient.

Furthermore, for sterilization of the air filter itself, it is necessary to have heat resistance and chemical resistance that can withstand autoclaves and EtO. And it is necessary to have repellency from water so that moisture in the air that condenses during compression does not adhere to the endoscope. Fluoropolymers such as PTFE are used as materials that satisfy these characteristics. and there are no substitute materials

Figure 2.3.3.

a PTFE filter is used as a ventilation filter for disinfectant bottles such as peracetic acid solutions. Since the peracetic acid disinfectant generates peracetic acid gas over time, the gas needs to be released by the PTFE filter that is moisture-permeable and waterproof with a porous structure to prevent bursting the bottle. In addition, this filter is required to have high chemical resistance to prevent deterioration by the internal disinfectant. PTFE are used as materials that satisfy these characteristics, and there are no substitute materials.

15. Tubes and catheters in medical devices

A clarification of the scope of “tube” in the derogation would be welcomed as this should not be limited to tubes which carry liquid and gases, as the same technical requirements also apply to a broader range of uses.

- Tubes (not heat shrink tubes)
  Tubes are used for convey fluids to the places.

Figure 3.1.1.

- Joints / fittings
  Joints / fittings are components to connect tubes to units and/or tubes to tubes.

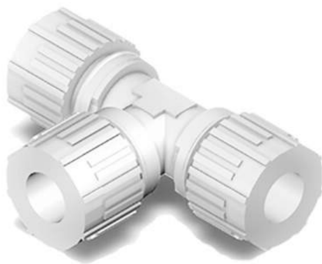

Figure 3.1.2.

- Heat shrink tubing
  By putting a thin and long object to be covered in a tube, heating it, and shrinking the tube,

the object is covered. It prevents parts from coming off or falling off, and strengthens the covered part. Fluoropolymer resin heat-shrink tubing is thin but has high electric insulation performance. PTFE and PFA are used as fluoropolymer resins.

Functions of PFAS required by heat-shrinkable tubing and availability of alternatives
Fluoropolymer resin heat-shrink tubing is thin but has high electric insulation performance. It can be used in applications where there is not enough space for electric insulation, and there is no alternative material available for applications that require tight spaces.

The functions and alternatives which tube and catheter requires:
The material of tube and catheter are determined by the types of fluids flowing through tubes. Fluoropolymers can be used as piping for fluids in the temperature range of -10°C to 200°C (PTFE) and about -40°C to 160°C (PFA), including acids, alkalis, organic solvents, ozone, and oils. Fluoropolymers (PTFE, PFA, PVDF) are the only plumbing materials that can be used when the fluids of flowing the tubes meets one or more of these characteristics.
Fluoropolymer resins are the only materials that can simultaneously provide and express multiple functions required for the proper functioning of chemical resistance/ cleanliness, repellency from water and oil, and heat resistance.

Examples of the products which incorporate "tube"

- **Endoscope**

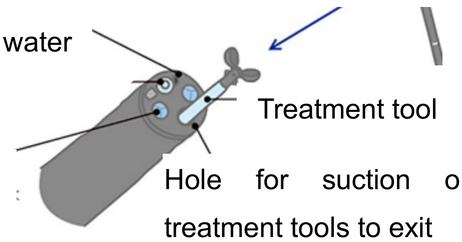

Figure 3.1.3.

A medical device that is inserted into the body from the oral cavity to observe and treat the inside of the lumen. A flow path of an air and water supply for passing water, air, or the like through a tip, a flow path of a forceps for inserting a treatment tool, and a flow path of a suction for sucking a body fluid or the like need to follow a complicated lumen shape.
Among flexible materials, chemical resistance, low friction, heat resistance, and non-adhesion are required, and PTFE and PFA are used.
Flexibility is a property necessary for insertion into complex lumens. Chemical resistance are

necessary characteristics for disinfection and cleaning to prevent infection after use.It is a necessary characteristic for resistance to body fluids such as stomach acid. Low friction is a characteristic necessary for inserting a treatment tool for collecting tissue and performing surgery in the lumen, from the operation part to the tip. Heat resistance is a necessary characteristic to perform autoclave sterilization at 136 °. Non-adhesiveness is a characteristic necessary for mucosa and the like not to stick in the flow path when inserting into a living body or sucking. PE can be mentioned as an alternative material, but it cannot be substituted because it is inferior in chemical resistance and heat resistance, so the quality of sterilization, disinfection, and cleaning is reduced, and the risk of infection increases.

In addition to these properties, biocompatibility is required. Biocompatibility means that the risk of toxicity such as allergic reactions, chronic toxicity, and genotoxicity is small.

Due to the chemical properties of fluorine compounds, the effect on living organisms is small, the purity of the material is high and the possibility of containing impurities is low, and the durability against chemical treatment is excellent and the possibility of unexpected deterioration is low.

When alternative materials other than PFAS, only bench test evaluation cannot adequately evaluate safety, and based on ISO 10993-1, biologically safe such as cytotoxicity, sensitization, irritant or intradermal reaction, systemic toxicity, subchronic toxicity, genotoxicity, implantation, hemocompatibility, etc. are evaluated again.

* Hereafter, the above idea is used for application examples for biometric contact points.

Figure 3.1.4.

In addition, the exteriors that contain these flow paths and other components inside and are inserted into the body also require chemical resistance, low friction, heat resistance, and non-adhesion in a flexible material, and PVDF (polyvinylidene fluoride) is used. The reasons for the need for each characteristic are the same as above.

◆ **Insulating tubes for surgical treatment tools**

In surgical procedures, high-frequency currents are applied to cauterize tissues and prevent bleeding. In order to cauterize only the intended portion, especially in the treatment tool called bipolar, a two-pole electrode is provided in the treatment tool. Therefore, pipes and rod-shaped members (ultrasonic drive members) serve as electrical paths, but heat shrinkable tubes by FEP are indispensable for insulating pipes and rod-shaped members and preventing short circuits in the electrical path between the two poles. In addition, in order to stabilize ultrasonic vibration, a function to attenuate unnecessary vibration is also essential.

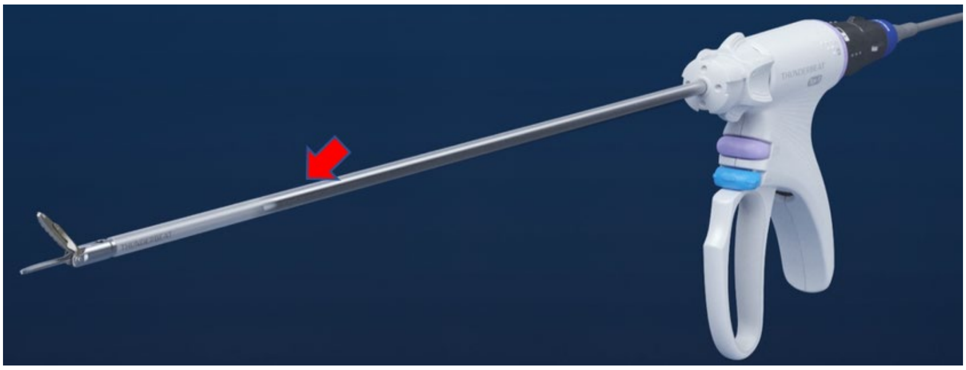

Figure 3.1.5.

This is due to the chemical resistance, heat resistance, electrical insulation, and low friction required for surgical treatment tools. In addition to these properties, biocompatibility is required. See "Biocompatibility" in the endoscope section of "Plumbing" for details.

◆ **Bipolar surgical RF instruments**

PFAS CAS: 30525-89-4

Figure 3.1.6

Arc resistance to RF- plasma; Cleanability of surfaces; safe dielectric strength at small layer thickness; Non- Slip- Stick effect for movement; low friction for moving parts (after cleaning cycles- grease would be removed); heat resistance for steam cleaning and disinfection; high chemical resistance for cleaning and disinfection (Peroxide, etc.)
PI is not flexible, has high slip- stick behavior
PEEK will burn down under RF- plasma (arc)
PET chemical resistance is to low, slip- stick behavior, non sufficient heat resistance
There is no hazard and exposure risk. All materials in contact are controlled via ISO 10993. This product is single used
All Cleaning disinfection tests have to be requalified, since low surface energy of PFA is unmatched it can be estimated that cleaning procedures have to be harsher in the future

- **Endoscopic treatment tool**

Figure 3.1.7.

A medical device for performing endoscopic procedures. In order to insert into the channel of the endoscope inserted into the body, it is necessary to follow the complex shape, and among flexible materials, PTFE and PFA are used because of their acid resistance, low friction, heat resistance, and non-adhesiveness requirements.
Flexibility is a property necessary for insertion into complex lumens. Acid resistance is a necessary characteristic for resistance to body fluids such as stomach acid. Low friction is a characteristic necessary for insertion into the endoscope channel to the distal end. Heat resistance is a necessary property in devices that use high-frequency energy to prevent damage to the device or/and endscopes during treatment. Non-adhesiveness is a characteristic necessary for mucosa and the like not to stick in the flow path when inserted into a living body or sucked.
PE can be mentioned as an alternative material, but since it is inferior at least in low friction, the treatment property is reduced due to the deterioration of insertability, so it cannot be substituted.
In addition to these properties, biocompatibility is required. See "Biocompatibility" in the endoscope section of "Plumbing" for details.

1. Description: Fluoropolymers for use in medical devices Endoscope Applications

2. PFAS substance(s) used: name and CAS number (If known):
PFAS substances including but not limited,
Poly(1,1,2,2-tetrafluoroethylene), CAS # 9002-84-0
Perfluoro-alkoxy polymer, CAS # 26655-00-5
Copolymer of hexafluoropropylene and tetrafluoroethylene CAS # 25067-11-2

3. It is well known that C-F bonding energy is much higher energy than C-C bonding energy, the unique crystal structure of fluoropolymers, lower surface energy, hydrophobic as well. Due to its unique microstructure structure, and repellency from water, fluoropolymers have been used in medical device, such as endoscope with many benefits, including but not limited, 1. excellent biocompatibility, biostability, and patient safety history. 2.resistant to chemical, enzyme, and microbiological attacks while eliminating biodegradation issues. 3. low friction allows moving parts to slide with ease, generating less heat, and undergoing less wear and tear. 4. low surface energy or hydrophobic makes it non-adhesion material combined with its moisture barrier and chemical resistance, makes it a valuable polymer for medical device industry especially for patient safety with reusable endoscope application which involves cleaning and disinfecting the devices so that they can be reused.

4. These unique chemical-physical characteristics of fluoropolymers make medical devices safer to use for patients. However, the unique properties of fluoropolymers make them difficult to replicate with other non-fluoropolymers. For instance, To the best practices in polymer industry, the alternative materials for fluloropolymers are proposed as follows: Chlorotrifluoroethylene (E-CTFE), Ethylene Tetrafluoroethylene (ETFE), and so on and so furth. However, the proposed alternative materials are still under the umbrella of 2021 OECD definition of PFAS “Any substance that contains at least one fully fluorinated methyl (CF3-) or methylene (-CF2-) carbon atom (without any H/Cl/Br/I attached to it)” Silicone rubber could be proposed as an alternative substances for certain applications but not suitable for endoscope application because of its higher on coefficient of friction, especially to tackle a surgical procedure with difficulty anatomy conditions.

◆ **Tube-shaped instruments and parts**

A grace period has been established for the use of Fluoropolymers and fluoroelastmers in catheters and tubes (6c). Catheter-based procedures require tubular components other than catheters itsself, such as Introducer Sheaths. Many of them require surface lubricity, biocompatibility, kink resistance, pushability, etc., similar to catheters, and hence tube-shaped instruments and parts should be included in 6c (Tubes and catheters in medical devices).

For example, ETFE is widely used in Introducer Sheaths, with 2-3 kg consumed annually in Europe. Although the same shape can be made from polyolefin/nylon materials, the risk of medical accidents due to kinking or rupture increases due to the difference in material properties. To avoid kinking and rupture, it is possible to increase the outer diameter (wall thickness) or use other polymers, but this not only makes operation difficult, but also has a negative impact on hemostasis and patient invasiveness, as the wound becomes larger. For the benefit of healthcare professionals and patients, ETFE are necessary.

◆ **Catheters and their manufacturing processes**

Heat shrink tubing, such as PFA, is used in the catheter manufacturing process, and no other polymers have been found to replace it. After placing a shrink tubing over the two different polymer materials coated on the core wire, and then heating them, the two polymers in the lower layer can be crimped and fused together. As a result, high-performance catheters with graded physical properties consisting of two different materials can be manufactured.
Since PFA shrink tubing has excellent heat resistance and easy peel property, it can be fused to the underlying materials each other without melting upon heating, and can be easily peeled off after the heating process.

Shrink tubing made of fluoropolymers used in the catheter manufacturing process should be registered as new application information or included in the scope of 6c tubes and catheters in medical devices.

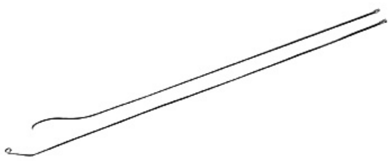

Figure 3.1.8. catheter

◆ **Tube for implantable medical devices**

Description: Fluoropolymers for use in medical devices Implants Applications
ENT –Myringotomy Ventilation Tube Application

Figure 3.1.9.

