4. Substitution of the potential alternative for the incumbent substance in a particular product will not substantially increase the cost of the product. For purposes of this criterion, a cost increase should be considered "substantial" if it exceeds the current rate of inflation at the time of the assessment. In addition, the cost should be evaluated based on the entire life cycle cost, which includes not only manufacturing, but also the maintenance and disposal costs.

In other words, an alternative cannot be considered "reasonably available" if: (i) it does not perform a required function at least as well as the incumbent substance; (ii) it does not satisfy any applicable standards, specifications or qualifying criteria necessary for deployment of the alternative; (iii) is not available at scale; or (iii) implementation of the alternative will appreciably increase the cost of the product.

With respect to costs in particular, MPCA should not assume that the adoption of an alternative will be cost neutral in terms of the manufacturing process. There are critical cost considerations around potentially needing to retool production facilities, changes in production yield, worker training, and disposal costs. In addition, MPCA should consider what effect the adoption of an alternative might have on the price of the final good and whether such a price increase would affect the ability of disadvantaged communities in Minnesotan to access or maintain important products like mobile phones, computers, automobiles, household appliances, and others.

3. **Should unique considerations be made for small businesses with regards to economic feasibility?**

It is reasonable to expect that small businesses will be disproportionately affected by the Law, since it will likely be more difficult for small businesses to identify, test and procure alternative(s) and to implement any process and/or equipment changes and/or employee training necessary to adopt the alternative(s). We encourage MPCA to consider opportunities to alleviate these burdens on small businesses, for example, through exemptions or delayed compliance deadlines.

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

An alternative should not be considered “reasonably available” unless it is demonstrated, through scientific data, to present less risk under intended conditions of use than the incumbent substance. In other words, a “safety” assessment should examine the comparative ***risks*** (i.e., hazards and exposures) presented by the incumbent and the proposed alternative. As a threshold matter, this would require MPCA to determine that the product containing the incumbent substance presents an appreciable risk to human health or the environment. If the incumbent substance does ***not*** present an appreciable risk, the substance should be designated as being CUU. Furthermore, any comparison of potential risks must include an assessment of the risks resulting from an increased likelihood of product or product component failure or decrement in product performance from the deployment of an alternative to the incumbent substance.

MPCA should articulate data quality criteria that will be applied in assessing relative risk and should adopt a weight of evidence approach to the assessment. Thus, for example, scientific studies should be accorded more weight than anecdotal evidence; surrogate data should be accorded less weight than data on the substance under consideration, and so forth.

MPCA should also consider sustainability impacts such as water use, consumption of raw materials, emissions reduction, energy efficiency, reliability during use, and avoiding the use of landfill capacity.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

Products in commerce that do not present a risk to human health or the environment should be presumed to be “essential for health, safety or functioning of society” without any time limit or reevaluation, since, if they do not present a risk, there is no basis to remove them from commerce. For other products, CUU determinations should last until demonstrably safer alternatives are identified that (i) are demonstrated to perform at least as well as the incumbent substance; (ii) satisfy any applicable standards, specifications or qualifying criteria necessary for deployment of the alternative; and (iii) can be implemented at scale and with no significant increase in costs.

Significant changes in available information that formed the basis of the original CUU determination should trigger a re-evaluation. Re-evaluation should apply to ***both*** affirmative CUU determinations, as well as CUU denials.

In no case should re-evaluations take place more frequently than 10 years. MPCA should consult with potentially affected industries to determine if a longer re-evaluation period may be necessary to evaluate alternatives or otherwise provide information for the re-evaluation process. In addition, for any CUU that is declined (including CUUs that were granted and then subsequently declined on reevaluation), manufacturers must be provided adequate time to transition to the alternative.

6. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

MPCA must establish an accessible and efficient process by which manufacturers and users (or their representatives) can request a CUU determination from MPCA. The process should be flexible enough to accommodate multiple uses of a substance to be addressed in a single request, rather than requiring separate requests for each individual application – which create a huge and unnecessary burden on both MPCA and stakeholders.

A manufacturer or user that makes a timely submission of a request for a CUU determination should not be penalized if MPCA is unable to process the request by the statutory deadline of January 1, 2032, for identifying CUUs. In such cases, the manufacturer should be exempt from the ban until MPCA makes a final determination on the CUU request. In addition, if MPCA rejects a CUU request, the Agency should be required to provide the requestor with a concise explanation of the specific factors and sources of information MPCA relied upon in rejecting the CUU request.

It is reasonable to establish a process to request a reevaluation of a CUU determination. However, there is no need to establish a process for making a “not a CUU” request for products that have not received a CUU determination. Furthermore, any process around the granting or re-evaluation of a CUU must protect trade secrets. In particular, the Agency must provide clear instructions regarding the specific steps that must be taken to officially assert and/or substantiate a trade secrets claim for information submitted that qualifies as a trade secret under Minnesota law, including the timeline by which such claims must be made. In addition, the Agency should define a process whereby a manufacturer or user is notified if its trade secret is subject to a public records request or is inadvertently disclosed by the Agency.

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

A representative list of products that should be designated as CUU is provided in Attachment A to this letter. This list is illustrative, not comprehensive.

8. **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

Yes, MPCA should propose some initial CUU determinations as part of the rulemaking process, to provide manufacturers, supply chains and downstream users in Minnesota with greater certainty about the regulatory status of products that are integral to their operations and daily lives.

Please let us know if you have any questions regarding the information presented in these comments. We would welcome the opportunity to discuss this crucially important with you, and we would be happy to provide you with additional relevant information regarding the products and applications identified in this submission. Should you have any questions or concerns, please reach out to Ahmed El Kassmi at 610-423-4312 or by email at ahmed.elkassmi@agc.com.

Sincerely,

Christopher F. Correnti

Representative list of CUU applications

Sector	Representative application(s)
Transportation	· Cable and wire coatings and sheathing for civil and military aircraft, aerospace, motor vehicles, watercraft, and other transportation modes, including high temperature sensor cables (e.g., sensor cables for emissions reduction and improvement of engine efficiency) · Mold release film for composites used for aircraft and helicopter fuselage, wings, etc. · Coatings for aircraft exteriors and interiors and motor vehicle exteriors · Fuel cell components including: polymer electrolyte, catalyst ink binder for Proton Exchange Membrane Fuel Cell (PEMFC), as well as humidifier/drier in balance of system for fuel cell vehicle to control moisture of incoming hydrogen required for reliable and efficient operation of the fuel cell. · Hoses and tubes, including brakes hoses, hydraulic hoses and fuel hoses to reduce evaporative fuel emissions in combustion engine vehicles · Oil seal components, piston rings, shock absorbers, bearings and gasket · Lubricants where other lubricants are not suitable, such as bushings for car door hinges, and trunk lids · In ABS and braking systems because of safety needs · Coatings for engine parts, protection film
Electronics	***Semiconductors*** · Molding assist film for power semiconductors packaging in Fuel Cell Vehicles and Battery Electric Vehicles · Coating for electronic semiconductor wires · Air and liquid filtration filters used in the semiconductor industry · Molded products for semiconductor equipment, tubes/release sheets used during semiconductor processing · Advanced Semiconductor Packaging · Pellicles for Semiconductor chip manufacturing

Sector	Representative application(s)
	· Seals, gaskets, O-rings, packings, linings and coatings for pipes and joints for semiconductor manufacture · Encapsulating material for UVC LED chip · Surface coatings of fixing films ***Batteries*** · Solid-state lithium batteries for electric vehicles ***Printed Circuit Boards*** · Mold release film in compression lamination of printed circuit boards, in semiconductors, optoelectronics components, standard packaging to protect memory chips and sensor devices used for mobile devices, data centers, and LED lens production · Substrate for print circuit board · Sound transmission membranes in circuit boards, antennas for mobile phones, technical / industrial linings, electromagnetic flowmeters · Heat-resistant sheath wire in electronic equipment operating at high frequencies and high temperature · Heat-exchanger flue gas de-sulfurization, SF6-circuit breakers, venting and insulation ***Cables & Wire, Other*** · Coating material for wires, coaxial cables and various other cables for chemical resistance conforming with international factory mutual standards (fire risk reduction) · Heat-resistant sheath wire in electronic equipment operating at high frequencies and high temperature · Optical fibers · Antifouling and mold-release coating agent for touch panel glasses, lenses and mirrors; functional anti-smudge coatings applied to various substrates (e.g. glass, metal, plastic), removing sebum and fingerprints on exterior parts (e.g. cover glass, housing, camera module in portable devices) especially smart phones and other touchscreen applications; coatings for automotive use (e.g. instrument panels with touchscreen interface); adhesion prevention for glass and parts for multifunctional printers
Communications	· Plastic optical fiber (POF) in telecommunication · Coating of special optical cables called “buffer tubes” · Coating of signal cables

Sector	Representative application(s)
	· Tubes and machine or injection molded parts, printed circuit boards material for use in high-speed communication technology
Medical devices and life sciences	***Tubes, catheters, etc*** · Catheters for intravenous and inside body interventions; small "non-kink" tubes; endoscopy; pancreatic and biliary stents; foreign body retrieval devices; balloon dilators; needles, brushes and specialty items; single use snares in colonoscopies; endoprostheses · Gaskets; diaphragms in medical ventilators/respirators and sterile syringe filters; membrane filters for sterile venting of gases, aggressive fluids, acids & non-aqueous solvents, gas filtration and aerosol sampling; humidifier/drier membranes used in CPAP (Continuous Positive Airway Pressure) machines; breath gas analyzers. · Artificial blood vessels · Dialysis-related devices · Surface coating for medical devices · Packaging of terminally sterilized medical devices · Coatings for biochip devices ***Equipment & Manufacture*** · Laminate rubber stoppers · Wire sheath material for medical equipment · Humidification or conditioning of various medical gasses · Tubes, seals, gaskets, O-rings, lining of vessels, pipes, valves, hoses, process control devices, pumps, gas scrubbers, dryers, evaporators, heat exchangers and connectors for pharmaceutical manufacturing equipment · Coating for image plate of medical printing film
Construction and Infrastructure	· Roofing and façade material for membrane structures such as train stations, sport stadia, shopping malls, airports, exhibition centers, bridges, greenhouses for commercial-scale growth of fruits, vegetables, flowers, etc. · Sports facilities and sewage disposal facilities · Light weight and composite constructions (development / future application) · Heat-resistant flexible wire · Architectural coatings and paints · Sliding bearings

Sector	Representative application(s)
	· Anti-graffiti overlay for traffic signage / safety · Laminate films to provide antifouling and touch-proofing of metals, fire and heat resistance and oil resistance to kitchen hoods
Food Contact and Processing	***Food industry*** · Seals, O-rings, gaskets, tubing and pipes, valves and fitments, tank linings, sensor covers, and non-adhesive coating for food equipment · Lining of food cans · Ion exchange membranes · Industrial-scale food and feed processing equipment, in seals, tubes, pipes, hoses, o-rings, gaskets, valves and fitments, conveyor belting, tank lining, filter membranes, sensor covers, lubricants and equipment specific to food and feed transport.
Energy	***Oil & Gas and Mining*** · Cables and cable outer "jackets", including sub-sea heating cables and self-regulating heating cables. · Structural or fluid handling components · Coating resin material for electrical wires for crude oil drilling · Wire insulation for downhole sensor cables, extract duct coating, trace heating for cold production areas, and self-regulating heating cables for cold areas · Dehumidification of sample gas for analysis · Packers, blow out preventers, seals, gaskets and O-rings ***Nuclear*** · Cables and wires, including cables of control rooms, sensor cables, and general cables for the industry. ***Photovoltaics and Wind*** · Building integrated photovoltaic (BIPV) modules, solar panels, molding wind turbine composites · Next-generation solar cells for BIPV and megasolar projects · Coatings for PV modules · Coatings for wind turbine blades and towers ***Hydrogen***

Sector	Representative application(s)
	· Proton Exchange Membrane Electrolyzer (PEMEL): water electrolysis, electromechanical hydrogen compressors and purification and electrolysis plant for renewable hydrogen production ***Other*** · Separator for REDOX flow batteries · Exchange Membrane Electrolyzer for anion exchange membrane water electrolysis (AEM) · Binders for electrode materials in batteries · Release films used for photovoltaic cells, proton exchange membrane of fuel cells, Li-ion batteries · Key polymer electrolyte, also used as a key ingredient of catalyst ink's binder for Proton Exchange Membrane Fuel Cell (PEMFC)) · Coating of tidal power cables · Humidification or conditioning of various gases
Manufacture/ Processing	***Chemical Industry*** · Coating material for industrial wires, coaxial cables and various other cables · Hoses, tubes, gaskets and other seals · Distillation column packings · Rotolining or electrostatic coating, e.g., vessels, tanks, pipes, tubes, elbows, complex manifolds, pump casings and filter housings · Electrodialysis processes for wastewater treatment (desalination and salt concentration) and separation of organic components and inorganic salts (cosmetics, medicals, food, medicine, and purification of intermediates in inorganic synthesis) · Expansion joints, compensators and bellows · Bearings, ball joints, hinges, calipers, valves · Ion exchange membranes for production of caustic soda, potash, chlorine for use in end products such as: paper, aluminum, wind turbines, hydrazine used in fuel cells, rocket fuels, pharmaceuticals, antiseptics, nylon, EDTA, soaps, cleaning agents, household bleaches and germicides, and many organic and inorganic chemicals

Sector	Representative application(s)
	Metal Plating · Acid recovery (acid and metal salt separation process by electrodialysis/diffusion dialysis) ***Water treatment*** · Industrial water treatment; electrodialysis ***Lubricants*** · Solid lubricants where other lubricants are not suitable; thread seal pastes · Coatings for improved rub and scuff resistance, reduction of friction, chemical inertness and temperature resistance and to impart release characteristics (e.g., mold release agents) ***Misc. Equipment*** · Manufacturing equipment such as belts, rollers, heat-sealers in dying, laminating, drying processes · Dryers used to remove moisture from gas samples prior to analysis to improve signal resolution · Dehumidification or humidification pretreatment in pneumatics or compressed gas · Manufacturing equipment, including seals, hoses, gaskets, o-rings, valves, linings in vessels, pipes, reactors, process control devices, pumps, gas scrubbers, 3D printers

SPAN™ SUSTAINABLE PFAS ACTION NETWORK

Office of Administrative Hearings (OAH)
c/o Rulemaking *eComments* website
https://minnesotaoah.granicusideas.com/
Minnesota Pollution Control Agency
Attention: Resource Management and Assistance Division

Regarding: Planned New Rules -- Currently Unavoidable Uses of PFAS

The Sustainable PFAS Action Network (SPAN) is submitting the following comments on the planned new rules that will govern how applicants may seek, and the Pollution Control Agency (MPCA) will consider and make, determinations that the presence of PFAS in a product represents a currently unavoidable use (CUU). Such determinations are of critical interest to SPAN Members because such determinations will establish which products will otherwise be banned from distribution in Minnesota commencing January 1, 2032.[1]

Background on SPAN

SPAN is a coalition of PFAS users and producers that are committed to sustainable, risk-based PFAS management. Our members advocate for responsible policies grounded in science that provide assurance of long-term human health and environmental protection while recognizing the critical need for certain PFAS materials as directly contributing to essential functions in our modern economy. In a recent study by INFORUM, a Washington-based economic consulting firm, critical PFAS-using industries, such as the automotive, aerospace, air conditioning and refrigeration, medical devices and pharmaceuticals, battery supplies, and semiconductor industries together account for more than six million jobs, annual wages over $600 billion, and more than $1 trillion to the nation's gross domestic product. SPAN was formed with these various and critical uses in mind, to ensure the health of the environment and consumers while maintaining America's global economic edge.

SPAN supports MPCA's efforts to establish a formal process that will ensure the approach taken by MPCA for considering and granting unavoidable use determination is timely, transparent, and has clearly established criteria which are applied fairly. In addition to responding to the specific questions upon which MPCA has requested comment, as set forth below in the numerical order as presented in MPCA's request for comment, SPAN is providing additional comments in its remarks to reiterate many of the topics addressed in its prior submittals to state government officials.

Specific Comments in Response to MPCA's Request

---

[1] As a coalition comprised of various member companies and entities, SPAN expects its member companies, when appropriate to do so, will submit proposals for CUU determinations that are pertinent to their individual products, chemistries, and needs. Nevertheless, SPAN encourages MPCA to take these comments into consideration and to eventually propose categorical CUU determinations which could encompass the uses identified in SPAN's comments below. Doing so will promote efficiencies and resource savings which could benefit MPCA and the regulated community by eliminating the need to issue product-by-product determinations.

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Response: SPAN recommends MPCA provide criteria, definitions, examples, as well as narrative guidance to the regulated community that will further clarify how the Agency will interpret the statutory definition of "currently unavoidable use" (i.e., a use of PFAS determined to be "essential for health, safety, or the functioning of society and for which alternatives are not reasonably available").

- SPAN recommends key terms in the Minnesota statute be further defined by MPCA. The rulemaking proposal should explain how MPCA interprets key terms in the CUU definition; specifically, "essential for health," "essential for safety," and "essential for the functioning of society." SPAN suggests such definitions clarify that "essentiality" involves the concept that if the PFAS-containing product (or use of PFAS) were unavailable, there could be a significant increase in negative healthcare outcomes, or an inability to mitigate significant risks to human health or the environment, or significant interruptions to the daily functions on which US society relies.

- Further, SPAN recommends that PFAS-containing products and uses of PFAS that are considered to be essential for the functioning of society should be defined to include (but not be limited to) PFAS that are critical to climate mitigation efforts, components in critical infrastructures, the delivery of medications, personal protective and lifesaving equipment, public transport, agriculture, scientific research and construction.

- Another key term for which it would be helpful for MPCA to interpret publicly is "alternatives are not reasonably available." Furthermore, it is unclear from the statute what MPCA will consider to be an "alternative" to a specific PFAS or its use in a particular product. For example, does MPCA interpret the term "alternative" to apply specifically and only to chemical alternatives that might be considered a "drop-in replacement" (e.g., a functional equivalent chemically for achieving the specific attribute provided by PFAS when present in a particular end use product), or to also include alternative manufacturing processes (e.g., that reduce or completely remove the use of PFAS in formulating a product), and/or to include *alternative end products* themselves which would negate the need to use a particular PFAS-containing product (e.g., these might include the substitution of the use of an umbrella made of sail cloth in lieu of the use of *outer wear/rain gear* with a PFAS-based water repellent coating).

    - To avoid inadvertently encouraging regrettable substitutions, SPAN recommends MPCA clarify it will consider a variety of important factors affecting whether an alternative is reasonably available. These should include (but not be limited to): (i) the performance capabilities of the alternative when compared to the PFAS-containing products (including the alternative's ability to meet technical specifications such as those required to meet government-issued requirements); (ii) the comparative health and environmental effects of the alternative versus the PFAS material under consideration (based on known effects supported by scientific studies); and (iii) the comparative length of service life and end-of-life disposition of the material in question compared to the alternative under consideration.

- In addition to definitions to be provided by MPCA, SPAN recommends the agency also provide examples of "currently unavoidable uses," and that these include (among others discussed below) all uses that have previously undergone reviews and received federal authorizations for specific uses pursuant to programs such as (but not limited to) the significant new alternatives program (SNAP) under the Clean Air Act; the EPA's new chemicals and significant new uses program under Section 5 of the Toxic Substances Control Act; drugs, medical devices, biologics, and diagnostics and equipment authorized under the Food and Drug Act (FFDCA); pesticides and devices subject to regulation under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA); and other federal programs whereby either the PFAS, or products containing them, have been deemed acceptable for their intended use by federal government agencies. This should include products which are subject to, or PFAS (or a PFAS-containing component) is necessary for meeting, federal specifications (e.g., Department of Defense requirements and military specifications, Federal Aviation Administration standards, NASA requirements).

- Rules to be established by MPCA also should recognize that while many of the product categories identified above may not fully satisfy the statutory provision in Section 8(a) of the law that refers to "a product for which federal law governs the presence of PFAS in a manner that preempts state authority," there are many additional categories of uses that, likewise, should be eligible for CUU determinations because there are, in fact, uses of PFAS which are critical to public health, safety, and/or the functioning of society and may not have reasonably available alternatives at this time. Such a more flexible approach that is not limited simply to a "federal preemption" criterion, will help MPCA concentrate its efforts on identifying non-essential consumer products for which the 2032 prohibition (or one to occur later) might be appropriate. SPAN recommends the following additional categories of products (and their raw materials, components, and replacement parts) be included in a categorical CUU determination to be identified in its eventual regulations:

    - Packaging for drugs, medical devices, biologics, diagnostics, and food contact articles and components subject to the oversight by the Federal Food and Drug Administration or the Department of Agriculture.
    - Items and products and substances required by state laws and regulations.
    - Used product offered for sale or resale, and products that are already owned but may be leased for use but for which ownership is retained by the lessor (e.g., office machinery, rental cars).
    - Transportation equipment including: automobiles, train engines and rail cars and components, packing containers and forklifts, ships and container vessels and services equipment, agricultural vehicles and equipment, motorcycles, construction equipment, wheel chairs and other forms of mobility assisting appliances.
    - Waste disposal equipment and equipment used in storage of waste and hazardous materials and products to ensure the safety and integrity of the containment and disposal systems.
    - Air conditioning, heating, ventilation, and refrigeration equipment and their components and parts including replacement parts and materials.
    - Heat transfer fluids for cooling of electronic components (e.g., data centers);
    - Appliances and equipment used in harnessing energy (e.g., windmills, solar panels).
    - Batteries and other components in electric vehicles.
    - Personal Protective Equipment and outwear for first responders and used in rescue, law

enforcement and defense application.

- Semiconductors, transistors, wiring, insulation, connections, housings and other electronics, and circuit boards which are not exposed (other than during repair or disassembly for disposal) as well as the final packaged semiconductor devices and articles containing them.

Examples of CUUs to be provided by MPCA, and the process established for seeking to add additional ones to the state's initial lists, should allow for latitude and flexibility to permit CUU determinations to be made for items not currently contemplated by MPCA during its impending rulemakings and to encourage, rather than discourage, innovation and economic development. The process established by MPCA should permit product manufacturers and PFAS-containing product users to request CUU determinations to be made even after the notification cycle is completed and continuing even after the 2032 product prohibitions take effect. This is needed to address as yet unknown innovations that might involve uses of PFAS in technologies and applications that could enhance energy efficiency or data processing or climate change mitigating methods, but which lawfully could not be brought to bear in Minnesota after the 2032 prohibitions take effect. MPCA should establish a CUU determination process that will encourage advances in the health care, engineering, transportation, energy storage and recovery, and other technologies that are yet unknowable.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Response: Yes. The standards for reasonably available alternatives should consider both the technical and economic feasibility of alternatives. MPCA should consider specifying that an alternative which is reasonably available must include technical and economic feasibility. This would require that an alternative be both readily available in sufficient quantities and will be available at comparable costs to the PFAS it is intended to replace, and that the alternative perform as well as or better than PFAS in a specific application of PFAS in a product or product component under pertinent specifications and use conditions. Businesses seeking CUU determination should be requested to provide information concerning the availability of alternatives as well as the technical and economic feasibility of the alternative. Furthermore, the health and environmental impacts of the use of alternatives also should be considered. For example, it might be possible to replace PFAS-containing heat resistant PPE for use by fire fighters with asbestos-containing alternatives, however, that particular substitution (or alternative) may not provide net health and environmental benefits which would outweigh the potential concerns related to the use of PFAS.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

Response: Yes. Economic feasibility should be a consideration in addition to technical feasibility (such as meeting performance characteristics). Special consideration for small businesses might include longer periods for prohibitions to take effect.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

Response: The safety of PFAS alternatives should be determined on a comparative basis by taking into consideration the entire lifecycle of the current (PFAS-containing) product in contrast to the "alternative" under consideration. For example, consideration should be given to the methods or manufacture of the alternative, the energy and environmental benefits of the continued use of an existing PFAS-containing product to a potential alternative, the service life of the existing product when compared to the alterative, and the likely environmental and health impacts of end-of-life treatment of and recyclability or disposal of the current and alternative material under consideration. Furthermore, the "safety" determination might need to involve a "comparative-risk" determination including whether an alternative may be available and should be considered for use which may contain PFAS, but a variety of PFAS for which there are fewer health or environmental concerns; in which case, it's use as a phased-in alternative should be considered and encouraged over time. Importantly, a "safety" determination also should consider the potential consequences of a potential failure of an alternative chemistry or PFAS-containing product, for example, if the alternative cannot meet technical standards that can affect safety. Such considerations are critical for PFAS-containing materials that must perform under challenging physical and chemical conditions and under repeated stresses, such as in aerospace and defense applications where failures can have devastating consequences.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?

Response: SPAN recommends MPCA have the authority to issue CUU determinations with appropriate conditions. For example, exemptions from a prohibition might be granted subject to an appropriate time limitation (e.g., a ten-year period with the ability to seek extensions if alternatives remain unavailable), and/or to be contingent on commitments from the product producer to minimize human exposures and environmental releases of PFAS to retain a currently unavoidable use designation. However, such an approach should take into consideration the availability of alternatives and the time required to obtain needed authorizations (e.g., government-issued approvals and customer qualification) before substitutions can occur. Extensions should be considered and granted if needed. Consideration also should be given to international requirements and treaties. Periodic reporting by the exemption recipient also could be a condition of the currently unavoidable use designation.

As noted above, SPAN reiterates that replacement parts for existing materials (including large and complex equipment and machinery) may need to continue to contain PFAS to meet technical and contract specifications and thus should not be prohibited even after the 2032 product prohibitions.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Response: The process MPCA establishes by which businesses may seek CUU determinations should, at a minimum, enable members of the regulated community to request a "currently unavoidable use" classification for one or more products and to provide information sufficient to support a finding by MPCA that there was a basis for MPCA to conclude the product met the criteria to be established for a CUU. If such determinations are to be made through a public rulemaking process, SPAN advocates that the process be open to the proponents and opponents of an unavoidable use determination.

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Response: SPAN Member companies, rather than SPAN itself, will be submitting such product and company-specific requests.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Response: Yes. As previously discussed, SPAN advocates that there are certain basic categories of use that should be considered to be unavoidable, and for which exemptions need not be sought by individual company-specific applicants. This will streamline the process for entities to seek such determinations for unique products and allow MPCA to focus on PFAS of high concern in non-essential uses which we believe is MPCA's ultimate intent with this rulemaking.

Other Comments from SPAN

- Span encourages MPCA to establish an entire framework for implementing its CUU determination program**.** SPAN recommends the state's process should enable potentially affected entities to not only apply for, but also provide guidelines, online resources, and an application portal providing administrative support for essential use determinations. The systems established should provide:
  - Deadlines for when applications must be submitted (including potentially variable timelines for different categories of products);
  - The required contents of such applications;
  - Definitive points in the application consideration processes inclusive of an interactive process whereby reviewers at MPCA may contact applicants to pose questions or seek additional information as required to assist MPCA in reaching a determination; and
  - Timelines for the consideration of and response to the applications (e.g., no later than 90 days following receipt of the application).

Reporting Requirements Under Subdivision 2: Although not responsive to the CUU comment solicitation, SPAN continues to encourage MPCA to prepare (in addition to the proposed regulations for its CUU process) and establish clear and practical reporting obligations for PFAS-containing consumer products under Subdivisions 2 and 3 of the law, which will provide information of value to MPCA's stakeholders, while ensuring any product prohibitions that are eventually codified and the CUU processes that is implemented pursuant to Subdivision 5 and 8 of the law are reasonable and risk-based, and accommodate essential PFAS uses and products that provide important societal benefits. The information gathered under the reporting requirements should be considered, evaluated, and inform any risk-based product restrictions issued by MPCA under Subdivision 5 of the law.

- SPAN advises that MCPA permit entities filing PFAS containing product reports to assert claims of confidentiality for information that is a trade secret or protected for national security reasons. SPAN also emphasizes that confidential information should be kept secure and protected from public disclosure or unintended disclosure, including through hacking efforts and commercial espionage.

- SPAN recommends that MCPA avoid duplicating EPA’s PFAS information collection efforts and place greater emphasis on gathering information on PFAS-containing substances, formulations, and other chemical mixtures that are produced in the state and will undergo further processing and use in the state in a manner that will provide an opportunity for releases and exposures to occur within Minnesota.

- SPAN suggests that MCPA adopt a “reasonably ascertainable” due diligence standard for manufacturers who are attempting to fulfill their reporting obligations and that MPCA make clear that manufacturers may reasonably rely on information provided by the suppliers, if the reporting party can document that proper inquiries were made to suppliers and the efforts they made to obtain information regarding the use of PFAS.

- SPAN requests MPCA clarify certain definitions, including the definition of “Intentionally added” PFAS. Specifically, MPCA should clarify that the definition does <u>not</u> include the following: manufacturing byproducts and impurities that might be unintentionally present in a product in commerce, and PFAS degradants that might be formed during product manufacturing but also be considered unintended components or contaminants.

- SPAN asks MPCA to clarify that the definition in the statute of “product” is, as was intended by the legislature, limited to those products made available to <u>consumers</u> for their personal use. The inclusion in the definition of products that are also made available to consumers for “commercial, or industrial use” or “for use in making other products” unintentionally expands the scope of the products on which the focus should remain. MPCA should include language in the proposal to make clear that PFAS-containing products that are used in commercial settings (e.g., office equipment) and in industrial and manufacturing applications (e.g., industrial and commercial devices, such as mechanized systems and robotics) are *excluded* from the reporting and prohibitions requirements under the law.

- SPAN requests MPCA to align its regulatory definition of PFAS (which currently is the overly-inclusive “single fully-fluorinated carbon atom” definition) with the EPA’s more targeted definition[2] in the TSCA 8(a)(7) reporting rule (a structural definition approach that relies on the presence of at least two fluorinated carbons) which covers significantly fewer substances than the “one fully fluorinated carbon” definition.

<u>Fees</u>: SPAN also recommends that reporting fees be modest and that reporting should be done using an online platform that has been tested and is efficient and “user friendly”. SPAN recommends that fees be

---

[2] EPA’s reporting rules at 40 CFR 705.3 define *Per- and polyfluoroalkyl substances* or *PFAS as* any chemical substance or mixture containing a chemical substance that structurally contains at least one of the following three sub-structures: (1) R-(CF2)-CF(R’)R”, where both the CF2 and CF moieties are saturated carbons; (2) R-CF2OCF2-R’, where R and R ’ can either be F, O, or saturated carbons; (3) CF3C(CF3)R’R”, where R ’ and R” can either be F or saturated carbons.

established on a "per report" basis, or on a per-company basis (as opposed to a "per product" basis) and in a manner that enables a single company filing reports for multiple products to avoid paying reporting fees on a per-product basis.

Prioritization

Although not the focus of the recent request from MCPA for input, SPAN has in its prior submissions supported MPCA using rulemakings as a means to ensure the regulated community and MCPA have a common understanding of the processes and criteria that MPCA will be using for purposes of prioritizing for potential prohibitions under Subdivision 5 of the statute. SPAN has advocated that MCPA should concentrate its resources on products and product categories that, as directed in Section 5(b) of the statute, "in the commissioner's judgment, are most likely to contaminate or harm the state's environment and natural resources if they contain intentionally added PFAS." SPAN continues to recommend that a risk-based evaluation process be structured and applied when identifying products for potential prohibitions. Such a process should take into consideration the factors affecting risk; specifically, hazard (e.g., toxicity, bioaccumulation, persistence) and exposures (e.g., production volumes, conditions of manufacture and use, methods of disposal).

Conclusion

SPAN appreciates the opportunity to provide constructive comments to MPCA and remains available to meet and confer with appropriate MPCA personnel to discuss these comments and other matters pertaining to PFAS and PFAS-containing products.

St. Paul, MN 55155-4194

Re: **<u>SEMI's Comments on the MPCA's Planned Rulemaking for Currently Unavoidable Uses of Intentionally Added PFAS in Products</u>**

Dear Commissioner Kessler:

On behalf of SEMI, the industry association serving the global semiconductor design and manufacturing supply chain, we write to offer comments on the regulations on per- and polyfluoroalkyl substances (PFAS) being developed by the Minnesota Pollution Control Agency (MPCA), as authorized in Minn. St. § 116.943 (Section 116.943). These comments discuss the MPCA's planned rulemaking governing currently unavoidable use (CUU) determinations for products containing intentionally added PFAS (the CUU Rule).

SEMI represents more than 530 member companies in the United States reflecting the full range of the country's semiconductor industry, including design automation and semiconductor intellectual property (IP) suppliers, device manufacturers, equipment makers, materials producers, and subcomponent suppliers. SEMI member companies are the foundation of the $2 trillion global electronics industry, and this vital supply chain supports 350,000 high-skill and high-wage jobs across the United States.

While SEMI fully supports the goal of limiting the release of PFAS into the environment, SEMI has serious concerns about the potential scope of these regulations as well as the risk of their incompatibility with Minnesota's own ambition to expand its semiconductor industry. With the indispensable role semiconductors play in the Minnesotan and American economy and in national security, it is critical that regulatory efforts avoid restricting semiconductor manufacturing, its corresponding supply chain, and future innovation. As such, SEMI has provided specific recommendations in these comments to inform future rule drafting in a way that would avoid irreparable harm to the semiconductor manufacturing industry in Minnesota.