PFAS substance(s) used: name and CAS number (If known):
PFAS including but not limited,
Poly(1,1,2,2-tetrafluoroethylene), CAS # 9002-84-0
Perfluoro-alkoxy polymer, CAS # 26655-00-5
Copolymer of hexafluoropropylene and tetrafluoroethylene CAS # 25067-11-2
Poly (ethene-co-tetrafluoroethene CAS # 25038-71-5

It is well known that C-F bonding energy is much higher energy than C-C bonding energy, the unique crystal structure of fluoropolymers, low surface energy, hydrophobic as well. Due to its unique microstructure structure, and hydrophobic characteristics, fluoropolymers have been used in medical device, such as implants with many benefits, including but not limited, i. excellent biocompatibility, biostability, and patient safety history. ii.resistant to chemical, enzyme, and microbiological attacks while eliminating biodegradation issues makes it a valuable polymer for some implant applications.

These unique chemical-physical characteristics of fluoropolymers make medical devices safer to use for patients. However, the unique properties of fluoropolymers make them difficult to replicate with other non-fluoropolymers. For example, to the best practices in polymer industry, the alternative materials for fluloropolymers are proposed as follows: Chlorotrifluoroethylene (E-CTFE), Ethylene Tetrafluoroethylene (ETFE), and so on and so furth. However, the proposed alternative materials are still under the umbrella of 2021 OECD definition of PFAS "Any substance that contains at least one fully fluorinated methyl (CF3-) or methylene (-CF2-) carbon atom (without any H/Cl/Br/I attached to it)" Silicone rubber could be proposed as an alternative substances for implants applications but with certain limitation beyond its mechanical properties.

16. Lubricants where the use takes place under harsh conditions or the use is needed for safe functioning and safety of equipment

Lubricating oil is used to control friction and wear of metal contacting parts when machines are combined to rotate, reciprocate, or otherwise operate. In addition to suppressing friction and wear, this oil also suppresses corrosion and frictional heat, and its sealing and cleaning properties allow the machine to operate smoothly.

Lubricating oil formulated with PFAS have the following characteristics

・Low friction: Reduces the adverse effects of friction on the lifetime and performance of components.

・Heat resistance: Resistance to chemical changes even when used in high-temperature environments. Resistance to ignition.

・Weatherability: Excellent oxidation stability and resistance to adverse effects of oxygen. Not decomposed by moisture.

・Chemical resistance: Resistant to chemicals such as acids and alkalis.

・Chemical resistance/cleanliness: Almost no deterioration of rubber and plastic materials.

There is no other lubricant besides fluorinated synthetic lubricants that can satisfy all of the above characteristics.

Lubricants in the products.

◆ **lubricant for endoscope**

In the inside of the driving part, grease mixed with PTFE and graphite fluoride are used to ensure low friction while having chemical resistance and heat resistance. As a sterilization method, there is a method using gases such as EOG and hydrogen peroxide, and since sterile gas also penetrates the inside of the product, chemical resistance is a necessary characteristic even for internal parts. Sterilization methods are limited by the methods that can be used depending on the region, and it is not enough to be able to correspond to any one as a product, but it is necessary to be resistant to all sterilization methods. In grease which does not contain PTFE as a thickener, it cannot be sterilized because of insufficient chemical resistance. In addition, molybdenum disulfide can be mentioned as an alternative to graphite fluoride, but this is also inferior in chemical resistance, so it cannot be sterilized and cannot be substituted.

17. Diagnostic laboratory testing

Piping materials, rubber materials, and sealing materials containing PFAS for high-precision dispensing in automatic clinical immunoassay analyzers and chemistry analyzers

Automatic clinical immunoassay analyzers and automatic clinical chemistry analyzers (hereinafter collectively called, "Automatic Analyzers") are a type of In-vitro Diagnostics (IVD) and Class A in-vitro diagnostic medical device under in-vitro diagnostic device regulation (IVDR). They are devices used to measure components in samples, primarily serum, plasma, and urine collected from human bodies, by producing luminescence or color reaction by mixing these samples with in-vitro diagnostic reagents. The result data are used by physicians to understand the health conditions of patients and may be provided to the patients as the results of medical checkups.

In recent years, Automatic Analyzers are required to operate at a faster speed to quickly produce results, maintain stable operation without stopping to respond to sudden orders, and ensure high accuracy in obtaining correct results. The performance of each function in the Automatic Analyzers, such as dispensing of samples and reagents and cleaning of on-board units to keep the cleanliness of the device, must be steadily maintained. Therefore, the materials including piping materials used for such functions require high chemical stability and mechanical strength.

Example 1: Piping materials for sample and reagent dispensing units

Currently, many Automatic Analyzers adopt pipetting-based dispensing methods, by which samples and in vitro diagnostic reagents are transferred respectively from blood collection tubes and reagent bottles to the cuvettes on the Automatic Analyzer for measurement. For those applications that come in direct contact with the fluids, disposable resin tips are often used for samples, which require contamination avoidance, while metal nozzles, such as those made of SUS (stainless steel), are adopted as reagent probes, which require durability to sustain repeated washing. While these locations are exposed to open air and are typically designed for periodical replacement, the piping that connects the tips and nozzles to the dispensing and aspiration pumps is usually located deep inside the device. Such piping is not easily replaceable, so it must be resistant to aging and external thermal and chemical disturbances. Furthermore, they are expected to possess pressure and bending resistance to accommodate high-speed operations pursued in recent years. The performance of such piping is expected to be maintained, at least, as long as the life of the device. In order to achieve these requirements, PTFE, PFA, and PVDF, which are types of perfluorinated polymers, are commonly adopted.

Consideration of non-PFAS alternative materials for Example 1)

One of the alternatives to PTFE, PFA, and PVDF as piping materials is Poly Ether Ether Ketone (PEEK). PEEK is believed to demonstrate excellent performance in terms of thermal and chemical stability along with pressure resistance. However, it does not have enough bending resistance, making it unsuitable for use with a driving part. PEEK also lacks flexibility, which makes it difficult for use in the joints between the piping and tips as well as the piping and pumps, which require high sealing integrity. To address these limitations, a different type of resin piping must be explored. While it may not be impossible, it would take a long time from the initial elemental study to the realization of the devices.

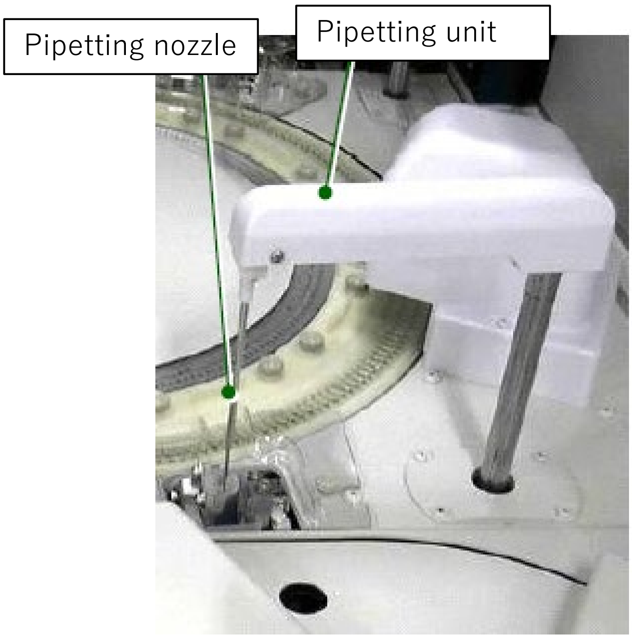

Figure 3.3.1. Example of the pipetting unit on the Automatic Analyzer

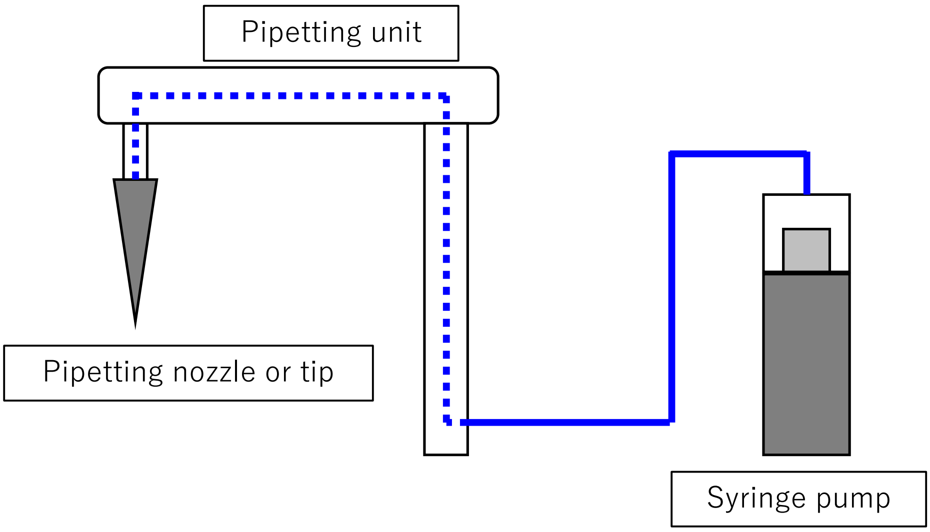

Figure 3.3.2. Schematic diagram of the piping example between the pipetting unit and the pump (The blue lines represent the piping)

The piping must possess high-pressure resistance so that it would not expand or contract under high-speed aspiration and dispensing by syringe pumps while accurately transmitting pressure without rupturing. In addition to flexibility as the piping inside the fast-moving pipetting unit, it must have elasticity as a resin to maintain high sealing integrity at joints with syringe pumps during pressurization and depressurization. Moreover, the material used for piping must be chemically resistant to fluids flowing through the pipe, such as pure water, samples, reagents, and cleaning agents. To fulfill all these requirements, PFAS tubes such as PTFE are currently adopted.

Example 2) Rubber material for solenoid valves and pumps for device cleaning

Currently, many Automatic Analyzers include some kind of components that are repeatedly used by being washed with water and cleaning agents. One of the examples is reaction cuvettes on a clinical chemistry analyzer. The reaction cuvettes are small temporary containers installed on the device. Each sample is dispensed into one of the cuvettes and mixed with reagents before being measured by the spectrophotometer. The cuvette is washed with cleaning agents after each measurement and repeatedly used. Pumps and solenoid valves must be equipped to drain wash water and cleaning agents. In many cases, a type of fluoroelastomer called FKM is used for their valves, diaphragm, and O-rings for sealing. The cleaning agents used for Automatic Analyzers are often strong-alkaline and contain surfactants to effectively clean mainly proteins and lipids present in samples such as serum. It is essential for the material to have excellent chemical resistance to withstand the conditions, making FKM an optimal selection for such applications.

Consideration of non-PFAS alternative materials for Example 2)

One of the materials that can be considered as an alternative to FKM as rubber material for pumps and solenoid valves is EPDM. FKM and EPDM demonstrate similar properties in terms of mechanical strength and chemical resistance under the presence of strong-alkaline fluids. However, EPDM is less resistant to acid fluids and has a risk of being broken when, for example, an acid cleaning agent is used to remove calcium scale deposited inside the Automatic Analyzers. Furthermore, FKM and EPDM have different compatibilities with various surfactants, making it challenging to select rubber material that stays stable with any alkaline, acid fluids and surfactant. The selection of materials must be based on the specific application and the type of fluids that come into contact with them. It is difficult to completely exclude FKM from the use in terms of a wide range of resistance to alkaline and acid fluids as well as many surfactants normally contained in cleaning agents.

Example 3) Thread sealing tape for various piping seals inside the device

Currently, many Automatic Analyzers include some kind of components that are repeatedly used by being washed with water and cleaning agents. One of the examples is reaction cuvettes on the clinical chemistry analyzer. Reaction cuvettes are small temporary containers installed on the device. Each sample is dispensed into one of the cuvettes and mixed with reagents before being measured by the spectrophotometer. The cuvette is washed with cleaning agents after each measurement and repeatedly used. A fluid control system, including pumps and solenoid valves, must be equipped to drain wash water and cleaning agents. PTFT thread sealing tape is used to seal the pipe fitting joints in the fluid control system. The cleaning agents used for Automatic Analyzer are often strong-alkaline and contain surfactants to effectively clean mainly proteins and lipids present in samples such as serum. Therefore, the sealing tape must have high chemical resistance and excellent performance in sealing off highly permeable cleaning agents. Consequently, PTFE thread sealing tape is often adopted for this purpose.

Consideration of a non-PFAS alternative material for Example 3)
Considering the use purpose of PTFE thread sealing tape as a sealing for pipe fitting joints, a possible option would be adhesive, or a method like welding.

However, they share a common drawback, which is the fact that their sealing is semi-permanent fixing. The fact makes them unsuitable for parts that require periodical replacement. Since the pipes in Automatic Analyzers, especially those that use PTFE thread sealing tape and have the cleaning agents running inside, have a chemical mixture of gas and fluid constantly flowing inside, they are always exposed to the risk of damage by fluid friction and need to be replaced when worn. Therefore, semi-permanent fixing is not practical.

When attempting to use an adhesive (including “liquid/paste pipe thread sealants without PFAS are available” mentioned in ”PTFE thread sealing tape” under E.2.13.2.7. Alternatives to fluoropolymers and PFPEs in building/construction mixtures and articles” of “ANNEX XV RESTRICTION REPORT”), the chemical resistance of the adhesive itself needs to be examined. Epoxy-based and silicone-based adhesives, for example, have comparatively good chemical resistance, but most of them are not resistant to strong-alkaline solutions containing surfactants. Therefore, they do not serve the purpose.

Currently, there are few sealing tapes available in the market that are not PTFE and not of semi-permanent fixing. There is a product such as a “high-temperature carbon-based sealing tape”, for example. However, it is not suitable as an alternative because the product is not widely available on the market and contains adhesive, making it inferior in chemical resistance. There are no other viable options at the moment.