Below we start by underscoring points made in our previous comments submitted on a separate MPCA rulemaking to implement the reporting requirements of Section 116.943. Namely, we discuss how all the MPCA's rulemakings to implement the statute must account for the essential need for PFAS in the semiconductor industry, which in turn underpins both the Minnesotan and national economies. We then organize our comments based around the nine questions in the MPCA's request for comments on the CUU Rule. Our responses to the MPCA's questions make the following points:

- The MPCA should adopt an interpretation of the statutory phrase "essential for health, safety, and the functioning of society" that is flexible enough to accommodate how broad CUU determinations are necessary to avoid adverse societal impacts. Since the statutory phrase contains terms that are naturally broad, it follows that the MPCA's interpretation should be in line with this legislative directive and also be broad.

- Costs must be considered in determining whether an alternative is reasonably available, and this evaluation should reflect not just the cost of the alternative in isolation, but the cost of executing the alternative throughout supply chains and at commercial scale.

- A safety evaluation for PFAS alternatives must consider the totality of risks of the alternative under a lifecycle approach, including but not limited to assessments of the alternative's intrinsic hazard, toxicity, and health risk profile, as well as risks concerning product safety, energy consumption, and disposal.

- CUU determinations should be indefinite since this will give manufacturers necessary repose and Section 116.943 does not authorize time-limited determinations. The MPCA should also encourage that determination requests be submitted by trade associations or other groups of manufacturers. The MPCA must provide sufficient protection of confidential business information (CBI) submitted as part of these requests, and the agency should be required to promptly respond to requests for determinations.

- The MPCA should encourage that CUU determinations be made for broad categories of products, rather than on a product-by-product basis. The latter process would waste both public and private resources, likely result in duplicate requests, and risk missing products that are clearly CUUs but are not covered by a determination because of arbitrary line drawing.

- As part of this rulemaking, the MPCA should grant a CUU determination that covers all uses of intentionally added PFAS in all materials and processes in the semiconductor value chain, including the final semiconductor devices on their own and when present in other end products (i.e., semiconductor devices present in industrial, commercial, and consumer products). This is because semiconductors make modern life possible, and they are therefore essential to health, safety, and the functioning of society. PFAS alternatives are also not reasonably available for use in the semiconductor industry.

I. WITHOUT CAREFUL DRAFTING, THE MPCA'S RULES TO IMPLEMENT SECTION 116.943 WILL SEVERELY DAMAGE CRITICAL INDUSTRIES AND THE HIGH-TECH ECONOMY

1. PFAS are Essential to the Semiconductor Industry

PFAS are essential to the semiconductor industry because of their low surface tension, high heat and chemical resistance, high thermal stability, radiation stability, electrical characteristics, compatibility with other chemicals, and other unique properties. These properties enable PFAS to fulfill the purity criteria required for semiconductor manufacturing. PFAS are used by the industry to meet many needs within the manufacturing process and can be found in various equipment, materials, and other critical components, including in the following:

- Control and distribution systems (pipes, pumps, valves, etc.);
- Various components in a wide range of processing tools;
- Ancillary articles (such as tubing, gaskets, containers, and filters);
- Lubrication (such as oils and greases);
- Heat transfer fluids and refrigerants for high-precision temperature control units and process chillers;
- Facility systems in semiconductor manufacturing factories such as water and chemical distribution, waste removal systems, and exhaust systems; and
- Process chemicals in photolithography, dry etching, cleaning, deposition, and other processes to reduce the potential for defects and to enable high-resolution microstructures and deliver required yield.

In short, the semiconductor manufacturing process is enormously dependent on PFAS, the majority of which currently have no viable alternatives.

2. **The Semiconductor Industry is a Crucial Part of Minnesota's Economy That Could Be Severely Damaged by the Rules**

Subdivision 2(d) of Section 116.943 makes it unlawful for companies to sell, offer for sale, or distribute for sale in the state a product containing intentionally added PFAS unless the manufacturer has reported the required information, and that manufacturer has received notification of MPCA-ordered testing under subdivision 4. In addition, subdivision 5 makes it unlawful for companies to sell, offer for sale, or distribute for sale in the state a product containing intentionally added PFAS starting January 1, 2032, unless the MPCA has determined by rule that the use of PFAS in the product is currently unavoidable.

Without the requested waiver from reporting for semiconductor manufacturers (as mentioned in our previous comments to the MPCA) and CUU determination for the semiconductors (as discussed in more detail below), Minnesota's robust semiconductor industry would suffer enormous damage. The state is home to one of the strongest semiconductor value chains in the United States, including a well-developed and robust design and fabrication network.[1] Minnesota-based companies annually export over $1.2 billion in semiconductor-related components and import nearly $575 million in semiconductor-related components.[2] According to the Minnesota Department of Employment and Economic Development, the state's semiconductor and other electronic manufacturing sector includes 153 firms supporting 9,588 jobs with an average annual wage of $68,692.[3]

PFAS are critical to the development and manufacturing of semiconductors, meaning that an overly broad and restrictive regulatory approach will cost Minnesota-based businesses and workers a major

opportunity to benefit from the robust federal industrial policy authorized in the *CHIPS and Science Act* (P.L. 117–167). Implementation of the MPCA's planned rules without incorporating the requests discussed in our comments will not only hinder Minnesota's high-tech economy and the many other sectors that rely upon it, but will also jeopardize the state's ability to capitalize on the billions of dollars that the federal government is planning to invest in the semiconductor industry via the CHIPS Program. In particular, the $500 million Minnesota Forward Fund, which was established in part as a resource for matching federal CHIPS funds, will be rendered unusable for one of its original purposes.

3. **The Rules Could Run Counter to National Efforts to Support the Domestic Semiconductor Industry**

Chip shortages resulting from manufacturing disruptions caused by the COVID-19 pandemic continue to impact global supply chains for several key industries and have highlighted the country's dependence on overseas suppliers of semiconductors and chips. Addressing these shortages has been one of the most bipartisan issues at the federal level with the Biden Administration and Congress working together to incentivize the reshoring of semiconductor and chip manufacturing to the United States.

In August 2022 Congress passed and the President signed the bipartisan *CHIPS and Science Act*. The goals of this law, which is focused on supporting domestic semiconductor manufacturing, are multifaceted. First, the law aims to reduce the dependence of the United States on foreign countries for critical semiconductor components, thereby ensuring a stable and secure supply chain. Second, the law aims to boost domestic innovation and competitiveness in the semiconductor industry by providing funding opportunities for research, development, and manufacturing capabilities. Finally, the law seeks to create high-quality job opportunities and strengthen the overall economy by revitalizing the domestic semiconductor manufacturing sector.

As part of the implementation of this law, Representative Betty McCollum (D-MN) and U.S. Senate Majority Whip Dick Durbin (D-IL) made the following remarks in a letter[4] to Secretary of Commerce Gina Raimondo:

> *Over decades of use, PFAS have been widely integrated into our modern society and in many cases, there are not currently any viable replacements for their function. These 'essential uses' are vital to our economic and national security, particularly in regard to their use in semiconductor manufacturing . . .*
>
> *. . . The CHIPS and Science Act provides a unique opportunity for the Commerce Department to engage and invest in tackling the issue of PFAS essential uses. This monumental legislation has set the U.S. on a course to onshore semiconductor manufacturing and continue to lead the world in advanced technology development and production . . . it is vitally important that [the National Semiconductor Technology Center] priorities include research into PFAS alternatives, as well as recycling, removal, and destruction of these harmful materials.*

---

[4] Letter from Rep. Betty McCollum and Senator Dick Durbin to Secretary Raimondo (May 22, 2023), https://mccollum.house.gov/sites/evo-subsites/mccollum.house.gov/files/evo-media-document/23.05.22-commerce-letter-support-pfas-alternatives-research-in-chips-act-implementation-mccollum-durbin.pdf.

More recently, the U.S. Department of Defense weighed in on the issue of PFAS in its Report on Critical Per- and Polyfluoroalkyl Substance Uses.[5] The findings highlight the singular and currently irreplaceable role that PFAS play in the semiconductor manufacturing process:

> *Currently, no alternatives to PFAS have been identified that can provide the functional properties required for photolithography or some applications in semiconductor manufacturing equipment. Even if alternative chemicals and technologies were discovered today, due to the extremely complex qualification process throughout the value chain, it would take another 15 years to deploy them in high-volume manufacturing. Therefore, continued access to PFAS is a prerequisite for high-volume and advanced semiconductors. Lack of continued access to PFAS could lead to an inability to produce and supply semiconductor manufacturing technology.*
>
> *Replacing most PFAS uses in semiconductor fabrication would require industry-wide retooling and other process innovations, at a minimum. Some might be achievable within 10 years, but many would not. As stated above, there are some PFAS uses for which no alternatives are known. For these uses, it may be necessary to invent novel chemistries and processes. Replacing PFAS in semiconductor fabrication could be a 25-year effort and may not succeed in all respects if alternatives cannot be identified or qualified at the microchip level.*

This federal effort recognizes that semiconductors enable critical technologies and industries that form the foundation of the U.S. economy, including the automotive industry, defense, electronics, communications, data storage and analysis, legal and regulatory infrastructure, scientific (including materials) research, medicine and medical devices, the green energy transition, transportation (including aviation), and much more. PFAS are used in all of these sectors, and any regulatory effort that too hastily and broadly restricts, and requires burdensome reporting tied to a restriction, on PFAS risks irreparable harm given these uses. Moreover, broad PFAS restrictions and reporting schemes can have the unintended consequence of hampering efforts to develop PFAS alternatives and develop capture, concentration, and destruction technology to prevent environmental release rather than funding and supporting such efforts, since there is no commercially available test method for determining the exact amount of all PFAS in products and research and development for PFAS alternatives will take many years to complete.

Unfortunately, unless carefully planned in light of our comments, the MPCA rules will run counter to the bipartisan effort to improve U.S. competitiveness in semiconductor and microchip development by adding costly and largely impracticable reporting requirements and material restrictions for PFAS in the semiconductor manufacturing process and in components of nearly all commercial and consumer electronic goods. The CUU Rule specifically should be designed to avoid these consequences, as explained further below.

[5] U.S. Department of Defense, Report on Critical Per- and Polyfluoroalkyl Substance Uses (Aug, 2022), https://www.acq.osd.mil/eie/eer/ecc/pfas/docs/reports/Report-on-Critical-PFAS-Substance-Uses.pdf.

II. RESPONSES TO THE MPCA'S SPECIFIC QUESTIONS ON DEVELOPMENT OF THE CUU RULE

1. Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

It is critical that the MPCA promulgate objective decision-making standards that address precisely how the agency will determine whether the use of PFAS in a given product is a CUU, and that these terms be interpreted flexibly and broadly. As the MPCA may be aware, the European Commission has for many years been working on a potential amendment to the Registration, Evaluation, Authorisation, and Restriction of Chemicals (REACH) chemical regulatory framework to incorporate an "essential use" standard for justifying exemptions from restrictions on highly hazardous substances. The complexity of that concept, and the risks of inadvertent omissions or adverse socio-economic impacts, have resulted in numerous delays and drafting challenges. The MPCA should likewise avoid this regulatory morass, and instead adopt practical and flexible definitions that correspond with the likewise practical and flexible terms used by the legislature in Section 116.943.

Section 116.943(j) defines "Currently unavoidable use" as "a use of PFAS that the department has determined by rule under this section to be essential for health, safety or the functioning of society and for which alternatives are not reasonably available." SEMI recommends that the MPCA adopt a *broad* concept of "essential" that is both consistent with the requirements of the statute and flexible enough to accommodate the possibility that broad exemptions may be required to avoid adverse impacts on the health, safety, and functioning of society. SEMI suggests that the MPCA consider a provision in the CUU Rule to this effect:

> *The commissioner shall grant a currently unavoidable use determination for PFAS applications or end products, and for the supply chain production activities required to produce such PFAS applications or end products, when the commissioner has evidence, or when a manufacturer, organization, or other entity has submitted evidence, that an application, product or category of products provides benefits relating to health, safety, or the functioning of society and that there are no reasonably available alternative substances or technologies for that use. A product shall be deemed to provide benefits to the functioning of society where the manufacturer has submitted evidence that the product fulfills identified consumer, commercial, or industrial demands for the product in Minnesota.*

This approach would strike an appropriate balance between that reflects the text of the statute, and therefore the legislative intent behind the statute. This is because it would require manufacturers to substantiate assertions that PFAS substitutes are not available, but would presume that ongoing uses where substitutes are not available would be permitted to continue. Further, this burden shifting will promote an objective, factual-based standard where the MPCA can prohibit or restrict products for which adequate evidence of harm to health or the environment exists. Our recommended provision also provides that the MPCA "shall" grant the CUU determination when sufficient evidence is in hand, thereby requiring the MPCA to act when warranted.

Moreover, as indicated in the suggested language above, the MPCA should clarify that uses of PFAS-containing products in manufacturing operations that take place in Minnesota would be covered by CUU determinations for end products that are the result of those operations. In other words, the CUU Rule should make it clear that the CUU determination should apply not only to the end product itself, but to each of the products and processes in the supply chain that are necessary to produce that exempted product. For example, given that articles used in semiconductor manufacturing require several PFAS, including PFA, PTFE, FKM, and PVDF fluoropolymer components, the supply chain that produces fluoropolymers must be covered by a CUU determination for semiconductors to render the determination meaningful.

2. **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

Costs must be considered in determining whether an alternative is reasonably available, and this evaluation should reflect not just the cost of the alternative in isolation, but the cost of executing the alternative throughout supply chains and at commercial scale. It is also critical that alternatives be considered available only where they provide equivalent or better performance. There are several applications in the semiconductor sector where there are no currently available alternatives that meet those requirements. With this in mind, we recommend that the MPCA include the following definition in the CUU Rule:

> *"Reasonably available alternative" means a substance, material, technology, process, or otherwise that is currently available at commercial scale and that, when used in place of intentionally added PFAS, does not result in:*
> *(a) A decrease in availability, performance, life expectancy, or durability of the product or of the supply chain production activities associated with that product;*
> *(b) An increase in manufacturing, design, testing, capital investment, or other costs for the product or for the supply chain production activities associated with that product; or*
> *(c) Risks to human health or the environment that would not be present, or present in lesser degrees, with use of the intentionally added PFAS, including but not limited to risks from toxicity, energy consumption, product safety, and disposal.*

In addition to recognizing the supply chain and commerciality concerns of the alternatives assessment, this definition reflects how the assessment must employ a lifecycle approach that considers all appropriate types of risk from several angles – including but not limited to not risks from toxicity, energy consumption, product safety (e.g., fire risk), and disposal. Only with these considerations will an alternative be viable, and the CUU Rule must reflect this reality.

3. **Should unique considerations be made for small businesses with regards to economic feasibility?**

The flexible consideration of costs and other factors in our above definition of "reasonably available alternative" reflects the fact that the alternatives process can affect businesses in different ways. This is true not just for large companies that could have numerous products subject to Section 116.943 and may therefore struggle with the total costs of implementing PFAS alternatives, but also for small businesses that may not be able to absorb these costs for just one or a few in-scope products.

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

Subsection (c) of our recommended "reasonably available alternative" definition mentioned above accounts for how an assessment of the safety of PFAS alternatives must consider the totality of risks of the alternative under a lifecycle approach, including but not limited to assessments of the alternative's intrinsic hazard, toxicity, and health risk profile, as well as risks concerning product safety, energy consumption, and disposal.

The safety of a PFAS alternative must be scoped out flexibly in the CUU Rule for several reasons. First, PFAS – especially when defined structurally, as is the case in Section 116.943 – is a diverse class of thousands of chemicals. While several individual PFAS have documented environmental and human health profiles, many do not as of yet.[6] It would likely be impossible, and at the least very difficult, for manufacturers to demonstrate to the MPCA that an alternative is safer than PFAS that currently have unknown toxicity profiles. Second, even if a chemical substance in isolation is labeled "safe" in terms of its hazard, exposure, and toxicity, it does not necessarily follow that a product is safer with this alternative than it is with PFAS. This is because the alternative may negatively impact other safety properties of the product, such as those relating to durability, flammability, energy consumption, and disposal. Therefore, the safety of PFAS alternatives as reflected in the CUU Rule must be defined expansively to account for the myriad of safety considerations that exist.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

CUU determinations should be indefinite, because this is needed to give manufacturers the necessary repose to rely on the originally issued determination, and Section 116.943 does not authorize a time-limited scheme. Indefinite determinations reflect how, especially for the semiconductor industry, the identification of PFAS, search for potential alternatives, testing of potential alternatives, and implementation of appropriate alternatives takes many years. Therefore, members of our industry need to be able to rely on a CUU determination for long enough for these steps to occur, and this time cannot be reliably estimated at the onset of the determination.

It would also waste both public and private resources for manufacturers to continually update, and for the MPCA to monitor and assess, CUU determinations on predetermined schedules. This reevaluation process would be akin to the European Commission's assessment of exemptions under the Restriction on Hazardous Substances Directive (RoHS), through which the Commission has contracted with the Oeko-Institut to provide support and technical assistance on such exemptions.[7] The process the MPCA would need to undergo to reevaluate CUU determinations would be even more complex than what is required under RoHS since Section 116.943 pertains to a much larger range of products and chemicals.

When circumstances change after a CUU determination is granted and which warrant a modification or removal of the determination, the manufacturer can notify the MPCA of this change. Only then should the agency be able to remove or modify the determination, since this will promote regulatory certainty and avoid arbitrary modifications or cancellations without the appropriate notice and input of the affected manufacturer. Likewise, if the MPCA initially rejects a CUU determination request, the agency

[6] *See, e.g.*, Agency for Toxic Substances and Disease Registry, *What are the health effects of PFAS?* (last reviewed Jan. 18, 2024), https://www.atsdr.cdc.gov/pfas/health-effects/index.html#:~:text=At%20this%20time%2C%20scientists%20are,do%20studies%20on%20lab%20animals ("At this time, scientists are still learning about the health effects of exposures to mixtures of different PFAS. Additional research may change our understanding of the relationship between exposure to PFAS and human health effects").
[7] *See* Oeko-Institut, RoHS Evaluations, https://rohs.exemptions.oeko.info/project-overview/background.

should be required to explain its reasoning for the rejection and the manufacturer should be given a clear opportunity to appeal the decision.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

The MPCA should encourage that CUU determination requests be submitted by groups of manufacturers or trade groups, since this will help avoid duplicate requests, will allow manufacturers to pool resources, and will ultimately reduce the MPCA's reviewing burden. This is approach is also consistent with a recent request for proposals on CUU determinations announced by the Maine Department of Environmental Protection (DEP) to implement that state's PFAS in products law.[8]

Stakeholders should not be permitted to request that use of a specific PFAS be classified as "not currently unavoidable. Section 116.943 does not authorize this process. Such requests would not be grounded in the CBI and trade secret information to which only regulated parties have access. Such requests would also be unnecessary since all stakeholders would have an opportunity to comment on the MPCA's rulemaking processes to execute CUU determinations.

Finally, the information to be submitted in support of CUU determination requests must be limited to what Section 116.943 authorizes. Specifically, this information should be cabined to:

- Identifying product information, including a brief description of product families or product categories when applicable (where the PFAS use and alternatives analysis are similar);
- Description of the intended use of the product and an explanation of why the product is essential for health, safety, or the functioning of society;
- Description of the function of intentionally added PFAS in the product;
- Description of why there are no reasonably available alternatives for the intentionally added PFAS in the product; and
- Any other information that the manufacturer wishes to include.

As part of any information required to be submitted in support of a CUU determination request, the MPCA must employ a well-defined CBI framework to protect manufacturers' valuable intellectual property. As expressed in our previous comments to the MPCA on the reporting rule under Section 116.943, semiconductor production – as well as the advanced manufacturing and technology sectors in general – treat the chemical composition of materials as proprietary information that is carefully protected and of significant commercial value.

Therefore, all of the MPCA's planned rules to implement Section 116.943 and which require submission of information from manufacturers need to include detailed provisions about how such information can be submitted (1) while respecting its status as CBI and trade secret; (2) in an aggregated manner to protect confidentiality while still providing for public release of nonconfidential portions; (3) through a

[8] Maine DEP, *PFAS in Products: Currently Unavoidable Uses* (updated Jan. 10, 2024), https://www.maine.gov/dep/spills/topics/pfas/PFAS-products/cuu.html (noting that "[p]roposals may be submitted by manufacturers individually or collectively" which Maine DEP confirmed in informal communications means that trade associations may submit proposals).

system with clear standards on what information will be kept confidential; and (4) with assurances on how such confidential information in the MPCA's possession will be protected from disclosure. Information that requires careful protection would include, for example, the identity of any PFAS in the product, the volume and concentration of such a substance, and any information related to sales volumes or production volumes.

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

As part of this rulemaking, the MPCA should grant a CUU determination that covers all uses of intentionally added PFAS in all materials and processes in the semiconductor value chain, including in upstream semiconductor supply chain industries, the semiconductor manufacturing process itself, and for final packaged semiconductor devices. Some examples of CUU PFAS applications in each of these three subcategories include:

- Uses in upstream semiconductor supply chain industries, including but not limited to uses of fluoropolymers and other PFAS in high-purity chemical production and packaging, and fluoropolymers and other PFAS integrated into semiconductor manufacturing equipment;
- Uses within the semiconductor manufacturing process, including but not limited to PFAS ingredients within specialty chemicals and fluids, fluoropolymers and other PFAS used in production of high-purity water and chemicals, and uses of fluoropolymers and other PFAS in facility systems; and
- Uses within final packaged semiconductor devices, including but not limited to PFAS contained in finished semiconductor devices and component parts such as encapsulants, thermal interface materials, adhesives, coatings, substrates, wiring, connections, and circuit boards.

The semiconductor industry has invested significantly in (1) identifying PFAS uses in the value chain for semiconductor manufacturing and in semiconductor devices, (2) phasing out PFAS use where possible (such as the use of perfluorooctane sulfonates, or PFOS, in photolithography), and (3) regularly evaluating the availability and efficacy of non-PFAS alternative chemicals or alternative processes or materials. Indeed, the industry has been a global leader in these efforts for many years, including decades of work on the phase-out of PFOS and PFOA.

These efforts increased substantially over the past three years in anticipation of the EU universal PFAS restriction proposal under REACH. In preparation for the public consultation that took place last year on that proposal, the semiconductor industry through the Semiconductor PFAS Consortium established a substantial industry-wide collaboration platform that made deep investments across the sector. That process documented PFAS uses in the semiconductor value chain, identified the unique functionality and performance attributes that various PFAS (including fluorinated polymers) conferred that made them essential to semiconductor production, and evaluated the availability of alternative substances, materials or processes.[9] This work culminated in over 600 pages of technical reports and substantiation,

[9] Additional detail on evaluation of potential alternatives for currently unavoidable uses of PFAS materials in semiconductor manufacturing can be found in Appendix A. The information contained therein is excerpted from SEMI's submission to European Chemicals Agency in response to the proposed PFAS restriction under REACH. That

broken down by broad sub-categories of uses and applications within our sector.[10] These materials, when considered in their totality, constitute more than ample substantiation for SEMI's request that the MPCA make a determination that all current PFAS uses within the semiconductor sector are CUUs.

In brief, these papers demonstrate that many different PFAS are used in chemical formulations, components of manufacturing process tools, facilities infrastructure, and packaging used to make the semiconductor devices that are integral to the modern world. The current semiconductor state of the art is critically reliant on the use of PFAS chemistry due to the inimitable characteristics of the element fluorine and substances containing fluorine. Given the unique properties of PFAS, it will be extremely difficult, and impossible in some instances, to find viable alternatives in the short and medium terms without substantially impeding or reversing the technologies that the modern economy relies on. The use of PFAS-free alternatives in our sector could also result in environmental impacts, such as from the potential for decrease in yield and therefore an increase in chemical concentrations, water usage, energy consumption, and waste generation.

To support our requested CUU determination, the Semiconductor PFAS Consortium papers linked to in footnote 11 address the following individual topics:

1. Background on Semiconductor Manufacturing and PFAS
2. PFAS-Containing Surfactants Used in Semiconductor Manufacturing
3. PFOS and PFOA Conversion to Short-Chain PFAS-Containing Materials Used in Semiconductor Manufacturing
4. PFAS-Containing Photo-Acid Generators Used in Semiconductor Manufacturing
5. PFAS-Containing Fluorochemicals Used in Semiconductor Manufacturing Plasma-Enabled Etch and Deposition
6. PFAS-Containing Heat Transfer Fluids Used in Semiconductor Manufacturing
7. PFAS-Containing Materials Used in Semiconductor Manufacturing Assembly Test Packaging and Substrate Processes
8. PFAS-Containing Wet Chemistries Used in Semiconductor Manufacturing
9. PFAS-Containing Lubricants Used in Semiconductor Manufacturing
10. PFAS-Containing Articles Used in Semiconductor Manufacturing

As a result of this industry-wide collaboration, SEMI has identified at least 60 distinct categories of critical PFAS uses throughout the semiconductor value chain (with many different sub-applications and specific PFAS chemistries used within each of these general use categories). A brief description of some of those uses with a description of unsuitable substitutions that have been considered, as excerpted from SEMI's input to the EChA request for public consultation to the proposed REACH PFAS restrictions, is included in Appendix A of these comments. It is important to note that any timelines provided for alternatives presume that there are no known alternatives at present and that such timelines start when a feasible replacement has been identified.

submission can be viewed at https://echa.europa.eu/documents/10162/17233/rest_pfas_rcom_part13_en.docx/5e750ee1-0541-fe43-8272-851fcbf75c4e?t=1686824437443&download=true (comments embedded on page 51).

[10] All of this information has been made publicly available at the following website for the Semiconductor PFAS Consortium, subject only to a short, free registration requirement: https://www.semiconductors.org/pfas/#:~:text=AND%20SEMICONDUCTOR%20PROCESSING%20%3E-,Technical%20Papers,-The%20Semiconductor%20PFAS.

As the detailed papers at the Semiconductor PFAS Consortium website explain, each of these general use categories, and each of the various sub-applications within these uses, relies on one or more PFAS for critical performance functions. In addition, alternative chemicals or processes are not available for these uses because they do not exist, or where they may exist they require substantial lead time (with timelines that extend beyond, and sometimes well beyond, 2032) to redesign and requalify equipment and production processes.

The Semiconductor PFAS Consortium website also includes two additional resource documents which have been incorporated by reference in our comments here:

- An overview paper that summarizes the key major PFAS use categories and identifies the impacts of premature restrictions on PFAS uses in our sector; and
- A socioeconomic impact assessment that is specifically focused on the foreseeable direct and indirect costs of a broad PFAS restriction in Europe, prepared as part of the industry's response to the proposed universal PFAS restriction under REACH. Although this paper is focused on the EU, the types and magnitudes of identified impacts are broadly representative of the effect of analogous restrictions as being implemented in Minnesota.

We believe even a review of this evidence will demonstrate to the MPCA that we have amply satisfied the burden to demonstrate the essentiality of PFAS for these uses as well as the substantial timelines that would be required to research and develop alternatives for all required uses, test them, qualify them, and integrate them into our value chain all before the 2032 prohibition takes effect.

8. **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

The MPCA should start making CUU determinations now, as part of this rulemaking, to give manufacturers sufficient time to plan for Section 116.943's 2032 material restriction compliance date. As mentioned above, one of these initial determinations should be granted for PFAS used in the semiconductor industry.

9. **Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.**

The MPCA must promulgate a binding schedule for reviewing and approving CUU determinations. While the MPCA will need sufficient time to undertake appropriate, reasoned, and objectively supported analyses of CUU determination requests, this must be judged against the arguably longer amount of time manufacturers will need to pursue data collection to fully understand the potential presence, functionality, and alternatives to PFAS applications in their products. All of this must occur well in advance of the 2032 compliance date to give manufacturers an opportunity to make necessary changes or, in drastic situations, change entire product lines. If CUU determinations are not timely reviewed and granted, companies may need to cease business operations altogether in Minnesota.

It is therefore essential that the CUU Rule include a binding schedule for the consideration and adoption of CUU determinations. In addition to the initial CUU determinations that will be integrated into the CUU Rule at the onset, SEMI recommends that the CUU Rule explicitly allow manufacturers to request CUU determinations at any time and at the very least through an annual submission process. The MPCA should then be afforded a maximum of 6 months to adopt a final decision on the request. If the agency fails to timely respond to a request, that should function as an automatic CUU determination for as long as the MPCA is late. This is crucial to avoid a situation where a manufacturer is forced to make a product unavailable in Minnesota because of a delay that is out of the manufacturer's control. Such a requirement is also in line with exemption processes in other chemical regulatory programs, such as RoHS Article 5 where a current exemption to the directive's restrictions remains valid until the European Commission decides on the renewal application. Without this binding schedule, manufacturers will be left in the dark for how long the MPCA will take to decide on a CUU determination request and therefore they cannot plan ahead for the 2032 compliance date.

III. COMMENTS ON FACILITATING PRODUCTIVE ENGAGEMENT WITH INDUSTRY

SEMI appreciates the MPCA's proactive outreach to the regulated community in advance of issuing draft rules and encourages the agency to maintain this approach going forward. Engaging interested stakeholders from the outset through listening sessions, webinars, and other venues will afford these parties the opportunity to inform the MPCA's rulemaking activities in a way that empowers the agency to meet its regulatory mandates while effectively ensuring the long-term viability and competitiveness of the affected industries.

Building on this, we understand that the MPCA plans to create two working groups in the coming months to inform the agency's Section 116.943 rulemaking efforts. One of these working groups will include technical experts from industry, and SEMI welcomes the opportunity to put someone forth from our organization to serve in this capacity to advocate for meaningful rules that reflect the concerns of the semiconductor industry.

IV. CONCLUSION

SEMI is committed to balancing the need for environmental protection and the sustainability of semiconductor manufacturing operations, which is a complex challenge. As such, SEMI is grateful for the opportunity to engage on the MPCA's planned CUU Rule and is available to meet at your convenience to further elaborate on the issues discussed in these comments. If you have any questions or would like to discuss our positions, please do not hesitate to contact Ben Kallen (bkallen@semi.org).

Sincerely,

Ben Kallen
Senior Manager, Public Policy & Advocacy
SEMI

Appendix A: Evaluation of Alternatives for Currently Unavoidable Uses (CUUs) of PFAS Materials Used in Semiconductor Manufacturing

The following information is excerpted from SEMI's PFAS use case examples in comments submitted to the European Chemicals Agency on the REACH PFAS restriction proposal.

Introduction: The unique properties simultaneously afforded by PFAS materials in terms of chemical resistance, temperature resistance, flexibility, low coefficient of friction, purity, non-flammability, etc., have led to thousands of applications in semiconductor manufacturing, where precision and purity of a wide range of highly complex equipment and a broad array of chemicals are required to deliver the exacting specifications demanded of advanced circuitry. The semiconductor industry has a long history of working toward more environmentally benign solutions including compliance with regulations on restricted materials. However, the ubiquitous nature of the applications space of PFAS in this industry, coupled with the lack of suitable alternative materials, makes substitution of PFAS an exceedingly difficult challenge, one whose magnitude cannot be overstated.

This appendix illustrates the numerous use cases of PFAS in semiconductors and the challenges posed when seeking alternatives by citing several examples where substitutions were evaluated but found to be insufficient. This is by no means intended by an exhaustive review of either all the applications of PFAS in semiconductor manufacturing, nor on the evaluations of alternatives. Rather it is meant to illustrate the expansive dependency that this industry has on this unique class of materials and how, despite wide-ranging efforts, alternatives do not meet the criteria required for safe and capable replacement. The examples below are arranged based upon the application space in which the PFAS material is used. For a more exhaustive description of the use of PFAS in the semiconductor industry, please see "The Impact of a Potential PFAS Restriction on the Semiconductor Sector", an SIA PFAS Consortium-commissioned summary prepared by RINA, available on the SIA website.[1]

Ultrapure Water Systems: Ultrapure water (UPW) is one the many materials essential to semiconductor manufacturing and UPW systems are fundamental components of any chip fabricator, or fab, infrastructure. Metal or organic contaminants must be avoided to prevent defectivity that can compromise performance, yield, and reliability. Pipes, valves, fittings, and seals composing UPW systems are required to bridge performance in terms of purity[2], mechanical properties[3], flame retardancy[4], chemical resistance, safety, and reliability. This requires the use of fluoropolymers, like poly(vinylidene fluoride) (PVDF), poly(terafluoroethylene) (PTFE), perfluoroalkoxy copolymer (PFA), and fluoroelastomers such as FKM and FFKM. Poly(propylene) (PP) and poly(vinyl chloride) (PVC), among other organic polymers, have been evaluated as replacements, but do not meet the purity, chemical resistance, and lifetime required.[5,6] Feasible substitutes have yet to be identified and there is no publicly available information on the status of research and development (R&D) processes and the required time for substitution.