Moreover, the “silicone-based thread-seal tapes” mentioned in ”PTFE thread sealing tape” under E.2.13.2.7. Alternatives to fluoropolymers and PFPEs in building/construction mixtures and articles” of “ANNEX XV RESTRICTION REPORT” seem to be referring to a product intended for covering basically the outside of pipe joints or repairing damaged pipes from the outside, such as Self-Fusing Silicone tape HDT2 from 3M Company. They do not share the same use purpose with PTFE thread sealing tape for sealing joints (mostly threaded portions) between a fluid control system and pipe fitting, and therefore they are not suitable as alternatives.

Based on the discussions above, if the restriction is imposed on the use of fluoropolymers and fluoroelastomer, there is a possibility that Automatic Analyzers may disappear from the European market, potentially affecting the provisions of medical service to European citizens.

TRELLEBORG

1 March 2024

Trelleborg Sealing Solutions feedback to the planned New Rules Governing Currently Unavoidable Use Determinations about Products containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837 of the Minnesota Pollution Control Agency (MCPA)

Submission in general:

To begin we would like to thank the Minnesota Pollution Control Agency for the opportunity to contribute comments to the Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837! Trelleborg Sealing Solutions as a downstream user, produces seals and polymer bearings for machines and equipment for an unimaginable segment of the entire society. These segments are both industrial as well as professional.

Fluoropolymers and fluoroelastomers are critical and essential contribution to all of society include:

- **Human and environmental health and safety** e.g.
  - Defense
  - Avoidance of major accidents
  - Chemical industry
  - Nuclear powerplants
  - Avoid catastrophes
- **Supply of** for instance
  - Energy
  - Food,
  - Drinking water
  - Raw materials
- **Healthcare** e.g.
  - Pharmaceuticals
  - Medical devices
- **Minimized energy consumption and prolonged maintenance cycles of a vast range of equipment and installations**

In general, customer requirements determine the nature of the materials used for the seals and bearings we manufacture. In cases of demanding conditions, ranging from very to extremely, of use by our customers fluoropolymers and fluoroelastomers represent the only choice. Fluoroelastomers and fluoropolymers possess unique properties. Properties such as: low coefficient of friction, chemical compatibility, wide temperature range for use (low to high), mechanical properties allowing high surface speeds, practically non-ageing, and compatibility regarding electron and gamma radiation. It is these unique properties that represent absolute prerequisites for many specific segment requirements. It is only when these unique properties are extremely essential, that fluoroelastomers and fluoropolymers are utilized. The high price of fluoroelastomers and fluoropolymers alone ensures that use of these materials is minimized. This fact drastically reduces the use of fluoroelastomers and fluoropolymers as well as human exposure and emissions to the environment. Additionally, the fluoroelastomers and fluoropolymers used in our products, meet OECD-criteria of “polymers of low concern.” They are neither bioavailable, water-soluble, or toxic. In essence, fluoropolymers and fluoroelastomers are safe for their intended uses.

Along with the previously mentioned, fluoropolymers and fluoroelastomers are in general, critical for innovation and for sustainability! Aims of many strategic initiatives of the United States of America like the Carbon Reduction Program, the Chips and Science Act and the Digital Government Strategy are simply impossible without the use of fluoropolymers and fluoroelastomers. For these reasons we seek for a formal time unlimited determination of Currently Unavoidable Uses (CUU) for all fluoropolymers and fluoroelastomers according to Minnesota Session Laws - 2023, Regular Session Sec. 21. [116.943] Products containing PFAS. This time unlimited determination must include all monomers and processing aids needed for manufacturing of all fluoroelastomers and fluoropolymers. The actions as mentioned above would contribute in a more than reasonable manner to limit the proposed restriction of PFAS and assure the standard and quality of living and future opportunities of the entire society.

Alternatives for fluoroelastomers and fluoropolymers do not exist! Consequences of a total ban of fluoroelastomers and fluoropolymers for uses of manufacturing of seals, bearings and many other products would be dramatic! This ban will greatly affect the standard and quality of living. Future opportunities of the entire society will be lost! A restriction or even ban of fluoroelastomers and fluoropolymers as irreplaceable materials would catapult us all back into the Middle Ages!

Submission in detail

1) Should criteria be defined for “essential for health, safety, or the functioning of society”? If so, what should those criteria be?

We fully agree with the position that has been expressed many times by leading global (business) associations that the idea to define uses essential for health, safety, or the functioning of society represents a departure from the current risk-based regulatory approach and poses a number of challenges and potential risks such as unclear definitions, substitution by less sustainable alternatives or delay in regulatory decisions. In case Minnesota Pollution Control Agency (MCPA) insists on implementing the idea to define uses essential for health, safety, or the functioning of society into state legislation it is therefore paramount to ensure the possible integration of this idea in a way that can enhance the system’s ability to regulate harmful substances without putting breaks on much needed innovation and competitiveness of industry.

We would like to clearly mention that the mere presence of a hazardous substance in a process or product is not a sufficient reason to apply the “essentiality” assessment. The idea to define uses essential for health, safety, or the functioning of society could therefore be a valid solution only if applied in a targeted manner, i.e., in case of proven risks to the health and environment, difficulties in managing these risks and if no acceptable alternatives or substitutes exist.

It is widely understood that chemical, physical and (eco-)toxicological properties of PFAS can vary greatly between the more than 10,000 PFAS. OECD recognizes the diversity of PFAS as a chemical class with diverse molecular structures and physical, chemical and biological properties. They state that their proposed PFAS definition “is based only on chemical structure, and the decision to broaden this definition is not connected to decisions on how PFAS should be grouped and managed in regulatory and voluntary actions”.

We are a downstream user producing seals and polymer bearings for machines and equipment for an unimaginable segment of the entire society. The fluoroelastomers and fluoropolymers used in our products, meet OECD-criteria of “polymers of low concern.” They are neither bioavailable, water-soluble, or toxic. In essence, fluoropolymers and fluoroelastomers are safe for their intended uses so that there is no risk as well as no reason to restrict or even ban fluoroelastomers and fluoropolymers at all!

Alternatives for fluoroelastomers and fluoropolymers do not exist! Consequences of a total ban of fluoroelastomers and fluoropolymers for uses of manufacturing of seals, bearings and many other products would be dramatic! This ban will greatly affect the standard and quality of living. Future opportunities of the entire society will be lost! A restriction or even ban of fluoroelastomers and fluoropolymers as irreplaceable materials would catapult us all back into the Middle Ages!

2) Should costs of PFAS alternatives be considered in the definition of “reasonably available”? What is a “reasonable” cost threshold?

To our best knowledge and understanding this is not applicable to our activities as we as a downstream user, producing seals and polymer bearings for machines and equipment for an unimaginable segment of the entire society. The fluoroelastomers and fluoropolymers used in our products, meet OECD-criteria of “polymers of low concern.” They are neither bioavailable, water-soluble, or toxic. In essence, fluoropolymers and fluoroelastomers are safe for their intended uses so that there is no risk as well as no reason to restrict or even ban fluoroelastomers and fluoropolymers at all!

Alternatives for fluoroelastomers and fluoropolymers do not exist! Consequences of a total ban of fluoroelastomers and fluoropolymers for uses of manufacturing of seals, bearings and many other products would be dramatic! This ban will greatly affect the standard and quality of living. Future opportunities of the entire society will be lost! A restriction or even ban of fluoroelastomers and fluoropolymers as irreplaceable materials would catapult us all back into the Middle Ages!

3) **Should unique considerations be made for small businesses with regards to economic feasibility?**

To our best knowledge and understanding this is not applicable to our activities as we as a downstream user, producing seals and polymer bearings for machines and equipment for an unimaginable segment of the entire society. The fluoroelastomers and fluoropolymers used in our products, meet OECD-criteria of "polymers of low concern." They are neither bioavailable, water-soluble, or toxic. In essence, fluoropolymers and fluoroelastomers are safe for their intended uses so that there is no risk as well as no reason to restrict or even ban fluoroelastomers and fluoropolymers at all!

Alternatives for fluoroelastomers and fluoropolymers do not exist! Consequences of a total ban of fluoroelastomers and fluoropolymers for uses of manufacturing of seals, bearings and many other products would be dramatic! This ban will greatly affect the standard and quality of living. Future opportunities of the entire society will be lost! A restriction or even ban of fluoroelastomers and fluoropolymers as irreplaceable materials would catapult us all back into the Middle Ages!

4) **What criteria should be used to determine the safety of potential PFAS alternatives?**

To our best knowledge and understanding this is not applicable to our activities as we as a downstream user, producing seals and polymer bearings for machines and equipment for an unimaginable segment of the entire society. The fluoroelastomers and fluoropolymers used in our products, meet OECD-criteria of "polymers of low concern." They are neither bioavailable, water-soluble, or toxic. In essence, fluoropolymers and fluoroelastomers are safe for their intended uses so that there is no risk as well as no reason to restrict or even ban fluoroelastomers and fluoropolymers at all!

Alternatives for fluoroelastomers and fluoropolymers do not exist! Consequences of a total ban of fluoroelastomers and fluoropolymers for uses of manufacturing of seals, bearings and many other products would be dramatic! 5) How long should PFAS currently unavoidable use determinations be good for?

In general, customer requirements determine the nature of the materials used for the seals and bearings we manufacture. In cases of demanding conditions, ranging from very to extremely, of use by our customers fluoropolymers and fluoroelastomers represent the only choice.

Fluoroelastomers and fluoropolymers possess unique properties such as:

- **low coefficient of friction**
- **chemical compatibility**
- **wide temperature range for use (low to high)**
- **mechanical properties allowing high surface speeds**
- **practically non-ageing**
- **compatibility regarding electron and gamma radiation.**

It is these unique properties that represent absolute prerequisites for many specific segment requirements. It is only when these unique properties are extremely essential, that fluoroelastomers and fluoropolymers are utilized. The high price of fluoroelastomers and fluoropolymers alone ensures that use of these materials is minimized. This fact drastically reduces the use of fluoroelastomers and fluoropolymers as well as human exposure and emissions to the environment. Additionally, the fluoroelastomers and fluoropolymers used in our products, meet OECD-criteria of “polymers of low concern.” They are neither bioavailable, water-soluble, or toxic. In essence, fluoropolymers and fluoroelastomers are safe for their intended uses.

Along with the previously mentioned, fluoropolymers and fluoroelastomers are in general, critical for innovation and for sustainability! Aims of many strategic initiatives of the United States of America like the Carbon Reduction Program, the Chips and Science Act and the Digital Government Strategy are simply impossible without the use of fluoropolymers and fluoroelastomers. For these reasons we seek for a formal time unlimited determination of Currently Unavoidable Uses (CUU) for all fluoropolymers and fluoroelastomers according to Minnesota Session Laws - 2023, Regular Session Sec. 21. [116.943] Products containing PFAS. This time unlimited determination must include all monomers and processing aids needed for manufacturing of all fluoroelastomers and fluoropolymers. The actions as mentioned above would contribute in a more than reasonable manner to limit the proposed restriction of PFAS and assure the standard and quality of living and future opportunities of the entire society.

6) How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

To our best knowledge and understanding this is not applicable to our activities as we as a downstream user, produce seals and polymer bearings for machines and equipment for an unimaginable segment of the entire society. The fluoroelastomers and fluoropolymers used in our products, meet OECD-criteria of “polymers of low concern.” They are neither bioavailable, water-soluble, or toxic. In essence, fluoropolymers and fluoroelastomers are safe for their intended uses so that there is no risk as well as no reason to restrict or even ban fluoroelastomers and fluoropolymers at all!

For these reasons we seek for a formal time unlimited determination of Currently Unavoidable Uses (CUU) for all fluoropolymers and fluoroelastomers according to Minnesota Session Laws - 2023, Regular Session Sec. 21. [116.943] Products containing PFAS. This time unlimited determination must include all monomers and processing aids needed for manufacturing of all fluoroelastomers and fluoropolymers. The actions as mentioned above would contribute in a more than reasonable manner to limit the proposed restriction of PFAS and assure the standard and quality of living and future opportunities of the entire society.

Alternatives for fluoroelastomers and fluoropolymers do not exist! Consequences of a total ban of fluoroelastomers and fluoropolymers for uses of manufacturing of seals, bearings and many other products would be dramatic! This ban will greatly affect the standard and quality of living. Future opportunities of the entire society will be lost! A restriction or even ban of fluoroelastomers and fluoropolymers as irreplaceable materials would catapult us all back into the Middle Ages!

7) **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

We as a downstream user of fluoropolymers and fluoroelastomers for manufacturing of seals and polymer bearings seek for a formal time unlimited determination of Currently Unavoidable Uses (CUU) for all fluoropolymers and fluoroelastomers according to Minnesota Session Laws - 2023, Regular Session Sec. 21. [116.943] Products containing PFAS. This time unlimited determination must include all monomers and processing aids needed for manufacturing of all fluoroelastomers and fluoropolymers. The actions as mentioned above would contribute in a more than reasonable manner to limit the proposed restriction of PFAS and assure the standard and quality of living and future opportunities of the entire society. The fluoroelastomers and fluoropolymers used in our products, meet OECD-criteria of “polymers of low concern.” They are neither bioavailable, water-soluble, or toxic. In essence, fluoropolymers and fluoroelastomers are safe for their intended uses so that there is no risk as well as no reason to restrict or even ban fluoroelastomers and fluoropolymers at all!

Alternatives for fluoroelastomers and fluoropolymers do not exist! Consequences of a total ban of fluoroelastomers and fluoropolymers for uses of manufacturing of seals, bearings and many other products would be dramatic! This ban will greatly affect the standard and quality of living. Future opportunities of the entire society will be lost! A restriction or even ban of fluoroelastomers and fluoropolymers as irreplaceable materials would catapult us all back into the Middle Ages!

8) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Trelleborg Sealing Solutions as a downstream user, produces seals and polymer bearings for machines and equipment for an unimaginable segment of the entire society. The fluoropolymers and fluoroelastomers we use are listed in the table below:

Chemical name	CAS No.
Ethylene-tetrafluoroethylene copolymer (ETFE)	25038-71-5
Tetrafluoroethylene-perfluoropropylene copolymer (FEP)	25067-11-2
Tetrafluoroethylene-propylene copolymer (FEPM)	–
Perfluoroelastomer (FFKM)	–
Fluoroelastomer (FKM)	9011-17-0 64706-30-5
Fluorosilicone Rubber (FVMQ)	–
Polychlorotrifluoroethylene (PCTFE)	9002-83-9
Perfluoroalkoxy polymer (PFA)	26655-00-5
Ethene, 1,1,2,2-tetrafluoro-, homopolymer (PTFE)	9002-84-0
Polyvinylidene difluoride (PVDF)	24937-79-9
Tetrafluoroethylene-propylene copolymer (TFE/P)	–
Modified Ethene, 1,1,2,2-tetrafluoro-, homopolymer (TFM)	9002-84-0

To provide an exhaustive list of all sectors and uses of relevance of all our activities is not possible. To allow all sectors and companies a legally secure assessment of their affectedness, the scope of the restriction must be communicated in a clear and transparent manner. A list of relevant substances containing IUPAC names and CAS numbers is required for the analysis of affectedness along global supply chains. The establishment of a comprehensive information obligation for "intentionally added" PFAS for at least five years prior to a comprehensive PFAS restriction represents, from our view, a suitable approach to control PFAS emissions and to prepare a more targeted regulation. This would also enable companies and authorities to define reasonable targeted risk minimization measures.

In general, customer requirements determine the nature of the materials used for the seals and bearings we manufacture. In cases of demanding conditions, ranging from very to extremely, of use by our customers fluoropolymers and fluoroelastomers represent the only choice.

Fluoroelastomers and fluoropolymers possess unique properties such as:

- **low coefficient of friction**
- **chemical compatibility**
- **wide temperature range for use (low to high)**
- **mechanical properties allowing high surface speeds**
- **practically non-ageing**
- **compatibility regarding electron and gamma radiation.**

It is these unique properties that represent absolute prerequisites for many specific segment requirements. It is only when these unique properties are extremely essential, that fluoroelastomers and fluoropolymers are utilized. The high price of fluoroelastomers and fluoropolymers alone ensures that use of these materials is minimized. This fact drastically reduces the use of fluoroelastomers and fluoropolymers as well as human exposure and emissions to the environment. Additionally, the fluoroelastomers and fluoropolymers used in our products, meet OECD-criteria of “polymers of low concern.” They are neither bioavailable, water-soluble, or toxic. In essence, fluoropolymers and fluoroelastomers are safe for their intended uses. Seals and polymer bearings made of or containing fluoroelastomers and fluoropolymers we produce are used for manufacturing, installation, operation, and maintenance of equipment of for instance:

- Aerospace
- Defense
- Energy sector
- Chemical Industry
- Manufacturing and processing of substances, mixtures and articles
- Pharmaceutical Industry
- Pharma manufacturing
- Medicinal products
- Medical devices
- Agriculture equipment
- Food manufacturing and processing Industry
- Drinking water & potable water supply
- Oil & Gas industry
- Refrigeration
- Air conditioning and heat pumps
- Automobiles
- Trucks
- Trains
- Ships
- Transportation

- Semiconductors
- Electronics Industry including electronic products
- Drives and motion control
- Material processing
- Machine manufacturing
- Equipment manufacturing
- Processing equipment
- Recycling Industry
- Fluid Power
- Machine tools
- Marine
- Presses
- Robotics
- Sanitation
- Insulating gas in electrical equipment
- Construction products
- Petroleum and mining
- Textile & leather Industry

The seals and polymer bearings made of or containing fluoropolymers and fluoroelastomers are critical and essential contribution to all of society include:

- **Human and environmental health and safety** e.g.
    - Defense
    - Avoidance of major accidents
    - Chemical industry
    - Nuclear powerplants
    - Avoid catastrophes
- **Supply of** for instance
    - Energy
    - Food,
    - Drinking water
    - Raw materials
- **Healthcare** e.g.
    - Pharmaceuticals
    - Medical devices
- **Minimized energy consumption and prolonged maintenance cycles of a vast range of equipment and installations**

Trelleborg Sealing Solutions as a downstream user, produces seals and polymer bearings made of or containing fluoroelastomers and fluoropolymers. In general we intend to seek for a formal time unlimited determination of Currently Unavoidable Uses (CUU) for all fluoropolymers and fluoroelastomers according to Minnesota Session Laws - 2023, Regular Session Sec. 21. [116.943] Products containing PFAS for the Harmonized Tariff System (HTS) codes as mentioned below:

- 3916 "Monofilament of which any cross-sectional dimension exceeds 1 mm, rods, sticks and profile shapes, whether or not surface-worked but not otherwise worked, of plastics"
- 3917 "Tubes, pipes and hoses, and fittings therefor (for example, joints, elbows, flanges), of plastics"
- 3920 "Other plates, sheets, film, foil and strip, of plastics, non-cellular and not reinforced, laminated, supported or similarly combined with other materials"
- 3921 "Other plates, sheets, film, foil and strip, of plastics"
- 3926 "Other articles of plastics and articles of other materials of headings 3901 to 3914
- 4016 "Other articles of vulcanized rubber other than hard rubber"
- 7326 "Other articles of iron or steel"
- 8481 "Taps, cocks, valves and similar appliances for pipes, boiler shells, tanks, vats or the like, including pressure-reducing valves and thermostatically controlled valves"
- 8482 "Transmission shafts (including cam shafts and crank shafts) and cranks; bearing housings and plain shaft bearings; gears and gearing; ball or roller screws; gear boxes and other speed changers, including torque converters; flywheels and pulleys, including pulley blocks; clutches and shaft couplings (including universal joints)"
- 8484 "Gaskets and similar joints of metal sheeting combined with other material or of two or more layers of metal; sets or assortments of gaskets and similar joints, dissimilar in composition, put up in pouches, envelopes or similar packings; mechanical seals"

9) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

From our view it would be more than meaningful if the Minnesota Pollution Control Agency (MCPA) would implement initial currently unavoidable use determinations for all flouropolymers and fluoroelastomers as part of this rulemaking including all raw materials for instance monomers and processing aids needed for manufacturing of these!

Trelleborg Sealing Solutions Germany GmbH

Geschäftsführer: Carsten Stehle (Vors.), Jennifer Ruffler, Dr. Thomas Uhlig
Sitz und Registergericht Stuttgart HRB 21275, Tax ID: DE 119553041, www.trelleborg.com/seals/de

Reasons are as follows:
Fluoropolymers and fluoroelastomers used in our products, meet OECD-criteria of "polymers of low concern"

- have documented safety profiles
- are thermally, biologically, and chemically stable
- are negligibly soluble in water
- are nonmobile, nonbioavailable, nonbioaccumulative, and nontoxic

In essence, fluoropolymers and fluoroelastomers are safe for their intended uses so that there is no risk as well as no reason to restrict or even ban fluoroelastomers and fluoropolymers at all!

10) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

We would like to thank the Minnesota Pollution Control Agency for the opportunity to contribute comments to the Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837!

Subject: Re: MPCA Request for Comments regarding Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Best Technology offers the following comments on the PFAS regulations being developed by the Minnesota Pollution Control Agency (MPCA) as authorized in Chapter 60 of H.F. 2310. The MPCA has requested comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Best Technology is a distributor of metal finishing equipment and chemicals to many vital industries in the U.S. As a small business, Best Technology has concerns for industrial users having unavoidable uses of some chemical used during manufacturing (not in a finished consumer product). Since starting in the early 1990s, Best Technology has always strived to offer technologically advanced products for use in surface finish manufacturing processes. Our products are used by our customers as in-process manufacturing not as a final consumer product.

For certain manufacturing process applications, regulated industries such as medical device, aerospace, semiconductor, etc. do not have viable technological PFAS-free alternatives. Best Technology looks forward to helping customers transition as soon as alternatives are developed and proven safe and effective.

Please consider the following comments and responses to the questions raised in the request for comments document.

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Yes, criteria should be defined for "essential for health, safety, or the functioning of society". Health and safety should be easier to define but "functioning of society" is a bit more vague. The economic impacts of unavoidable use should be considered if the impacts are large enough to disrupt critical infrastructure of our essential economic industries (semiconductor, medical device, aerospace/defense, etc to name a few). The above-mentioned industries rely on many essential applications for which there are no substitutes. The current legislation poses a serious threat of completely shutting down these critical industries. A law so broadly defined really places a lot of responsibility on the commissioner/MPCA to allow applications which there are literally no alternatives yet are critical to maintaining health, safety and functioning of society.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Continued regulatory pressure has put extreme cost constraints on companies of various sizes. The "reasonably available" PFAS alternatives costs should really be based on the "essential for health, safety, or the functioning of society" classification.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

According to the Small Business Administration, small businesses contribute 64% of new jobs and 44% of U.S. economic activity. Going back to question #1 (functioning of society), if costs to change to "reasonably available" alternatives make it cost prohibitive to operate a small business many jobs of Minnesotans are at risk. This is not to say that small businesses should be completely exempt from PFAS regulations, they should have to exhibit the large cost impact and perhaps the government could offer grants to implement changes.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

Potential PFAS alternatives should be held to similar standards of scientific based safety standards as PFAS.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?

Hopefully PFAS alternatives come along with advancements in technology. Considering this, reassessment every 5 years seems to be a logical timeframe.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Yes, the MPCA should have stakeholders request a PFAS use be considered for currently unavoidable use. Similar documentation of "essential for health, safety, or the functioning of society" should be evaluated.

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Our company distributes some chemicals which contain PFAS (as defined by Minnesota law but not EPA proposed definition) however the chemicals are not part of a physical finished good/product. The chemical is used during manufacturing only. When the chemical is used correctly in industrial, medical device, aerospace and general manufacturing cleaning, the chemical completely evaporates well before the manufacturing process is completed, leaving nothing behind. So in all cases, products "do not become part of or contained in the finished goods or article", regardless of when it is used during the manufacturing process. The intention of the MN law aims to protect the environment (ground water, etc) and human safety. Based on the intended use of our products, there is no environmental or human safety impact.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Yes, some guidance from the MPCA would be very helpful for businesses trying to do what is right with a law that is broad-ranging and vague.

9) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

Best Technology appreciates the opportunity to provide these comments and looks forward to collaborating with MPCA and other stakeholders to ensure that the residents of Minnesota continue to have access to products that enhance their daily lives safely.

Submitted through https://minnesotaoah.granicusideas.com/

Mr. Quinn Carr, Rule Coordinator
Ms. Maya Gilchrist, Data Analyst and Technical Lead
Minnesota Pollution Control Agency
520 Lafayette Road North
St. Paul, Minnesota 55155-4194

RE: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-483

Dear Mr. Carr and Ms. Gilchrist:

The Alliance for Automotive Innovation[1] (Auto Innovators) appreciates the opportunity to provide input on the Minnesota Pollution Control Agency's (MPCA's) request for comment on planned new rules governing determinations of Currently Unavoidable Uses (CUUs) of PFAS in products. We understand that the main purpose of this rulemaking is to establish criteria and processes through which MPCA will make decisions on the uses of intentionally added PFAS that will qualify as CUUs in products sold, offered for sale, or distributed in Minnesota.

Auto Innovators represents the auto manufacturing sector, including automakers that produce and sell approximately 95% of the new light-duty vehicles in the United States, equipment suppliers, battery producers and semiconductor makers. Our mission is to work with policymakers to realize a future of cleaner, safer, and smarter personal transportation and to work together on policies that further these goals, increase U.S. competitiveness, and ensure sustainable, well-paying jobs for citizens throughout the country.

Auto Innovators has been actively involved in federal and state activities related to PFAS, including responding to all requests for comment from MPCA. Our comments and recommendations presented here are informed by the regulatory experiences in not only Minnesota but also, and not limited to, Maine, California, Washington, and other states with pending PFAS legislation.

MPCA is currently requesting comment on workable criteria for the CUU rule and definitions contained in subdivision 1 of Minn. Stat. § 116.943. MPCA states that "[t]he definitions in subdivision 1 listed above are a starting point of related terms possibly requiring clarification."[2] We read this

Active in Washington, D.C. and all 50 states, the association is committed to a cleaner, safer, and smarter personal transportation future. www.autosinnovate.org.

[2] Minnesota Pollution Control Agency Request for Comments: Planned New Rules Governing Currently Unavoidable Use Determinations About Products Containing Per- and Polyfluoroalkyl Substances (PFAS), Revisor's ID Number R-4837, *available at* https://www.pca.state.mn.us/sites/default/files/c-pfas-rule3-01.pdf.

request to suggest that MPCA can expand on the definitions provided in the statute and has the authority to do so.

Our comments and recommendations will focus on:

- Clarification of Definitions
- Response to Specific Questions Raised by MPCA

A. Clarification of Definitions

1. Currently Unavoidable Use (CUU)

The definition of "currently unavoidable use" in statute is "a use of PFAS that the commissioner has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available."[3]

We recommend expanding on this definition to state the following:

> ***"Currently unavoidable use"*** *means a use of PFAS that the commissioner has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available. This includes products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by Federal or State Laws and Regulations.*

Additionally, we propose a new definition to further clarify "essential for the functioning of society."

> ***"Essential for the functioning of society"*** *includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, law enforcement, lifesaving equipment, essential transportation vehicles including passenger vehicles, and construction.*

We propose this additional definition to make clear that transportation vehicles, including passenger vehicles, are essential for the functioning of society. Personal vehicles are key for transportation and getting around, and thus the functioning of society—particularly, we expect, outside of major cities like Minneapolis, St. Paul, and Rochester. If this definition remains unchanged, our industry's ability to apply for an unavoidable use designation may be harmed. By further defining what is meant by "essential for health, safety, or the functioning of society," MPCA would provide a more substantive set of criteria and circumstances warranting a CUU exemption. This additional clarity would facilitate the development of more focused CUU exemption requests and aid MPCA in its reviews of such requests.

[3] Minn. Stat. § 116.943 subd. 1(j).

It is also imperative to acknowledge that the phrase "for which alternatives are not reasonably available" involves a multi-pronged decision review and must include factors such as: whether any potential substitutes are commercially available, either domestically or from a foreign supplier; whether an alternative that has been developed has passed through EPA's new chemicals review program without any restrictions that would make it unavailable; whether the alternative has been validated for use in the product for which a CUU is being requested (in our case a motor vehicle); whether the alternative has been approved by federal agencies and whether the part manufactured using that alternative has been tested and found to conform to all applicable Federal Motor Vehicle Safety Standards (FMVSS), as well as greenhouse gas emissions and fuel economy standards as appropriate.

By way of example, we refer MPCA to the definitions in California's Safer Consumer Products Act that recognize the importance of further defining alternatives[4]:

> "Economically feasible" means that an alternative product or replacement chemical does not significantly reduce the manufacturer's operating margin.
>
> "Functionally acceptable" means that an alternative product meets both of the following requirements:
> (A) The product complies with all applicable legal requirements; and
> (B) The product performs the functions of the original product sufficiently well that consumers can be reasonably anticipated to accept the product in the marketplace.
>
> "Technically feasible" means that the technical knowledge, equipment, materials, and other resources available in the marketplace are expected to be sufficient to develop and implement an alternative product or replacement chemical.

Therefore, we recommend adding a new definition that would further define the term "alternative" as used in the definition of "currently unavoidable use" and would clarify MPCA's expectations in terms of alternatives availability.

> ***"Reasonably available alternative"*** *refers to a substance or chemical that, when used in place of PFAS, results in a functionally equivalent product and that, when compared to a PFAS that it could replace, would reduce the potential for harm to human health or the environment, or has not been shown to pose the same or greater potential for harm to human health or the environment as that PFAS. To be reasonably available means a PFAS alternative which is readily available in sufficient quantity and at a comparable cost to the PFAS it is intended to replace and functions as well as or better than PFAS in a specific application of PFAS in a product or product component. Alternatives include reformulated versions of products, including versions reformulated by removal or addition of one or more chemicals or substances, that result in the reduction or removal of intentionally added PFAS from the product. Alternatives also include changes to the manufacturing process that result in the reduction or removal of PFAS from a product.*

[4] 22 Cal. Code Regs. § 69501.1.

2. Intentionally Added

As currently defined, “intentionally added” means “PFAS deliberately added during the manufacture of a product where the continued presence of PFAS is desired in the final product or one of the product's components to perform a specific function.”[5]

We recommend clarifying and expanding this definition as follows:

> ***“Intentionally added”*** *means PFAS deliberately added during the manufacture of a product where the continued presence of PFAS is desired in the final product or one of the product's components to perform a specific function. Intentionally added PFAS also includes any degradation byproducts of PFAS serving a functional purpose or technical effect within the product or its components. Products containing intentionally added PFAS include products that consist solely of PFAS. Intentionally added PFAS does not include PFAS that is present in the final product as a contaminant.*

.

We propose this modification to address the issue of contaminants. Contaminants are not intentionally added PFAS and consequently do not serve any specific function or technical effect in the final product. The presence of a contaminant is likely to be at a de minimis or undetectable level and therefore will pose little to no exposure pathway.

3. Manufacturer

We have no suggested changes for this definition but recommend that MPCA develop guidance regarding due diligence for the importer who is responsible for identifying the presence of PFAS in an imported product. MPCA should adopt some version of the guidance that EPA has prepared for its TSCA Section 8(a)(7) PFAS reporting rule[6]:

> Submitters are required to exercise certain levels of due diligence in gathering the information required by the section 8(a)(7) rule. You must report your information to the extent that the information is known to or reasonably ascertainable by you and your company. The term “known to or reasonably ascertainable by” is defined in 40 CFR 705.3, meaning all information in a person’s possession or control, plus all information that a reasonable person similarly situated might be expected to possess, control, or know.

4. Perfluoroalkyl and Polyfluoroalkyl Substances or PFAS

As currently defined “perfluoroalkyl and polyfluoroalkyl substances” or “PFAS” means “a class of fluorinated organic chemicals containing at least one fully fluorinated carbon atom.”[7]

---

[5] Minn. Stat. § 116.943 subd. 1(l).

[6] U.S. Environmental Protection Agency, Instructions for Reporting PFAS under TSCA Section 8(a)(7) (Oct. 2023), at 4-2, *available at* https://www.epa.gov/system/files/documents/2023-11/tsca-8a7-reporting-instructions-10-11-23.pdf.

[7] Minn. Stat. § 116.943 subd. 1(p).

We recommend clarifying and expanding this definition to state the following:

> ***"Perfluoroalkyl and polyfluoroalkyl substances" or "PFAS"*** *means* *non-polymeric perfluoroalkyl and polyfluoroalkyl substances that are a group of man-made chemicals that contain at least 2 fully fluorinated carbon atoms, excluding gases and volatile liquids, and that have a Chemical Abstracts Service (CAS) number. "PFAS" includes PFOA and PFOS and excludes refrigerants and fluoropolymers.*

By defining PFAS as "a group of man-made chemicals that contain at least 2 fully fluorinated carbon atoms" MPCA will provide consistency with EPA's definition of PFAS as well as those of other states with PFAS laws. By adding the precision of "2 fully fluorinated carbon atoms," the PFAS definition will allow focus on a narrower but more relevant group of PFAS that may pose a concern. We recognize that this is not the definition in the enabling legislation and that MPCA may be constrained by that definition. We have provided this recommendation in the event that MPCA determines that it may have some flexibility in further defining PFAS of concern.

We also encourage MPCA to exclude chemicals that do not have Chemical Abstracts Service (CAS) numbers. CAS numbers are the universal identifier used to identify a chemical substance or molecular structure in an unambiguous manner and to discern between many possible systematic, generic, or proprietary chemicals. In the absence of CAS numbers, the automotive sector will be unable to search its Material Safety Data Sheets (MSDS) or use its International Material Data System (IMDS).

Because of the importance of this clarification, we request that it be added to the definition itself, as suggested above. MPCA should also define regulated PFAS with a list of chemical names and CAS numbers. That would clearly define the universe of chemicals that require notification and further clarify reporting requirements.

Auto Innovators also requests that MPCA provide further guidance on how they expect the regulated community to report on PFAS chemicals that have a CAS number but "are withheld by other persons or are otherwise unavailable." What due diligence is required to seek out PFAS chemicals that may be present in a product but are claimed as confidential business information (CBI) by the supplier or other entity or covered by non-disclosure agreements?

MPCA should also exempt fluoropolymers and refrigerants from the definition of PFAS, as suggested above. The current definition of PFAS being used by MPCA includes the refrigerants that are used in motor vehicle air conditioning (MVAC) applications. Those refrigerants are already the subject of regulations covering hydrofluorocarbons (HFCs) at both the state and federal levels; in fact, those regulations have resulted in the industry undertaking over the past several years the behemoth task of transitioning from one type of refrigerant to another that has a lower global warming potential. Banning use of the refrigerant now currently used in our vehicles would require original equipment manufacturers (OEMs) to have an available alternative that is also approved by all of those HFC regulations and would result in OEMs having to significantly redesign and reengineer our recently revamped MVAC systems and vehicles, possibly even with a need to retrofit older vehicles. Similarly, fluoropolymers satisfy widely accepted criteria to be considered polymers of low concern, indicating that they do not present a significant risk to human health or the environment. For this reason, fluoropolymers should be regulated differently from PFOA and PFOS. The definition of PFAS needs to be revised to exempt these substances.

5. Product

As currently defined, "product" means "an item manufactured, assembled, packaged, or otherwise prepared for sale to consumers, including but not limited to its product components, sold or distributed for personal, residential, commercial, or industrial use, including for use in making other products."[8]

We would recommend expanding this definition to state the following:

> ***"Product"*** *means an item manufactured, assembled, packaged, or otherwise prepared for sale to consumers, including but not limited to its product components, sold or distributed for personal, residential, commercial, or industrial use, including for use in making other products. For complex durable goods, "product" would encompass the complete product such as a complete vehicle, including replacement and service parts. This definition does not include the packaging for any product.*

This expanded definition accounts for the fact that complex durable goods such as vehicles may contain multiple components that contain PFAS. It would be unworkable both for MPCA and the regulated community to apply for CUU exemptions for each individual component given that all CUU exemptions would need to be approved in order to continue to sell and service the complete product, in this case, a vehicle, in the state of Minnesota. This recommended approach is consistent with the approach adopted by the state of Maine and recognizes the practicality of complete product reporting, which we discuss further below in our response to Question #6.

We recommend adopting the definition proposed by Maine DEP that would exclude packaging used in marketing, handling, or protecting a product. Maine sensibly proposed to exclude packaging that serves an essential purpose in protecting the product as it moves through the channels of trade.

For further clarification, we recommend adding a new definition that would further define the term "complex durable good." Our proposed definition is consistent with the TSCA definition[9]:

> ***"Complex durable goods"*** *means manufactured goods composed of 100 or more manufactured components, with an intended useful life of 5 or more years, where the product is typically not consumed, destroyed, or discarded after a single use.*

6. Product Component

We have no recommended changes for the definition of product component. We ask that MPCA recognize that in some circumstances, like for motor vehicles, product components can be sold separately in order to keep a product functional and in service; regardless, they should not be treated as independent products.

---

[8] Minn. Stat. § 116.943 subd. 1(q).

[9] 15 U.S.C. § 2605(c)(2)(D)(ii)(II).

B. Response to Specific Questions Raised by MPCA

1. Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Yes, criteria to further define the elements that MPCA will consider as it makes CUU decisions is critical to providing clarity and transparency into this key process. We suggest that "criteria" include specific clarification of the definition of CUU itself as well as the addition of definitions for key terms in that definition. By specifying key criteria, MPCA will provide a more precise set of requirements for requesting and granting a CUU exemption. For MPCA staff reviewing CUU requests, additional criteria will provide for greater consistency in MPCA decision-making; for the regulated community, criteria will assist in understanding eligibility and in developing a CUU request (and determining whether to make a request) and for the general public, criteria will allow oversight of how CUU exemptions are being granted or denied.

Additional criteria that MPCA should consider in its decision-making process and should be captured in either the regulatory preamble or regulatory text include:

- Are any potential substitutes commercially available, either domestically or from a foreign supplier?
- Does the alternative provide the same safety and functionality required to meet federally regulated performance standards such as fire safety, efficiency, weight requirements, etc.?
- If an alternative has been developed, has it passed through EPA's new chemicals review program without any restrictions that would make it unavailable?
- Has the alternative been tested for use in the product for which a CUU is being requested?
- Has the alternative been regulated or cued up for regulation by either the federal government or a U.S. state government?

As presented in more detail in the previous section A.1. on definitions, we would recommend expanding the definition of "currently unavoidable use" and adding a definition for "reasonably available alternative."

2. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Yes, the combined costs of identifying, developing, validating, and implementing an alternative should be considered by MPCA when making decisions about CUU exemptions. These costs include but are not limited to costs associated with redesigning product components to be PFAS free; costs associated with testing for performance and safety standards and compliance with federal and other state requirements; and the time and cost of development, testing, and application for use within the United States. The cost of using a PFAS alternative should not be substantially higher than that of use of the PFAS, as the difference is likely to be passed on to consumers and increase the price of many consumer goods.

In a CUU exemption decision, these costs should be weighed against the costs to Minnesota's residents if motor vehicles are not available for sale in Minnesota, as well as costs associated with regrettable substitution should a chosen alternative become the subject of future regulation.

For example, PFAS alternatives in the semiconductor industry's microelectronics applications must have requalification if a manufacturer substantively alters the fabrication process, which can easily exceed $10 million.[10] Similar costs can be expected for any major modifications to automotive components. If drop-in replacements (i.e., functionally equivalent and safer, cleaner, or greener alternatives) were readily available, substitutions would already have been made given the focus on PFAS. PFAS applications in passenger vehicles support advanced emissions, battery, safety, electronics, and other cutting-edge technologies.

3. <u>Should unique considerations be made for small businesses with regards to economic feasibility?</u>

Yes, A large portion of the automotive industry supply chain is comprised of small businesses. It is important to support these businesses to provide stability to the overall automotive supply chain.

4. <u>What criteria should be used to determine the safety of potential PFAS alternatives?</u>

Approved and commercially available test methods for PFAS and alternatives are still under development and their availability is limited. In their absence, comparing risk profiles of PFAS with those of alternative chemistries is challenging and could easily lead to regrettable substitution. In fact, experience with chemical substitution based on rigorous risk assessments has still resulted in regrettable substitutions. For example, while not a PFAS application, consider the move to methyl tertiary-butyl ether (MTBE) as a replacement when tetra-ethyl lead was banned for use in gasoline. MTBE proved to be of equal, if not greater, environmental concern and was ultimately the subject of a national phase-out.[11]

For this reason, it is all the more critical that as alternatives are developed, they go through rigorous testing and evaluation before they are deemed an appropriate substitute. After such a determination is made, it will still take a number of years to ensure durability and functional equivalency to be able to phase in to product development cycles. A CUU exemption for vehicles and their replacement parts is warranted at this time, while the sector and its supply chain explore substitution options.