Heat Transfer Fluids: Fluorinated heat transfer fluids (HTF), along with fluorinated refrigerants, are used in semiconductor manufacturing to provide precise temperature control in numerous processing and testing steps. HTFs are commonly use in plasma processing such as dry etch and thin-film deposition, where, to be compatible with the materials of construction of the equipment chambers, the materials must be electrically non-conductive, as well as being appropriately non-toxic, non-flammable and not subject to inducing contamination issues[1] across a wide range of operating temperatures that require precise control.[7] Currently, non-PFAS alternatives, such as synthetic hydrocarbon oils, silicone oils, or ethylene glycol/de-ionized water mixtures cannot simultaneously meet these performance attributes.[8,9,10,11,12] Similarly, non-PFAS alternative refrigerants, such as carbon dioxide or ammonia, cannot support the low-temperature operating points, have low energy efficiency, and are toxic or flammable.[13] For more detailed discussion of the use PFAS as HTFs for use in the semiconductor industry, see the SIA PFAS Consortium White Paper on the SIA website.[14]

Lubricants: PFAS lubricants are used to reduce friction and wear between surfaces and as sealants to prevent the ingress of foreign materials into the lubrication clearance zone. Semiconductor manufacturing requires high-performance PFAS lubricants to prevent the creation of particles within cleanrooms and the extreme physical environments present in the manufacturing environments, as well as remaining inert, non-off gassing, and UV stable. Currently no alternatives are known to exist, as alternatives such as silicon-based lubricants do not offer the necessary technical performance. It is important to keep in mind that PFPEs were introduced in semiconductor applications mainly because of safety reasons due to their stability and non-flammability.[15] Any alternative would need to offer these same technical attributes, so as not to decrease the overall safety of these systems potentially causing safety incidents, explosions, injuries, and damage to manufacturing facilities. Specifically, non-PFAS lubricants generate more heat as the lubricant breaks down, which results in lost productivity via indirect routes of increased wear and loss of precision leading to increased defect rates. This has direct implications including reduced productivity and costs through machine downtime for maintenance, cleaning and relubrication activities and replacement of parts. The best potential PFAS-free alternatives are believed to be silicone-based oils and lubricants; however, these have a limited temperature range when compared to PFAS alternatives, they are prone to off gassing, and have compatibility issues with some elastomers. As such, the applications in which they can be used are limited. Silicone-based oils and lubricants are also very contaminating[16] and could lead to productivity loss.[17] For more detailed discussion of the use PFAS as Lubricants for use in the semiconductor industry, see the SIA PFAS Consortium White Paper on the SIA website.[14]

Photolithography Applications: There are multiple applications if photolithography that require the use of PFAS materials due to the unique attributes these materials provide that cannot be replicated with other chemistries by nature of the unparalleled strength of the carbon-fluorine bond and the strong electronegativity of fluorine atoms. For example, photoacid generators (PAGs) are essential components of chemically amplified resists, which are materials used to define the fine circuitry of all advanced semiconductor chips. Several non-PFAS photoacids are have been proposed as alternatives, which upon detailed investigation, prove not to be suitable for high resolution imaging as the results are significantly inferior to the performance shown by PFAS containing PAGs, by showing higher photospeed, poorer feature quality, and excessive top-loss,[18] or acute toxicity.[19] For in depth description of the use PFAS as in PAGs for use in photolithography, see the SIA PFAS Consortium PAG White Paper and PFOS/PFOA Case Study on the SIA website.[14]

Another lithographic application requiring PFAS involves their use in top-antireflective coatings (TARCs). TARCs represent the largest product group by volume, accounting for more than 50% of PFAS use in lithography. TARCs are used to suppress reflectivity, which can compromise image integrity. PFAS materials are used as they provide the appropriate optical properties, specifically very low refractive index at the imaging wavelength. A non-PFAS alternative considered was the use of silica nanoparticles[20], but this failed for practical reasons at customer sites.

Other lithographic applications using PFAS include their use as surfactants in photoresists and bottom-antireflective coatings (BARCs); high contact angle barrier layers in immersion lithography, both as immersion topcoats or in topcoat-free photoresists[21]; and as photo-imageable poly(benzoxazoles) and poly(imides), used in packaging. For an exhaustive review of these applications, included attempts at identifying alternatives, see the SIA White Paper on Surfactants[14], as well as the aforementioned RINA white paper.[1]

Seals and Gaskets: Fluoroelastomers, such as FKM and FFKM, are well known industry standard choices for vacuum seals in semiconductor processing equipment, due to their broad resistance to plasma, aggressive chemistries, and high temperature requirement that are inherent in efficient semiconductor manufacturing processes. Lifetime of seals made from proposed substitute materials such as EPDM or silicone for 'in-chamber' sealing applications will be dramatically reduced due to the increased etch rates, particle formation, permeation, outgassing and general incompatibility with common semiconductor processing conditions. In the best case, implementing the proposed alternatives will result in equipment that is in a constant, infeasible state of repair, with negative impacts on manufacturing yields, both driving significant cost increases and reducing competitiveness. At worst, proposed alternatives are completely incompatible with application conditions, and pose serious safety concerns for fab operation. Performance of fluorinated elastomers compared to such alternatives is well documented in literature for over 40 years.[22,23,24] We know of no non-fluorinated elastomeric sealing materials in production, early development, or even ideation that could come close to matching the overall performance of fluorinated elastomers as seals in wafer processing equipment.

Gases for Plasma Deposition and Etch: Perfluorocarbons (PFCs) and hydrofluorocarbon (HFCs) are used in thin film deposition, plasma etch/wafer clean, and chamber cleaning steps in the semiconductor manufacturing process. Silicon and its compounds are the basis of the manufacturing of semiconductors. PFCs and HFCs are unique in their ability to react with silica compounds in predictable, controllable, and selectable ways. It must be noted when discussing alternatives, that the uses described above are broad terms to describe a process, but in actuality, each use in the semiconductor manufacturing process is unique (e.g., 100+ different instances alone of plasma etching for one device) and can require different material(s) or compositions to meet the performance requirements.[1] Currently non-PFAS alternatives simply do not exist. The proposed alternatives, nitrogen trifluoride (NF_3) or sulfur hexafluoride (SF_6) often used in conjunction with various hydrocarbons (C_xH_y) or fluorine (F_2) gas, create significant environmental or safety concerns. First, using the alternatives in these processes creates PFAS byproducts which is antithetical to the intent of this regulation. Additionally, mixing an oxidizer (NF_3) with a flammable (hydrocarbons) creates an additional fire safety risk. Moreover, NF_3 and F_2 are toxic and present worker safety concerns.[25,26] Finally, NF_3 and SF_6 possess high global warming potentials (GWP) and are subject to regulation under the EU F-Gas regulation (517/2014).[27]

Articles: Articles is a broad term used to describe various components or 'parts' of more complex systems or equipment used in semiconductor manufacturing. This far-reaching definition includes simple components such as tubing, containers, gaskets, valves, and filters, to more complex, integrated parts such as capacitors, robots, sensors, or power supplies. These are just a few of the hundreds of articles that are used in semiconductor manufacturing equipment, in the infrastructure of the fab itself, or in the supply chain of the various materials used in fabs. PFAS materials play an indispensable role in many articles, as they provide the unique combination of properties required to deliver the precise control essential to chip manufacturing. Particularly critical to many articles is that these attributes are retained for the duration of a fab existence or, in the case of consumable parts, that they last as long as possible to avoid frequent replacement, which is costly, time-consuming, and waste generating. A detailed overview of the wide-ranging use of PFAS in articles used in semiconductor manufacturing can be found in SIA PFAS Consortium Articles White Paper on the SIA website.[14]

A prime example illustrating the necessity of PFAS use for articles is in the handling of specialty chemicals. Hundreds of chemicals are used in today's semiconductor manufacturing processes.[28,29] Impurities such as particles, metal ions, and organic contaminants can lead to yield and reliability problems.[30] Contamination control is critical in proactive and predictive yield management, especially in high volume manufacturing (HVM) in the semiconductor industry to drive down cost.[31] The strict requirements for clean chemicals, as well as compatibility issues, necessitated the selection and use of the robust and clean filters available. Specifically, electronic grade, concentrated 96% sulfuric acid is a high purity chemical used for cleaning and etching applications in semiconductor manufacturing. The acid is typically heated from 90 to 150 °C and filtered continuously. Because of the high temperature, strongly acidic and oxidizing environment, only fluorocarbon PTFE membrane can withstand the aggressive acid, and as such, PTFE has been the workhorse in the industry for this application.[32,33,34,35] Currently, there is no known commercially available membrane filter that can replace PTFE membrane for this type of application.

Finished Semiconductor Devices: Several different PFASs are used in various materials and manufacturing steps during device packaging. There is a great deal of diversity in the types of packages used and necessary to connect the integrated circuit chip to the outside world, such as a printed circuit board (PCB). For substrates and the package, the mechanical, electrical, and thermal properties drive various material properties necessary to meet demands for miniaturization and increased device density. With these demands the resistance-capacitance (RC) delay now exceeds the transistor gate delay and becomes and device performance liming factor.[36] The PFAS used provide thermal and chemical stability to enable a variety of critical performance capabilities to ensure environmental and mechanical protection to the die during processing and use. Across this breadth, there are properties that stand out as essential such as thermal and chemical resistance, low dielectric constant, low residue transfer, improvement of wetting/spread, and the ability to reduce surface energy and photo-imageable functionality. Also, in a wide array of specialty MEMS packages processing and function of the device has been proven nearly impossible replace or to achieve without PFAS. A detailed overview of the wide-ranging use of PFAS in packaging and substrates used in semiconductor manufacturing can be found in SIA PFAS Consortium PFAS-Containing Materials Used in Semiconductor Manufacturing Assembly Test Packaging and Substrate Processes on the SIA website.[14]

Cables: Materials used in cables for semiconductor manufacturing processes need to ensure sufficient functional performance like signal integrity without introducing contaminants into the process. There are currently no known alternative materials that would meet the necessary combination of demanding performance requirements of semiconductor manufacturing process. The current and only known viable solution are fluoropolymers, such as FEP, PFA, PTFE and expanded PTFE, all of which provide a dielectric constant in the desirable range of 1.0 to 2.2. A low dielectric constant drives the ability to carry electrical signals with low loss and high signal velocity.[37] Alternative materials with somewhat comparable dielectric constants exist but they have maximum continuous service temperatures in the 80 to 150°C range,[38] falling below the requirements in semiconductor manufacturing (up to 260°C under vacuum). Hydrocarbon based polymers such as polyethylene (PE), polypropylene (PP), foamed PE, hydrocarbon elastomers, and ethylene propylene diene monomer elastomers (EPDM) have maximum continuous service temperatures in the 80 to 150°C range, falling below the requirements in semiconductor manufacturing of up to 260°C under vacuum.[38] Silicone rubber has a reasonably good maximum continuous service temperature and dielectric constant, albeit not a good as fluoropolymer-based material, but is a highly outgassing material that is not suitable for semiconductor manufacturing process applications.[39, 40, 41] Polyether ether ketone (PEEK) can be attacked, for example, by strong acids even at room temperature.[42] At elevated temperatures it is more readily attacked even by weak acids and cannot function as a seal above 170°C. Any alternative material capable of meeting the functional performance requirements would have to be invented. Such a material development is inherently unpredictable, likely to be a lengthy and demanding process and may not be successful.

Summary: The examples provided here are only a tiny fraction of the myriad use of PFAS in semiconductor manufacturing. Not mentioned explicitly, but also critical to this industry are applications as surfactants and in liquid chemistries for cleaning, wet-etching, or metal plating; other uses in packaging technology, such as adhesives, release layers and encapsulants; as well as uses in chemical transport and delivery, mask making, etc. More extensive discussion on these applications and more can be found in the series of White Papers produced by the SIA PFAS Consortium.[14] Each application has their own unique requirements, for which PFAS materials have been chosen because of the unique attributes of these materials. While replacements have been evaluated, more often than not, materials cannot be found that have the combination of attributes to be suitable substitutions. The references provide evidence to this effect and are complemented by significant amounts of confidential or unpublished information from representative companies that is sensitive to their individual business objectives.

Subject: Request for comments – Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing PFAS

Dear Minnesota Pollution Control Agency:

The National Electrical Manufacturers Association (NEMA) represents nearly 325 electrical equipment and medical imaging manufacturers that make safe, reliable, and efficient products and systems serving the building systems, building infrastructure, lighting systems, industrial products and systems, utility products and systems, transportation systems, and medical imaging markets. Our combined industries account for 370,000 American jobs in more than 6,100 facilities covering every state. These industries produce $124 billion in shipments and $42 billion in exports of electrical equipment and medical imaging technologies per year.

NEMA appreciates the opportunity to provide comments on the Planned New Rules Governing Currently Unavoidable Use (CUU) determinations about products containing PFAS that will be promulgated by the Minnesota Pollution Control Agency (the "MPCA" or the "Agency") pursuant to Minnesota Statutes 116.943, subdivision 5(c)("Amara's Law").

NEMA recognizes the legal requirements that a currently unavoidable use be one determined by rule to be "essential for health, safety or the functioning of society and for which alternatives are not reasonably available." With this in mind, the following are uses NEMA recommends be included on a forthcoming draft list of CUUs:

- All uses of PFAS and PFAS-containing products that have undergone reviews and received authorizations in the context of federal programs such as (but not limited to) the US Environmental Protection Agency's (EPA's) new chemicals and significant new uses program under Section 5 of the Toxic Substances Control Act; EPA's significant new alternatives program (SNAP) under the Clean Air Act; programs overseen by the US Food and Drug Administration (FDA) concerning drugs, medical devices, biologics, and diagnostics and equipment under the Food and Drug Act (FFDCA); pesticides and devices subject to EPA regulation under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA); and other federal programs whereby either the PFAS, or products containing PFAS, are determined to be acceptable for their intended use by these (and other) federal government agencies. This classification also should include products and materials having uses in programs overseen by other federal agencies such as the Department of Defense (e.g., products and materials meeting DoD requirements and military specifications), the

Federal Aviation Administration (e.g., performance rules and regulatory controls governing the design, manufacture, installation, and maintenance of aircraft parts and replacement parts), and similar NASA-issued requirements.

- All uses of PFAS and PFAS-containing products and related items (including chemical substances and mixtures) required by state laws and implementing regulations administered by state agencies responsible for maintaining public health, community safety, and the environment.

- All uses of PFAS in electrical equipment that are critical contributors to meeting our nation's goals relating to electrification, energy security, safety, reliability, durability, and sustainability. These products include electronic components found in pacemakers, electronic sensors, industrial automation relays and soft starters, circuit boards, gas-insulated power grid equipment, wiring, lighting equipment, solar panels and semiconductors. Additionally, PFAS applications that increase reliability and safety of the electrical equipment.

- PFAS used in the manufacture of zinc air hearing aid batteries, lithium-ion batteries, Nickel Metal Hydride (Ni-MH) & Nickel Cadmium Batteries, lithium primary batteries, alkaline button batteries, and coin shaped lithium rechargeable batteries.

- PFAS containing materials and articles used as components of transportation equipment including automobiles, train engines and rail cars and components, packing containers and forklifts, ships and container vessels and their services equipment, agricultural vehicles and equipment, motorcycles, construction equipment, wheelchairs and other forms of mobility assisting appliances.

- Air conditioning, heating, ventilation, and refrigeration equipment and their components and parts including replacement parts and materials.

- Appliances and equipment and component parts used in harnessing energy (e.g., windmills, solar panels) and conserving energy. These should include building materials intended to insulate and to sustain temperate conditions within.

- PFAS used in the manufacture and within products intended to store energy such as batteries and other components critical to electric vehicles.

- PFAS used in the manufacture of semiconductors and electronic equipment and devices including component parts such as transistors, wiring, insulation, connections, housings, circuit boards and component parts that are not exposed to the user (other than during repair, disassembly, or disposal).

The above is not to be considered an exhaustive list and in the future, there could be other proposals for CUU determinations. NEMA recommends that MPCA codify a process by which product manufacturers and PFAS-containing product users may continue to submit requests for CUU determinations on a going-forward basis (even after final CUU listings are established) to permit flexibility in the event items, products, and PFAS uses (including those not currently contemplated) are identified for which reasonable CUU determinations should be granted.

Additionally, NEMA would like to make MPCA cognizant of the fact that electrical manufacturers may face some challenges collecting information about PFAS present in products. Upstream suppliers may be reluctant to provide manufacturers with specific information about the type of PFAS used. Upstream suppliers may claim that the use of PFAS is essential but may not provide details due to confidentiality concerns. MPCA should allow the use of supplier statements to substantiate a manufacturer's request for CUU. To facilitate this, MPCA should set up a system that would allow upstream suppliers to provide information directly to MPCA.

NEMA also suggests that MPCA should consider coordination with other jurisdictions, such as Maine, to create an approach that allows manufacturers to submit currently unavoidable use requests that can apply to multiple jurisdictions.

NEMA appreciates this opportunity to provide comments to MPCA on CUU determinations.

Regards,

Karin Moore

Response to Request for Comments
PFAS in Products Currently Unavoidable Use Rule

To Whom It May Concern:

Datwyler Pharma Packaging USA, Inc. ("Datwyler") would like to express its appreciation for the opportunity to provide comment to the Minnesota Pollution Control Agency (MPCA) with regard to its planned new rules governing Currently Unavoidable Use (CUU) Determinations about Products Containing Per- and Polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837.

Datwyler, as a leading provider of high-quality, system-critical elastomer components, is a strategic engineering partner for innovative systems in global markets such as Healthcare, Mobility, Connectivity, General Industry and Food & Beverage. Among other things, Datwyler components in billions of syringes and in every second car around the world make an important contribution to patient and driver safety under demanding conditions. Specifically for Healthcare, our sites in the Belgium, China, Germany, India, Italy, and the United States take great responsibility to help improve patients' lives and see ourselves as a vital link between our customers and their patient. As a preferred solution partner to global pharmaceutical companies, Datwyler's Healthcare components for vials, prefilled syringes, and cartridges in the pharma packaging industry provide customers with drug and packaging stability, compatibility, and container closure integrity in the pharmaceutical and biotech markets.

Beginning January 2032, products containing intentionally-added PFSA which are sold, offered for sale, or distributed in Minnesota are banned unless determined as CUU by the MPCA, by rule, under the authority of Minnesota Statutes 116.943, subdivision 5(c); and Minnesota Statutes 116.943, subdivision 9. In its rulemaking process to establish criteria and processes through which future decisions on what, if any, uses of intentionally-added PFAS will qualify as CUUs, the MPCA has posed a few questions to inform rulemakers of relevant issues that must be considered. Datwyler hereby respectfully submits the responses contained within this submission for consideration.

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Yes – Datwyler requests the MPCA to further define the criteria by which PFAS-containing products can be classified as *essential for health, safety, or the functioning of society* so that manufacturers who are delegated with the responsibility to submit proposals for CUU determinations can be best guided when reviewing and preparing documentation about PFAS-containing products. In light of PFAS in medical devices and components, including but not limited to the elastomer closures and seals, Datwyler advises that the MPCA must keep in mind preservation of patient access to healthcare and protection of the medical supply chain.

Other rulemakers have provided a definition that *essential for health, safety, or the functioning of society* "means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies."[1] In this definition, there is a clear definition of how the essential nature of products can be assessed and which areas and industries necessitate a fundamental review as an all-out ban would be detrimental to a critical function the state impacts on behalf of the citizens of the state.

The definition also goes on to state that "[p]roducts or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations." [2] With this additional criteria, there is less concern for an overlap in the potential for conflicting rules to make the essential determination too complex.

Lastly, the definition continues that "Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction." [3] These examples help drive understanding of some of the critical areas that lawmakers are considering and taking careful consideration to understand what and how a ban would affect these activities and industries.

As a manufacturer of fluoropolymer-coated elastomer closures for pharma packaging, Datwyler assents that such a definition strikes a good balance between environmental protection with patient access to healthcare and the protection of the medical supply chain, thus avoiding critical drug shortages on the market.

1,2,3 https://www.maine.gov/dep/spills/topics/pfas/PFAS-products/cuu.html

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Yes – Datwyler urges the MPCA to consider the costs of the alternative itself as well as the costs of implementing such alternatives. In some cases, even if there a PFAS-free alternative available, lost business in the industry may not be able to be regained due to the nature and process of qualifying the alternative by submission to the relevant health authorities (e.g. US Food and Drug Administration) requiring too much investment of time, resources, and finances, with uncertainty of approval.

Further, the *reasonably available* criteria should not be viewed purely as economic feasibility – it should also encompass the technologic feasibility as well. In some cases, there is no functionally equivalent alternative to the current use of PFAS, even with extensive investments in current research and innovation.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

Uncertain – Further definition and guidance is needed of what constitutes as a "small business" as well as for how long the unique considerations would be kept in place. These considerations may need to be determined with case-by-case rulings by the MPCA.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

There exists an element of concern in the proposal to consider all -CF_2 containing materials, without differentiating between the macromolecular Fluoropolymers with other smaller PFAS. Posing a definition of "all -CF_2 containing materials" to be inclusive of polymeric PFAS (like PTFE, PVDF, and FKM), shows that there is a limit to the understanding of the safety potential for these materials.

Polymeric PFAS have been analytically tested and have been deemed non-toxic, not bioavailable, non-water soluble, and non-mobile molecules that do not exhibit environmental or human health implications like other PFAS may. Because of this, we believe that criteria such as these should be used in evaluating these materials. Many assessments have shown that, in the limited chance a suitable alternative can be identified, the critical performance characteristics frequently cannot be met by the alternative compared to fluoropolymer based materials.

Safety should be evaluated with to also include function of the alternatives. Any replacements should result in functionally equivalent products that either maintain or reduce the potential of causing harm to human health or the environment. Critical performance characteristics should be defined and demonstrated by the stakeholder within the CUU determination proposal.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

Datwyler stipulates that especially for critical infrastructure CUU determinations, such as those impacting Human Medicinal Products, should have a TIME-UNLIMITED determination. In other cases, the length of the determination should be decided keeping in mind the application and life-cycle impact to society. It must be kept in mind that if a change in determination status may create a dramatic shortage and unavailability of a critical need such as medicines, or else a re-evaluation would be detrimental to balancing environmental protection with the continuation of essential services provided to the citizens of Minnesota.

In the case of new developments, re-evaluation may be sought, but in certain cases like that of healthcare, such re-evaluations may prove unhelpful. For example, within healthcare, an estimated 1 of every 5 injectable drugs for human medicinal products around the world are manufactured with packaging systems utilizing a fluoropolymer barrier coated rubber closure due to the nature of the medicine being protected for delivery. As future medicines become even more difficult to stabilize and have more sensitivities, an increased usage of fluoropolymer coated rubber closures is expected. If these medicinal products were to be banned due to the closures used in their packaging systems not maintaining CUU determination, there would be a dramatic shortage and unavailability of life-saving injections (e.g., chemotherapies, mRNA vaccines, biological drug developments, future cell-and-gene therapies), especially with new developments and drugs that are targeting commercial use within the first years after PFAS restrictions are put in place. Restarting such stability and approval exercises is virtually impossible for all drug products currently using fluoropolymer-coated closures and will induce shortage of medicinal products available to patients needing these treatments in the field.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Stakeholders, such as manufacturers of the products, should respond to a request for proposal by the MPCA and submit a proposal for a CUU determination for a PFAS-containing product to the MPCA's review and conclusion. Stakeholders should not be able to submit a proposal for a CUU determination to be obsoleted, but rather should be permitted to request for a re-evaluation on the subject CUU determination that the MPCA can then resolve whether or not to fulfil such request at its decision.

The proposals for CUU determination should provide information similar to that requested for PFAS reporting in Minnesota Statutes 116.943, subdivision 2(a). Due to the sensitivity of trade secrecy, Datwyler requests that the MPCA balance public availability of data and trade secrecy as part of the reporting requirements. In particular, in the requirements listed in Minnesota Statutes 116.943, subdivision 2(a), subsection 3, there is a request for identification of PFAS by its chemical abstracts service (CAS) registry number “in the exact quantity determined”. Such a requirement may be excessive in this case as the focus should be on the clear demonstration of CUU requirements that the PFAS-containing product is *essential for health, safety, or the functioning of society* as well as how *alternatives are not reasonably available*. Datwyler recommends that proposals not focus on the listing of CAS numbers and instead focus on demonstrating how alternatives are not reasonably available.

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Looking at the unique and essential use of fluoropolymer coatings on elastomeric closures used for primary packaging to ensure compatibility with parenteral drugs, Datwyler welcomes the opportunity to submit a proposal for CUU determination for the product class of fluoropolymer-coated closures for primary packaging systems of medicinal products. Datwyler’s elastomer closures are essential packaging components for pharmaceutical and biotech drug products.

Parenteral/Injectable primary packaging systems of sensitive drug medicine intended to be injected (e.g., oncology chemotherapy, individualized cell/gene therapy, novel biological-based drugs, and other medicines sensitive to migrating substances from the rubber) depend on closures that have limited to no interactions with the drug medicines while maintaining barrier properties. Fluoropolymer coatings (applied with either the spray or film technology) create such an inert barrier between the rubber of the closure and the medicine within the packaging. Any changes by replacing parts with non-fluoropolymer alternatives would require development, qualification, validation, registration and approval, and are thus not economically feasible. There would also be a need by pharmaceutical and biotech companies to reallocate investment that would have gone to the development and manufacture of life-saving drug products as these companies would need to reallocate significant resource and refocus on substituting, revalidating and reregistering many parts of their process and products. The whole industry would also need to partake in a huge regulatory undertaking, further diverting attention and investment away from developing novel therapies for life-threatening diseases.

Not designating fluoropolymer-coated closures a CUU determination would severely limit the delivery and availability of medicines and life-saving treatments to the patients seeking treatment from healthcare professionals in Minnesota.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Yes – Datwyler would humbly request that the MPCA consider the proposal in response to question 7 to make an initial CUU determination in order to assist in the understanding and demonstrated application of the process by which the MPCA shall evaluate further proposals.

9) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

At this time, Datwyler seeks to reiterate to the MPCA that there exists an element of concern in the proposal to consider all -CF_2 containing materials, without differentiating between the macromolecular Fluoropolymers with other smaller PFAS. Posing a definition of "all -CF_2 containing materials" to be inclusive of polymeric PFAS (like PTFE, PVDF, and FKM), shows that there is a limit to the understanding of the safety potential for these materials. Datwyler highly advises that the MPCA consider clarifying the CUU criteria to allow for a streamlined review of such fluoropolymer uses that have been analytically demonstrated to be non-toxic, not bioavailable, non-water soluble, and non-mobile molecules that do not exhibit environmental or human health implications.

Datwyler keeps sustainability at the forefront of its vision and remains committed to balancing the need for environmental protection with the need for pharma packaging components designed to protect the efficacy and functionality of medicines, which is a complex challenge. Thank you for allowing us to provide these comments and for taking the time to consider these views during the rulemaking process. Datwyler admires the significant task being undertaken by the MPCA to balance environmental impacts of PFAS with maintaining essential functions of health, safety and a functioning society for all Minnesotans. Datwyler welcomes the opportunity to further engage with the MPCA and other stakeholders in this rulemaking process and offers to answer questions and provide technical perspectives in further discussions during the rulemaking process. If further information is needed about the materials included in this submission, please contact Roman Ventura by email at roman.ventura@datwyler.com.

Respectfully submitted,
Datwyler

The Vehicle Suppliers Association

March 1, 2024
Katrina Kessler
Commissioner
Minnesota Pollution Control Agency
520 Lafayette Road N
St. Paul, MN 55155

RE: Request for Comments: Planned New Rules Governing Currently Unavoidable Use Determinations About Products Containing Per-and polyfluoroalkyl Substances (PFAS)

Dear Commissioner Kessler,

MEMA, The Vehicle Suppliers Association, submits these comments to the Minnesota Pollution Control Agency (MPCA) on its request for comments on planned new rules governing currently unavoidable use (CUU) determinations for products containing PFAS.

MEMA is the leading trade association in North America for vehicle suppliers, parts manufacturers, and remanufacturers. It has been the voice of the vehicle supplier industry since 1904.

Automotive and commercial vehicle suppliers are the largest employer of manufacturing jobs in the United States employing over 900,000 people throughout the country. Direct, indirect, and induced vehicle supplier employment accounts for over 4.8 million U.S. jobs and contributes 2.5 percent to U.S. GDP.

Suppliers lead the way in new vehicle innovations. Member companies conceive, design, and manufacture the OE systems and technologies that make up two-thirds of the value of every new vehicle and supply the automotive aftermarket with the parts that keep millions of vehicles on the road, fueling international commerce and meeting society's transportation needs. MEMA members are committed to safety and sustainability.

Vehicle suppliers play a crucial role as the innovators and manufacturers of a multitude of technologies and wide range of components, systems, and materials that improve vehicle safety, emissions, and efficiency. PFAS play a crucial role in allowing vehicle suppliers to meet these safety and sustainability goals. The industry seeks to minimize the use of PFAS where possible, but for many components there are no currently available substitutes.

INTRODUCTION

Motor vehicles are composed of about 30,000 parts, each critical to the safe and efficient function of the vehicle[1].These parts and components are manufactured by suppliers for use in all vehicles on the road. This includes new motor vehicles as well as the aftermarket components necessary for the repair and maintenance of the existing fleet. The sheer number of parts illustrates the need for critical use determinations for the industry to allow the necessary research, development, and safety certifications to take place.

PFAS are critical to the production of motor vehicle parts and components and are therefore essential for the functioning of society. PFAS are extremely durable and can withstand extreme use and high temperature applications- all qualities that are necessary for automotive uses.

MEMA urges MPCA to exclude commercial medium and heavy-duty vehicles and their components from this regulation and provide an initial CUU determination as a part of this rulemaking. Doing so would give the industry the necessary time to identify which products contain PFAS and continue research and development of alternatives.

THE STATUTORY LANGUAGE LIMITS APPLICATION TO PRODUCTS SOLD TO A CONSUMER

MPCA must remain faithful to the language of the statute in developing its CUU determination criteria, as well as making initial CUU determinations. Minnesota Session Law-2023, Chapter 60, H.F. No. 2310 defines a product as: "an item manufactured, assembled, packaged, or otherwise prepared for sale to consumers, including but not limited to its product components, sold, or distributed for person, residential, commercial, or industrial use, including for use in making other products[2]." MPCA must interpret this definition to exclude commercial medium and heavy-duty vehicles, and their parts and components. Commercial vehicles and their parts are sold to fleet owners, not individual consumers, for business purposes, and therefore fail the first test of being an item manufactured, assembled, packaged, or otherwise prepared for sale to consumers.

MINNESOTA MUST PROVIDE CUU DETERMINATIONS FOR ALL MOTOR VEHICLE PARTS AND COMPONENTS

MPCA must provide CUU determinations for all motor vehicle parts and components for the following reasons:

First, PFAS are critical to the production of motor vehicle parts due to their durability. Notably, PFAS play a crucial role in the transition to clean transportation, which is made possible through the work of the vehicle supplier industry. For example, the ability of battery manufacturers to meet the demand for electric vehicles would be greatly impacted by restrictions on the use of PFAS. A recently released report from the U.S. Department of

[1] Sabhadiya, Jingesh *"40 Basic Parts of a Car."* February 2021
[2] Minnesota Session Laws. *"Chapter 60—H.F. No. 2310."* 2023

Defense states that it would take over 10 years to find a replacement for PFAS in batteries[3]. Once discovered, prominent lithium battery manufacturers estimate it would take 30 years to fully identify and incorporate a PFAS alternative. Given the length of time needed, MPCA should consider a lengthy CUU determination period for the motor vehicle industry, where additional safety compliance concerns must be addressed while identifying alternatives. It is crucial that MPCA consider both cost and feasibility as it develops its definition for "reasonably available" alternatives.

PFAS are also instrumental in the development of the hydrogen sector. Deployment of hydrogen fuel cell technology is crucial to meeting emissions standards. PFAS are used along the hydrogen value chain, particularly in the form of fluoropolymers, which underpin the electrolyzer and fuel cell systems. One use of fluoropolymers in hydrogen deployment is membrane electrode assemblies (MEA), which constitute the core of PEM electrolyzers or fuel stacks. Membranes provide essential functions in fuel cell and electrolyzer application, such as preventing short circuits. Industry has worked for decades to increase the efficiency of the fuel cells, notably decreasing the thickness of membranes. However, the industry still lacks reasonable alternatives to the use of PFAS in these parts. For example, while fluorine-free membranes are available, the durability is markedly poor, lasting only a few dozen hours compared to over 25,000 hours[4]. This example shows that MPCA must also consider performance in its definition of "reasonably available" alternatives.

Third, vehicle parts and components are essential for health, safety, and the functioning of society. Minnesota law states that beginning January 1, 2032, products containing intentionally added PFAS will be ineligible for sale unless MPCA has granted a CUU determination for the product. Without broad exemptions for the motor vehicle industry, it is likely that the sale of all classes of motor vehicles and their parts will be effectively banned within the state. This would create major disruptions to everyday life, as both passenger and commercial vehicles would be affected, creating an impact that will be felt far beyond the motor vehicle sector.

For example, interruptions to heavy-duty vehicle applications can impact the provision of critical services, such as the delivery of groceries, medical supplies, fuel, and other utility applications like ambulances. As a result, MEMA foresees the need for CUU determinations for all vehicle components sold and manufactured today.

Not only are PFAS critical to clean transportation, but PFAS are used in a wide array of crucial safety components in vehicles. To preserve vehicle safety, substitutions cannot be made without careful research and development, followed by certification to safety standards. This creates lengthy timelines that are in direct conflict with a 2032 total ban of PFAS. MPCA must consider safety in considering PFAS alternatives and should defer to the safety standards that are provided by the Department of Transportation and other

---

[3] Department of Defense. *"Report on Critical Per- and Polyfluoroalkyl Substance Uses."* August 2023
[4] Hydrogen Europe. "*Hydrogen Europe Position Paper on PFAS.*" January 2023

standards-developing organizations.

Motor vehicle uses of PFAS are essential to health, safety, and the functioning of society. MEMA urges MPCA to grant the motor vehicle industry an initial CUU determination as it develops these criteria. Anything less will effectively ban the sale of all classes of automobiles and their parts in the state of Minnesota. Given the large number of vehicle parts, a CUU determination is necessary to allow suppliers the time to identify PFAS in products and conduct research and development for replacements. MEMA appreciates MPCA's consideration of our comments as it prepares its criteria for CUU determinations. For more information or questions, please contact Emily Sobel, MEMA senior manager of regulatory policy at esobel@mema.org.