At a minimum, we would recommend that MPCA not identify any chemical as a PFAS alternative that is included on any of the following lists: EPA's TSCA 2014 Workplan Chemicals,[12] California's

---

[10] U.S. Department of Defense, Report on Critical Per- and Polyfluoroalkyl Substance Uses (Aug. 2023) at 12, *available at* https://www.acq.osd.mil/eie/eer/ecc/pfas/docs/reports/Report-on-Critical-PFAS-Substance-Uses.pdf.

[11] Thomas O. McGarity, *MTBE: A Precautionary Tale,* 28 Havard L. Rev. 282 (2004), *available at* https://tri-s.com/wp-content/uploads/2018/07/MTBE_A_precautionary_tale-enhanced.pdf.

[12] U.S. Environmental Protection Agency, TSCA Work Plan for Chemical Assessments: 2014 Update (Oct. 2014), *available at* https://www.epa.gov/sites/default/files/2015-01/documents/tsca_work_plan_chemicals_2014_update-final.pdf.

Safer Consumer Products Priority List,[13] or Washington State's Safer Products for Washington program.[14] These chemicals are all being considered for regulation under the appropriate statutes and may be unavailable for use in the future.

5. How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

We recommend any CUU exemption for the automotive sector cover a minimum of 15 years. The minimum design cycle for a vehicle is typically five years, with additional time necessary for testing and determination of compliance with state and federal regulations. Replacement parts CUU exemptions should have no expiration dates and should remain valid for the full life of the vehicle that the replacements parts were designed to maintain.

6. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

We recommend that MPCA adopt the same approach to product identification for a CUU exemption that Maine is taking pursuant to 38 M.R.S. § 1614. Also, it is appropriate and important that MPCA and Maine consider providing reciprocity for CUU findings, since deviations from each other's CUUs would be disruptive for the flow of interstate commerce. Their proposed rule on reporting stated:

> Reporting multiple products or product components together under a single GPC [global product classification] code or HTS [harmonized tariff schedule] number under subsection A above is allowed, so long as;
> (1) All products to be so reported fall within the same GPC brick code or HTS number,
> (2) The same PFAS are present in every product, and
> (3) Each PFAS is present in every product, either:
> (a) In a substantially similar amount as determined by a commercially available analytical method, or
> (b) If reporting by range of concentration is available, within the same concentration range.[15]

For a CUU exemption for the automotive sector, we would propose that requests be permitted at the whole vehicle level (see proposed revised definition for "product" and discussion above) and be

---

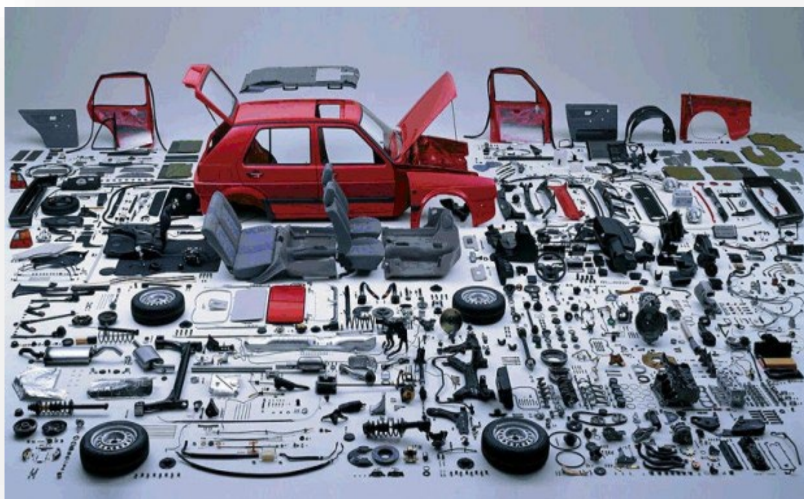
[13] *Priority Products*, California Department of Toxic Substances Control, https://dtsc.ca.gov/scp/priority-products/.

[14] Washington Department of Ecology, Priority Consumer Products Report to the Legislature (July 2020), https://apps.ecology.wa.gov/publications/documents/2004019.pdf.

[15] Maine Department of Environmental Protection, Posting Draft: Chapter 90: Products Containing Perfluoroalkyl and Polyfluoroalkyl Substances, *available at* https://www.maine.gov/dep/bep/2023/01-19-23/Chapter%2090%20Draft.pdf. Maine appears to also be basing their CUU application and decision-making on GPC/HTS groups as well. See *PFAS in Products: Currently Unavoidable Uses*, Maine Department of Environmental Protection, https://www.maine.gov/dep/spills/topics/pfas/PFAS-products/cuu.html.

permitted to be submitted by an individual manufacturer, a consortium, or automotive trade organizations, as Maine is allowing. This request would cover current production vehicles, and replacement / accessory parts and operating materials, defined as parts and materials that are intended to enhance, maintain, or repair current production vehicles.

The automotive industry sells around 15 million vehicles each year across the nation, and the same vehicles sold in Minnesota are sold in the other 49 states as well. A single vehicle has tens of thousands of individual parts as single parts, subassemblies, and assemblies, as depicted in the graphic below. Requesting a CUU exemption for individual parts that may contain PFAS will not only overwhelm MPCA staff reviewing these requests but will also place an unreasonable burden on automobile manufacturers, with no added value for MPCA or the public.



Given the lack of viable alternatives at this time, as well as the lead time necessary to test, verify, and incorporate a change in a chemistry once an alternative is available, it is appropriate and necessary to consider the vehicle as a whole at this time for a CUU exemption. In the future, it may be appropriate to consider certain subassemblies or parts separate from the vehicle as a whole.

If there are stakeholders that have concerns about the granting of any specific CUU, any request to deny or rescind that CUU should be accompanied with specific responses to the criteria presented earlier when considering the availability of alternatives.

7. <u>In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.</u>

We anticipate submitting a CUU determination request for motor vehicles and motor vehicle equipment (parts and operating materials) (the product) used for transportation (the use). Please also see our response to Question #6 above for additional details.

8. <u>Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?</u>

Yes. In keeping with our recommended revised definition of CUU, making some initial determinations as examples of what uses meet the criteria adopted by MPCA (see recommended criteria above) would be appropriate and would provide some certainty for manufacturers that sell products that are "essential for health, safety, or the functioning of society and for which alternatives are not reasonably available." Further clarification and/or a definition surrounding "essential" will similarly assist in providing certainty and clarity.

We recommend that MPCA identify motor vehicles, motor vehicle equipment, and replacement parts and operating materials necessary to maintain those vehicles as a CUU in the anticipated rulemaking. This determination would be wholly consistent with the proposed definition, the proposed criteria and, as a benchmark, with the U.S. Department of Homeland Security Cybersecurity & Infrastructure Security Agency's assignment of critical infrastructure uses during and following the COVID-19 pandemic,[16] which include:

- Workers supporting or enabling transportation and logistics functions, including truck drivers, bus drivers, dispatchers, maintenance and repair technicians, warehouse workers, third party logisticians, truck stop and rest area workers, driver training and education centers, Department of Motor Vehicle (DMV) workers, enrollment agents for federal transportation worker vetting programs, towing and recovery services, roadside assistance workers, intermodal transportation personnel, and workers that construct, maintain, rehabilitate, and inspect infrastructure, including those that require cross-jurisdiction travel.
- Workers supporting personal and commercial transportation services including taxis, delivery services, vehicle rental services, bicycle maintenance and car-sharing services, and transportation network providers.
- Vehicle repair, maintenance, and transportation equipment manufacturing and distribution facilities.
- Workers who support the construction and maintenance of electric vehicle charging stations.
- Workers who repair and maintain vehicles, aircraft, rail equipment, marine vessels, bicycles, and the equipment and infrastructure that enables operations that encompass movement of cargo and passengers.
- Workers critical to the manufacturing, distribution, sales, rental, leasing, repair, and maintenance of vehicles and other equipment (including electric vehicle charging stations) and the supply chains that enable these operations to facilitate continuity of travel-related operations for essential workers.

---

[16] U.S. Department of Homeland Security, Advisory Memorandum On Ensuring Essential Critical Infrastructure Workers' Ability To Work During The Covid-19 Response (Aug. 10, 2021), *available at* https://www.cisa.gov/sites/default/files/publications/essential_critical_infrastructure_workforce-guidance_v4.1_508.pdf.

Motor vehicles and the replacement parts and operating materials to repair them are essential for health, safety, and the functioning of society. If Minnesota residents did not have access to functional vehicles to get to medical appointments, places of employment, and food and grocery stores, there would be far-reaching repercussions for quality of life and functioning of society for Minnesota residents. One estimate has Minnesota with the fifth-highest average miles driven per year by drivers, at 17,887,[17] and with residents outside of major metropolitan areas driving significantly greater distances to reach essential medical and other services. Clearly, vehicles are key for transportation in Minnesota and a lack of availability of personal transportation could jeopardize health and safety and disrupt the standard functioning of society.

Finally, Minnesota is implementing an aggressive plan to mandate that automakers bolster availability of all electric and hybrid vehicles across the state.[18] PFAS are critical to the technologies underlying electrification and enable achievement of the state's emissions standards.

Conclusion

Our recommendations provide a framework that emphasizes the key questions that must be asked and answered when assessing whether to grant a CUU exemption for PFAS use. The availability of alternatives, as we have defined them, is key to making these CUU decisions.

Thank you for considering our comments. We would be happy to discuss them with you in further detail, as well as to discuss PFAS in products issues more generally. We can also provide information on PFAS uses in our industry and the nature of our supply and production chain. I can be reached at cpalin@autosinnovate.org or at 202-326-5511.

RE: Request for Comments: Planned new Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID number R-4837.

Iwaki America stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality in critical applications in order to meet stringent safety standards.

We manufacture chemical process metering (dosing) pumps and magnetic drive centrifugal pumps, which require PFAS components depending on the application. These critical applications require the handling of corrosive or hazardous fluids where leakage prevention is crucial. Examples include water treatment, power generation, chemical manufacturing, mining, battery manufacturing, desalination and many others.

In line with our commitment to finding balanced solutions, we have worked through our industry associations: Hydraulic Institute, Fluid Sealing Association, Valve Manufacturers Association, the Water and Wastewater Manufacturers Association (a.k.a. the Flow Control Coalition) which have developed a comprehensive Currently Unavoidable Uses (CUU) proposal, that is being submitted to the states of Maine and Minnesota. This proposal is founded upon expert knowledge of the design of critical processes, and incorporates valuable insights gathered from diverse stakeholders including design engineers, end-users and manufacturers of critical system components.

By engaging engineers and experts from the various segments of the fluid handling industry, the Associations have applied a collaborative, systems level approach to this complex issue. Highly corrosive materials, high temperatures, harsh environments, accessibility and life-cycle considerations all are part of the design criteria of the industrial and other process systems which currently require PFAS as there are no viable alternatives to handle toxic substances, prevent hazardous leaks and fugitive emissions, ensure clean air and water, etc.

Iwaki America actively participated in the consultation process and supports the Flow Control Coalition's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS and ensuring that critical functions of industry and society continue while at the same time, mitigating adverse impacts on businesses, communities, and public health.

Sincerely,

Philip Berdos
Manufacturing Engineer

Katrina Kessler
Commissioner, Minnesota Pollution Control Agency
520 Lafayette Road N
St. Paul, MN 55155-4194

Re: **<u>Comments to MPCA's Planned PFAS in Products Currently Unavoidable Use Rule</u>**

Dear Commissioner Kessler:

The PFAS Pharmaceutical Working Group ("PPWG")[1] is a group of manufacturers and distributors of drugs, biologics, animal drugs, and medical devices. PPWG appreciates the opportunity to provide comments on the Minnesota Pollution Control Agency ("MPCA") planned new rule concerning determinations for currently unavoidable uses ("CUUs") of PFAS in products (the "CUU Rule"). Minn. St. § 116.943 ("Section 116.943"), subdivision 5(c) restricts the sale, offer for sale, and distribution for sale of products containing intentionally added PFAS beginning January 1, 2032 unless the MPCA has determined by rule that the use of PFAS is a CUU. "Currently unavoidable use" is defined in subdivision 1 as "a use of PFAS that the commissioner has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available." The CUU Rule would implement this statutory language.

PPWG previously submitted comments on a separate MPCA rulemaking (the "Reporting Rule") to implement Section 116.943, subdivision 2, which requires reporting on intentionally added PFAS in products by January 1, 2026. We reiterate our request in those comments that the MPCA state expressly that U.S. Food and Drug Administration ("FDA")-regulated products and their packaging are out of scope of the Reporting Rule. We also acknowledge that Section 116.943, subdivision 8(b), expressly exempts FDA-regulated products from the statute's testing provisions in subdivision 4 and the material restrictions in subdivision 5. Notwithstanding this exemption, PPWG still has serious concerns with how the material restrictions may impact products in medical and pharmaceutical product supply chains to the extent these products are not covered by the exemption. For example, if the restriction applied to certain products used by upstream suppliers or to non-FDA regulated products used by medical and pharmaceutical product manufacturers for research and development ("R&D"), manufacturing, or distribution of their medical and pharmaceutical products, that may negatively affect the production of our

[1] PPWG's member companies, which include their subsidiaries and affiliates, are Amgen Inc.; Bristol Myers Squibb Company; GSK; Merck & Co., Inc.; Pfizer, Inc.; and Roche.

members' FDA-regulated products or the ability to continue manufacturing these products within the specifications or marketing authorizations granted by FDA. This would contribute to uncertainty over whether certain critical medical and pharmaceutical products can remain on the market in Minnesota, thereby directly contravening the legislature's intent to ensure Minnesotans' continued access to lifesaving drugs and devices.