Sincerely,

Alex Boesenberg

MEMA Vice President of Regulatory Affairs

Minnesota Pollution Control Agency
Syensqo Response to Proposed Rulemaking on Essential Uses of PFAS
March 1, 2024

On behalf of Solvay Specialty Polymers USA, LLC, member of the Syensqo group ("Syensqo"), we appreciate the opportunity to submit comments to the Minnesota Pollution Control Agency concerning the treatment of PFAS chemistries in commerce.

Syensqo is a global leader in advanced materials and specialty chemicals. Our tailor-made range of products and constantly evolving research offers everyday sustainable market-based solutions for next-generation transportation, resource efficiency, consumer goods, healthcare, and industrial production to accommodate U.S. consumers' needs. Syensqo, through its predecessors, has been connecting people and scientific minds for 160 years. Innovation is at our core and part of our DNA. In the United States, Syensqo employs over 5,000 people working in 50 sites across 25 states. Our U.S. footprint includes our composite materials manufacturing site in Winona, Minnesota where we have 265 employees. This site is critical to the American aerospace and defense industrial base and provides irreplaceable materials for military and civilian applications.

We are a science company with a remarkable past, aiming to reinvent the future with our technologies, particularly in the emerging clean energy markets. In that vein, in October 2022, Solvay Specialty Polymers, LLC (a subsidiary of Syensqo) was awarded a $178M grant from the Department of Energy (DOE) as part of an Infrastructure Investment and Jobs Act battery material funding program to produce a PVDF fluoropolymer production facility in Augusta, GA.[1] This facility has the potential to provide enough PVDF fluoropolymer to supply more than 5 million EV batteries per year at full capacity, and the project is expected to create more than 500 local construction jobs and 100 highly-skilled jobs. Once fully operational, our project is an American investment that will fill a significant domestic supply gap with all major feedstocks, including fluorspar (a designated critical mineral), coming from North America.

We strongly oppose an "currently unavoidable use" construct being applied to the entire class of PFAS chemistry for the reasons outlined below. Further, Syensqo respectfully requests a full exemption for fluoropolymers manufactured without fluorosurfactant process aids.

---

[1] *See https://www.energy.gov/sites/default/files/2022-10/DOE%20BIL%20Battery%20FOA-2678%20Selectee%20Fact%20Sheets%20-%201_2.pdf*

SYENSQO
ADVANCING HUMANITY

I. *<u>This type of restriction is incompatible with complex critical supply chains and economies of scale.</u>*

Manufacturers of fluoropolymers (and other polymeric PFAS substances) need sufficient sales and volume to justify the immense capital and operation costs of an advanced chemical facility, and remain cost competitive in a truly global market (that exists for advanced polymer chemistries). For example, if only fluoropolymer coatings for architectural applications are deemed "currently unavoidable," but these coatings that are used in a vast array of other industrial applications are not approved, the loss of overall demand would be significant to manufacturers. Syensqo's facilities service a multitude of different industries for different applications. In many cases, we are multiple tiers removed from our products' end use as a material supplier. This dynamic extends across our entire portfolio of fluorinated products. Allowing only "currently unavoidable uses" in specific downstream sectors – rather than analyzing specific PFAS chemistries' risk profiles – would severely endanger the supply of materials for the approved uses by the state. The demand of PFAS products from these small subsectors cannot support the weight of the entire industry.

The US Department of Defense specifically highlights this problem as a key national defense vulnerability in their recent, "Report on Critical Per- and Polyfluoroalkyl Substance Uses."

> "PFAS are critical to DoD mission success and readiness and to many national sectors of critical infrastructure, including information technology, critical manufacturing, health care, renewable energy, and transportation…
>
> Emerging environmental regulations focused on PFAS are broad, unpredictable, lack the specificity of individual PFAS risk relative to their use, and in certain cases will have unintended impacts on market dynamics and the supply chain, resulting in the loss of access to mission critical uses of PFAS. These market responses will impact many sectors of U.S. critical infrastructure, including but not limited to the defense industrial base. Collectively, international and U.S. regulatory actions to manage PFAS' environmental impacts and identify and eliminate PFAS from the market, and the resulting market changes, pose risks to DoD operations and the defense industrial base supply chain. In addition, impacts to the global PFAS supply chain will present risks to the DoD Foreign Military Sales program and to North Atlantic Treaty Organization interoperability."[2]

Ultimately, the market will adapt and the supply of these critical materials will be available from foreign manufacturers who do not have the same environmental, labor, climate, and safety controls as U.S. suppliers. Moreover, it is highly likely that these critical supply chains will relocate to geopolitical adversaries and further disrupt domestic security for key manufacturing inputs. A downstream-agnostic approach that focuses on deeming specific

---

[2] *See https://www.acq.osd.mil/eie/eer/ecc/pfas/docs/reports/Report-on-Critical-PFAS-Substance-Uses.pdf*

chemistries as "currently unavoidable" would rectify this problem and preserve critical supply/demand dynamics.

II. *The regulation does not follow the science and fails to recognize key differences in PFAS chemistries.*

Syensqo actively promotes the continued responsible and safe manufacture, use and placement of products which are essential to U.S. industry and to the decarbonization of the global economy. We take the subject of PFAS very seriously, and health and safety are our top priorities.

The regulation currently does not recognize the distinct differences in PFAS chemistries, particularly with respect to fluoropolymers which present low hazards to human health and the environment. These chemistries are vital to the critical industries that are the foundation of our sustainable future, including hydrogen-based energy, semiconductor manufacturing, EV batteries, and aerospace and defense applications.

Specifically, fluoropolymers are molecules that are inert, relatively large and have "documented safety profiles; are thermally, biologically, and chemically stable, negligibly soluble in water, nonmobile, nonbioavailable, nonbioaccumulative, and nontoxic."[3] Moreover, some of these fluorinated substances are even completely insoluble, including FKM (a fluoroelastomer) and PFPE lubricants.

III. *Alternative assessments should recognize the responsible manufacturing of certain PFAS chemistries.*

Major concerns about fluorochemistry have focused on the use of fluorosurfactant process aids used in the production of polymers.

> "The objective of this analysis is to evaluate the evidence regarding the environmental and human health impacts of fluoropolymers throughout their life cycle(s). Production of some fluoropolymers is intimately linked to the use and emissions of legacy and novel PFAS as polymer processing aids. There are serious concerns regarding the toxicity and adverse effects of fluorinated processing aids on humans and the environment." [4]

Over the last several years, we have invested millions of dollars to advance our technology where we now produce all of our fluoropolymers in the U.S. without the use of fluorosurfactants. Fluorosurfactants are non-polymeric process aids that help ingredients work together in manufacturing some fluoropolymers and historically included PFOA and PFOS, that are among the PFAS substances under the most intense spotlight. We were able to develop a next generation, more sustainable range of specialized fluoropolymers without the

A Critical Review of the Application of Polymer of Low Concern Regulatory Criteria to Fluoropolymers II: Fluoroplastics and Fluoroelastomers. Integr. Environ. Assess. Manag. 2023, 19, 326–354.*

[4] *See Lohmann, Rainer, Ian T. Cousins, Jamie C. DeWitt, Juliane Glüge, Gretta Goldenman, Dorte Herzke, Andrew B. Lindstrom, et al. 2020. "Are Fluoropolymers Really of Low Concern for Human and Environmental Health and Separate from Other PFAS?" Environmental Science & Technology 54 (20): 12820–28. https://doi.org/10.1021/acs.est.0c03244*.

use of fluorosurfactants while keeping the unique properties of these products, as required for special applications.[5]

A recent November 2023 scientific review specifically analyzed how the industry has responded to these claims amid new regulatory actions globally on "essential use"/"currently unavoidable use"/etc.,

> "Because they are concerned about the negative aspects of the fluorinated polymerization aids (FPAs or surfactants) currently used to replace PFOA, FP [fluoropolymer] manufacturers have been overcoming the great challenge to produce FPs free from FPAs…***FPs produced without any FPAs should be exempt for all uses across all industries including consumer applications as they raise no risk to the environment or to mammal and human health, in addition to the fact that FPs also match the PLC [polymer of low concern] criteria.***"[6] (Emphasis added.)

The supply of fluoropolymers for critical product supply chains is currently a delicate balance between market demand and regulation. A full exemption for fluoropolymers that are responsibly manufactured for industrial uses represents a path forward to address environmental, national security and economic competitiveness priorities. Thank you for your consideration. We encourage the state to take all measures to implement this statute with the widest possible interpretation for critical supply chains while recognizing the individual upstream chemistries that enable them. It's vital that these chemistries are not only allowed in commerce, but have sufficient demand to sustain production.

Very truly yours,

David A. Cetola
Vice President, Global Government Affairs

Re: Comments on New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837 for portable 3D measurement-enabled video borescope and remote visual inspection systems

To whom it may concern:

Baker Hughes, on behalf of our subsidiary Waygate Technologies, submits the following comments for an unavoidable use determination for our non-destructive testing equipment, as further described below. Many of our products are used for industrial asset monitoring to ensure the safe, reliable, and efficient operation of industrial equipment in power plants, transportation infrastructure, manufacturing plants, and other industrial operations.

1. *Provide a brief description of the type of product including, if applicable, the Global Product Classification (GPC) brick category and code, or if GPC is not applicable than the Harmonized Tariff System (HTS) code.*

Waygate Technologies (a subsidiary of Baker Hughes) designs and manufacturers portable 3D measurement-enabled video borescope or remote visual inspection

T + 1 713.439.8600
575 N. Dairy Ashford Rd.
Houston, Texas 77079, USA

systems. These products are classified under the Harmonized Tariff Schedule under **HTS Code: 9031.49.9000 - Other Optical Instruments and Appliances, others**.

Our video borescope or remote visual inspection equipment are handheld systems that feature a long (typically 2-10m in length), narrow (4-8 mm) insertion tube with an illuminated tip fitted with a high-resolution camera and optics. Images are relayed to an operator screen who can control where the tip pointing via a joystick. Units can operate for years and undergo thousands of bending operations with no degradation to the amount of bend, image quality, or other factors. Proprietary image analysis software allows operators to identify manufacturing defects, damage that occurred during operation, or other issues. Assessments such as decisions to continue operation or to take an asset out of service (e.g, aircraft engine) can be made and documented.

2. *Describe the intended use of the product and explain how it is essential for health, safety or the functioning of society.*

Our inspection equipment is built with a rugged and ergonomic design that allows for precise inspections in the toughest environments including aerospace, power generation, pharmaceuticals, oil and gas, automotive, food and beverage industries, and more. The units are sealed against fluid and particulate ingress, and are rugged against spills, impacts, drops, or temperature extremes. Their use provides industrial, transportation, and power generation asset owners the ability to troubleshoot equipment on-site with minimal disassembly and costly reassembly and requalification.

Houston, Texas 77079, USA

Baker Hughes

3. *Describe how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, provide citations to that requirement.*

PFAS (fluoropolymers) are used throughout the videoprobe system including: gaskets and seals for ingress protection; wire/cable electrical insulation; and components designed to reduce wear/friction on moving parts. Fluoropolymers such as PTFE, expanded PTFE, Viton, and others provide chemically inert, temperature-resistant, flexible, durable, and low-friction properties critical to the long-term operation of the device.

4. *Describe whether there are alternatives for this specific use of PFAS which are reasonably available.*

Alternatives to certain fluoropolymers that mimic one or two properties (e.g., flexibility, chemical resistance, etc.) do exist, but alternatives that can mimic the broad spectrum of properties, particularly low-surface friction, are few or non-existent.

Re: Comments on New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837 for Baker Hughes' valve products

To whom it may concern:

Baker Hughes, on behalf of our subsidiaries listed below, submits this request for an unavoidable use determination for our valve products. The Baker Hughes products that contain PFAS and are subject to these comments include Dresser valves and associated brands, including Consolidated, Masonelian, Becker and Mooney.

To support this request, we are incorporating the request submitted by the Flow Control Coalition, which is a coalition comprised of the following trade associations the Fluid Sealing Association, Hydraulic Institute, the Valve Manufacturers Association and Water and Wastewater Equipment Manufacturers Association. We are members of the Valve Manufactures Association. Please see the attached comments submitted by the Flow Control Coalition as support for our comments.

If you have any technical questions regarding this submittal, please contact Jeanne Beres Jeanne.beres@bakerhughes.com.

Baker Hughes

Baker Hughes, on behalf of our subsidiaries listed below, submits the following comments for an unavoidable use determination for our compression, gas and steam turbine, and our condition monitoring equipment, as further described in the attached file named Baker Hughes UUD Product Request (1 March 2024).xlsx.

These products may contain PFAS polymers of low concern which are indispensable and used in countless industrial processes to support the production, processing, building and manufacturing of oil and gas; chemical; construction; power generation (traditional and new energy sources); mining; pharmaceutical; pulp and paper, water and wastewater; semi-conductor production; construction and data centers; transportation and food & beverage, along with many, many others. They are essential for health, safety and the functioning of society.

The specific PFAS substances used in our products are due to their properties in effective sealing, creating barriers for emissions, reducing energy use, performance in highly corrosive or high temperature environments, when access to the system is difficult and dangerous, and in providing a safe and reliable production process.

The Baker Hughes products that contain PFAS and are subject to these comments include Bently Nevada, Waygate Technologies, Panametrics, Druck, Reutor-Stokes, and Nuovo-Pignone. The attached spreadsheet provides the details of these products and the rationale for this UUD.

If you have any technical questions regarding this submittal, please contact Ranjith Nair at ranjithm.nair@BakerHughes.com.

We appreciate the opportunity to submit these comments. Please contact Ranjith Nair or me if there are any questions.

Sincerely,

Joseph M. Dawley

SEMICONDUCTOR INDUSTRY ASSOCIATION

RECEIVED
By: OAH on 3/1/2024
Alex Gordon Attachment 1

**Comments of the
Semiconductor Industry Association (SIA)
To the
Minnesota Pollution Control Agency (MPCA)
Resource Management and Assistance Division
Request for Comments
On the
Rulemaking on
PFAS in Products Currently Unavoidable Use Rule**

March 1, 2024

The Semiconductor Industry Association (SIA)[1] appreciates the opportunity to submit a proposal to the Minnesota Pollution Control Agency (MPCA) on its request for comments[2] on the rules governing currently unavoidable use (CUU) determinations about products containing per-and polyfluoroalkyl substances (PFAS).[3] SIA submits this proposal on behalf of its members,[4] the semiconductor industry, at large, and other manufacturers in the semiconductor supply chain.

SIA Request for Semiconductor Uses to be Deemed "Currently Unavoidable Uses"

Under the auspices of SIA, the Semiconductor PFAS Consortium has published technical papers documenting the industry's use of PFAS in various applications, including information regarding the unique functional properties of particular PFAS in our manufacturing processes, the absence of non-PFAS alternatives in meeting performance requirements, and the technical obstacles and long lead times needed to identify and adopt potential substitute chemicals. Each of these technical papers are available for download at https://www.semiconductors.org/pfas/, and we incorporate these papers into these comments by reference.[5] These papers provide the technical basis for our request for Minnesota to ensure the definition of "currently unavoidable use" encompasses the following uses of PFAS throughout the entire semiconductor value chain, or to designate as part of this initial rulemaking that the following uses of PFAS in the entire semiconductor value chain as "currently unavoidable uses":[6]

---

[1] SIA is the voice of the semiconductor industry, one of America's top export industries and a key driver of America's economic strength, national security, and global competitiveness. Semiconductors – the tiny chips that enable modern technologies – power incredible products and services that have transformed our lives and our economy. The semiconductor industry directly employs over a quarter of a million workers in the United States, and U.S. semiconductor company sales totaled $275 billion in 2022. SIA represents 99 percent of the U.S. semiconductor industry by revenue and nearly two-thirds of non-U.S. chip firms. Through this coalition, SIA seeks to strengthen leadership of semiconductor manufacturing, design, and research by working with Congress, the Administration, and key industry stakeholders around the world to encourage policies that fuel innovation, propel business, and drive international competition. Additional information is available at www.semiconductors.org.

[3] *Minnesota Session Law - 2023, Chapter 60, H.F. No. 2310, https://www.revisor.mn.gov/laws/2023/0/Session+Law/Chapter/60/#laws.3.21.2*

[4] Semiconductor Industry Association, *Members*. See: https://www.semiconductors.org/about/members/

[5] We are happy to provide a zip file of these documents, but they are unable to be attached to our submission on the MPCA portal. Please contact agordon@semiconductors.org if the zip file is requested.

[6] Environmental policy has long-embraced the concept of providing an exemption for critical or essential uses of restricted substances, dating to the treaty to phase out ozone-depleting chemicals. Montreal Protocol on Substances that Deplete the Ozone Layer (1987), https://ozone.unep.org/treaties/montreal-protocol. In addition, the scientific and environmental community has endorsed the application of a critical use exemption to the regulation of PFAS. See

- Manufacturing Processes – PFAS-containing chemicals, gases, and materials used in semiconductor manufacturing, including but not limited to the following applications:
  - Surfactants
  - Photo-acid generators (PAGs)
  - Fluorochemicals used in semiconductor manufacturing plasma-enabled etch and deposition
  - Heat transfer fluids (HTFs)
  - Materials used in semiconductor manufacturing assembly test packaging and substrate processes
  - Wet chemistries
  - Lubricants

- Semiconductor Devices – Semiconductor devices, components, and packages

- Fab Equipment, materials, and infrastructure – Semiconductor manufacturing tools, parts, materials, ancillary equipment, and infrastructure used during semiconductor manufacturing or at semiconductor manufacturing facilities

SIA's comments below include additional background on semiconductor manufacturing and PFAS, general comments on the MPCA rulemaking, and specific answers to MPCA's questions.

1. Background on Semiconductor Manufacturing and PFAS

Semiconductors form the essential building blocks of modern technology, enabling innovations that make the world smarter, greener, more productive and efficient, and better connected. Semiconductors enable critical technologies and industries that form the foundation of the U.S. economy, including the automotive industry, defense, electronics, communications, data storage and analysis, legal and regulatory infrastructure, scientific (including materials) research, medicine and medical devices, the green energy transition, transportation (including aviation), and much more. With up to tens of billions of transistors on a single piece of silicon, producing these complex devices requires highly advanced processes and equipment, as well as the use of chemicals, gases, and other materials with specific performance and functional attributes. Today, the smallest transistor is just 3 nanometers in size – 5 atoms thick and 30,000x thinner than a human hair. The fabrication process can include up to 1,400 process steps, with each process step typically involving the use of a variety of unique, highly sophisticated machines and materials. The supply chain for semiconductor manufacturing is extremely complex, as noted by numerous U.S. government publications.[7]

The Madrid Statement on Poly- and Perfluoroalkyl Substances (PFASs), available at https://www.ncbi.nlm.nih.gov/pmc/articles/PMC4421777/. In the case of PFAS, a similar, broad-based exemption is necessary to ensure there are no disruptions to the semiconductor value chain.

[7] The White House, 100-day Supply Chain Review, *Building Resilient Supply Chains, Revitalizing American Manufacturing, and Fostering Broad-Based Growth*, June 2021. See: https://www.whitehouse.gov/wp-content/uploads/2021/06/100-day-supply-chain-review-report.pdf

Department of Defense, *Securing Defense-Critical Supply Chains An action plan developed in response to President Biden's Executive Order 14017*, Feb. 2022. See: https://media.defense.gov/2022/Feb/24/2002944158/-1/-1/1/DOD-EO-14017-REPORT-SECURING-DEFENSE-CRITICAL-SUPPLY-CHAINS.PDF

PFAS are among the inputs essential to chip manufacturing, used in a wide range of industrial processes and consumer products. Although the semiconductor industry accounts for only a small fraction of the world's total PFAS usage, many uses of specific PFAS are essential to semiconductor manufacturing. PFAS have essential uses in a wide variety of applications because they possess certain critical performance and functional attributes needed to manufacture semiconductors as well as the sophisticated equipment and infrastructure needed to support the manufacturing process. The carbon-fluorine bonds and structure of PFAS give them unique physical and chemical properties, such as strong electronegativity, low refractive index, good thermal stability, good barrier properties, hydrophobicity, low dielectric current, thermal resistance, chemical resistance, low surface adherence, resistance to grease and stain, anisotrophic etching capability, selective metal oxide removal, reduced shedding, high-temperature thermal stability, low adhesion strength, chemical inertness, low volatility, UV resistance, flame resistance, and low coefficient of friction, among others. This range of critical properties across the many different types of PFAS and applications, are indispensable in many industrial and consumer applications, including semiconductor manufacturing.

The Semiconductor PFAS Consortium[8] has identified over 1000 uses of PFAS in the semiconductor manufacturing process, fabrication plant equipment, end-use devices and assembled packages, and associated supply chain. Each use is essential to producing the final chip. There are currently no known substitutes for the vast majority of these applications. Identifying, developing, and qualifying suitable substitutes will require new inventions, and if found, the process of introducing substitutes into high volume manufacturing is complex; the process can take anywhere from 5 to 25 years, and in many cases will never be possible.

2. Comments on the MPCA Rulemaking

Given the complexity of semiconductors and related systems, MPCA must recognize that even just one use of PFAS deemed not to be a CUU could inadvertently prohibit the import of semiconductors into the state and cause all semiconductor manufacturing in Minnesota to cease operations.

MPCA should recognize that Minnesota has a vibrant semiconductor industry. In 2023 alone, Minnesota chipmakers, such as Polar, SkyWater, Honeywell, and Seagate, exported over $1.1 billion in semiconductor products. And importantly, Minnesota manufacturers imported $796 million worth of semiconductors that are then incorporated as components into other products.[9] Semiconductor equipment manufacturers in Minnesota, such as Onto Innovation and Tokyo Electron, exported over $200 million worth of machinery. Without a CUU for semiconductor products and the products needed to manufacture semiconductors, these totals would drop to zero. Semiconductor fabrication facilities and equipment manufacturing facilities in the state would be forced to cease operations, and all companies would be prohibited from purchasing semiconductors necessary for their products to function. Such a restriction would inevitably drive business and jobs out of the state.

---

[8] In January 2021, SIA facilitated the establishment of the Semiconductor PFAS Consortium, an international group formed to collect the technical data needed to formulate an industry-wide approach and better inform public policy and legislation regarding the semiconductor industry's use of PFAS. The consortium membership is comprised of semiconductor manufacturers and members of the supply chain including chemical, material, and equipment suppliers. To date, the Consortium has published a series of nine technical papers summarizing the uses of PFAS in the semiconductor industry and significant technical challenges to replace these substances in the range of uses in the fabrication process and fab equipment. Additional information is available at www.semiconductors.org/pfas/ Semiconductor PFAS Consortium, Background on Semiconductor Manufacturing and PFAS, May 17, 2023.
[9] U.S. Census Bureau. HTS codes 8541, 8542, and 8486.

MPCA also should be aware of the investments into the state's semiconductor industry made by the Minnesota State Legislature and signed into law by Governor Walz during the 2023 session. Under Chapter 53, Senate File 3035, Minnesota will invest up to $250 million to match federal funds made under the CHIPS and Science Act.[10] The semiconductor presence in Minnesota is on track to expand in the coming years, but without a CUU for semiconductor manufacturing, semiconductor equipment, and the corresponding supply chains, Minnesota will miss out on the opportunity to participate fully in the CHIPS programs, which runs counter to the initiatives undertaken by the state legislature and governor's office.

In order to avoid these significant adverse socio-economic impacts in Minnesota's economy and the quality of life of Minnesota residents, SIA requests that MPCA craft a broad, categorical CUU that exempts from the 2032 PFAS restriction the entire semiconductor value chain, including materials, tools, and processes, and when present in end use devices and assembled packages.

As described earlier in this submission, included in a CUU for the semiconductor industry should be a general category of usage that includes all CUUs throughout the semiconductor value chain, including the upstream semiconductor supply chain industries, the semiconductor manufacturing process itself, as well as the final packaged semiconductor devices that are produced. Examples of CUU PFAS applications in each of these three subcategories are as partially listed below and including:

- Manufacturing processes - Uses within the semiconductor manufacturing process, including but not limited to PFAS ingredients within specialty chemicals and fluids, fluoropolymers and other PFAS used in production of high purity water and in containment and transport of high purity water and chemicals, and uses of fluoropolymers and other PFAS in facility systems.

- Semiconductor devices - Uses within the final packaged semiconductor devices, including but not limited to finished semiconductor devices and component parts such as encapsulants, thermal interface materials, adhesives, coatings, substrates, wiring, connections, and circuit boards.

- Fab Equipment, materials, and infrastructure - Uses in upstream semiconductor supply chain industries, including but not limited to uses of fluoropolymers and other PFAS used in high purity chemical production and packaging, fluoropolymers and other PFAS integrated into semiconductor manufacturing equipment, PFAS used to manufacture the semiconductor manufacturing equipment, and the PFAS substances supplied for use in semiconductor manufacturing.

3. Reservation of Rights

Please note that this submission is on behalf of the semiconductor industry as a whole, but is not intended to preclude the possibility that individual companies within the semiconductor sector may have additional or more specific information that they intend to submit. SIA's

[10] Office of Governor Tim Walz, *Governor Walz Signs One Minnesota Budget into Law*. Available at: https://mn.gov/governor/covid-19/news/?id=1055-579302#:~:text=The%20bill%20invests%20%24500%20million,the%20CHIPS%20and%20Science%20Act. Minnesota Employment and Economic Development, *Minnesota Forward Fund.* Available at: https://mn.gov/deed/business/financing-business/deed-programs/forward-fund/

submission should therefore be understood as being without prejudice to comments that individual companies may choose to submit.

Moreover, please note that this is an *initial* comment – it is intended to provide key background to MPCA on semiconductor uses of PFAS for which alternatives are not “reasonably available” – based on our understanding that MPCA’s current request for comment will inform future regulatory actions. Although we believe that this submission and the documentation that we incorporate by reference here provides more than ample substantiation for ensuring a CUU designation by MPCA as commented here, we reserve the right to submit additional information in subsequent formal rulemakings that MPCA undertakes.

Finally, we note that, like many other sectors of the manufacturing economy in Minnesota, we continue to have significant concerns about Chapter 60, and believe that MPCA could take steps to further reduce the under-appreciated burden imposed under the law on manufacturing facilities and other reporting companies in Minnesota. In addition to adopting broad CUU designations for the 2032 prohibition, MPCA should broadly apply the discretion available under the statute to provide categorical exemptions from the reporting duty.

We remain hopeful that further legislative improvements to the statute are possible, but in the meantime believe that MPCA should exercise its authority through rulemaking to streamline these requirements in a manner that more appropriately balances risks and costs. We focus here only on the CUU designation in response to MPCA’s request for comment on that topic, and look forward to further engagement with MPCA as it elaborates its regulatory interpretations of the statute in the coming months.

4. Answers to Specific Questions

1) Should criteria be defined for “essential for health, safety, or the functioning of society”? If so, what should those criteria be?

Yes, MPCA should employ a broad concept of “essential” that is both consistent with the requirements of the statute and flexible enough to accommodate the possibility that broad exemptions may be required to avoid adverse impacts on the functioning of society. We suggest that MPCA grant CUU exemptions for both PFAS use applications and end products, and for the supply chain production activities required to produce such PFAS applications or end products, when a manufacturer has submitted documentation that an application, product, or category of products is essential to the health, safety, or the functioning of society and that there are no reasonably available alternative substances or technologies for that use, and that a product shall be deemed to provide benefits to the functioning of society.

Moreover, as indicated in the suggested language above, MPCA should clarify that uses of PFAS-containing products in manufacturing operations that take place in Minnesota would be included in the exemption wherever the manufacturing process produces an end product that is itself deemed “essential.” In other words, MPCA should make it clear that the “essential” designation and related exemptions should apply not only to the end product itself, but to each of the products and processes (and manufacturing equipment used) in the supply chain that are necessary to produce that exempted product. It is reasonable for MPCA to make a CUU determination that includes the use of PFAS in a given product as well as all uses of PFAS needed to manufacture such product, so long as there are no reasonably available alternatives.

Although semiconductors, semiconductor manufacturing equipment, and the semiconductor supply chain likely already fall under a common understanding of the phrase, the definition should specifically reference as examples semiconductors, semiconductor manufacturing equipment, and the semiconductor supply chain.

If MPCA does not include specific examples, then MPCA should ensure that "essential for health, safety, or the functioning of society" includes products, product components, and the supply chains necessary to manufacture such products and product components.

2) **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

Yes, costs of PFAS alternatives should be considered in the definition of reasonably available.

A "reasonable" cost threshold should be where the cost of using the alternative is comparable to the cost of using the PFAS.

In determining a cost of use threshold, MPCA should consider that implementing a PFAS alternative, in the vast majority of cases in the semiconductor industry, will cost substantially more than solely the purchase of the substance. Instead, qualifying and integrating a single new substance into high-volume semiconductor manufacturing could take years, hundreds of engineers, the replacement of process technology or equipment, and even the redesign of a given product. Therefore, a "reasonable" cost of use threshold should include consideration of all the costs necessary to implement and use the PFAS alternative.

MPCA also should consider that a single PFAS substance may be replaced by several non-PFAS substances in order to achieve the same performance and characteristics. Therefore a "reasonable" cost threshold should include all substances that may collectively need to be implemented to replace the specific PFAS.

3) **Should unique considerations be made for small businesses with regards to economic feasibility?**

No comment

4) **What criteria should be used to determine the safety of potential PFAS alternatives?**

MPCA should align with any Federal regulation or determination, such as those that may be prescribed by the U.S. Environmental Protection Agency.

5) **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

Currently unavoidable use determinations should be made indefinitely, at least for the semiconductor industry, until the uses are no longer currently unavoidable. Any time limitation would be arbitrary, as it is impossible to predict with specificity the pace of innovation and science needed to find and integrate alternatives to PFAS and render existing uses of PFAS "avoidable." An indefinite CUU determination is necessary to allow for business predictability in the state. If semiconductor manufacturers, for example, were at risk of losing their CUU status after a given amount of time, that would be an incentive to invest in capacity elsewhere.

For the semiconductor industry, based on the findings of the Semiconductor PFAS Consortium, in some cases, specific applications of PFAS will never be able to be replaced, and many applications may require years, if not decades, to identify a viable substitute, qualify it, and integrate it into high-volume manufacturing. MPCA should also be aware that in some cases, PFAS substances may be replaced by other PFAS with improved environmental and health profiles.

If, however, MPCA sets a specific time limit for the CUU determination, it should provide a process for extending the CUU.

Significant changes in available information could trigger a re-evaluation. MPCA should invite affected stakeholders to provide comment during any re-evaluation process.

6) **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

As previously discussed, MPCA should allow for CUU determinations based on a broad category of products, product components, or product manufacturing processes (e.g., semiconductors, semiconductor manufacturing equipment, and semiconductor manufacturing.) Additionally, MPCA should allow trade associations or other stakeholders to request CUU determinations on behalf of multiple companies or a collective industry. Both of these functions will allow MPCA to streamline the CUU determination process, preserving valuable MPCA and company resources.

The CUU determination process should be based on scientific and technical information relating to whether the use of PFAS in a specific application is currently unavoidable. MPCA should endeavor to minimize the burden of submitting a CUU request, while also ensuring that affected stakeholders are required to provide information sufficient to validate that the use of PFAS is currently unavoidable.

7) **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

MPCA should establish a broad CUU that covers the entire semiconductor value chain, including semiconductors when PFAS is present in end-use devices and assembled packages; semiconductor manufacturing equipment; semiconductor manufacturing materials; and all products necessary for the manufacturing of semiconductors, semiconductor manufacturing equipment, and semiconductor manufacturing materials.

- Manufacturing processes - Uses within the semiconductor manufacturing process, including but not limited to PFAS ingredients within specialty chemicals and fluids, fluoropolymers and other PFAS used in production of high purity water and in containment and transport of high purity water and chemicals, and uses of fluoropolymers and other PFAS in facility systems.

- Semiconductor devices - Uses within the final packaged semiconductor devices, including but not limited to finished semiconductor devices and component parts such as encapsulants, thermal interface materials, adhesives, coatings, substrates, wiring, connections, and circuit boards.

- Fab Equipment, materials, and infrastructure - Uses in upstream semiconductor supply chain industries, including but not limited to uses of fluoropolymers and other PFAS used in high purity chemical production and packaging, fluoropolymers and other PFAS integrated into semiconductor manufacturing equipment, PFAS used to manufacture the semiconductor manufacturing equipment, and the PFAS substances supplied for use in semiconductor manufacturing.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Yes, initial CUUs will ensure business predictability for relevant stakeholders.

SIA also recommends MPCA ensures that the entire semiconductor value chain is included in the definition of essential for health, safety, or functioning of society.

9) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination

MPCA should consider adopting a process for reciprocity with other states that promulgate similar regulations on determinations of currently unavoidable uses of PFAS. A CUU of PFAS in one state should be accepted as a CUU by MPCA, and MPCA should work with its peer agencies in other states to ensure they accept CUUs designated in Minnesota. This will be valuable for consistency and interstate trade, and reduce the resource burden on both the regulatory committees reviewing the requests, as well as the companies submitting them.

MPCA also should take into account the limited potential risk of exposure from uses in the semiconductor industry, the chemical management practices in the semiconductor industry, and the fact that these chemicals are not intended to be released from the finished product under normal conditions of use.

5. Additional Information Regarding Semiconductor Industry Uses of PFAS: Critical Applications Throughout Value Chain

The semiconductor industry has invested significantly in identifying PFAS uses in the value chain for semiconductor manufacturing and in semiconductor devices during the past 25 years, in phasing out PFAS use where possible, namely the use of PFOS and PFOA in photolithography,[11] and in regularly evaluating the availability and efficacy of non-PFAS alternative chemicals or alternative processes or materials. The semiconductor industry has

[11] World Semiconductor Council, Joint Statement of the 21st Meeting of the World Semiconductor Council (WSC), May 2017, at pages 24-26 (Annex A). See: https://www.semiconductorcouncil.org/wp-content/uploads/2017/05/21st-WSC-Joint-Statement-May-2017-Kyoto-Final1.pdf

reduced its PFC emissions in plasma etch and chamber cleans, despite increasing usage of PFCs over time.[12] Efforts are ongoing to innovate and implement new PFAS abatement and process optimization technologies. Our industry has been a global leader in these efforts.

These efforts have been increased substantially during the past 3 years in anticipation of the EU "universal PFAS" restriction proposal under REACH. In preparation for the public consultation that took place last year on that proposal, the semiconductor industry established a substantial industry-wide collaboration platform that made deep investments across the sector. That process documented PFAS uses in our value chain, identified the unique functionality and performance attributes that various PFAS chemicals and fluorinated polymers conferred that made them essential to semiconductor production, and evaluated the availability of alternative substances, materials, or processes. This work culminated in over 700 pages of technical reports and substantiation, broken down by broad sub-categories of uses and applications within our sector. These materials, when considered in their totality and incorporated to this submission by reference, constitute more than ample substantiation for our request that MPCA designate all current and future PFAS uses within the semiconductor value chain as CUU applications that are exempt from the 2032 prohibition. All of this information has been made publicly available for download at semiconductors.org/PFAS.[13]

In brief, these papers demonstrate that many different PFAS are used in chemical formulations, components of manufacturing process tools, facilities infrastructure, and packaging used to make the semiconductor devices that are integral to the modern world. The current semiconductor state of the art is critically reliant on the use of PFAS compounds due to the particular properties that these substances provide. The technical papers identify the many functional attributes possessed by certain PFAS in meeting the rigorous performance requirements of fabricating semiconductors. Given their unique properties, it will be extremely difficult, and impossible in most instances, to find viable alternatives, without substantially impeding or reversing the technologies that the modern world currently relies on. In some cases, PFAS with a higher risk-profile may be replaced by PFAS with an improved environmental and health profile – a necessary, stepwise progress trajectory. There are also environmental impacts with not using PFAS, such as the potential for decrease in yield and therefore cause an increase in chemical, water, energy consumption, and waste generation.

The papers address the following individual topics:

1. Background on Semiconductor Manufacturing and PFAS
2. PFAS-Containing Surfactants Used in Semiconductor Manufacturing
3. PFOS and PFOA Conversion to Short-Chain PFAS-Containing Materials Used in Semiconductor Manufacturing
4. PFAS-Containing Photo-Acid Generators Used in Semiconductor Manufacturing
5. PFAS-Containing Fluorochemicals Used in Semiconductor Manufacturing Plasma-Enabled Etch and Deposition
6. PFAS-Containing Heat Transfer Fluids Used in Semiconductor Manufacturing
7. PFAS-Containing Materials Used in Semiconductor Manufacturing Assembly Test Packaging and Substrate Processes
8. PFAS-Containing Wet Chemistries Used in Semiconductor Manufacturing
9. PFAS-Containing Lubricants Used in Semiconductor Manufacturing

---

[12] Semiconductor PFAS Consortium, PFAS-Containing Fluorochemicals Used in Semiconductor Manufacturing Plasma-Enabled Etch and Deposition, June 2023, at page 6. See: https://www.semiconductors.org/wp-content/uploads/2023/06/FINAL-Plasma-Etch-and-Deposition-White-Paper.pdf

[13] Semiconductor PFAS Consortium, Semiconductor Industry Association. See: semiconductors.org/PFAS

10. PFAS-Containing Articles Used in Semiconductor Manufacturing

Additionally, a peer-reviewed journal article published by Professor Chris Ober and colleagues at Cornell University summarizes the uses of fluorinated materials in the lithography process and concludes: “The addition of small quantities of fluorinated materials enables patterning capabilities that are otherwise not possible to achieve, and this leads to superior device performance. The compact size of the fluorine atom and its strong electron withdrawing characteristics make it stand out in the periodic table and gives fluorocarbon materials unique properties, unmatched by other chemical compounds.”[14]

As a result of this industry-wide collaboration research effort, we have identified more than 60 distinct categories of critical PFAS uses throughout the semiconductor value chain (with many different sub-applications and specific PFAS chemistries used within each of these general use categories). A general description of those uses is found in the Table A.49 appearing in the industry’s submission made during the EU REACH PFAS consultation.[15]
The contents of this table correlate directly with the information that is likely to be required by MPCA when final rules are established for its PFAS in products notification requirements, including, for instance, a brief description of the type of products, a description of the intended use, a description how the specific uses are essential to the function of the product, and finally, the information about alternatives. It is important to note that the timelines provided in the table for alternatives presume that there are no known alternatives and that such timelines start when a replacement that meets necessary performance requirements has been identified.

As the detailed materials developed by the Semiconductor PFAS Consortium indicate, each of these general use categories, and each of the various sub-applications within these uses, relies on one or more PFAS chemicals and fluoropolymers for critical performance functions, for which alternative chemicals or processes are either not available or, where alternatives may exist, require substantial lead time (with timelines that extend beyond, and sometimes well beyond, 2032) to redesign and requalify equipment and production processes.

The Semiconductor PFAS Consortium also published two additional resource documents, which we incorporate by reference in our submission:

- An overview paper that summarizes the key major use categories and identifies the impacts of premature restrictions on PFAS uses in our sector.[16]
- A socioeconomic impact assessment that is specifically focused on the foreseeable direct and indirect costs of a broad PFAS restriction in Europe, prepared as part of the industry's response to the proposed universal PFAS restriction under REACH. Although this paper is focused on the EU, the types and magnitudes of identified impacts are broadly representative of the effect of analogous restrictions if adopted in Minnesota and throughout the U.S.[17]

Rather than attempt to itemize each such PFAS application and substantiate it individually – a process that is not possible to complete, especially in the limited time provided for this submission, let alone for MPCA to review in a timely fashion – our submission incorporates each of these much more detailed papers by reference. We believe even a cursory review of this evidence will demonstrate to MPCA that we have amply satisfied the burden to demonstrate the essentiality of PFAS for these uses as well as the substantial timelines that would be required to research and develop alternatives for all required uses, test them, qualify them, and integrate them into our value chain within the short period of time available before the 2032 prohibitions take effect.

We request that MPCA consider these materials in formulating a general CUU determination for all PFAS currently in use throughout the semiconductor manufacturing value chain, including (for example) chemicals used in semiconductor manufacturing and related equipment (including chemicals and fluoropolymers in articles, and wet chemicals manufactured for and used in various production applications), as well as final semiconductor products and devices that contain PFAS chemicals and fluoropolymers within the devices and assembled packages.

***

SIA appreciates the opportunity to submit this proposal and looks forward to continuing to work with the MPCA in the development and implementation of these rules. Please contact Alex Gordon at agordon@semiconductors.org with any questions.

RE: MPCA Request for Comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Dear Mr. Carr,

Plumbing Manufacturers International (PMI) appreciates the opportunity to provide comments to the Minnesota Pollution Control Agency (MPCA) on its *Request for Comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per- and polyfluoroalkyl substances (PFAS)* published in the December 18, 2023, Minnesota State Register.

PMI is an international, U.S.-based trade association representing manufacturers that provide 90% of the plumbing products sold in the United States. PMI members manufacture water-efficient toilets, urinals, faucets, showerheads, and other plumbing products at more than 70 locations across the country for the residential and commercial marketplace. These products are readily available at home improvement stores, hardware stores and showrooms in all 50 states, as well as online. **In Minnesota, plumbing manufacturers contribute $936.7 million to the economy, provide more than 5,600 good paying jobs with their wholesale and retail partners, and generate $319.8 million in wages.**

Given their vital role in all types of construction in delivering safe drinking and industrial water to Minnesota residents, PMI is requesting that all plumbing products utilized in residential and commercial construction, as well as those used in public infrastructure be designated as "currently unavoidable use".

Maine DEP defines "essential for the functioning of society" on its website[1] as: *Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure,*

[1] https://www.maine.gov/dep/spills/topics/pfas/PFAS-products/cuu.html

delivery of medicine, lifesaving equipment, public transport, and construction. Plumbing products meet several aspects of this definition. Infrastructure is the foundation of a thriving society. As an essential part of critical infrastructure, plumbing systems are key to maintaining the health and safety of the public through reliable delivery of safe, clean water, and removal of waste. These systems significantly contribute to proper sanitation and disease prevention. Plumbing products contribute directly to sustainability by providing critical water supplies to communities and households. These products offer vital functions for critical infrastructure, consumer goods and industrial applications; and contribute to a safe and healthy environment for communities.

Additional Information Regarding the Need for a CUU Designation for All Plumbing Products

Plumbing products are designed for a long service life. For example, plumbing products used in critical infrastructure are designed to last 30 to 50 years and consumer plumbing products such as faucets and showerheads are designed to last for over 10 years. PMI members are in the process of evaluating the presence of PFAS in their supply chains, but it is important to note that to date, it does not appear that PFAS in plumbing products would provide an exposure pathway for consumers. PFAS may be present in some plumbing products in the areas of lubricants, sealants and coatings which provide functions such as flexibility, corrosion and mold prevention, heat and water resistance, and water-tight seals. Lubricants and sealing products containing PFAS are used to ensure that safety-critical gaskets and o-rings used in plumbing products function properly and last an extended period of time in harsh environments. While rarely viewed or touched by a consumer, these components are critical sealing devices preventing leaks in plumbing systems, fire prevention systems, and gas connections. They reduce the risk of potentially dangerous and costly water/gas leaks in and near homes and buildings, all while withstanding challenging environments including harsh cleaning chemicals, extreme temperatures, and high pressures.

Plumbing fixtures/fittings that have contact with drinking water are required to undergo rigorous third-party testing for chemicals that are regulated by the U.S. Environmental Protection Agency (EPA) which is in the process of finalizing the first enforceable national drinking water standards for PFAS.[2] Once those regulatory limits are established, existing third-party certification requirements for plumbing products will reflect those limits.

For some technologies and products, there are no current alternatives for the mechanical properties, longevity, and safety benefits that are provided by PFAS. PFAS bans or phaseouts without appropriate CUU designations could prohibit essential products from being manufactured, sold and distributed. The timing for availability of viable alternatives will take

[2] Federal Register: U.S. Environmental Protection Agency (EPA) – Proposed Rule on the Per- and polyfluoroalkyl substances (PFAS): Perfluorooctanoic acid (PFOA) and Perfluorooctanesulfonic acid (PFOS) National Primary Drinking Water Regulation Rulemaking, Docket: EPA-HQ-OW-2022-0114 https://www.epa.gov/sdwa/and-polyfluoroalkyl-substances-pfas

years or even decades to develop and that's IF alternatives that protect the public water supply can be identified. Alternatives and repair parts often can't be redesigned because the PFAS-bearing part can't be redesigned with non-PFAS bearing material to fit in the same way and still function, or because the manufacturer decides to design a whole new product line rather than develop PFAS-free replacement parts for an existing product line. Analysis reported in the consultation submission by figawa e.V., DGMT, and AE, to the European Chemicals Agency (ECHA)[3] estimates a replacement timeline of up to 33 years for replacement of current plumbing fixtures and fittings with alternatives as follows:

> *A total substitution timeline of 22 years is estimated if provision of spare parts is not included. When spare parts are also included, the substitution timeline extends to 28-33 years. In the long term, the use of substitute products might only be possible in certain areas but would require major design changes. Supply of spare and maintenance parts for existing networks in operation may not be possible and may result in expensive replacements before the end of service life. The vast number of affected networks with such technology would require immense investments. Altogether this could endanger public and industrial water supply and the benefit for the environment is marginal as materials in contact with drinking water are already subject to high standards.*

Federal agencies have recognized products used in construction as essential to the functioning of society. During the COVID-19 pandemic, the U.S. Department of Homeland Security, Cybersecurity & Infrastructure Security Agency (CISA), worked with other agencies to issue a definitive federal list of essential workers by industry sector. The federal government deemed construction and building materials as essential industries, recognizing plumbing as an essential function within these industry sectors. Agencies recognized manufacturing and commercial operations related to all building materials as essential. Building sector products also typically include sealants and adhesives.

Conclusion

Because of the essentiality to society of all plumbing products, PMI requests that they be granted the CUU designation as a class of products rather than requiring individual companies to seek CUU designations by each type of product, requiring analysis of thousands of products, many of which do not contain PFAS or include trace amounts with no consumer exposure.

PMI also recommends that MPCA use similar criterion as Maine DEP for PFAS and requests that MPCA establish an ongoing process for granting CUU designations in the future so that manufacturers and industries that do not receive an initial CUU designation can apply in the

Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

On behalf of the Minnesota Chamber of Commerce (Chamber), a statewide organization representing more than 6,300 businesses and more than a half a million employees throughout Minnesota, we appreciate the opportunity to comment on the Minnesota Pollution Control Agency's (MPCA) request for comments governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS).

As the MPCA proceeds on the rulemaking, it is important to note that PFAS are an integral part of our economy in Minnesota and are vital for climate adaptation and mitigation, energy, public infrastructure (water, waste and transportation), and health care. Their use allows our businesses to remain competitive in a national and global marketplace. The rules and regulations adopted will have significant economic and fiscal impacts on the State of Minnesota.

1) **Should criteria be defined for "essential health, safety or the functioning of society?" If so, what should those criteria be?**

The MPCA should define criteria for "essential health, safety and the functioning of society". There are many chemicals in the PFAS class and all of them should not be regulated the same. PFAS are also regulated on the federal level under the Toxic Substances Control Act, the Federal Food and Drug Act and the Federal Insecticide, Fungicide and Rodenticide Act and these regulations should be considered when creating the criteria. In fact, products required or permitted under federal, or state law or regulation should be presumed essential for the health, safety and functioning of society.

Criteria developed should also take into account the availability of alternatives, their functionality, cost and accessibility in the marketplace. In addition, the criteria must include an assessment of the feasibility and practicality of any prospective alternative which requires the substitute must satisfy the health and safety criteria imposed on the existing product and use.

The concept of "essential" must be broadly interpreted to cover all categories: including, but not limited to transportation, water and waste management, energy production and conservation, appliances, semiconductors, communications, health care, food contact, processing, and manufacturing.

The State of Maine has defined "Essential for Health, Safety or Functioning of Society" and could be used as a starting point for the MPCA:
"Essential for Health, Safety or the Functioning of Society" means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations. Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Costs should be considered and broadly defined. First, the alternative must be available at an equivalent price. Also costs for "reasonably available" should consider many factors including technical and economic feasibility of alternatives. Performance, reliability and availability must also be factored into any equation.

Environmental, health and safety impacts of alternatives should be based on objective, quantifiable and peer reviewed data and cost considerations must include changes in productions facilities, safety and re-training of employees, additional disposal costs and the timing necessary for transition. An alternative should not be deemed "reasonably available" unless it is in current mass production and ready for delivery upon demand.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

Small businesses will be greatly impacted by the law and consideration should be given to possible exemptions based on employee count or sales in Minnesota. Testing and reporting requirements will be especially onerous and costly for small businesses and possible exemptions, or to the extent funds are available, grants/loans should be considered to help alleviate the financial burden that will be placed on these small businesses.

4) What Criteria should be used to determine the safety of potential PFAS alternatives?

Existing federal and state law programs should be the starting point for any criteria for alternatives. Any proposed alternative must be subject to the same federal and state assessment and approval process as the product or use proposed to be replaced. Scientific studies and data must be included as well as a reduction of potential risk to human health and the environment. Sustainability impacts on water use, energy efficiency and reliability should also be considered.

5) **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?**

The unavoidable use determinations should be ongoing until a scientifically proven, peer-reviewed, economically feasible alternative is identified, and reviewed and approved by the federal or state authority with jurisdiction over the product or its use. If significant changes in available information occur, the interpretation of the information should be applied to the existing use as well as the alternative. Important to note is that any change in the determinations of currently unavoidable use will have a fiscal impact on the economy and should be a factor in any decision.

6) **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not to be determined to be currently unavoidable? What information should be submitted in support of such requests?**

Any process that the MPCA uses for the determination process of currently unavoidable use should be available as soon as possible, and be open, convenient, flexible, efficient, and cost sensitive so as to not burden the agency or the manufacturers who are impacted. Any request that a use be determined to not to be a currently unavoidable use, must provide scientifically, peer-reviewed data regarding the functionality, performance, safety, health and environmental impacts of suggested alternatives. Sufficient timelines and public input should be established for a response to such a request. Finally, an essential component must be the absolute protection of proprietary information and business sensitive information.

7) **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

From the Minnesota Chamber of Commerce view, it will be difficult to assess how many members and products will request a currently unavoidable use determination. The State of Maine received over 2,000 requests for an extension to their reporting requirements so that would indicate many products could also seek currently unavoidable use determination. Many sectors are essential to the health, safety and functioning of society and we think it would be safe to assume that the transportation, energy, electronics, medical, communications, defense, manufacturing and food and agriculture industries each will seek currently unavoidable use determination.

8) **Should MPCA make some initial currently unavoidable use determination as part of this rulemaking using the proposed criteria?**

The MPCA should make some initial determinations of currently unavoidable use in the rulemaking process. This would provide some clarity and certainty to manufacturers and the supply chain. Any attempt to streamline an already tedious and strenuous process would be helpful to the business community.

Thank you for the opportunity to provide comments on this proposed rule. Please feel free to contact me with any questions.
Sincerely,

Tony Kwilas

Re: Planned New Rules Governing Current Unavoidable Use Determinations about Products Containing Per- and Polyfluoroalkyl Substances (PFAS)

Revisor's ID Number R-4837
OAH Docket No. 71-9003-39667

Dear Ms. Kessler:

The Association of Equipment Manufacturers (AEM) appreciates the opportunity to comment on the Minnesota Pollution Control Agency's (MPCA) request for comments on the *Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per- and Polyfluoroalkyl Substances (PFAS)*, hereafter referred to as the Planned Rule. We look forward to sharing the expertise and technical knowledge of our industry sectors. We believe it is critically important when developing regulations, that the interest of all stakeholders be considered and understood.

AEM is the North American-based international trade group representing off-road equipment manufacturers and suppliers with more than 1,000 member companies and over 200 product lines in the construction, agriculture, mining, forestry, and utility industries. The equipment manufacturing industry in the United States supports 2.8 million jobs and contributes roughly $288 billion to the economy every year. Our industries remain a critical part of the U.S. economy and represent 12 percent of all manufacturing jobs in the United States. Original Equipment Manufacturers (OEMs) develop and produce a multitude of technologies over a wide range of products, components, and systems that ensure off-road equipment remains safe and efficient, while at the same time reducing carbon emissions and environmental hazards. Finished products have a life cycle measured in decades and are designed for professional recycling of the entire product at the end of life.

The off-road equipment manufacturing industry understands the value and importance of using sound science to inform future policymaking decisions. AEM strives to be a key stakeholder in these policymaking discussions. To ensure that new rules meet their objectives, AEM intends to provide commentary on several MPCA questions listed in the Request for Comments document.

1. **<u>Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?</u>**

Minnesota statutes 116.943 states that:

> *Beginning January 1, 2032, a person may not sell, offer for sale, or distribute for sale in this state any product that contains intentionally added PFAS, unless the commissioner has determined by rule that the use of PFAS in the product is a*

> *currently unavoidable use. The commissioner may specify specific products or product categories for which the commissioner has determined the use of PFAS is a currently unavoidable use.*

The law goes on to grant the commissioner rulemaking authority to make determinations on what constitutes a *current unavoidable use*, and which products may receive an exemption from the requirements of the regulations.

In the request for comment, MPCA asked for feedback from interested stakeholders on whether the agency should define the term *essential for health, safety, or the functioning of society*, presumably to use this definition as a criterion for determining what does and does not constitute a *current unavoidable use*. Off-road OEMs manufacture a wide variety of complex product types that are sold around the world. The market and compliance requirements are growing in number and complexity in an ever-changing regulatory environment. To ensure that policymakers and effected industry stakeholders meet the overarching objectives of a law, AEM strongly believes that regulations should contain clear, understandable, and achievable compliance criteria for businesses and individuals to follow. This will reduce confusion, save time and money, and foster a better understanding between regulators and the regulated community.

The stated aim of the statute focuses on restricting products that contain intentionally added PFAS. However, the exemption standard utilizes a product function, the term *Current Unavoidable Use,* as the only qualifier. It is not clear what the term *use* means within the context of the larger rule. Is this a reference to the chemical's role in the manufacturing process, or the attributes it conveys to the end product? Or is the term *use* meant for the purpose and function of the product itself? To make sure all stakeholders understand the adopted language, it is important to define the term *Use* and understand how it ties into our product lines, before we define *essential for health, safety, or the functioning of society*. With this in mind, AEM supports a definition similar to the one found in the European Union's Registration, Evaluation, Authorization and Restriction of Chemicals (REACH) law, Article 3 (24) [1]:

> a *use* should refer to any processing, formulation, consumption, storage, keeping, treatment, filling into containers, transfer from one container to another, mixing, production of an article or any other utilization. Furthermore, this use must satisfy the need for the technical function provided by the chemical for a specific end use in a particular setting.

This definition provides clarity on the relationship between identified chemicals of concern and their relationship to the product. It also helps harmonize regulatory definitions in multiple jurisdictions around the world, easing the industry's overall compliance burdens.

With the concept of *use* fully defined, we can address the criteria for determining what products could meet the *essential for health, safety, or the functioning of society* threshold. This term should be divided into two different categories, (1) health and/or safety, and (2) the functioning of society.

(1) Is the *use* of the substance necessary for health and/or safety?
  a. Necessity should be assessed to demonstrating and verifying whether a use is necessary for the following elements:
    i. Preventing, monitoring or treating severe health issues
    ii. Sustaining basic conditions for human life and health

---

[1] https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=CELEX:32006R1907

iii. Managing and preventing health crises and/or emergencies
iv. Personal safety
v. Public safety
vi. Addressing a danger to animal health which cannot be contained by other means.

(2) Is the *use* of the substance critical for the functioning of society?
  a. Criticality should be assessed by demonstrating and verifying whether a use is critical for any of the following elements:
    i. Providing resources or services which are critical for society (Construction, Agriculture, utility, mining, forestry)
    ii. Managing societal risks and impacts from natural and man-made crises and emergencies.
    iii. Protecting and restoring the natural environment

The final criteria should assess potential alternatives.

(1) Are there alternatives that are acceptable from the standpoint of the environment and human health:
  a. Can alternatives for the specific use be identified?
  b. Are the alternatives safer, technically, and economically feasible, and available at scale?
  c. Do alternatives provide the level of performance which is sufficient from a society point of view?

Assuming the product meets these definitions, the product should receive an exemption from the MPCA. Otherwise, the product exclusions will start to have negative impacts on human health, public safety, and the functioning of society as a whole.

2. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Should Cost of PFAS alternatives be considered in the definition of "reasonably available"?

As defined in the previous section on establishing criteria for determining *essential for health, safety, or the functioning of society*, economic feasibility is a major component of this consideration. If a product is deemed critical to the functioning of society, the PFAS *use* in that product will likely provide the technical functionality to achieve the identified critical end use. When alternatives either do not exist or are so expensive as to make their purchase unattainable, then cost must be considered when making these determinations, due to that fact cost would be the factor jeopardizing the availability of the product for use in the marketplace.

AEM member companies manufacture products that provide critical functions for our modern world. Off-road equipment grows and harvests food, provides emergency repairs to critical infrastructure, constructs buildings and homes, provides municipal waste processing, among many other critical ends uses. While the work provided by off-road equipment is critical, the machines that work them are heavy capital investments for equipment and fleet owners. For these owners, equipment is cost effective for the work they need to perform, but with change they will become more expensive and less cost effective. As these costs pass on to the customer, contractor, or municipality, the consequences will pass on to the public, which expects and needs the services these machines provide. For these reasons, AEM believes costs should be a consideration when considering the definition of "reasonably available".

Reasonable Cost Threshold:

When developing a reasonable cost threshold, it is important to note that the cost of the new material should not be the only consideration used in making this determination. The next section will define some of these concepts more fully, but for the OEM, the costs associated with identifying, testing, validating, and implementing a new material into a product redesign is an expensive, years long activity. These activities are done to make sure new parts and components meet critical performance, durability, safety, and quality requirements, and may dwarf the extra costs associated with a PFAS alternative.

Consequently, the costs associated with using potential PFAS alternatives extend far beyond the product manufacturer. New materials may require more frequent, and more expensive, maintenance costs. They may not provide the same level of durability, leading to a premature obsolescence of the machine and an increase in societal waste generation. Not to mention the added risks associated with using a new material in a very mature industry used to the safety benefits designed into their components and sub-systems. These later points may be difficult to fully quantify, but they have very real consequences in our industry.

Understanding that the cost associated with adopting new materials in complex industries, such as the off-road equipment sector, is not a simple cost differential between two different substances. The real-world costs are based on a series of complex manufacturing activities, knock-on effects through the value chain, and the customer use experience. AEM recommends that MPCA take these other variables into consideration when developing a reasonable cost thresholds.

3. Should unique considerations be made for small businesses with regards to economic feasibility?

The cost of compliance for chemical regulations is quite high for many industries based on a variety of factors. In particular, the off-road equipment industry has had very little expertise and history regarding the identification, collection and storage of data needed to comply with chemical management regulations. This educational issue, endemic throughout the supply chain, is compounded by the wider compliance environment many of these companies operate in. Smaller manufacturers of components often do not store chemicals above the reporting thresholds required under the EPA's CDR or SARA 313 reporting rules. As a result, many companies in our supply chains and industry-at-large never cultivated the systems or expertise needed to gather and store the relevant chemical data for the components and parts they manufacture and distribute. This means that almost all companies in our industry, and most off-chemical manufacturers in other industries, will need to develop the regulatory expertise and compliance systems from scratch. This undertaking will be immensely expensive for any manufacturer, and prohibitively so for small businesses.

Their task is made more difficult due to the CBI protections many bulk chemical manufacturers utilize to conceal the composition of their products, making downstream identification and reporting extremely challenging to accomplish. Additionally, International suppliers follow various global regulations which differ from U.S. mandated chemical reporting requirements, deepening the data collection obstacles faced by our supply chains. Absent a data reporting system adopted globally across our industry sectors that can track and monitor chemical substances throughout the supply chain, it remains an extraordinarily difficult task for a single OEM to know the chemical composition of the articles they currently market in the U.S.

To illustrate these challenges, some manufacturers possess supply chains that run twenty (20) layers deep, with tens of thousands of unique suppliers scattered throughout the world. Collecting data on the presence of PFAS across hundreds of thousands of individual parts from tens of thousands of different companies is a colossal task. The lack of a *de minimis* reporting threshold ensures that manufacturers will need to collect information for all their parts and components to determine the presence, or lack thereof, of PFAS. The effort and time necessary to coordinate, educate, discipline, and gather useful data throughout the supply chain is a daunting task that will take years to organize and execute.

In comments supplied to the EPA, AEM calculated that the cost of accurately identifying and reporting a single chemical for an OEM would cost over half a million dollars. This estimated cost assumes information provided to the OEM is accurate, complete, and delivered on time. It is also important to note that this estimate does not account for any potential redesign and replacement efforts for phasing the chemical out of use in an off-road machine. For a family of chemicals as large as PFAS, the costs will be an order of magnitude higher.

Assuming a company is looking to identify a single PFAS chemical throughout their product lines, and the industry does not experience any disruptions, obstacles, missing data, or dead ends on their path to gathering the required chemical data, it would take roughly 36 months, or 6240 working hours for a single worker per firm[2] to complete the data gathering process. Using the EPA's estimate of a Technical Professional's wage of $80.50/hour[3], that leads to a total cost of $502,320 per firm. With a supply chain of over 10,000 individual companies, that means the total cost of the data gathering effort for the off-road equipment industry is a minimum of $5 billion dollars in accumulated costs. See Table 1 below:

Table 1: Estimated Costs for Off-Road Equipment Industry to Comply with the Data Collection and Reporting Requirements for a Single Chemical Substance

	COST TO EQUIPMENT MANUFACTURING INDUSTRY
NUMBER OF AFFECT FIRMS	10,000
AVERAGE TIME BURDEN PER FIRM (HRS)	6240
TOTAL TIME BURDEN (HRS)	62,400,000
AVERAGE COST PER FIRM	$502,320
TOTAL COST TO INDUSTRY	$5 Billion

If data collection efforts from industry supply chains produce poor quality information, fail to report information downstream, or prove infeasible to execute, the industry will need to turn to laboratory testing for their parts and components. Due to the lack of a *de minimis* threshold, the product manufacturers will need to test each product down to the detection limit to demonstrate compliance with the Planned Rule. Off-road equipment may contain over 100,000 unique parts in a single product, making testing a time consuming and costly endeavor. Assuming every company in the supply chain only manufactures a single product, uses a GC scan at a cost of $1,000 per part, and receives completely accurate results, testing will cost each company roughly $100 million dollars. With over 10,000 firms, the total cost to the equipment manufacturing industry would be over $1 trillion dollars. Furthermore, testing would create additional constraints on industry, as available time and resources at viable testing laboratories would be overrun with industry PFAS testing requests. These testing bottle necks would extend the compliance timeframe out to well over a decade. Without regulatory relief, this effort would be infeasible to execute on an industry wide level. See cost assumptions for testing in Table 2 below:

---

[2] Many firms have teams of individuals performing this function, but for the sake of simplicity we will assume a single worker per firm.

[3] EPA (2020). Economic Analysis for the Proposed Rule for Reporting and Recordkeeping Requirements for PFAS. November 2020.

Table 2: Estimated Costs for the Off-Road Equipment Industry to Comply with the Data Collection and Reporting Requirements for a single chemical using Lab Testing of Articles

	COST TO EQUIPMENT MANUFACTURING INDUSTRY
NUMBER OF AFFECT FIRMS	10,000
AVERAGE NUMBER OF PARTS PER FIRM	100,000
TOTAL COST OF GC TEST PER PART	$1,000
AVERAGE COST PER FIRM	$100,000,000
TOTAL COST TO INDUSTRY	$1,000,000,000,000

In reality, the supply chain currently lacks the systems and education required to collect and transmit accurate and complete chemical data to the OEMs. Equipment manufacturers are currently seeing very low quality and inaccurate chemical data from their suppliers. To comply with the data requirements in the rule, most collection efforts will necessitate the use of laboratory testing. Meaning that the cost of compliance in the off-road equipment industry alone will be in the billions of dollars and take years to complete. In this environment, most manufacturers, but small entities in particular, will have an incredible challenge meeting the requirements of the rule. To help these companies survive, AEM suggests that MPCA introduce *de minimis* thresholds, a common universal reporting list of PFAS chemicals, alignment with EPA (and global) chemical rules, simplified reporting requirements, among other administrative changes to reduce the compliance burden.

4. What criteria should be used to determine the safety of potential PFAS alternatives?

When establishing criteria to determine the safety of potential PFAS alternatives it is important to consider an alternative substance under a wholistic approach. It is obvious that when looking at alternatives, policymakers should avoid chemicals that are more persistent, bioaccumulative, and toxic than the PFAS their intended to replace. However, one should also consider the wider safety, environmental, and human health repercussions that potential replacements of PFAS could cause. Generally speaking, policymakers should avoid replacement chemicals that exacerbating existing, or result in new, safety, environmental or health hazards, or eliminate the use of products critical to the functioning of society.

<u>Essential Uses</u>

Off-road equipment must meet highly demanding industry wide technical specifications due to the challenging environments in which these types of machines operate. Manufacturers design their products to operate for decades under extremely harsh, demanding, and arduous work environments. In these environments, materials, parts, and components need to meet rigorous design and testing requirements to ensure the safety of the operator and other workers on the jobsite.

The technical functions of the components and systems help inform the safety and operational design requirements of the machine. These technical characteristics include, but are not limited to, the following variables:

- Pressure - various systems, such as the hydraulic and engine systems, experience extreme pressure environments up to 500 bar.

- Temperature - the engine compartment, regenerative breaking components[4] and exhaust system operate at temperatures as high as 800°C.
    - Off-road equipment must also contend with cyclical temperature cycling due to machine exposure to outdoor conditions; temperatures ranging from as -57°C to 230°C.
- Mechanical – machines expose parts and components to a high degree of mechanical wear and tear. Sealing parts must survive the shear forces due to the mechanical movement of the equipment.
- Chemical resistance - seals interact with various fluids and gases, requiring a high degree of chemical and corrosion resistance to ensure the reliability of exposed parts.
    - Exposure to substances such as fuel, hydraulic fluid, coolant with additives like 2-ethyl hexanoic acid, and carboxylic acids, exhaust gas fumes (highly acidic) and engine oil (highly alkaline).
- Electrical and flammability resistance – the weight, power, and fuel of the machine creates electrical and flammability risks. Components, parts, and systems must include design elements to mitigate these risks.
- Vibration - up to 45.0 mm/s which can cause high frequency fatigue to components due to the repeated strain imposed. The mechanical alternating stress between joint components will make joints undergo cyclic tension and pressure, which may cause the generation, expansion, and extension of cracks.
- UV - Long-term durability against factors such as ultra-violet (UV) light due to exposure to outdoor environments.
- Material Weight – The use of lightweight materials to reduce energy consumption and CO_2 emissions.
- Hazardous Locations - Operation in hazardous or explosive environments requiring ATEX rating (the minimum safety requirements for workplaces and equipment used in explosive atmospheres), such as in chemical plants, mining, and petrochemical applications.
- Durability – Equipment must remain highly reliable over periods of up to, and beyond, 40 years.
- Environmental - Withstand harsh environments, such as:
    - Landfills where machines will experience consistent exposure to a wide variety of substances and mechanical damage.
    - Mining and earth moving equipment where operation in extremely dusty, humid, wet, muddy, and damp environments is necessary. The operation of such equipment is often up to 24 hours a day over extended periods of time. Due to the need to carry heavy payloads over rough terrain, the energy and therefore high temperature requirements of these systems are especially demanding.