For instance, certain logistics equipment may be essential to pharmaceutical research, or certain materials or equipment may be critical in manufacturing pharmaceuticals to meet FDA's quality standards. These products may be irreplaceable components in the R&D or manufacturing of end products that are subject to CUU determinations. In other words, narrow application of the CUU standard could harm the suppliers of materials that source items necessary for the continued marketing of products covered to CUU determinations, causing unintended ripple effects that would undermine the Minnesota Legislature's and the MPCA's attempt to preserve access to products that represent CUUs of intentionally added PFAS.

We request that the MPCA craft a CUU Rule that avoids this result. Specifically, the agency should:

- Develop criteria and definitions that account for how a restriction on a particular PFAS use may impact not only the direct use of an end product, but how that restriction may impact other products and processes up and down supply chains (e.g., material sourcing and procurement, R&D, manufacturing, and distribution). Therefore, the criteria for assessing what is "essential for health, safety, or the functioning of society" should consider societal impacts that may be broader than direct use of the end product itself. In addition, direct and indirect supply chain costs and risks should be considered in determining whether alternatives are "reasonably available."

- Specify that CUU determinations are indefinite, and provide a transparent process involving opportunity for regulated industry comment prior to the proposed withdrawal or modification of a previously issued determination. Section 116.943 does not authorize a time-limited determination, and an indefinite determination is necessary to ensure regulatory predictability for not only the specific product covered by the determination, but also for other products and processes that rely on that specific product. For similar reasons, the MPCA should be required to timely respond to requests for determinations so that companies have proper notice about what PFAS uses may continue.

- Where appropriate, make CUU determinations for broad categories of products intended for certain health and safety uses, rather than make CUU determinations on an individual product-by-product basis. For many types of products, making CUU determinations for individual products would almost certainly omit some products that are critical to health and safety. Applying CUU determinations to groups of products or categories of products intended for specified uses would be more efficient, would promote consistent treatment across related products, and would accomplish statutory objectives.

- Prioritize any requests for CUU determinations that are for products used in medical and pharmaceutical product R&D, manufacturing, and distribution supply chains. Given that the MPCA should expect a very large number of requests for CUU determinations, this will aid in making sure requests relevant to medical and pharmaceutical products do not get lost in the queue.

I. WHILE THE FDA-REGULATED PRODUCT EXEMPTION SHOULD APPLY BROADLY, CONCERNS FOR DRUGS AND DEVICES REMAIN

The statutory exemption in Section 116.943, subdivision 8(b) applies to "a prosthetic or orthotic device or to any product that is a medical device or drug or that is otherwise used in a medical setting or in medical applications regulated by the [FDA]" (emphasis added). This is a clear legislative direction that the exemption should be interpreted broadly. Nonetheless, we still have concerns for uses of intentionally added PFAS that may not be directly covered by the broad FDA-regulated product exemption but, if subject to Section 116.943's material restriction, may cascade to affect the availability, efficacy, quality, reliability, price, or safety of exempted, FDA-regulated products.

One example is an upstream supplier whose product is directly affected by the material restriction, and this supplied item therefore becomes more expensive or unavailable to customers (e.g., medical and pharmaceutical product manufacturers) or to other actors further up the supply chain. This could have negative downstream effects on the production of FDA-regulated products including on production costs, product availability, and product safety and effectiveness, as medical and pharmaceutical product manufacturers would need to scramble to find alternatives to the supplied item or at least incur increased costs in their manufacturing processes. These manufacturers also may need to obtain FDA approval for the related change to their manufacturing process. For instance, if the PFAS content of certain gaskets, pipes, and other equipment were restricted more generally at the supplier level, this could impact the availability and price of what is supplied to medical and pharmaceutical product manufacturers, regardless of whether the manufacturer's activity is covered by Section 116.943's FDA-regulated product exemption. Depending on the resulting modification in the supplier or material used, the manufacturer may need to notify and possibly seek approval from FDA for the change.

Another example is a medical and pharmaceutical product manufacturer who cannot use a product containing intentionally added PFAS in activities to the extent those activities are not directly covered by Section 116.943's FDA-regulated product exemption, though those activities nonetheless impact the manufacturer's systems that make production of the FDA-regulated product possible. For example, a manufacturer may use certain PFAS-containing logistics equipment in drug or medical device manufacturing. It was clearly not the legislature's intent in passing Section 116.943 for such products critical to the safe and effective manufacture and use of FDA-regulated products to be banned, as it would directly undercut the statute's FDA-regulated product exemption. The CUU Rule should avoid this consequence as we recommend below.

II. CRITERIA AND DEFINITIONS IN THE RULE SHOULD RELFECT R&D, MANUFACTURING, DISTRIBUTION, AND SUPPLY CHAIN IMPACTS

The MPCA's request for comments specifically asks for comments on defining CUU criteria, including the terms "essential for health, safety, or the functioning of society" and "reasonably available." For the former, we recommend adopting the following provision:

> *The commissioner shall grant a currently unavoidable use determination for PFAS applications or end products, and for the supply chain research, development, and production activities required to produce such PFAS applications or end products, when the commissioner has evidence, or when a manufacturer, organization, or other entity has submitted evidence, that an application, product, or category of products provides benefits related to health, safety, or the functioning of society and that there are no reasonably available alternatives for that use.*
>
> *A product shall be deemed to provide benefits to health, safety, or the functioning of society where the commissioner has evidence, or the manufacturer, organization, or other entity has submitted evidence, that the product contributes to:*
>
> *(a) For health – physical or emotional health or wellness, including but not limited to evidence that the product supports the manufacture, distribution, or research and development of any product subject to the exemption in Minn. St. § 116.943, subdivision 8(b);*
>
> *(b) For safety – the safety or security of the public from danger, injury, or property damage; or*
>
> *(c) For the functioning of society – identified consumer, commercial, or industrial demands for the product.*

This provision accomplishes a number of necessary objectives. First, it helps avoid arbitrary and subjective determinations by stating that the MPCA "shall" grant the requested determination if the manufacturer has submitted qualifying evidence. It also clarifies that the MPCA should grant a CUU determination *sua sponte* when the agency has sufficient evidence to do so, since Section 116.943 does not require that CUU determinations be made only upon manufacturer request. Second, this provision clarifies that the determination should apply not only to the end product itself, but to the products and processes in the supply chain that are necessary to produce that product. Without this, a CUU determination could be substantially undermined, or even rendered meaningless, given that it is not possible to produce end products without upstream activities.

Third, this provision appropriately explains what information should be submitted to demonstrate health benefits. Health benefits should be described expansively to not only capture acute physical health attributes, but also emotional health and wellness values. Furthermore, this description of qualifying health benefits makes clear that a prominent example is that the product to be subject to the CUU determination is essential because of the product's role in drug and device manufacturing, distribution, or R&D. Fourth, and like with health benefits, benefits to safety and the functioning of society should be described broadly to capture the naturally broad scope of these terms.

We also recommend the following definition of "reasonably available alternative":

> *"Reasonably available alternative" means a substance, material, technology, process, or otherwise that is currently available at commercial scale and that, when used in place of intentionally added PFAS, does not result in:*

(a) A decrease in availability, performance, life expectancy, quality, or durability of the product or of any upstream or downstream manufacturing, distribution, or research and development activities associated with that product;

(b) A significant increase in manufacturing, design, testing, capital investment, or other costs for the product or for any upstream or downstream manufacturing, distribution, or research and development activities associated with that product; or

(c) Risks to human health or the environment that would not be present, or present in lesser degrees, with use of the intentionally added PFAS, including but not limited to risks from toxicity, energy consumption, product safety, product unavailability, and disposal.

Like with our recommended provision on essentiality, this definition recognizes that the evaluation of any potential alternative must involve an assessment of how the alternative may affect other parts of the supply chain, particularly to avoid unintended impacts on other products such as those covered by Section 116.943's FDA-regulated product exemption. Likewise, this definition accounts for how the evaluation of an alternative must consider the real, commercial availability of the alternative. The evaluation must also consider the costs of the whole process for designing and implementing the alternative, including the costs that may be borne by other companies in the product's supply chain. Lastly, the risks associated with an alternative can have substantial impacts on the alternative's availability. Our recommended definition reflects how these risks could stem not only from toxicity of the alternative itself, but also from risks across the product's lifecycle. These risks could include, but are not limited to, sustainability considerations (energy consumption, climate impacts, etc.), manufacturing product safety, end product safety and efficacy (e.g., shelf life, stability), end product unavailability (e.g., health risks of skipping doses or delaying treatment because of unavailability), and disposal.

III. CUU DETERMINATIONS SHOULD BE INDEFINITE AND TIMELY ISSUED, AND MODIFIED OR REVOKED ONLY WITH NOTICE AND COMMENT

The MPCA also specifically requested comment on whether CUU determinations should be time-limited and whether significant changes should trigger a reevaluation of a determination. CUU determinations should be indefinite because Section 116.943 does not authorize a time-limited process, and it would waste both public and private resources to reevaluate determinations on a predetermined schedule. The MPCA and manufacturers would bear significant ongoing expenses to constantly reevaluate CUU determinations, each of which may involve a technical assessment akin to the European Commission's assessment of exemptions under the Restriction on Hazardous Substances Directive ("RoHS"). Pursuant to RoHS, the European Commission contracted with the Oeko-Institut to provide technical support and assistance in evaluating such exemptions.[2] The reevaluation of CUU determinations would be even more complex than what is performed by the European Commission given the larger scope of products and chemicals affected by Section 116.943.

[2] *See* Oeko-Institut, RoHS Evaluations, https://rohs.exemptions.oeko.info/project-overview/background.

Likewise, CUU determinations should be indefinite because this gives both directly affected manufacturers and other stakeholders in impacted supply chains the necessary repose to rely on a determination without fear that it could be unexpectedly revoked or modified. As an example, changes to FDA-regulated products take many years to implement, in part because of modifications that require FDA approval. The European Chemicals Agency ("ECHA") recognized this extensive timeline by including 13.5-year derogations for medical devices in its PFAS restriction proposal.[3] At the very least, this indicates that any periodic review of previously issued CUU determinations should be conducted based on long time horizons, especially for determinations that may affect FDA-regulated products. Moreover, any such review should not require that the full CUU criteria be re-explained or re-justified, since this would in effect operate as an entirely new CUU determination process that Section 116.943 does not authorize. Instead, the review should be limited to a brief statement from the manufacturer, organization, or other entity on whether reasonably available alternatives continue to not exist.

For similar reasons, the MPCA should be required to timely respond to requests for CUU determinations; if the agency fails to respond by the required deadline, that should function as an automatic determination for as long as the MPCA is late. This is in line with exemption procedures under other chemical regulatory programs, such as RoHS Article 5 through which an existing exemption to the directive's restrictions remains valid until the European Commission has decided on a renewal application.

Likewise, a CUU determination should only be revoked or modified after proper public notice and comment; if a determination is revoked or modified, the MPCA should be obligated to explain its reasons for the decision and then give manufacturers a clear opportunity to appeal the decision. These procedures will act as safeguards to ensure that impacted stakeholders from across supply chains are able to properly plan for and then rely on CUU determinations. It will also give stakeholders beyond the direct manufacturers of the impacted product, such as medical and pharmaceutical product supply chain partners, opportunities to explain to the MPCA the importance of the determination and provide relevant information.

IV. WHERE APPROPRIATE, CUU DETERMINATIONS SHOULD BE MADE FOR BROAD PRODUCT CATEGORIES RATHER THAN PRODUCT-BY-PRODUCT

The MPCA should make CUU determinations for broad categories of products, rather than on a product-by-product basis. Section 116.943 does not require that CUU determinations be made only for individualized products. Like with time-limited determinations as mentioned above, this would waste both public and private resources as manufacturers will likely end up preparing and submitting several requests for like products, and the MPCA will need to carefully compare requests to assess potential duplication. Moreover, this process would almost certainly omit some products that should be covered by a CUU determination but are not because of arbitrary line drawing in the scope of the determination.

CUU determinations made for broad product categories would also be in line with the U.S. Environmental Protection Agency's ("EPA's") Toxic Substances Control Act ("TSCA") PFAS Reporting Rule, 40 C.F.R. Part 705. Under that rule, manufacturers are to report PFAS in

[3] ECHA, PFAS Restriction Proposal, Annex XV Report (Mar. 22, 2023), https://echa.europa.eu/documents/10162/1c480180-ece9-1bdd-1eb8-0f3f8e7c0c49.

their products through use of broad consumer and commercial product category codes found in table 5 to 40 C.F.R. § 705.15(c)(4). These codes were taken from EPA's TSCA Chemical Data Reporting program, which were in turn based on Organisation for Economic Co-operation and Development harmonized codes.[4]

V. PRIOROTIZE DETERMINATIONS FOR PRODUCTS USED IN DRUG AND DEVICE R&D, MANUFACTURING, DISTRIBUTION, AND SUPPLY CHAINS

The legislature recognized the importance of protecting Minnesotans' access to lifesaving medical and pharmaceutical products through the FDA-regulated product exemption in Section 116.943. In addition, and as discussed in our comments on the Reporting Rule, states are largely preempted from regulating medical and pharmaceutical products because these items are already heavily regulated by the FDA. Therefore, the FDA-regulated product exemption in Section 116.943 also avoids disputes about the scope of federal preemption as applied to Section 116.943's material restriction.