---

[4] Such as break resistors which recover the heat from breaking to decrease the overall energy requirements of the system.

- Exposure to salt spray due to their operation near the sea.

PFAS provides the material properties required to satisfy these various operating conditions. Without a material equivalent that can meet these technical specifications, the equipment and the individual safety and performance systems will fail, causing immediate and dangerous risks for the machine operator and other workers in the vicinity. It is essential that any replacement material meets the necessary performance requirements and still offers the same safety, durability, and quality attributes offered by the original PFAS chemical.

Risk to Public Policy Goals

The off-road equipment industry stands at the intersection between societal environmental goals and the practical commercial requirements of today's end-users. This position requires manufacturers to strike a perfect balance between the work requirements of their customers and the aspirations of the public and global policymakers. Despite this tension, the off-road manufacturing industry remains committed to providing solutions that can satisfy both stakeholders. As our industry looks to the future, PFAS provides crucial attributes manufacturers need in order to develop new technologies, prevent unintended environmental hazards, and ensure our equipment continues to operate safely.

Environmental concerns

Fluid Leaks:

Almost all off-road equipment requires the use of various fluids to enable the operation of specific machine functions. These fluids run in different systems for numerous purposes. Among these functions:

- hydraulic fluid enables power transfers to the hydraulic systems,
- coolant ensures the engine operates within the ideal temperature range,
- fluid coatings work to prevent corrosion, and
- oils reduce friction between moving parts

While these fluids provide useful functionality to our equipment, they also can cause environmental hazards such as leaks and spills. Equipment manufacturers strive to eliminate these leaks to prevent environmental damage, protect worker safety, and ensure the long-term viability of their products.

Fluoropolymers, such as PTFE and fluoroelastomers, provide crucial characteristics that prevent hose and seal failures throughout the machine. These chemicals possess high temperature, chemical and mechanical resistance, making them ideal for sealing applications. This combination of traits helps ensure the long-term viability of various hoses, seals, gaskets, O-rings, and valves placed throughout the machine. Without fluoropolymers, end-users would likely experience much higher rates of fluid leaks, environmental spills, safety issues, component failures, damage to the machine, and premature obsolescence of the machine itself. Currently there are no known technically, or economically, feasible alternatives to these substances.

Climate Change & Ozone Depletion

Various international stakeholders are working to mitigate the impact that humans have on the climate. Like many other sectors, the off-road equipment industry continues to develop new strategies and solutions to reduce its environmental footprint. These efforts may include replacing current refrigerant options with lower GWP alternatives, developing zero-emission powertrains, or working to build new system efficiencies within the equipment to reduce fuel burn. Fluorinated gases will remain a critical substance in these efforts, without which the path to more environmentally friendly technologies will be much more difficult to achieve.

- Refrigerants: Refrigerants and refrigerant systems are already highly regulated for their contribution to atmospheric ozone depletion, and, more recently, their global warming potential. Recently, our organization successfully concluded an application for the use of HFO-1234yf as a refrigerant in off-road equipment through the EPA's Significant New Alternatives Policy (SNAP) program. Commonly used in the automotive sector, HFO-1234yf not only delivers zero ozone depleting potential (ODP), but also provides a greatly reduced global warming potential (GWP) when compared to its immediate predecessor, HFC-134a.

  Unfortunately, many governmental jurisdictions incorrectly identify these fluorinated refrigerants as PFAS chemicals based on the adoption of overly broad regulatory definitions. For this reason, any family wide restriction on PFAS would invariably restrict the use of this substance as a refrigerant in off-road equipment and eliminate the associated environmental gains.

- Alternative Power: Regulatory bodies have a decades long history of looking at on-road and off-road engines to address air quality criteria pollutant concerns. With a growing focus on climate change, policymakers are also looking at engines to help address concerns over GHG emissions. Manufacturers will need to develop new low carbon powertrain technology solutions to achieve the criteria pollutant and GHG reduction levels set by regulators. Within the off-road sector, manufacturers are researching new alternative power technologies, such as lithium-ion batteries, hydrogen fuel cells, and alternative fuels to provide low carbon solutions to their customers and markets they serve. Once again, PFAS provide the functional characteristics required to help foster the maturity and adoption of these new technologies across the market. Without access to certain PFAS, none of these technologies will remain viable in the future.

Waste Streams

Certain PFAS provide advantageous properties that ensure the long-term functionality of off-road equipment. Preserving the useful life of hoses, seals, gaskets, coatings, and electrical components ensures the machine continues to operate for an extended period under severe conditions. Without the use of certain PFAS, machinery in the field will prematurely fail requiring an accelerated need for new parts and components, thus increasing the generation of waste.

Additionally, future broad-based prohibitions or restrictions of PFAS could jeopardize the off-road industry sector's general recycling and remanufacturing efforts. The off-road sector invests a lot of time and money to ensure their equipment is responsibly recycled, remanufactured, and resold into secondary markets. These efforts reduce the amount of wasted materials the industry produces, prevents equipment from going to landfills, and avoids the premature obsolescence of our products. Any restriction of materials needs to protect against endangering these recycling efforts, and the associated unintended environmental consequences.

Safety Concerns

Safety concerns are perhaps the most important issue the off-road industry attempts to mitigate in their design processes. Heavy equipment, operating in hazardous environments, and under severe stress with various workers on the job site provides ample safety challenges for equipment manufacturers to consider. Under these conditions, machine operators look for reliable and durable equipment with the appropriate safety standards designed into the machine. Several PFAS play a key role in ensuring the products continue to operate safely:

- Fluoropolymers in seals and hoses ensure hydraulic systems maintain pressure. Sudden pressure losses due to hydraulic hose failures can cause loads to drop suddenly on a jobsite, significantly increasing potential harm to workers.
- Heavy equipment operates at very high temperatures, requiring unique chemical solutions to mitigate any potential fire issues. Due to the pressure and temperature stability some PFAS chemistries are used to decrease the potential for fire, thereby protecting worker safety.

Undesirable Alternatives

Any transition to a PFAS alternative must avoid regrettable substitutions. Materials must satisfy national and international legal and regulatory requirements. Furthermore, they must not present an even greater risk to the environment, human health, or present new safety risks to the work site and operator.

Off-road equipment manufacturers require thorough testing and validation of new materials prior to their integration into a final product design. Substance specifications vary based on their intended purpose within the larger machine. Due to the nature of the work, manufacturers often require highly durable and robust materials that can operate consistently under very extreme conditions. Replacing proven materials with alternative substances can, under the right circumstances, produce desirable environmental outcomes. However, transitioning away from irreplaceable or highly specified materials can often lead to higher environmental and human health risks, as well as suboptimal product performance outcomes.

For example, FKM materials provide high chemical, temperature and pressure resistance in gaskets, seals, and hoses. This material performs so well, that it is widely considered to be irreplaceable for the continued operation of most modern equipment. Its closest alternative, ethylene propylene diene monomer (EPDM), also known as synthetic rubber, does not perform well in the high pressure and temperature environments found in modern equipment. More troubling, synthetic rubber utilizes N-methylpyrrolidone (NMP) during its synthesis, which is a regulated Substance of Concern (SoC) in a variety of regulatory jurisdictions.

It is important to ensure that OEMs receive enough time and support when transitioning away from regulated substances. Companies struggle with making informed and responsible decisions when faced with short implementation timeframes, discordant regulatory requirements, and overprescribed rulemakings. Policymakers need to provide appropriate exemptions, time, resources, and public-private collaboration necessary to ensure manufacturer stakeholders can identify and adopt desirable alternatives for their SoC.

With this in mind, AEM recommends that MPCA make sure that, when establishing criteria for PFAS alternatives, the new material must meet the safety, durability, quality, and performance requirements of the original PFAS materials, and must satisfy the need to avoid regrettable substitutions.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

Off-Road Equipment Challenges and Assumption to Finding Alternatives for PFAS

For most PFAS use cases, there are no currently known technical alternatives available for use in off-road equipment that does not compromise the safety, durability, or reliability of the finished product. AEM members produce equipment designed to consensus safety standards and subject to third party certifications, customer requirements, and regulatory testing obligations. Changes to materials and formulations which affect fit, form, function, performance, or safety must undergo extensive testing to ensure any new designs meet internal quality benchmarks, design specifications, and regulatory requirements.

Due to the challenges inherent to the off-road industry, it is extremely difficult to estimate the time needed to identify, test, and qualify alternative chemical substances for each end use. The estimates from AEM and their member companies are based on the following assumptions:

- A suitable and viable technical alternative material exists (although as described above, there are no known current technical alternatives for most PFAS use cases).
- Manufacturers do not encounter dead ends during their material assessments, and suitable characteristics are identified the first-time test are completed.
- Supply chain issues throughout the world do not hamper shipping and transportation timelines.
- The total number of PFAS substances used in off-road equipment is a manageable size (roughly 10-20 chemicals at a time). Manufacturers will try to conduct simultaneous redesign work wherever possible, but they cannot implement changes across all product lines simultaneously as test cells, qualified staff, and other resources are all limited. The higher the number of PFAS substances used in the components and systems of the end-product, the longer the timeline will be.

Any transition away from PFAS requires significant time and resources to simply identify and qualify any PFAS-free material for use in the off-road equipment sector. AEM's member companies estimate that this effort would require a complete re-direction of all engineering resources within each member company to accomplish this task alone. Global engineering resources are extremely limited, with almost all companies facing severe staffing and human resource challenges. As such, off-road equipment manufacturers will need significant additional resources and time to address the qualification requirements for PFAS-free components, due to the fact that any individual company is highly unlikely to have the resources on hand to accomplish this task. This type of activity will impact all other R&D projects and other internal development programs. It is likely that all these activities would pause in order to focus enough resource on PFAS qualification activities. If no exemption were granted, it is highly likely that all product sales, manufacturing activities, and service actions in the state of Minnesota would stop until suitable alternatives are identified, tested, designed, and qualified.

Off-Road Equipment PFAS Replacement Timeline

Off-road equipment operates in some of the most demanding and severe environments over a product life cycle measured in decades. The equipment are highly complex pieces of machinery requiring each manufacturer to undertake component and system level qualifications to ensure the necessary performance characteristics are met.

Working under these design requirements, and the assumptions listed in the previous section, AEM member companies estimate that replacing a manageable number of PFAS substances at one time would take at least 15 years for new equipment and 30 years for replacement parts and components. This estimate assumes the timeline starts at the date at which an alternative has been identified to ensure the OEM can maintain the systems in the machine which safeguard the operator, maintenance personnel, the worksite, and the environment.

These product re-design and validation assumptions have precedence in other chemical management and environmental rulemakings. In their recently published, *Decabromodiphenyl ether and Phenol, Isopropylated Phosphate (3:1); Revision to the Regulation of Persistent, bioaccumulative, and toxic Chemicals Under the Toxic Substances Control act (TSCA)*[5] proposed rule, EPA granted the off-road equipment industry, along with other similar industries, a 15 year transition period for new equipment and 30 year transition period for replacement parts for a single chemical substance; Phenol, Isopropylated Phosphate (3:1) (PIP 3:1). Furthermore, during engine emission rulemakings[6], which focus only on the engine and aftertreatment system redesigns, regulators like EPA, California Air Resource Board (CARB), and the EU Commission provide a 7-13 year transition (depending on the power category) to produce new certified engines. While these two rules are different from the requirements promulgated in Amara's Law (HF2310), the reality is that these two other rules are simpler to comply with and grant the off-road equipment industry extended timelines to implement the design changes needed to meet the requirements of the law.

<u>Criteria for Establishing Timelines for Unavoidable Use Determinations:</u>

The off-road equipment industry provides a useful case study in adopting a cautious approach to establish unavoidable use determination timelines. Off-road machines are large, highly complex products, with specific design requirements, and extremely long supply chains, making large scale design changes impossible to implement in short periods of time. If a suitable alternative exists, it is unlikely that all industries require the same timeline to transition their products away from the use of PFAS. Assuming this is true, it is important to establish certain criteria for determining a timeline.

Speaking on behalf of off-road equipment, MCPA should grant a current unavoidable use determination when there are no PFAS alternatives that are technically suitable, economically feasible, commercially available, legally compliant, and safe. We understand that overtime these conditions may change and will require careful consideration on behalf of industry stakeholders to determine what an appropriate timeline looks like. That said, AEM strongly believes that the any PFAS alternative must satisfy these listed criteria prior to ending a current unavoidable use determination:

- Technically suitable: The PFAS alternative meets or exceeds the technical properties associated with the PFAS equivalent. This ensures that any replacement material provides the safety, quality, durability, and performance characteristics needed for the machine to operate successfully. If the new substance does not meet these technical requirements, the machine is likely to experience elevated safety risks, performance failures, premature obsolescence, and increased waste.

---

[5] https://www.federalregister.gov/documents/2023/11/24/2023-25714/decabromodiphenyl-ether-and-phenol-isopropylated-phosphate-31-revision-to-the-regulation-of

[6] https://www.epa.gov/regulations-emissions-vehicles-and-engines/final-rule-control-emissions-air-pollution-nonroad

- Economically Feasible: The PFAS alternative is reasonably priced. If the new alternative is too expensive, the increase in price will threaten the long-term viability of the entire construction, agricultural, mining, utility, and forestry industry.
- Commercially Available: The PFAS alternative is available for purchase at scale. When developing new substances, chemical manufacturers and material processors require time to commercialize these products and distribute enough material for use throughout the global supply chain. OEMs, in turn, require their own time to test and validate new materials prior to adoption.
- Legally Compliant: The PFAS alternative is legally compliant with domestic and international law. Many components in off-road equipment are regulated under other regulatory frameworks. For instance, emissions-related components cannot be altered without notifying and, in many cases, re-certifying the engine with EPA, CARB, the EU, and other regulators. This process takes a substantial amount of time and resources to complete.
- Safe: The PFAS alternative is safe for handling, storage, manufacturing, and use. If the new material does not meet this requirement, it should not be used in the marketplace. This requires extra time and resources to prove.

Off-road equipment manufacturers produce machines to meet a host of different requirements. These include safety, regulatory, environmental, and customer requirements. Validating new components, parts, and systems takes time and cannot be accelerated without sacrificing important features. To achieve a successful outcome and with safe and durable results, a change of this magnitude should be validated and substantiated on an industry level. Other industries operate under similar types of demands. Therefore, it is crucial to keep these criteria in mind when establishing unavoidable use determination timelines.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

The off-road equipment industry manufactures safe equipment using consensus safety standards with decades of experience using components and materials that satisfy well-tried safety principles. Companies in these sectors will innovate and differentiate themselves on performance, efficiency, functionality, and a host of other features, but prefer to move together when it comes to safety. Therefore, to maximize worker safety and avoid largescale market disruptions, it is important that current unavoidable use determinations apply to the industry as a whole and consider industry wide acceptance and approval of potential PFAS alternatives, rather than on a company-by-company basis. This process will mitigate safety risks on the workplace and guarantee a smoother transition when viable PFAS alternatives are identified.

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

AEM represents off-road equipment manufacturers and suppliers with more than 1,000 member companies and over 200 product lines in the construction, agriculture, mining, forestry, and utility industries. Off-road equipment encompasses a large variety of products and product types. While many of these products use similar components, parts and systems, their intended function and use cases may differ substantially between equipment types; requiring a more complete definition to fully encompass the off-road sector. Generally, off-road equipment includes the following types of machines:

- Mobile off-road equipment,
- Large scale fixed installation,
- Large scale stationary industrial tools,
- Alternative power applications, and
- Attachments and implements.

The definitions of each of these categories are as follows:

- Off-road mobile machine: any mobile machine, item of transportable industrial equipment, or vehicle with or without bodywork or wheels which:
    - Is not intended for carrying passengers or goods on the road,
    - Includes machinery installed on the chassis of vehicles intended for the transport of passengers or goods on the roads,
    - Installed with a combustion engine – either an internal spark ignition (SI) engine, or a compression ignition diesel engine,

- Large Scale Fixed installations: cover a combination of several types of machines which include, but are not limited to, tower cranes, light towers, crushers, and screeners:

    - A combination of several types of apparatus and, where applicable, other devices;
    - Assembled, installed and de-installed by professionals;
    - With the intention to be used permanently in a pre-defined and dedicated location;
    - And it has to be large-scale.

- Large scale stationary industrial tools: include, but are not limited to, cranes and blow-out preventers.

    - An assembly of machines, equipment and/or components, functioning together for a specific application;
    - Permanently installed and de-installed by professionals at a given place;
    - Used and maintained by professionals in an industrial manufacturing facility or R&D facility;
    - And it has to be large-scale.

- Alternative power applications: Products intended to power off-road equipment, such as batteries, battery packs, and recharge equipment.

- Attachments & implements associated with the above equipment (i.e., towed mowers, sprayers, buckets, forks)

PFAS Use Cases in Off-Road Equipment

The off-road equipment industry, defined by its diverse end-use applications, harsh working environments, and extremely long product lifecycles, demands unique material solutions to meet the safety, environmental and performance requirements of the marketplace. Future regulatory, customer, and societal pressures will continue to push this sector to develop and adopt new technologies to tackle global policy concerns, especially issues around climate change, engine emissions, circular economy concepts, enhanced recycling, energy usage, and sustainable supply chain issues. This complex mixture of impending market conditions requires industry access to distinctive material chemistries to accomplish these goals. Due to their highly specialized and unique properties, PFAS chemicals help provide a critical building block for OEMs to meet these objectives. While some industries may find alternatives to specific PFAS applications with sufficient research and development, there are many critical uses which cannot be replaced. Broad restrictions on PFAS will damage product innovation and could render future technology development goals impossible to achieve.

PFAS Essential Use Cases

Manufacturers design their products to operate for decades under extremely harsh, demanding and arduous work environments. Equipment materials, parts, and components need to meet rigorous design and testing requirements to ensure critical product functions continue to operate safely and effectively on the jobsite. With their many useful chemical and physical traits, PFAS provide crucial characteristics necessary to meet various equipment design challenges.

- Seals: All off-road machines use fluids to ensure the equipment continues to perform their intended functions. Fluid applications include hydraulic fluid, oil, fuel, refrigerants, coolant, among others. Sealing technology, such as O-rings and gaskets, prevents fluid leaks and ensures water, dirt, dust, and debris stays out of the equipment.

  Properly designed seals must meet various design characteristics to ensure they operate in a reliable, continuous, and efficient manner. The mechanical functions inside a off-road vehicle exposes parts and components to various stressors:

  - Pressure - various systems, such as the hydraulic and engine systems, experience extreme pressure environments up to 500 bar.
  - Temperature - the engine compartment and exhaust system operate at temperatures as high as 800 °C.
  - Chemical - seals interact with various fluids, requiring a high degree of chemical and corrosion resistance to ensure the continued operation of exposed parts.
  - Mechanical – machines possess a high degree of mechanical wear and tear, sealing parts must survive the shear forces due to the mechanical movement of the equipment.

  PFAS are the only chemical family known to provide the combination of thermal stability, chemical resistance, low frictional characteristics, and sealing capabilities required to operate in this harsh machine environment. Several PFAS chemicals, known broadly as fluoropolymers, which include Polytetrafluoroethylene (PTFE), Fluoroelastomer (Viton), and Polyvinylidene fluoride (PVDF) possess many of these crucial chemical traits and have no known substitutes, making them irreplaceable for the heavy equipment off-road industry.
  Replacing PFAS with inappropriate material substitutes would compromise the functionality of corresponding parts and components, ensuring increasing failure rates, fluid leaks, safety issues, and shorter vehicle lifetimes.

- Hoses: Similar to seals, hoses are required to transport fluids from one location to another, prevent fluid leaks, and maintain the cleanliness of the equipment's components and systems. Many hoses in the off-road industry use fluoropolymers to safeguard the durability of the machine by protecting its components from various internal pressure, temperature, and chemical stressors.

  Under these conditions fluoropolymer lined hoses, especially those with PTFE, provide a necessary level of protection to ensure the durability and long-term reliability of the component. There are no known viable alternatives for PTFE used in hoses. Alternatives, such as rubber hoses, provide less durability, as well as decreased flexibility and strength over time. Inappropriate alternatives will result in increasing fluid leaks, damage to the machine, loss of fluid power, and increasing safety risks for the operator.

- PTFE Tape: Over the operational lifetime of a machine, leaks will inevitably occur. Operators looking to fix fluid leaks from seals and hoses require the appropriate materials to withstand the normal operating conditions found inside off-road equipment. PTFE tape provides this level of assurance.

- Hydraulic Fluid: Hydraulic fluid enables the transfer of power from the engine to end-use hydraulic systems. The vast majority of off-road equipment rely on hydraulic systems to carry, push, dig or lift heavy loads. Without this important technology, much of the work performed today would require radically different, and less efficient, technology solutions. Prominent examples of machines and systems that use hydraulic power include excavators, cranes, forklifts, lifts, dozers, graders, loaders, shovels, trenchers, and concrete pumping systems, among others.

  Hydraulic fluids must possess a variety of crucial properties to protect the longevity of the hydraulic system and its components. In turn, the durability of these systems helps ensure that the machine continues to operate in a safe and efficient manner. Pin hole leaks, sudden drops in pressure, or contamination of the fluid can all cause serious safety issues for the operator or maintenance team. To avoid these types of safety concerns, hydraulic fluid producers utilize certain PFAS based chemicals to provide the corrosion, chemical, temperature and wear resistance needed for the system to operate smoothly.

- Refrigerants: Temperature management is a crucial product design requirement in the off-road sector. Many machines have enclosed operator cabins near large diesel engine exhaust systems, with few options for ventilation due to environmental concerns. Ensuring equipment operators remain comfortable while working is an important safety and comfort feature needed in modern machines.

  Ideal refrigerants need to possess off-corrosive and off-toxic characteristics with a low global warming potential (GWP), zero ozone depleting potential (ODP) and a low boiling point. Most widely adopted refrigerants, such as hydrofluorocarbons (HFCs), hydrofluoro-olefins (HFOs), and hydrochlorofluoroolefins (HCFO's) are used extensively in the automotive, aerospace, and off-road sectors. These substances break down quickly in the atmosphere into substances that naturally occur in the environment. Unlike most PFAS chemicals of concern, which may last thousands of years without breaking down, most modern refrigerants have an atmospheric lifetime measured in days, months and in some cases years.

  Due to the inconsistencies in defining what is, and what is not, a PFAS chemical, refrigerants sometimes find themselves included with this larger group. Refrigerants, such as HFC-134a and HFO-1234yf, may find themselves in scope of certain PFAS regulatory requirements despite possessing none of the chemical attributes or risk profiles which make PFAS a concern to policymakers. An accurate assessment of these substances using scientifically accurate definitions would help exclude them from the broader definition of a PFAS seen in recent legislative and regulatory actions.

- Paints: Coatings protect off-road equipment from chemical, weather, or water erosion. Well-designed coatings can help extend the useful life, and maintenance requirements, for off-road products, and are highly valued by OEM's and their customers. Many coating providers use PFAS in their paints to improve the flow, spread, and glossiness of the coating, as well as to decrease bubbling and peeling. They are also used in specialty paints to give stain-resistant, graffiti-proof, and water-repellent properties.

- Alternative Power: Policymakers have long sought to reduce the emissions of criteria pollutants and decarbonize the off-road sector. OEMs and engine manufacturers are looking at many new alternative power sources and technology solutions to meet their ESG goals. While the industry will continue to innovate and experiment in this space, it is clear that PFAS chemistries will play a crucial role in many of these future developments. Two of the most widely discussed technology solutions, batteries, and hydrogen fuel cells, use PFAS to fulfill crucial functionality.

    - Batteries utilize chemical binders to hold the internal active materials together to maintain a strong contact between the electrodes and the current collectors. Battery manufacturers use Polyvinylidene Fluoride (PVDF) as a binder in lithium-ion batteries due to its electrochemical and thermal stability, as well as its acceptable binding properties for the cathode. Additionally, certain fluorinated compounds are also used to coat the anodes to prevent unwanted reactions with the electrolyte. Due to their long lasting and chemical stable properties, the fluorinated compounds help extend the useful life of the battery.

      Under standard industry practices, batteries are manufactured in clean-room conditions, preventing the release of any PVDF into the surrounding environment. These closed conditions make it impossible for any PFAS materials to escape. Furthermore, battery recycling operations recover the PVDF through hydrometallurgical treatment processes. The collected PVDF is further broken down and captured by gas scrubbers, preventing any further release.

    - Hydrogen fuel cells use a proton exchange membrane (PEM) to separate the anode and the cathode. The PEM uses fluoropolymers to separate the protons from the electrons at the membrane surface, allowing only the protons to permeate to the cathode. In this technology, the fluoropolymers provide crucial properties that enable the fuel cell to produce electricity. The fluoropolymers used in the fuel cell PEM have no known alternative replacement.

Other examples: fire retardants, electrical insulation (Equipment), personal protection equipment including gloves/shielding/aprons (e.g. Nitrile, Viton)

Based on the critical benefit of the off-road equipment industry to society, the complex nature of these machines and their supply chains, as well as the fact that PFAS provides crucial safety functions and has no known alternatives, AEM recommends MPCA grant off-road equipment a current unavoidable use determination.

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria.

AEM supports the criteria outlined in this comment when considering current unavoidable use determinations as well as the criteria needed to establish realistic timelines for these classifications. Assuming these criteria are adopted and used by MPCA when making their determinations, AEM supports making some initial current unavoidable use determinations as part of this rulemaking.

AEM appreciates your consideration of these comments.

Please feel free to contact me at Jmalcore@aem.org if you have any questions or require any further information.

Best Regards,

Jason Malcore

Minnesota Rulemaking for Unavoidable Uses

Submission by DuPont de Nemours, Inc.[1]

March 1, 2024

The following comments are respectfully submitted to MPCA by DuPont de Nemours, Inc.[1] for consideration to support the adoption of rules necessary to implement the entirety of Minnesota Session Law – 2023, chapter 60, article 3, section 21 for currently unavoidable use definition and the determination process.

MPCA Question 1 - Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Response to MCPA question 1 - Yes, there should be criteria for determining "essential for health, safety and functioning of society". Determining criteria for uses that are essential to the health, safety and functioning of society can also help to prevent unintended consequences or regrettable substitutions that may negatively impact society and the environment. The criteria for determining "essential" PFAS should include two key criteria 1) "where alternatives do not exist" and 2) "necessary for the health, safety and functioning of society".

For criterion one, the onus of proof should lie with industry (manufacturers and downstream users) to demonstrate why alternatives do not exist or where the use of PFAS is currently unavoidable. Condition of use where alternatives do not exist should be defined by comparing the physical and chemical attributes of the PFAS directly to the attributes of non-PFAS alternatives. Industry should also be required to demonstrate why the PFAS used in unavoidable uses can be manufactured responsibly, used safely, disposed of properly such that they are safe for human health and the environment relative to the alternatives. Specific physical attributes should also be directly connected to how the need for that attribute supports the health, safety, and critical functioning of society. For example, the superior chemical inertness of PFAS compared to other materials leads to its selection for prevention of corrosion, prevention of leaks of hazardous materials, and avoidance of unwanted chemical reactions. Such events can adversely impact high-purity manufacturing and can lead to explosions, exposures, or toxic contamination.

PFAS uses where alternatives could lead to significant unintended consequences include military defense systems, chemical manufacturing, hazardous chemical storage and transport, production of hydrogen, aerospace fuel systems, semiconductor manufacturing, and pharmaceutical manufacturing. PFAS are also selected for superior high and low temperature performance, whereby certain PFAS have operational temperature ranges far higher, far lower, and far broader than any other alternative materials. These essential uses where temperature is a key factor for safe operation avoid catastrophic failures or limitations in equipment used in military, satellites, ocean navigation, aerospace, communication systems and medical applications supporting the critical functioning of society. The manufacturer and down-stream user collectively can most effectively demonstrate why alternatives are not equivalent, what unintended consequences of substitution may exist and the associated societal benefits.

Such physical properties that cannot be matched by alternatives must also be directly connected to the second necessary criterion: essential for the safety, health, and critical functioning of society. Uses or "use-segments" that are necessary for the health, safety and critical functioning of society should be very carefully defined in the implementation phase of the law. Defining and supporting exemptions for unavoidable uses of PFAS in the rule making phase can support avoiding unintended consequences (failures, exposures, explosions, leaks, etc.), supply

[1] DuPont de Nemours, Inc. includes, and refers to, its fully owned subsidiaries.

chain disruptions, stagnation of economic growth, and slowing or reversing advances in technologies that support sustainability, reducing the impacts of global warming and the reduction of greenhouse gas emissions. Defining and supporting exemptions for unavoidable uses of PFAS in the rule making phase also helps to minimize actions that do not materially protect human health and the environment and reduce the potential for negative impacts to the health, safety, and critical functioning of society due to regrettable substitutions or unintended consequences.

While MPCA will need to obtain broad input and carefully consider necessary use-segments, the following currently unavoidable, general uses that support significant societal benefits are provided below as a starting point:

- Medical applications, pharmaceutical precursors, medical devices, and equipment that is deemed necessary to protect society from disease, etc. (consider consulting pharma, medical device manufacturers, or healthcare workers)
- Military uses/applications (see DoD report[2]) or consult the military or military equipment manufacturers)
- F-Gases where alternatives do not exist, F-gases (particularly low global warming potential F-Gases) where they protect society, our food system and communication systems from the effects of global warming, including advances in technologies such as the use of fluorinated polymers in HVAC systems to improve energy efficiency and protect critical infrastructure and data storage systems.
- F-Gases used as foam insulating agents (also known as blowing agents) where alternatives do not exist. Such materials contribute to energy efficiency via their unmatched foam expansion, air sealing and thermal insulating properties and work to protect society, our food and pharmaceutical supply, critical infrastructure, and decarbonize the buildings in which we live and work.
- PFAS used to support the safety and critical functioning of chemical manufacturing and the storage of essential hazardous, corrosive, or explosive substances
- PFAS used to support the safety and critical functioning of transport vehicles (train, planes, automotive, ocean-going vessels, and other passenger and cargo transport vehicles)
- Navigation, communication, and defensive safety systems
- PFAS including fluoropolymers and fluoroelastomers necessary for Semiconductor manufacturing– please see https://www.semiconductors.org/pfas/ for more information
- Lubrication systems and sealing systems operating under harsh conditions where alternatives do not exist
- Municipal, industrial, and agricultural water and wastewater treatment systems that utilize unique polymeric PFAS to improve water security and efficient recycle and reuse
- Analytical standards, analytical testing equipment, monitoring systems required for critical measurements, detection, signaling and safety monitoring
- Energy exploration, conservation, research and harvesting including hydrogen, Solar, wind, oil, hydroelectric and gas where recovery occurs under harsh conditions, or the asset lifetime is critical to the economic feasibility of the alternative energy technology.
- PFAS used to support reducing the impacts of climate change, conservation of natural resources and the realization of the UN strategic development goals which include reducing global warming, energy conservation, protection biological diversity

It is also important to note that the “unavoidable” uses of PFAS in the list proposed above support uses with significant societal benefit and are produced in industries with regulatory compliance and waste disposal obligations. These uses do not contribute to widespread human or environmental exposure because PFAS are used sparingly only where alternatives do not exist, are manufactured, and used in controlled industrial settings, and are disposed of in ways that do not contribute to environmental contamination (consumed and converted, incinerated, disposed

[2] Critical Per- and Polyfluoroalkyl substances Pursuant to Section 347 of the James M Inhofe National Defense Authorization Action for Fiscal Year 2023 (Public Law 117-263), August 2023

of in hazardous waste landfills or recycled). If these use-segments or uses of PFAS are deemed unavoidable uses, the entire supply chain including the production of raw materials needs to be considered as exempted.

MPCA Question 2 - Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Response to MPCA Question 2 – Yes, the cost of alternatives should be considered in determining the definition of "reasonably available".. For applications supporting safety and critical functioning of society, PFAS are typically more expensive than most alternatives and are therefore usually only used when alternatives do not meet very specific critical property attributes. PFAS are chosen for their performance attributes, not because they are more affordable; therefore, the cost of alternatives is already a consideration in the use of PFAS. In Europe as part of the ECHA PFAS Restriction Proposal, costs associated with converting to alternatives where alternatives exist (including lengthy product re-qualifications) are considered and are used to support derogation (transition) periods. Additionally, down-stream users who can convert to alternatives will also need to account for the costs of unintended consequences that may result from converting from PFAS to non-PFAS alternatives. These costs and unintended consequences may include unplanned releases or worker exposures, the need for additional redundant systems, higher potential for explosions, increased safety requirements, higher operating costs, increased down time, reduced maintenance intervals, reduced product lifetime, abandonment of capital assets (to costly to retrofit), increased maintenance costs, lack of spare parts for long service equipment, unplanned systems specification changes and resultant practices, and supply chain disruptions. The cost of a PFAS alternative could negatively impact both the ability of users to manufacture their products and the cost of the final product in commerce, pricing alternative materials and products too high for their critical uses which are essential for health, safety, or the functioning of society. As is standard in commerce, newly invented compounds come at a high premium to industry, placing them out of reach for some end uses. It will be important for the cost threshold of an alternative to be considered in relation to the specific end use category. The definition of a "reasonable" cost threshold is dominated by the specific end use, requirements for performance and the complexity of infrastructure impacts and therefore is difficult to specify. It should be noted that it took nearly 7 decades, until 2021 to finally phase out of leaded gasoline (one product) globally after determining it was a health and environmental hazard in the 1950s.

MPCA question 3 - Should unique considerations be made for small businesses with regards to economic feasibility?

Response to MPCA question 3 – In short, yes. Small businesses may be disproportionately impacted by PFAS restrictions. Other states have recognized this (see small business exemption under Maine PFAS Q&A - https://www.maine.gov/dep/spills/topics/pfas/PFAS-products/). If testing is required for verification, small businesses may not have the financial means to pay for testing. Because testing is complex and because external laboratories capable of testing are limited, testing costs for even large companies is challenging. Additionally, if small toll manufacturers have a mix of PFAS and non-PFAS tolling operations, or if their processing equipment relies on hardware that uses PFAS, needing to replace capital or losing the PFAS tolling portion of their operation could cause their operation to no longer be viable.

MPCA question 4 - What criteria should be used to determine the safety of potential PFAS alternatives?

Response to MPCA question 4 -

The safety of non-PFAS alternatives should be directly compared to the safety of the PFAS under evaluation for substitution. Avoidance of regrettable substitutions is a common practice in industrial product stewardship and process safety management procedures. The key is ensuring that toxicology and exposure data exists under the use and disposal conditions and that the full lifecycle impacts are considered. It is important to ensure that the alternative is not a regrettable substitution.

One example of a regrettable substitution would be substituting an alternative in place of a PFAS polymer that is considered a "Polymer of Low Concern"[3] [4] by scientists and coined as "safe and essential" by the Plastics Europe FluoroPolymers Group (FPG). While persistent (they are designed to be durable and sustainable), they are not considered toxic, mobile, biologically available or bioaccumulative. Replacing a fluoropolymer or fluoro-elastomer with a non-PFAS alternative could therefore be a regrettable substitution. For example, polyvinylidene difluoride (PVDF -a polymer used in many medical applications and in water treatment) and FFKM (a perfluoro-elastomer used in harsh conditions, including sealing applications involving hazardous substances) both belong to the class of high molecular weight fluoropolymers/fluoro-elastomers that are considered polymers of low concern. In just these two examples, fluoropolymers/fluoro-elastomers are safer compared to non-PFAS alternatives because they are more chemically inert. I f additional information is needed for the MPCA to consider exempting fluoropolymers and fluoroelastomers based on essentiality and safety, industry and various associations (ACC, CEFIC, PlasticsEurope - FPG and other trade organizations representing the auto industry and semiconductor manufacturing) can provide numerous reports and evidence to suggest that in essential use applications, fluoropolymer and fluoro-elastomers are safe compared to non-PFAS alternatives as they are essentially inert, non-toxic, not mobile, not biologically available and do not bioaccumulate.

Another example are fluorinated gases (F-gases) hydrofluoroolefins and hydrochlorofluoroolefins, generally referred to as HFOs, that are used in specialty foams including extruded polystyrene board stock (XPS) and low-pressure spray polyurethane foam (LP SPF) insulation and sealants. HFOs are safer alternatives to high global warming potential hydrofluorocarbons (HFCs) and are safer than highly flammable hydrocarbons. XPS and LP SPF foam technologies have recently transitioned to HFOs as required by various state, federal (e.g., US AIM Act), and international air regulations (e.g., greenhouse gas and/or global warming regulations). HFO chemistries have unsaturated carbon bonds and only one fully fluorinated carbon with estimated environmental half-lives on the order of just a few days and have not been found in drinking water sources or food. These gases and volatile liquids have extensive chemical-specific toxicological profiles and safety assessments available and are not considered toxic or bioaccumulative. HFOs are a key component of insulating and sealing foams, which have specific unique properties to meet numerous end-use requirements. There are no technically- proven, safer alternatives to HFOs in XPS or LP SPF foams.

MPCA question 5 - How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

Response to MPCA question 5 - Unavoidable use determinations should remain in place until safer and more sustainable alternatives are discovered/identified and can be implemented. Significant changes in available information about alternatives or new scientific data should trigger a re-evaluation. Alternatively, re-evaluation could be time based. For example, Minnesota could consider re-evaluation of CUU 10 years after implementation. A third possibility would be to require industry to notify the MCPA when alternatives are found. Most product development timelines for applications supporting the safety, health and critical functioning of society are on a minimum 10-year development timeline, many are even significantly longer.

MPCA question 6 - How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Response to MPCA question 6 - Yes, stakeholders (manufacturers, industry users and downstream users) should be accountable (burden of proof) to request an unavoidable uses determination. However, this may put a significant initial and ongoing burden on MPCA. MPCA could choose to describe/include unavoidable use determinations by segment in the implementation phase of the law. If that is not acceptable to MPCA, MPCA would need to set up a request system/program for companies to request an unavoidable use determination. MPCA would also then need to identify subject matter experts to review and approve unavoidable uses on an ongoing basis.

Including unavoidable use determinations (as exemptions) in the implementation phase with a provision to re-evaluate after some period of time or as new data becomes available is likely a more manageable alternative for industry and MPCA. MPCA also needs to consider how to protect confidential and/or proprietary information.

The second question in 6, includes the following question, "Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable?" Stakeholders should only be allowed to request a use that is currently avoidable. Unavoidable uses should only be able to be requested by a user or manufacturer within the same product category because they would have the ability to provide substantiating evidence and data to support the request. In this case, the unintended consequences would still need to be thoroughly examined by the MCPA committee before making an informed decision.

The answer to the third question in 6, "What information should be submitted in support of such requests?", will be highly dependent upon the PFAS and category of use. In general, information should be quantitative and include documented research and performance data for the PFAS and alternatives. This information should not only include technical feasibility at a market scale, but also the relative cost of the alternative, impact to the final product cost to the consumer and confirmation that the PFAS used to make or in the product supports the safety, health, and critical functioning of society. Please note, in order to request information to "make a determination", MCPA will need a process to handle what is likely to be considered confidential and/or proprietary information.

MPCA question 7 - In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Response to MPCA question 7 - The following information includes 7 examples of what may be considered by MPCA to support a determination of unavoidable use.

Unavoidable Use example 1: PFAS used in <u>Photolithography in Semiconductor Manufacturing</u>

DuPont's photolithography business urges the state to review the information at https://www.semiconductors.org/pfas/ which documents essential use of PFAS substances within the semiconductor industry. In short, all applications in the semiconductor industry where PFAS are currently used will likely be submitted for currently unavoidable use determinations by us and/or other participants in the semiconductor manufacturing industry.

Unavoidable Use example 2: PFAS used in <u>specialty lubricants (including dry film lubricants) and greases used under harsh conditions</u>

The use of PFAS polymers in lubricants (including dry film lubricants) and greases, used under harsh conditions where alternatives do not exist, in the following industries should be considered unavoidable uses: transportation (aviation, automotive, ocean-going vessels, rail transport), defense and military, electrical power generation and distribution, medical equipment, energy recovery and harvesting (natural gas, hydrogen, oil, wind, hydroelectric), electrical systems (lubrication of high voltage circuit breakers), and in the petrochemical nuclear, and chemical industries. These are unavoidable uses because alternatives do not perform at very high temperatures, very low temperatures, simultaneously over a wide range in temperatures, are not chemically inert, and/or may not be compatible with or able to lubricate plastics or composite materials use for lightweighting EVs.

The use of alternatives that cannot meet very specific key physical attributes may lead to unintended consequences like cross contamination from additives that are not inert or more hazardous, increase corrosion rates, unexpected catastrophic failures, increased lubrication and maintenance cycles, increase equipment down time, increased maintenance or parts replacement costs, fires or explosions, generation or release of hazardous substances (decomposition products) or limiting operability of existing equipment supporting safe operation of equipment designed to support the safety, health and critical functioning of society. High and low temperature performance, oxidative stability and inertness of fluorinated lubricants is needed across multiple industries which include, but are not limited to, aerospace, space shuttles, medical cryogenics, etc.) whereby inertness and oxidative stability also prevents contamination in high purity manufacturing such as food processing, pharmaceutical manufacturing, power generation or where corrosion inhibition can prevent explosions, fires, or release of toxic byproducts.

Unavoidable use example 3: the use of polymeric PFAS in <u>wire insultation materials</u> used for transport (rail, aerospace, military) and oil extraction equipment operating under harsh conditions

The use of polymeric PFAS such as polytetrafluoroethylene - PTFE (CAS 9002-84-0), fluorinated ethylene propylene – FEP (CAS 25067-11-2) and perfluroalkoxy alkane – PFA (CAS 26655-00-5) that are used in specialty wiring materials in applications in aerospace, military, transport, and downhole pump wire insulation where alternatives do not exist, should be considered unavoidable uses.

A combination of properties afforded by these wiring insulation materials in powertrain applications in rail, aerospace, military, and extraction equipment is essential due to the challenging operating conditions. For aerospace applications, wires are specified according to heat resistance and voltage rating as described in standards such as Standard SAE AS4372C[5]. Other critical properties include arc resistance, flame resistance, low smoke emission, and a 30+ year service life to name a few. The essential requirements for wiring used in rail transport powertrain applications are high continuous operating temperature, broad chemical resistance, low moisture uptake, corona resistance and a 20+ year service life. Arc tracking is the ability for electrical discharges to scorch the insulating material and leave an electrically conductive carbon deposit. This phenomenon is avoided with these PFAS materials.

Such defects have been implicated in air disasters that have resulted in heavy loss of life[6]. Therefore, high resistance to arc tracking, as measured and required by standard IEC 60112:2020, is an essential property offered by these PFAS materials. All civil and military aircraft utilize polymeric PFAS extensively in their design. To put this into perspective, one large aircraft may contain approximately 300 miles of wires and cables, in around 100,000 individual

---

[5] "Performance Requirements for Wire, Electric, Insulated Copper or Copper Alloy" Standard SAE AS4372C published by SAE International (2019) available at https://www.sae.org/standards/content/as4372c/

[6] "Air transportation safety investigation report A98H0003" by the Transportation Safety Board of Canada https://www.tsb.gc.ca/eng/rapports-reports/aviation/1998/a98h0003/a98h0003.pdf accessed 2 June 2023

cable lengths[7]. If this use of PFAS was not considered an unavoidable use, current aircraft could not be serviced or repaired and would need to come out of service. Re-qualifying this quantity of components for all designs of commercial aircraft would be an incredible undertaking. A socioeconomic assessment outlining the air transport industry, although not directly created to look specifically at the impacts of PFAS, provides an appreciation of the breadth of industries and economic sectors that would be profoundly impacted by disruptions to air transport[8] [9].

Powertrain applications in rail and extraction also require >200°C service capability. The insulation must also be robust and resistant to corrosive materials such as oils and cooling fluids due to the challenging operating environment. Reliability is essential since downtime and repair is disproportionately expensive in these specific applications. Rail motor technology continues to move towards higher operating voltages and switching speeds which enables greater power handling for faster and more efficient train control[10] but requires wire insulation which must withstand corona discharge degradation. To ensure that motors can continue to operate, the corona resistance of the insulation must be increased by decreasing the dielectric constant of the insulating material which is best afforded by using polymeric PFAS materials[11]. Although there are many designs of motor for different types of rail application (including locomotives, metro vehicles, and high-speed trains) all motors use different combinations of these polymeric PFAS insulting materials.

Unavoidable use example 4: the use of <u>perfluoroelastomer machined/molded parts</u> (O-rings, seals, gaskets, etc.) in aerospace, military/defense, energy recovery and processing (wind, oil, gas, hydrogen, and hydroelectric), semiconductor manufacturing and industrial processing (chemical, pharmaceutical and nuclear)

The use of perfluoroelastomer machined or molded parts (O-rings, gaskets, seals, etc.) used in applications that support the safety and critical functioning of society in industries such as aerospace and military/defense applications, energy recovery and processing (wind, oil, gas, hydrogen, hydroelectric), semiconductor manufacturing and industrial processing (chemical, pharmaceutical and nuclear), operating under harsh conditions, where alternatives do not exist, should be considered as currently unavoidable uses.

Perfluoroelastomers offer a unique combination of superior thermal stability, chemical resistance (inertness), and sealing effectiveness under both static and dynamic conditions that is unmatched by any other alternatives.

Perfluoroelastomer machined/molded parts are used as sealing elements in the form of O-ring or custom seal geometries in various mechanical parts, shaft bearings, bushings, T-Seals, boots, stacks, V-rings, packing systems, valves, pumps, wireline and drilling tools, mechanical seals in rotating equipment (e.g., pumps, mixers), compressors, filters, couplings, spraying heads, cleaning installations, dosing systems, sampling systems, filling equipment,

centrifuges, instrumentation (e.g., level gauges, flowmeters, gas analyzers, laboratory equipment), fuel burners, ozonators, bonded door, poppet valves, plasma chambers, isolation valves, wafer handling, viewports, gas line feeds, gas injection, and electrostatic chucks. The versatility of perfluoroelastomer parts allows for customized geometries to meet specific sealing requirements in a diverse range of seal types such as T-seals, packers, S-seals, V-rings, stacks, boots, X-rings, tri-lobes, electrostatic chucks, protective seals, bonded doors, and metal bondings.

Based on thorough analysis of alternatives, including advances of research and investment over the last 20 years by industry, it can be concluded that technically suitable alternatives do not exist in the critical applications described above while providing comparable physical attributes needed for safety and critical functioning of society. Currently available alternatives lack the critical physical attributes noted above and if substituted could lead to critical or even catastrophic failures such as releases of hazardous materials, process contamination and unexpected failures in critical applications. It is also important to note that due to the high cost of manufacturing perfluoroelastomers compared to other potential alternatives, these materials are only used in applications where alternatives do not exist.

Unavoidable use example 5: The use of fluoropolymer composite molded/machined parts and shapes in high performance industrial operating environments where chemical resistance, strength, light-weighting and low coefficient of friction is required

The use of fluoropolymer composite molded/machined parts and shapes in applications that support the safety and critical functioning of society in applications such as, but not limited to, chemical processing, telecommunications, transportation (including aerospace, rail, ocean going vessels, transport vehicles including electric vehicles), semiconductor manufacturing, military and defense, energy harvesting and processing (i.e., hydrogen, oil, hydroelectric and natural gas), and industrial manufacturing, operating under harsh conditions, where alternatives do not exist, should be considered as currently unavoidable uses.

Fluoropolymer composite parts and shapes have durability which allow long service life (entire lifetime of the system) and avoidance of catastrophic failures when operating under harsh conditions. Like other fluoropolymers these fluoropolymer composite materials (molded and machined shapes and parts) demonstrate exceptional temperature resistance, mechanical strength, chemical resistance, and resistance to wear (self-lubricating) unmatched by any alternative. These materials have afforded advances in fuel efficiency in aircraft and automotive vehicles, light-weighting for electric vehicles, and have supported the transformation from a fossil fuel economy into a renewable energy economy (including electric, wind and hydrogen). These fluoropolymer composite materials have unmatched durability and chemical resistance characteristics which are critical for managing chemical emissions in industrial chemical processes from a wide variety of hazardous chemicals for which these materials are compatible. These fluoropolymer composite materials also play a critical role in semiconductor fabrication, both in containing toxic chemical environments and preventing defects in integrated circuits.

Some specific applications include use in aircraft wear strips and track liners for wing frame braking and vibrational wear control in engine nacelles, in high temperature applications that prohibit the use of oil lubrication (threat of fire/combustion), in aircraft bushings operating under high G-forces, in industrial applications including wind energy liners, in spherical bearings for military and defense equipment, in energy recovery operations in oil and gas where valves, pumps, fittings, and seals need to operate under extreme temperature, speed, force and pressure and in semiconductor manufacturing for wafer cleaning and resist stripping where extremely aggressive wet chemical / plasma conditions and elevated temperatures exist.

Based on thorough analysis of alternatives, including advances of research and investment over the last 20 years by industry, it can be concluded that technically suitable alternatives for fluoropolymer composite materials do not exist in the critical applications described. Currently available alternatives lack the needed critical physical attributes and if substituted could lead to critical or even catastrophic and unexpected failures in critical applications. These materials also provide durability to extend the lifetime of critical costly assets and infrastructure. It is also important to note that due to the high cost of manufacturing perfluoropolymer composites compared to other potential alternatives (steel metallic composites, other non-fluorinated plastics), these materials are only used in applications where alternatives do not exist.

Unavoidable Use example 6: The use of PVDF micro- and ultrafiltration membranes in <u>water and wastewater treatment systems</u>

Water treatment membranes made from the fluoropolymer polyvinylidene fluoride (PVDF, [-C2H2F2-] CAS # 24937-79-9) enable domestic, agricultural, and industrial water users to fulfill their progress to practice more sustainable water and wastewater management. Water security and human health improve tremendously when water and wastewater treatment is enabled by fluoropolymer micro- and ultrafiltration (MF/UF) membranes for the removal of bacteria, pathogens, viruses, and suspended molecules/particles. Many socioeconomic analyses related to water and wastewater treatment around the world have been published.[12] [13] [14] [15] [16] [17] [18] These reports emphasize that no society is immune to water's impact. Shortages of safe water and wastewater management can disrupt homes, schools, industry, agriculture, and even public health and safety. Alternatives to PVDF have been studied alongside other polymer types like polysulfone (PS) and polyether sulfone (PES) for making membranes, but due to the combined mechanical robustness, chemical tolerance, and excellent separation properties, after nearly 30 years of research and optimization, 77% of the MF/UF membranes used globally in water and wastewater treatment systems are PVDF based.

Water treatment membranes are federally regulated for safe use by the FDA. PVDF is an approved substance for use as a component of articles intended for repeat use in contact with food (21CFR177.2510).

Unavoidable Use example 7: The use of hydrofluoroolefin HFO-1234ze(E) and hydrochlorofluoroolefin HCFO-1233zd(E) in <u>specialty insulating and sealing foams.</u>

DuPont is a downstream user of fluorinated gases ("F-Gases"), in particular hydrofluoroolefins (HFOs) HFO-1234ze(E) and HCFO-1233zd(E) (hereafter referred to as "HFO ze & zd"). This narrow subset of two ultra-low global warming potential HFO compounds are used as foam insulating blowing agents in low-pressure spray polyurethane foam (LP SPF) products and extruded polystyrene board stock (XPS) products. Alternatives to HFO ze & zd do not exist today for these insulating foam blowing agents in LP SPF and XPS. Substantial research spanning over a decade has been done to date to identify alternatives to fluorinated gases in these uses, considering an exhaustive set of options available today and driven by the US AIM Act[19] [20] and subsequent US EPA regulations including the recent Technology Transition[21] regulation[22] and the long standing Significant New Alternatives Program[23] under the amended Clean Air Act of 1990[24], and the Montreal Protocol and its Kigali Amendment[25]. That research has revealed that, different from some other foam insulation technologies, no technology alternatives to HFOs are available today that can meet the requirements of LP SPF and XPS product applications in the U.S.

The LP SPF and XPS sub-use sector represents a relatively small business field in Minnesota with only 1 XPS manufacturing site in Minnesota. Across the US, there are only 5 LP SPF product manufacturers and 3 XPS product manufacturers in total that may sell product into MN. As a result, we expect only a few relevant users or manufacturers of these products will provide comments to MPCA on the use of HFOs in these specialty foams.

The volume of HFO ze & zd foam blowing agents used in the LP SPF and XPS markets are very small. The HFO ze & zd used in this sector are not persistent, not bioaccumulative, and not toxic substances, as demonstrated by the REACH dossiers[26] [27] and many other public documents including the 2023 United Nations Environment Programme (UNEP) report[28]. The HFO ze & zd used in this sub-sector can theoretically break down into trifluoroacetic acid (TFA), which has been classified as a persistent substance, at a theoretical yield of 0% to a maximum of 4%.[29] [30] [31] [32] However, according to a recent United Nations Environmental Effects Assessment Panel (UN EEAP) study conclusion, "TFA does not bioaccumulate nor is it toxic at the low to moderate exposures currently measured in the environment or those predicted in the distant future."[33]. This conclusion is further supported by the REACH persistent, bioaccumulative and toxic PBT assessment of TFA which notes "… it is neither fulfilling the criteria for toxic and

bioaccumulative (PBT-substances), nor the criteria for very bioaccumulative substances (very persistent-very bioaccumulative (vPvB) substances according to REACH directive".[34] The emissions of TFA associated with HFO use are not expected to pose an environmental or health concern based on the exposures expected through at least the end of the modeled time range, year 2100, as reported by the UN EEAP.[35]

LP SPF and XPS play a critical role in achieving Minnesota's climate goals; by enabling energy efficiency gains through insulation and air sealing functionality delivered through its application. Manufacturers of different types of insulation products may comment that their products meet some of the unique features of XPS or LP SPF, however there is no drop-in replacement product in the market which meets all unique properties and requirements of the applications. Those other "not-in-kind" insulation products are not alternatives to XPS or LP SPF. XPS and LP SPF products will continue to play a key role in meeting policy objectives under the Minnesota *Next Generation Energy Act of 2007*36 and Minnesota's Climate Action Framework that includes a top 6 goal of "Clean energy and efficient buildings37 38 For example, LP SPF and XPS help enable energy efficiency targets required to meet policy objectives. Since there are no technical alternatives to produce LP SPF and XPS without HFO ze & zd, these solutions would be eliminated from the market at entry into force, thereby compromising the ability of Minnesota to achieve its climate goals. It would also eliminate the LP SPF and XPS solutions from the market and remove these solutions as a tool for reducing greenhouse gas (GHG) emissions in buildings through the improved energy efficiency that LP SPF and XPS deliver. The impacted value chain that would be forced to exit the market includes product formulators, contract manufacturers, distributors, professional users, and end-use sites of the products including commercial buildings such as hospitals and schools in the State.

MPCA question 8 - Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Response to MPCA question 8 - Yes, as affirmed by the comments provided above in response to questions 1 – 7 above.

MPCA question 9 - Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

Response to MPCA question 9 –

No additional questions or comments.

RE: *Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS)*
Revisor's ID Number R-4837

Dear Commissioner Kessler,

Minnesota Center for Environmental Advocacy ("MCEA")[1] and CURE[2] appreciate the opportunity to provide comment on the Minnesota Pollution Control Agency's ("MPCA") Request for Comment on the proposed new rules governing currently unavoidable use determinations about products containing per- and polyfluoroalkyl substances ("PFAS").

The purpose of this comment is primarily to respond to MPCA's first, fourth, and fifth questions for consideration identified in the request for comments:

> (1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?
>
> (4) What criteria should be used to determine the safety of potential PFAS alternatives?
>
> (5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?

---

[1] MCEA is a Minnesota non-profit organization whose mission is to use the law, science, and research to preserve and protect Minnesota's natural resources, its wildlife, and the health of its people. For over forty years, MCEA has worked with citizens and government decision-makers to protect and improve the quality of Minnesota's environment.
[2] CURE protects and restores resilient communities and landscapes by harnessing the power of people who care about them. We are rural-based, with staff across Minnesota. CURE knows rural people, lands, and ecosystems are vital to helping solve some of the biggest problems faced by Minnesota and the nation.

The final rules MPCA adopts pursuant to this rulemaking must be designed to protect human health. MPCA is well aware that PFAS are harmful in shockingly low concentrations, and that swift and strong action must be taken to prevent additional PFAS loading into Minnesota's landscapes, surface waters, and groundwater. For decades, chemical manufacturers have misled the public and regulators by falsely claiming that PFAS are safe. As a result, PFAS have been added to countless consumer and industrial products and research and development into safe alternatives has lagged.

Industry has reaped enormous profits by manufacturing and adding harmful chemicals to everyday products used by children, pregnant mothers, and vulnerable Minnesotans, deceiving regulators and the public by withholding toxicological information demonstrating the true threat posed by PFAS. This law - Minn. Stat. § 116.943 - must put an end to the practice of putting profit over human health. The Legislature has spoken loudly: Minnesota is closed for business to products containing intentionally-added PFAS. MPCA must uphold this clear legislative directive by ensuring that only those products that are indeed essential are allowed to remain on our shelves. MCEA and CURE offer the following suggestions for how MPCA can ensure exactly that.

A. MPCA Should Employ the Precautionary Principle Throughout This Rulemaking

MPCA should employ a precautionary approach here to protect the health of Minnesotans from PFAS bioaccumulation. A precautionary approach advocates for decisive regulatory action in the face of the unknown extent of health and societal costs of PFAS in our environment and drinking water. The principle states that: "where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation."[3] Despite the many decades that PFAS has been used in the United States, the chemical complexity and numerosity of PFAS has resulted in a deficient scientific understanding of PFAS. Of the thousands of known PFAS, the vast majority have not been thoroughly evaluated for toxicity, though all of them appear to have the characteristic of long-lived persistence in the environment.[4]

---

[3] Rio Declaration on Environment and Development, UN Conference on Environment and Development, 13 June 1992, Princ. 15, UN Doc. A/CONF.151/6/Rev.1 (1992).

[4] For California regulators' take on why toxicity at low levels plus persistence across all PFAS is a serious concern, see Cal. Env't Prot. Agency, Dep't of Toxic Substances Control, Safer Consumer Prod. Program, *Factsheet on PFASs in Consumer Products: Key Points for Decision Makers* (2023), https://dtsc.ca.gov/wp-content/uploads/sites/31/2023/09/PFAS-Factsheet.pdf [hereinafter "DTSC Fact Sheet"].

The continued use of PFAS will irreversibly raise the level of environmental and human exposure because of PFAS's environmental persistence. The carbon-fluorine bond is one of the strongest known chemical bonds, which makes it very difficult to break down.[5] This characteristic causes PFAS to be resistant to degradation, which means that any additional releases will cause environmental concentrations to increase and remain elevated for the foreseeable future. Raised environmental concentrations increases the probability of the occurrence of already known health effects and other, unknown, risks. The high persistence of PFAS within the environment and our lack of knowledge on the chemical structures, properties, and toxicological profiles of PFAS led over 200 scientists to advocate within the 2015 Madrid Statement that production and use of PFAS should be limited.[6] Unfortunately, since 2015, the quantity and usage of PFAS has only proliferated.

Applying the precautionary principle would lead to the inescapable conclusion that all PFAS use must be rapidly reduced or else irreversible harm will cause unmanageable consequences.[7] The extreme persistence of all PFAS is reason alone to regulate it as a class so as to avoid the chemical industry switching to a new type of PFAS every time an older one is shown to be harmful.[8] If regulation waits until environmental concentrations of PFAS rise and all adverse effects are identified, human and environmental exposure to PFAS and its associated effects will not be easily reversible.

Remediation technologies for PFAS that would clean the entire impacted landscape are prohibitively expensive and experimental and are therefore unlikely to contribute much to lowering PFAS environmental concentrations.[9] These emerging

technologies are also ineffective at addressing many types of contamination and do not work at all for some short-chain PFAS.[10] In short, a failure to rapidly reduce PFAS will further externalize cleanup costs and public health harms to the State. Minnesotans should not be forced to pay the tab for continued use of PFAS while manufacturers pass years claiming to be in the process of developing safe alternatives.

A precautionary strategy for PFAS regulation is needed to offset the future costs of PFAS by improving regulatory compliance and reducing the negative consequences of allowing PFAS in essential products long-term. As the scientific understanding of PFAS progresses, we will undoubtedly face wide-scale contamination that will require remediation with technologies that are not yet scalable and affordable. As we work to address this problem, now is not the time to push the financial impacts of PFAS use to future generations. Addressing the problem in a swift and decisive manner, to "turn off the tap" of PFAS entering Minnesota and its environment, will reduce our future PFAS remediation burden and allow time for remediation technology to develop to meet market demands.

B. Thorough Reporting and Examination of all Intentionally Added PFAS is Essential to Determine Whether the Product and PFAS Function are Currently Essential

A robust reporting requirement is vital to determining whether the product and function of PFAS is essential. Therefore, MPCA should resist any efforts to relax reporting requirements. Reporting requirements under Minn. Stat. § 116.943, subd. 2 mandate manufacturers to submit information to the commissioner that includes a description of the product, the purpose of PFAS in the product, and the amount of PFAS.[11] Reporting is required for new products "sold, offered for sale, or distributed in the state" and must be updated when there is significant change to the information or at the request of the commissioner.[12] All products, whether meant for personal, residential, commercial, or industrial use, must be treated the same.[13]

Minnesota requirements are bolstered by updated Environmental Protection Agency ("EPA") Toxic Substances Control Act ("TSCA") rules for PFAS. EPA rulemaking under TSCA Section 8(a)(7) will require most manufacturers and importers to report to EPA by 2025 all PFAS that are known or reasonably ascertainable to be known that have been used in articles since January 1, 2011.[14] The scope of this PFAS reporting requirement includes PFAS identifiable by CAS number as well as those with accession numbers,

---

[11] Minn. Stat. § 116.943, subd. 2.
[12] Minn. Stat. § 116.943, subd. 2(c).
[13] Minn. Stat. § 116.943, subd. 1(q).
[14] 15 U.S.C. § 2607(a)(7); 40 C.F.R. pt. 705.

generic names containing "fluor," and confidential chemicals without any identifying information.[15]

MPCA's reporting mandate here should be appropriately construed to include all PFAS. The whole class of PFAS should be evaluated with extreme caution, and all PFAS should be presumed dangerous until evaluated. Minnesota's current definition of PFAS demands such an application when it defines PFAS to include any of "a class of fluorinated organic chemicals containing at least one fully fluorinated carbon atom."[16] This encompasses all PFAS intentionally added to products, whether viewed as slightly safer than counterparts or not.

Products containing emerging short-chain PFAS should be evaluated equally as strictly as long-chain PFAS. PFAS are a diverse class of chemicals that transport differently in the environment depending on the length of their fluoroalkyl chains.[17] Manufacturers have replaced some long-chain PFAS, such as long-chain PFOA and PFOS, with short-chain PFAS due to claims that the shorter chain length makes them less prone to bioaccumulation and therefore less of a danger to human health. However, short-chain PFAS are much less well-studied than traditional long-chain PFAS, which makes a full assessment of the bioaccumulative and toxic effects difficult. Furthermore, it is apparent that short-chain PFAS are as environmentally persistent as long-chain substances and tend to be highly mobile once released into the environment.[18]

C. Criteria for "Essential for Health, Safety, or the Functioning of Society" and Potential PFAS Alternatives Should Incorporate the Essential-Use Concept

MPCA should incorporate the essential-use concept when defining criteria for evaluating whether a use of PFAS is "essential for health, safety, or the functioning of society and for which alternatives are not reasonably available."[19] The essential-use approach determines whether PFAS use within a given product is essential by applying three considerations: (1) whether the product is currently essential for health, safety, or the functioning of society, (2) whether the function the PFAS provides as part of the product is essential, and (3) if the product and function are necessary, whether a viable

[18] Arlene Blum et al., *supra* note 6.
[19] Minn. Stat. § 116.943, subd. 1(j).

alternative exists.[20] This approach assesses current uses of PFAS with the ultimate goal of phasing out all non-essential uses. Products containing intentionally added PFAS must serve an essential use to society and the function of PFAS within the product must be unavoidable due to a lack of viable alternatives.

The essential-use concept is a policy approach that will help guide MPCA as it defines the contours of the non-essential use ban. MPCA can take guidance from the growing number of countries and U.S. states employing the essential-use concept in PFAS regulation. Essential use originated from the Carter administration's amendments to TSCA in 1978, which banned "non-essential" aerosol sprays, and the 1987 Montreal Protocol.[21] In 2015, the Global PFAS Science Panel first proposed the idea of regulating PFAS as a group of substances under the essential use concept.[22] Essential use has been developed as a regulatory tool in the European Commission's chemical strategy and several European states have separately committed to phasing out all non-essential uses of PFAS by 2030.[23] Several U.S. states have also employed the essential-use concept when considering how to phase out the use of intentionally added PFAS in products.[24]

The regulation of PFAS globally is likely to inform PFAS manufacturing norms and affect the presence and concentrations of PFAS in products that are imported into Minnesota. By applying the essential-use concept, MPCA will harmonize Minnesota's non-essential use ban with other jurisdictions that have taken aim at PFAS. This ensures Minnesota will remain part of the global marketplace and that manufacturers will not have to adopt special provisions to do business in Minnesota.

1. MPCA Must Determine Whether a Product Containing PFAS and the PFAS Function Within that Product Are Essential

---

[24] *Policies for Addressing PFAS*, SAFER STATES, https://www.saferstates.org/priorities/pfas/ (last visited Feb. 29, 2024).

MPCA should not apply an approach that excludes whole product sectors as essential; each intentional use of PFAS within a product must be examined separately to determine whether it is truly essential. Under Maine's "PFAS in Products" law,[25] essential for the functioning of society is defined similarly to Minnesota, except that it includes a set of non-exclusive product sectors where PFAS may be essential. Essential "includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction."[26] Minnesota law holds no such reference to product sectors, and therefore further supports the consideration of PFAS in products on an individual basis. For example, if PFAS was used to make stain resistant fabric covers for bus seat cushions, this function is not essential to society merely because it fits within the public transportation sector.

MPCA should view other jurisdictions' conclusions on whether a product with intentionally-added PFAS qualifies for an essential use exemption as probative evidence MPCA can consider when making its own independent evaluation. For example, if another state or the EU were to deem artificial turf containing PFAS non-essential, this information should inform, but not automatically make, MPCA's decision.[27] The bar for the exception should be significantly higher when other jurisdictions have already rejected the reasoning proffered.