To avoid undermining the exemption and its critical functions, the MPCA should prioritize requests for CUU determinations concerning products used in medical and pharmaceutical product R&D, manufacturing, distribution, and supply chains. This prioritization could include, for example, flagging such requests for expedited review outside of a normal first-come, first-served queue. This can help protect the integrity of medical and pharmaceutical product manufacturing, distribution, R&D, and supply chains in the event of a backlog of CUU determination requests.

VI. CONCLUSION

PPWG thanks the MPCA for considering its comments to inform future drafting of the CUU Rule. If you have any questions, please feel free to contact me.

Sincerely,

Ryan J. Carra

Re: PFAS in Products Currently Unavoidable Use Rule; Revisor's ID Number R-4837

Dear Commissioner Kessler:

AGC Chemicals Americas ("AGCCA") and its parent company, AGC America, Inc., appreciate this opportunity to provide comments on the Minnesota Pollution Control Agency's (MPCA's) planned new rules for determining Currently Unavoidable Uses ("CUU") of PFAS chemicals in products, pursuant to Minnesota Statutes 116.943, subdivision 5(c) (the "Law").

AGCCA manufactures and supplies a range of specialized industrial chemicals and materials, including resins, coatings, films and membranes, that are incorporated into a wide range of products essential to the daily lives of Minnesota residents and businesses. Many of these materials are comprised of fluoropolymers. Although fluoropolymers fall within the extremely broad definition of "PFAS" used in the Law, they are very much *unlike* the PFAS chemicals that have been found in drinking water, groundwater and blood samples, such as PFOA and PFOS. For example, unlike those PFAS chemicals of concern, fluoropolymers are not soluble in water, so they cannot enter drinking water or groundwater. Furthermore, fluoropolymers do not degrade into smaller, water-soluble molecules. Also, fluoropolymers are not bioavailable nor do they degrade to smaller, bioavailable molecules, so they do not present toxicity concerns associated with PFAS chemicals of concern. Indeed, peer-reviewed studies demonstrate that, because of these and other characteristics, fluoropolymers satisfy internationally-recognized criteria for being "Polymers of Low Concern" (PLC) -- i.e., polymers deemed to have insignificant environmental and human health impacts.[1]

---

[1] *See "A critical review of the application of polymer of low concern regulatory criteria to fluoropolymers II: Fluoroplastics and fluoroelastomers," Korzeniowski, Stephen H., et al., Integrated Environmental Assessment and Management 19, 2 (2023): 326–354. DOI: 10.1002/ieam; "A Critical Review of the Application of Polymer of Low*

Fluoropolymers also possess a unique combination of properties that make them critical to the performance of a wide range of products and technologies, such as semiconductors, fuel cells, wind turbines, printed circuit boards, coated wires, batteries, solar photovoltaics, avionics, aircraft components, motor vehicle engines, manufacturing equipment, scientific instruments, and laboratory and diagnostic equipment, among others. This unique, and irreplaceable, combination of properties includes the following:

- **Heat resistance**: fluoropolymers are able to maintain their physical properties at very high temperatures. This makes them particularly suitable for use in aerospace and electronic components.

- **Chemical resistance**: fluoropolymers are highly resistant to chemicals, acids, fuels, and solvents. This makes them a material of choice for use in chemical processing equipment, aerospace, automotive and pharmaceuticals.

- **Mechanical resilience**: mechanical properties include high tensile strength, flexibility, and impact resistance. This is particularly important in applications such as seals and gaskets as well as architectural films and coatings.

- **Electrical properties**: fluoropolymers have low dielectric constant, high insulation durability, and are used as sheathing materials for wire and cable due to their excellent electrical properties.

- **Inertness**: fluoropolymers are inert, non-reactive and stable (they do not degrade or decompose over time). These properties make them critical to a wide range of industrial and commercial applications in situations where equipment is likely to be exposed to chemicals.

- **Cryogenic properties**: fluoropolymers present excellent cryogenic properties, which makes them particularly suitable for use in high-tech applications such as aerospace, electronics or chemical industries.

- **Separation / barrier properties**: fluoropolymers have excellent moisture barrier and superior gas separation properties. Fluoropolymer membranes are essential to the production of clean hydrogen.

- **Dielectric properties**: dielectric properties cover low dielectric constant (Dk) and dissipation factor (Df) and are unaffected by fluctuations in temperature and humidity. This makes fluoropolymers a critical material for use in electronics and telecommunication applications.

- **Weather resistance**: fluoropolymers are able to maintain their physical properties even when exposed to harsh weather conditions, e.g., environmental degradation, including

---

Concern and Regulatory Criteria to Fluoropolymers," Integrated Environmental Assessment and Management, Henry, Barbara.J., et al.,14, 3 (2018): 316-334. DOI: 10.1002/ieam.4035.

exposure to ozone, ultraviolet radiation and extreme temperatures. This makes them an essential material for architectural coating and films.

- **Durability**: fluoropolymers can withstand harsh conditions while maintaining their physical properties. This makes them particularly important for use in seals, gaskets, and wires and cables insulation.

- **Non-stick properties**: fluoropolymers prevent sticking, making them a material of choice for applications for which sticking is a concern.

This unique *combination* of properties underlies the irreplaceability of fluoropolymers in a wide range of applications, including those noted above. Alternative materials may be able to achieve comparable performance to fluoropolymers for one or a few specific parameters or properties, but overall, due to deficiencies in other properties, they have lower performance and other disadvantages as compared to fluoropolymers. Thus, while alternatives might be considered to be comparable in one or two areas of performance, they often fail to offer the combination of properties that fluoropolymers deliver. It is also important to highlight that, because fluoropolymers are generally more expensive than potential alternatives, for applications where the superior performance of fluoropolymers is **not** necessary, the market has already switched to non-fluoropolymer alternatives.

The unmatched performance of fluoropolymers across multiple areas of performance means that, for most applications in which fluoropolymers are used, attempting to substitute other materials for fluoropolymers will result in a loss of reliability and durability that in many instances will have negative effects on health, safety and the environment as well as negative economic impacts. For example, if a seal or gasket fails in a piece of heavy equipment or a heavy-duty vehicle due to temperature, chemical and mechanical stresses, the failure of that seal could threaten worker safety and result in releases of chemicals into the environment, in addition to causing economic losses due to repair costs and equipment down time. These adverse impacts are averted by the use of fluoropolymers.

Similarly, if a household or commercial appliance fails because a printed circuit board in the appliance was not protected by a fluoropolymer coating and suffered an electrical short as a result, the repair costs and, perhaps collateral costs (e.g., from spoilage) will cause economic loss to the consumer, which will disproportionately impact members of disadvantaged communities. Alternatively, in such a circumstance, the affected appliance might be disposed of prematurely, creating unnecessary waste, unnecessarily occupying landfill space, and unnecessarily consuming virgin resources to manufacture a replacement machine.

Because of the favorable health and environmental safety profile of fluoropolymers, as well as their irreplaceability in a wide range of products and applications that are essential to the daily lives of Minnesota residents and the daily operations of Minnesota businesses, fluoropolymers should be designated as CUU. Moreover, because fluoropolymers are critical components in such a wide range of essential products and applications, as illustrated by the examples described above, we believe it is impossible to compile a comprehensive list of essential products for which fluoropolymers are CUU – which is why fluoropolymers themselves should be designated as CUU. In this regard, we urge MPCA to heed the admonitions of the US Department of Defense in their recent report surveying uses of PFAS compounds that are critical to the national security of the United States.[2] In that report, the Department concluded that:

> PFAS are critical to DoD mission success and readiness and to many national sectors of critical infrastructure, including information technology, critical manufacturing, health care, renewable energy, and transportation. . . . Most of the structurally defined PFAS are *critical to the national security of the United States*, not because they are used exclusively in military applications (although a few are) but because of the civil-military commonality and the potentially broad civilian impact. (emphasis in original)[3]

Importantly, many of the critical PFAS applications identified by DoD are fluoropolymer applications. These include:

- subcomponents in modern Li-ion batteries: electrolyte solutions, cathode binders, separator coatings, casing materials, and gaskets;
- semiconductor fabrication;
- microelectronics applications, including base laminate materials used in Radio Frequency (RF) and microwave circuits;
- printed circuit boards;
- mold release agents and films typically used in composite manufacturing processes;
- hoses, tubing, hydraulic system lines, O-rings, seals and gaskets, tapes, and cables and connectors widely used in civil and military aircraft, space systems, vehicles, weapon systems, utility systems, and other applications;
- resins for specialty high-temperature or weather-/UVresistant composites; and
- specialty filters and membranes (e.g., aviation filters).[4]

Finally, it is noteworthy that the Department of Defense spent nearly $100,000 and took more than one year to complete its report. Nevertheless, the Department highlighted that the information on critical uses contained in the report "represents a fraction of the mission critical PFAS uses" due to a lack of knowledge about the composition of products and components.

---

[2] US Department of Defense, Report on Critical Per- and Polyfluoroalkyl Substance Uses (August 2023), available at: https://www.acq.osd.mil/eie/eer/ecc/pfas/docs/reports/Report-on-Critical-PFAS-Substance-Uses.pdf ("DoD report").

[3] Id. at 15.

[4] Id. at A1-A7.

Therefore, DoD noted, "a more complete understanding of PFAS essential uses would require an extensive and complex evaluation of the market, a gap analysis of current requirements for manufacturer-provided product information, and illumination of the value chain of products." In other words, identifying all currently unavoidable uses of PFAS is a herculean task, and the DoD's year-long effort to catalogue such uses touched only the tip of the iceberg. For this reason and others articulated above, we urge MPCA to designate fluoropolymers (and articles manufactured from fluoropolymers) as CUU, since it is impossible to identify all individual products and components in which the use of fluoropolymers is currently unavoidable.

Below we address the specific questions for which MPCA has sought comment in the Agency's Request for Comments.

1. Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

MPCA should define criteria for determining "essential for health, safety or functioning of society." Moreover, products in commerce that do not present a risk, or present only an insignificant risk, to human health or the environment should be presumed to be "essential for health, safety or functioning of society" since, if they do not present a risk, there is no basis to remove them from commerce. Because fluoropolymers have been demonstrated to satisfy internationally accepted criteria for being polymers of low concern, MPCA and stakeholder time and resources should not be wasted on an essentiality analysis. Neither should Minnesota residents and businesses be denied access to a wide range of products important to their daily lives simply because those products contain a polymer of low concern.

If a potential significant risk to human health or the environment is identified with respect to the use of PFAS in a product, MPCA should conclude that the product is "essential for health, safety or functioning of society" if any of the following criteria are satisfied:

- If the product or one or more of its components were not available:
  - There would likely be an increase in negative health outcomes or safety threats;
  - It would likely be more difficult to mitigate risks to human health or the environment;
  - Threats to critical infrastructure[5] or supply chains will likely increase or become more difficult to mitigate;
  - Systems, products, functions or services that are relied upon for the ordinary daily functioning of society will likely become less available or less reliable

[5] For purposes of defining critical infrastructure we urge MPCA to consider the sixteen critical infrastructure categories identified by the Cybersecurity and Infrastructure Security Agency (CISA), which can be found at the following URL: https://www.cisa.gov/topics/critical-infrastructure-security-and-resilience/critical-infrastructure-sectors.

- The product, or one or more components, is required by federal or state law or regulation (e.g., to satisfy emissions standards or safety requirements)
- The product or component is integral to one or more of the following:
  - climate mitigation
  - critical infrastructure
  - delivery of medicine
  - lifesaving equipment
  - transportation
  - manufacturing or construction
  - critical and emerging technologies[6]

More generally, the concept of "essential" must be interpreted broadly in order to be workable. Under a narrow interpretation of it might be argued that products such as cell phones, laptop computers, or automobiles are not "essential to the functioning of society" since society can continue to function without these conveniences. But a constrained interpretation such as this fails to properly account for the fact that these types of products are both beneficial and an essential feature of our society. Similarly, under a narrow interpretation of "essential" it could be argued that products such as refrigeration units are not "essential to health" since people can live healthy lives without refrigeration. However, this narrow interpretation ignores the critical role that refrigeration plays in supporting good health by preventing food spoilage and preserving pharmaceuticals. These are merely a few examples of the types of products that, if they became unavailable, would cause massive social and economic dislocation. To avoid this type of disruption we strongly urge MPCA to adopt a broader interpretation of "essential".

Finally, we urge MPCA to heed DoD's warning against overly-broad restrictions on PFAS chemistries. As the Department noted:

> Emerging environmental regulations focused on PFAS are broad, unpredictable, lack the specificity of individual PFAS risk relative to their use, and in certain cases will have unintended impacts on market dynamics and the supply chain, resulting in the loss of access to mission critical uses of PFAS. These market responses will impact many sectors of U.S. critical infrastructure, including but not limited to the defense industrial base.[7]

In developing regulations interpreting the concept of "essential" MPCA should ensure that the term is interpreted broadly enough to encompass uses of PFAS that are important to the ordinary daily functioning of society.

[7] DoD Report at 15.

2. **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

Cost is just one factor that must be considered in assessing whether an alternative is "reasonably available" to replace an incumbent chemical in a product. Specifically, an alternative should be found to be "reasonably available" only if the following criteria are satisfied:

1. The proposed alternative is demonstrated to perform the functions of the incumbent substance in a particular end use application at least as well as the incumbent substance, based on objective, quantifiable data.

2. The proposed alternative is demonstrated to satisfy any applicable standards, specifications or qualifying criteria necessary for deployment of the alternative in a particular end use application.

3. Existing supply chains for the proposed alternative can support, without interruption, the increased demand that would result from substitution of the incumbent substance.