PFAS should be banned from products that cannot be justified by any health or social welfare explanation. For example, lithium-ion batteries contain PFAS in the electrolyte, electrodes, and other battery components. [28] A wide range of products are made from this technology, from laptops to children's toys. Short-term disposable uses of PFAS in lithium-ion batteries should be prohibited. To the extent that any PFAS use in lithium-ion batteries is ultimately deemed necessary, a large sector of cheap disposable products should be blocked from sales pending product-by-product justification. Many of these products are sold online, and MPCA will have to work with online sellers to assure that they do not allow sales into Minnesota of prohibited classes of products.

2. **"Reasonably Available" Should Encompass Alternatives that Achieve Similar Functionality and Performance**

Non-essential uses of PFAS should encompass products where safer alternatives that can achieve similar, but not identical, functionality and performance are available to substitute for the current PFAS use.[29] MPCA should not construe "reasonably available" to mean that an alternative must perform identically to the product containing PFAS. The term "reasonably available" should allow small decreases in the effectiveness or performance of the product for a PFAS alternative. Small changes in the functionality of a product can be acceptable and reasonable, especially where the effectiveness of substitutes will improve with further research. The goal of eliminating PFAS use cannot be effectively achieved with a definition for this term that would only allow substitutes that exactly match or exceed the functionality of the previous PFAS use.

Where safer alternatives are not immediately available, the definitions within Minn. Stat. § 116.943 should be construed broadly to encourage the development of alternatives for currently unavoidable uses. Some PFAS uses are currently unavoidable because they provide vital functions that presently lack a viable alternative. However, the essential nature of the product should not be considered permanent. Limiting the category of "currently unavoidable use" to those uses that are truly a health and human safety priority will incentivize further development of alternatives to PFAS.

Also, MPCA must recognize that when it comes to the sale of goods, the global marketplace is designed to respond to regulations such as this one. If an alternative product is currently available in another market, such as Europe, but is not yet for sale in Minnesota, that alternative should still be considered "reasonably available." Only in circumstances where there is a permanent or near-permanent obstacle to obtaining the alternative product, such as anti-dumping controls or high enough tariffs to make imports effectively impossible, should the alternative be deemed unavailable to the U.S. economy. New product alternatives will rapidly develop in response to jurisdictions with similar prohibitions on PFAS-containing products; manufacturers must be prepared to adopt these alternatives.

3. **MPCA Regulations Should Be Enforced with the Intention of Phasing Out All Essential Uses in the Future**

MPCA should clarify that all products deemed to have a currently unavoidable use will be required to phase out PFAS in the future. Designating a currently unavoidable use gives manufacturers time to develop non-PFAS alternatives. It does not excuse

[29] Monika A. Roy et al., *Combined Application of the Essential-Use and Functional Substitution Concepts: Accelerating Safer Alternatives*, 56 ENV'T SCI. & TECH. 9842, 9842-46 (2022), https://pubs.acs.org/doi/10.1021/acs.est.2c03819.

industry taking no action and continuously arguing that no PFAS alternative applies to their product. The European Union has proposed a full ban, encompassing even essential products, that would start in 2039.[30] Minnesota law does not currently suggest a date for full phase-out, but its use of "currently" in "currently unavoidable use" necessitates consideration of a time when all PFAS use is deemed avoidable due to technological advances.

D. "Currently Unavoidable Use" Determinations Should Employ Regular Review of Alternatives

MPCA should employ an iterative process that requires regular review of alternatives to determine whether the use of PFAS in a product still qualifies as unavoidable. This review is necessary to ensure a product once deemed essential is not granted an overly generous or permanent exemption from Minnesota' ban on PFAS. All PFAS have harmful effects that come at a high cost to public health and the environment. PFAS are water-soluble, which allows them to accumulate in human and animal tissues, such that its presence can be measured years after exposure. PFAS have been proven to be harmful to human health at concentrations measured in parts per trillion and exposure has been linked to a range of devastating human health problems including certain forms of cancer, elevated cholesterol, liver disease, decreased fertility, thyroid problems, adverse developmental effects, and changes to immune system and hormone function.[31] Children, pregnant women, and workers exposed to PFAS on the job are especially vulnerable to these effects.

MPCA should operate from the presumption that any unavoidable use finding expires after one year unless the manufacturer makes a showing that there is no alternative at the time that the exception would expire. This expiration must happen every year no matter whether MPCA has finished processing the prior year's submission – a manufacturer's submission must not be effectively a shield to future regulation or prohibition if MPCA does not act within a set time. Only MPCA's action to renew an exception should count as a renewal, and failure to act should return the PFAS-containing product to the regular default: a prohibition on its sale in Minnesota. The goal of this legislation is to force market changes to find alternatives to PFAS. Without an aggressive plan to regularly review exemptions, the health of all Minnesotans and the environment remain at risk and the intent of the legislation is imperiled.

[31] Carol F. Kwiatkowski et al., *Scientific Basis for Managing PFAS as a Chemical Class*, 7 ENV'T SCI. & TECH. LETTERS 532, 532-43 (2020), https://pubs.acs.org/doi/10.1021/acs.estlett.0c00255.

Products containing PFAS that have life-saving effects, such as medical implants, provide a good case for a currently unavoidable use designation if there is no currently available alternative. Although PFAS may play a role in the effectiveness and durability of medical implants,[32] allowing products to continue to use PFAS in the long-term poses a health threat to the device's users and to society at large, which will be exposed to PFAS from the manufacturing, use, and disposal of such devices. Regularly employing review of currently unavoidable use will incentivize involving toxicology and safety concerns early in medical device development.

E. Additional Information is Relevant to MPCA's Interpretation of "Currently Unavoidable Use"

MPCA provided additional questions for comment, and MCEA and CURE briefly respond to several of these here.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"?

No, that is not evident on the face of the legislation and would unjustifiably expand the exemption beyond what was intended by the Minnesota Legislature. Mere costs do not make an alternative unavailable, and MPCA lacks the expertise to set prices across the entire market for goods to administer a "reasonably available" standard for the wholesale and retail prices of thousands of products and goods. How would a cost standard be applied to trade secret chemical mixtures used by few companies with few suppliers? Will MPCA need economists with expertise in every relevant field to assess cost submission data? If the federal government has a trade sanction against a particular product, that situation may go beyond a cost issue and functionally make something unavailable while the sanction is in effect.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

No, products containing PFAS that are produced from small and big businesses are equally persistent and equally harmful to human health and the environment. Allowing additional feasibility considerations for small businesses could incentivize larger companies to spin off their PFAS-manufacturing units to exploit the exception. Larger chemical companies have already used these strategies to limit themselves from

[32] Sainath Babu, *Navigating the Complex World of PFAS Regulation for Medical Devices*, MED INST. (Oct. 20, 2023), https://medinstitute.com/blog/navigating-the-complex-world-of-pfas-regulation-for-medical-devices/.

PFAS liability.[33] The Minnesota Legislature did not intend for smaller businesses to be given the ability to bypass their carefully constructed PFAS regulations which are intended to apply broadly to all manufacturers.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Members of the public, outside experts, and competitors should be given every opportunity to identify uses that are avoidable, either because the product is not essential or because there are available alternatives. Such third-party submissions should only be required to allege a prima facie showing of facts or arguments that goods are avoidable. Manufacturers should then be required to rebut that showing with substantial evidence because they have significantly better access to information about product inputs and alternatives considered. If a manufacturer is not able to bring substantial evidence to rebut a prima facie argument, MPCA should remove the product from the exception.

Ultimately, the amount of information required by a third-party submitting a request for MPCA to consider a faulty exception should be considerably less than would apply to a manufacturer's response to a challenge. This would favor public participation and public health by empowering community members to meaningfully participate in the process, and it would help MPCA to make Minnesota a safer place to live.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

No, that would merely complicate the task for MPCA prior to finishing this already historic rulemaking. Application of the rules should not be conflated with setting protective standards for public health and the environment. If no product can meet MPCA's standards after the rules are finished then the public will be more protected from PFAS contamination, an overall benefit to society.

[33] *Dupont Completes Spin-off of the Chemours Company*, CHEMOURS (July 1, 2015), https://www.chemours.com/en/news-media-center/all-news/press-releases/2015/dupont-completes-spin-off-of-the-chemours-company; James Bruggers, *Chemours and Dupont Knew About Risks But Kept Making Toxic PFAS Chemicals, UN Human Rights Advisors Conclude,* INSIDE CLIMATE NEWS (Feb. 26, 2024), https://insideclimatenews.org/news/26022024/un-chemours-pfas-north-carolina/.

Conclusion

MCEA and CURE strongly urge MPCA adopt and enforce broad definitions of PFAS that apply the essential use concept to closely restrict the amount of products that qualify for the currently unavoidable use exception. This principle requires MPCA assess each product containing PFAS on its essentiality, and MPCA should not allow an exception merely because the product fits within a sector that has an important role in society, like health or renewable energy. An alternative that is "reasonably available" within this framework should include alternatives that have slight or excusable decreases in effectiveness. This is necessary to best meet the policy goal of eliminating PFAS in manufactured products and honors the precautionary principle's approach of prioritizing human and environmental health.

A precautionary approach to defining and ultimately enforcing Minnesota's ban on products containing PFAS will also help defend the health and safety of Minnesota citizens and the environment by considering the dangers of bioaccumulation. Scientific uncertainty on the toxicity of PFAS must compel MPCA to rapidly accelerate the adoption of comprehensive PFAS bans, not an excuse to wait until more detailed information is available on the many thousands of PFAS chemicals in use in Minnesota today. Regular review of essential use determinations and removal of products from this exception will be vital for effectively phasing out PFAS use to best keep Minnesotans and the environment safe.

Before the
Minnesota Pollution Control Agency
Request for Comments
Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing PFAS
Revisor's ID Number R-4837

Comments of the Chemical Users Coalition

The Chemical Users Coalition ("CUC") appreciates the opportunity to provide our comments on the Planned New Rules Governing Currently Unavoidable Use ("CUU") Determinations about Products Containing PFAS (the "Planned Rule") that will be promulgated by the Minnesota Pollution Control Agency (the "MPCA" or the "Agency") pursuant to Minnesota Statutes 116.943, subdivision 5(c) ("Amara's Law"). CUC is an association of companies from diverse industries that are interested in chemical management policy from the perspective of those who use, rather than manufacture, chemical substances.[1] CUC encourages the development of chemical regulatory policies that protect human health and the environment while simultaneously fostering the pursuit of technological innovation. Aligning these goals is particularly important in the context of chemical management policy in a global economy. CUC Members have been actively engaged with federal and state regulators on PFAS-related legislation and regulation.

The MPCA, in the Request for Comments, is seeking comments on specific questions: The following are CUC's responses to those specific questions on which the MPCA requested input.

1. Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Amara's Law defines "currently unavoidable use" as "a use of PFAS that the commissioner has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available." CUC suggests that greater clarity and detail from MPCA should be provided in the upcoming rulemaking to explain the criteria to determine when a PFAS use will qualify as "essential for health, safety or the functioning of society." MPCA should, in a rule, define these terms so that the regulated community clearly understands the criteria MPCA will use to judge essentiality.

CUC recommends that products or product components that are "essential for health, safety or the functioning of society" are those that, if unavailable, would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the

[1] The members of CUC are Airbus S.A.S., The Boeing Company, Carrier Corporation, HP Incorporated, IBM Company, Intel Corporation, Lockheed Martin Corporation, the National Electrical Manufacturers Association, Raytheon Technologies Corporation, Sony Electronics, Inc., and TDK U.S.A. Corporation.

environment, or significantly interrupting the daily functions on which society relies. CUC also recommends that there should be an opportunity under the rules developed for applicants seeking a CUU determination may demonstrate PFAS or a PFAS use is "essential for health" without the need to also show that without the PFAS or its use there would be a "significant increase" in "negative health outcomes". This would allow room for the development of (and the Agency's ability to exempt) uses that are innovative and (at present) unforeseen, and which would otherwise become subject to the 2030 ban. Furthermore, products or product components that are "essential for health, safety or the functioning of society" also include those that are required by federal or state laws and regulations or are necessary for the purposes of national security, defense or space exploration. Products or product components that are "essential for the functioning of society" are those that are used in or to address climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, aerospace, aeronautics, public safety and defense, and construction.

The interpretation of the phrase "alternatives are not reasonably available" must also be defined clearly by MPCA. CUC recommends that MPCA should take into account, when defining the term, that certain products, including but certainly not limited to products and components in the aerospace and defense sector, are often subject to batteries of qualifications tests, customer approvals, and "Type Certifications" with various regulatory bodies such as the Department of Defense and Federal Aviation Administration. Therefore, alternatives that appear initially to be available may not be reasonably available because they must be subjected to these processes that may take years to qualify and complete.

Furthermore, in many sectors there are often no readily available substitutes due to safety concerns. While a substitute (including a non-PFAS alternative) may exist on the market, it may be the case that such a substitute is more flammable, toxic, or otherwise unsafe—leading to an unwanted regulatory outcome (and possibly regrettable substitutions). MPCA must carefully factor in regrettable substitution when defining the "reasonable availability of alternatives."

To better understand what products are "essential," MPCA should consider conducting analyses to project the impact to the State if/when products from various sectors can no longer be sold due to the sales restriction under Amara's Law. The findings from such analyses should be made public and provided to the state legislature.

Additionally, MPCA should consider the possibility of making CUU determinations based on the specific use of PFAS, and not solely on a finished-products level. This categorical approach could ease the regulatory burden both on industry and on the agency, as industry would not need to have each specific product "evaluated" for essentiality, and MPCA would not need to consider myriads of individual products.

2. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

CUC recommends that cost be taken into consideration, and economic analyses should be conducted to determine whether alternatives are "reasonably available." CUC believes that anytime use of alternative substances is mandated, a significant increase in cost to manufacturers and in generation of waste is anticipated. Due to the research and development required to manufacture products using alternatives, the trial and error will lead to increased production costs and generation of products that do not function as needed and that will need to be discarded. The research and development activity also could lead to a diversion of resources from production of the product and consequently product shortages resulting in harm to the larger economy.

Furthermore, despite undertaking research activities, there is no guarantee that a manufacturer will identify alternatives that are available. The goal of the research and development process is to determine if, using alternative substances, products that perform just as well as the original products can be manufactured. Similar to what was done when developing the original products, the alternative products would also be required to obtain the same quality certifications, satisfy the same customer standards, and meet required safety evaluations. This is estimated to take a significant amount of time and money, which is another "cost" factor involved in the regulatory structure imposed by the statute.

In addition, costs must also be considered for replacement and spare parts for products that have long useful lives, such as those used by the aerospace and defense sector, among others. The inability to procure and sustain such products over the entire life cycle undermines the intended functionality of the products and may lead to early obsolescence, a costly and potentially dangerous situation that must be avoided, particularly in the case of replacement and spare parts found in products utilized for national security.

If these costs associated with the use of alternatives have significant negative impact upon business and society, such alternatives are not "reasonably" available.

3. Should unique considerations be made for small businesses with regards to economic feasibility?

CUC believes that MPCA must consider the magnitude of the economic impact that may be experienced by regulated small businesses, the total number of regulated small businesses that may experience the economic impact, and the percentage of regulated small businesses that may experience the economic impact. A small business may not be able to conduct research and development, redesign production methods, or purchase alternative substances due to prohibitive costs. Once MPCA has quantified and qualified the impact, it should develop criteria to establish what is indeed "economically feasible" for a small business.

4. What criteria should be used to determine the safety of potential PFAS alternatives?

CUC suggests that MPCA consider the following factors:

- Whether the alternative substance is subject to any restrictions on its use, concentration, or specific properties.
- Considering the toxicological data on the alternative substance, including studies on acute and chronic toxicity, carcinogenicity, and reproductive effects (or the potential lack of such data for new alternatives that have not been adequately studied).

- Assessing the likely exposure levels and potential risks to workers during product manufacturing, or to consumers during the other phases of the product's lifecycle, considering use patterns, frequency, and duration as well as disposal.
- Whether the alternative substance interacts negatively with other materials in the product or packaging, potentially leading to safety concerns.
- Assessing if that use of the alternative substance could compromise the integrity, durability, or safety of the overall product.
- The environmental impact of the alternative substance, including its biodegradability and potential harm to ecosystems.
- Reported adverse events related to use of the alternative substance.

All of these factors should be assessed by comparing the current (PFAS-containing) product in contrast to the "alternative" under consideration. Furthermore, the "safety" assessment might need to involve a "comparative-risk" determination that includes whether an alternative may be available and should be considered for use which may contain PFAS, but a variety of PFAS for which there are fewer health or environmental concerns, in which case, its use as a phased-in alternative should be considered and encouraged over time.

5. How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

CUC recommends that "currently unavoidable use determinations" should be effective for at least five years, as, under Amara's Law, PFAS is a group of substance that may potentially encompass thousands of chemicals. A significant amount of time will be needed for research and development and for adequate supply to be made available for alternatives. However, CUC also suggests that MPCA consider indefinite exemptions, until further information is available, for products/sectors where it is clear that alternatives do not exist and are not reasonably anticipated to be identified in the foreseeable future. The CUC also supports the indefinite renewal of currently unavoidable use determinations.

CUC also strongly recommends that MPCA adopt a review and resolution process for newly identified PFAS in products. The statutory and impending regulatory definitions of PFAS are extremely broad and the supply chains complex, creating an inevitable situation of discovering PFAS post implementation of the program. A review and resolution process would enable business entities to present rationale or justification for newly identified currently unavoidable use(s) as well as time for MPCA to make determinations and/or grant exemptions based on criticality and unavoidable use.

6. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Relying on agency rulemaking for individual product determinations will result in a significant burden being placed on MPCA, and MPCA simply will not be able to manage determination requests in a timely fashion. In order to ensure that exemptions for currently unavoidable uses can be considered and responded to in a timely and efficient manner, CUC recommends that MPCA establish an administrative process by which commercial entities may seek a determination that a use is currently unavoidable. MPCA should identify the kinds of evidence it would consider credible and sufficient to support a timely determination. MPCA should be required to make that determination administratively and in accordance with a deadline (e.g., 60 days).

MCP should consider at least the following factors in determinations:

- The cost of acquiring and processing the alterative substance compared to the existing ones.
- Changes in manufacturing processes that may affect overall production costs.
- Whether an underlying federal or state requirement necessitates use of the PFAS for the purposes of national security, defense, aviation, or space exploration.
- Whether products or product components are "essential for the functioning of society" including those that are used in or to address climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, aerospace, aeronautics, public safety and defense, and construction.
- The likely exposure potential and levels for consumers during the product's lifecycle, considering usage patterns, frequency, and duration.
- Whether any potential alternative materials can meet the required specifications, performance standards, and quality benchmarks for the product.
- The impact of an alternative on the longevity and reliability of the final product.
- The availability of a consistent and reliable supply of the alternative materials.
- The reliability and stability of the suppliers providing the new materials.
- Safety standards and regulations applicable to the use of the alternative materials.
- Whether an alternative material will be compatible with existing manufacturing equipment and processes.
- The environmental impact of the new substance in products throughout their lifecycle, from extraction to disposal.
- Needed testing, prototyping, and (re)qualification for any alternative substance to identify any issues or improvements needed.

MPCA should be cognizant of the fact that product manufacturers may face some challenges providing information about PFAS present in products. Upstream suppliers may be reluctant to provide manufacturers with specific information about the type of PFAS used. Upstream suppliers may claim that the use of PFAS is essential but may not provide details due to confidentiality concerns. MPCA should allow the use of supplier statements to substantiate a manufacturer's request. To facilitate this, MPCA should set up a system that would allow upstream suppliers to provide confidential information directly to MPCA. Furthermore, MPCA should develop and implement a review and resolution process to allow for newly discovered currently unavoidable uses that are identified post implementation of the program.

CUC suggests that MPCA should consider coordination with other jurisdictions, such as Maine, to create an approach that allows manufacturers to submit currently unavoidable use requests that can apply to multiple jurisdictions.

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

CUC Member companies, rather than CUC itself, we be submitting such product and company-specific requests. However, see CUC's further input in our response to item 9, below.

8. **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

We highly suggest MPCA make some initial determinations as to what uses of PFAS constitute "currently unavoidable use." The investigation of the use of PFAS is anticipated to take a significant amount of time and resources. If initial determinations can be made (for example for categories of product uses), that would alleviate some of the burden on the industry to find alternatives that may not exist and would allow the industry to focus on complying with the regulatory requirements where there are feasible alternatives.

Initially, CUC recommends that any PFAS containing products or product components that are "essential for health, safety or the functioning of society" as well as those that are required by federal or state laws and regulations or are necessary for the purposes of national security, defense or space exploration be granted a categorical exemption or considered a currently unavoidable use. Products or product components that are "essential for the functioning of society" are those that are used in or to address climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, aerospace, aeronautics, public safety and defense, and construction.

9. **Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.**

CUC suggests that MPCA consider Interstate Chemicals Clearinghouse Alternatives Assessment Guide as a resource to be used in developing the criteria and process for alternative assessment.

CUC also considers (in addition to the suggestions above) the following categories of PFAS uses that would be suitable starting points for MPCA to propose as CUUs when seeking further public comment. The categories listed below are ones which CUC Members consider to be "essential" due to their criticality to health, safety, and the public welfare and for which CUC Members understand there are no current “drop in” chemical alternatives that meet the technical and performance standards required for such products and uses.

- Certain medical devices and appliances (such as MRI and other imaging equipment) with PFAS-containing components (and their replacement parts) that are not specifically subject to an authorization which would qualify as a “federal preemption” determination.
- Products, supplies and spare (replacement) parts that are necessary for the purposes of national security, defense or space exploration, including but not limited to aircraft, naval vessels, communication/radar systems, satellites, and space vehicles.
- Gear, apparel, and personal protection equipment used by first responders such as fire fighters, EMTs, and rescue workers.
- Transportation equipment containing PFAS-containing parts and components such as aircraft, rail cars and train engines (including service equipment and replacement parts),
- PFAS containing waste disposal and waste movement equipment and storage devices for such materials.
- Appliances and equipment used in harnessing “clean” energy (e.g., windmills, solar panels).
- Energy storage equipment, such as batteries and other components in electric vehicles and stationary devices.
- PFAS used in the production of semiconductors, circuit boards, and related electronic products and their components. This should include PFAS used in the semiconductor manufacturing process; PFAS used in the production of semiconductor manufacturing equipment (and in replacement parts for such equipment); as well as PFAS that may remain present in semiconductors and the final packaged semiconductor devices that are produced. This CUU determination should extend to PFAS contained within electronic equipment and related devices which include semiconductors among their component parts or contain transistors, wiring, insulation, connections, housings, and electronic component parts that may include PFAS for purposes of ensuring reliability, limiting electronic interference, providing for safety, and other critical performance attributes.
- To the extent not included among those items CUC has identified above, our Members also support MPCA providing CUU determinations for PFAS uses in electrical equipment that contribute to meeting the nation’s goals relating to climate preservation, electrification, energy security, human health and safety, and product reliability, durability, and sustainability. These products should include electronic components found in medical devices (e.g., imaging equipment and pacemakers), electronic sensors, industrial automation relays and soft starters, gas-insulated power grid equipment, insultation for wiring, and PFAS uses critical for the safe operation of essential and emergency lighting equipment,
- All uses of PFAS and PFAS-containing products and materials necessary to manufacture the products described above.

Conclusion

CUC appreciates the opportunity to submit the foregoing comments and reserves its right to submit additional or modified comments at a later date. We would welcome the opportunity to meet with the MPCA staff to address our comments and to assist in crafting implementing rules.

Letter of Support

Mozarc Medical stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. Additionally, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.

In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Maine and Minnesota. Their proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders including our company. By engaging experts from various industries, Claigan Environmental has adopted a collaborative approach to address this complex issue.

Mozarc Medical actively participated in the consultation process and supports Claigan Environmental's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

FLUIDSEALING ASSOCIATION

Letter of Support

The Fluid Sealing Association stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that fluoropolymer and fluoroelastomer PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.

In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Maine and Minnesota. This proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders. By engaging experts from various industries, Claigan Environmental has adopted a collaborative approach to address this complex issue.

The Fluid Sealing Association actively participated in the consultation process and supports Claigan Environmental's submission with respect to the industrial sealing devices which include mechanical seals, compression packing, gaskets and expansion joints and their components. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

Re: Comments of Interest Party, The Vision Council
Planned New Rules Governing Currently Unavoidable
Use Determinations about Products Containing Per-and
Polyfluoroalkyl substances (PFAS); Revisor's ID Number R-4837

Dear Commissioner Kessler:

The Vision Council (TVC), as an interested party, respectfully comments on the Minnesota Pollution Control Agency's (MPCA) planned new rules governing currently unavoidable use determinations for products containing per- and polyfluoroalkyl substances (PFAS). Serving as the global voice for vision care products and services, including optical laboratories, The Vision Council is a nonprofit organization representing the manufacturers, suppliers, and retailers of the optical industry through education, advocacy, and consumer outreach. Our members include companies that manufacture, import, and distribute prescription and non-prescription spectacle lenses, prescription eyeglasses, spectacle frames, non-prescription sunglasses, non-prescription reading glasses, low vision products and ophthalmic equipment, as well as optical retail companies that sell these class I medical devices.

While our membership is working to identify the full scope of the use of PFAS in optical products, we have identified that certain lens coatings contain PFAS. Lens coatings are applied to spectacle lenses – both prescription and nonprescription (also called plano) – to provide different special properties for cosmetic, safety and comfort reasons. These include coatings that impart anti-reflective ("AR"), scratch resistance, UV-protection, tints, blue-blocking and anti-fog properties to the lens, and which may contain PFAS. Thus, these comments, while submitted on behalf of the eyewear manufacturing and distributing industries, are particularly relevant to those members who manufacture and use such lens coatings.

In its request for comments, MPCA has requested response to a set of questions. TVC comment as follows.

1. *Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?*

Left without a more detailed definition or criteria giving meaning to that term, individuals and companies must sort through the range of definitions of "essential" to determine whether a PFAS in their product meets the threshold of a currently unavoidable use. MPCA must set out criteria to avoid the subjectivity of construing whether "essential" contemplates "indispensable" or "very important" or "necessary" or "needed." TVC submits that MPCA should adopt criteria supporting a broad interpretation of what constitutes essential. By doing so, the entire clause can be interpreted to promote the goal of removing PFAS where their presences are unconnected to health benefits, safety enhancement or societal betterment, but at the same time does not foreclose the ability of manufacturers and distributors to prove an unavoidable use because MPCA adopted a strict definition of essential that subsumes the currently unavoidable use exception in all but very limited cases.

2. *Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold.*

Costs must be considered as a factor in determining when something is "reasonably available." Not just the actual cost of replacing one chemical with another. MPCA must understand that engineering out a PFAS from a specific substance used to make a particular product is more complex than simply swapping out a PFAS for a replacement chemistry. There is a cost in determining the appropriate alternative, one reflected in the research and development needed to find a workable substitute and then possibly to reconfigure production facilities to effectuate the changes. It does not stop there, however. Focusing on medical devices[1] such as those made by TVC members, changes made to existing FDA cleared devices could trigger new regulatory requirements and testing to clear those changes for U.S. commerce. And newly refigured products may need new customer approval, which could result in time delays or even lost business. In other words, addressing what constitutes "reasonably available" will not lend itself to defined

[1] FDA regulated medical devices are outside the scope of the state's 2032 PFAS ban but are still subject to the reporting requirements that go into effect in 2026.

cost thresholds but by necessity require ad hoc review based on the specific facts at hand.

3. *Should unique considerations be made for small businesses with regard to economic feasibility?*

Yes, unique, or heightened consideration, must be given to small businesses when it comes to evaluating the economic feasibility of such companies' ability to meet the requirements of the law. The various costs identified in response to question 2 above hit small businesses especially hard for obvious reasons.

4. *What criteria should be used to determine the safety of potential PFAS alternatives.*

At this time, TVC is unable to offer meaningful comments on this question and defers to comments filed by entities with relevant research and development resources and current data on this issue.

5. *How long should PFAS currently unavoidable for use determination be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?*

Unavoidable use determinations should remain in effect until safer alternatives are developed and economically feasible. MPCA should promulgate regulations providing for re-authorization or new evaluation of products benefitting from an existing unavoidable use determination. Such a re-authorization requirement would be triggered when safer, replacement substances are developed and market-available for that product and which could be utilized instead of the exempt PFAS.

6. *How should stakeholders' requests to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, should stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?*

As MPCA has yet to set out the process by which an entity may request a currently unavoidable use determination, TVC reserves the right to comment when such plan is published for comment. At a minimum, however, such a process must be flexible and subject to broad application for similar products made of similar

THE VISION COUNCIL

Alexandria, VA 22314
P: 703.548.4560
thevisioncouncil.org

PFAS-containing substances. Otherwise, determinations too limited in application will simply engender more reviews of similar products, taxing the resources of MPCA, slowing down the review process for all currently unavoidable use determinations, and adding layers of cost to both the private parties and the state. The process should incorporate ease of submission, opportunity for quick agency turn-arounds, and broad application to, and self-certification of, similar products of similar substances.

TVC does not see a benefit of creating a means by which entities can solicit a determination that a substance does not qualify for a currently unavoidable use determination, nor do we support such a process. Furthermore, TVC questions whether the current statute contemplates such a process and believes that in light of the absence of any statutory authority for a converse reporting requirement, any such rulemaking at this time would be ultra vires.

7. *In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.*

As addressed earlier in this letter, TVC recognizes that certain coatings used on prescription and plano lenses contain PFAS. Because these coatings contain PFAS, various health and safety benefits are imparted to spectacle lenses used in eyeglasses (one of the most widely used medical devices in the U.S.), sunglasses, reading glasses, and other eyewear utilizing lenses. These coatings have been utilized for decades, so their removal from the market would set back eyecare to the pre-coating era.

8. *Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?*

Yes. TVC believes that publication of some determinations at this time will benefit both stakeholders and the state as the parties move forward to rolling out a comprehensive methodology allowing for the issuance of currently unavoidable use determinations.

9. *Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavailable use determinations.*

None currently.

Thank you for your consideration of our comments. Please feel free to contact either of us if you require any more information regarding this letter.

SUBJECT: Planned New Rules Governing Current Unavoidable Use Determinations about Products Containing Per- and Polyfluoroalkyl Substances (PFAS)
Revisor's ID Number R-4837
OAH Docket No. 71-9003-39667

The Power Tool Institute (PTI) is pleased to be provided with an opportunity to submit comments to the Minnesota Pollution Control Agency relating to currently unavoidable uses (CUU) of PFAS. PTI is a trade association of the leading power tool manufacturers in the United States.

Our member companies include:

- Chervon North America, Inc.
- Festool USA, LLC
- Hilti, Inc.
- Koki Holdings America Ltd.
- Makita U.S.A., Inc.
- Robert Bosch Tool Corporation
- Stanley Black & Decker Corporation
- STIHL Incorporated
- Techtronic Industries – North America

Our members manufacture both corded and cordless power tools, the latter of which is a fast growing segment of the power tool industry. Cordless power tools rely heavily on rechargeable lithium-ion batteries. PFAS is a critical component in the cells of rechargeable batteries. PFAS is also used in the construction of power tools to provide lubrication, sealing, resistance to environmental stressors, and electrical insulation.

1. Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Multiple states have active bills in their legislature relating to the regulation of PFAS in products. To reduce the burden of tracking PFAS use in products spread across multiple definitions of "essential for health, safety, or the functioning of society", the State of Minnesota should consider how other states and organizations have defined this term. For example, during Maine's recent comment period they provided the following definition for ***Essential for Health, Safety or the Functioning of Society:***

"…means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations. Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction."[1]

Furthermore, PFAS is also a concern at the international level. The Royal Society of Chemistry published an article in the journal Environmental Science: Processes & Impacts, *The concept of essential use for determining when uses of PFASs can be phased out.*[2] The article is attached as Annex A. This paper includes a discussion of essentiality categories to help facilitate the phase of out non-essential uses of chemicals of concern, with PFAS as the example. Policy makers should consider using a sound, consensus based scientific methodology that has been used internationally to establish criteria that defines "essential for health, safety, or the functioning of society". This would help streamline future PFAS regulation.

2. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Yes, costs of PFAS alternatives should be considered in the definition of "reasonably available". These costs should include more than any increased cost of raw materials. They should consider the cost to implement a PFAS alternative. Costs include the resources required to research, test, evaluate, and implement the alternative in the manufacturing process. PTI members manufacture products to meet consensus developed safety standards, customer requirements, and other applicable regulations. Proving and maintaining compliance to safety standards often involves stringent design control and third party certification. Evaluating potential alternatives takes time and resources. Validation testing must be performed to ensure a PFAS alternative meets all design, quality, performance, and safety specifications. Only after all these criteria have been met would a manufacturer commit the additional financial resources required to update a third party certification to include the PFAS alternative material. Policy makers should consider the cost of implementing a PFAS alternative within the definition of "reasonably available."

3. Should unique considerations be made for small businesses with regards to economic feasibility?

Ensuring the cost of power tools is not unnecessarily increased is relevant for the economic feasibility of small business. Power tools are frequently seen as an investment by those in the skilled trades such as mechanics, technicians, machinists, electricians, plumbers,

[2] ***Environ. Sci.: Processes Impacts***, 2019,**21**, 1803-1815

carpenters, roofers, and others in the construction industry. Workers in these roles are commonly employed by small, local, businesses with close ties to the communities they serve.

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

PFAS is currently used in a large variety of products across the economy. It is important policymakers first understand the impact a PFAS's current use in the product has on the environment and human health. They also need to understand the impacts of potential PFAS alternative. Policymakers should avoid requiring PFAS alternatives that exacerbate or result in new environmental and human health hazards.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

PFAS CUU determinations should not be time limited. As described in item 2, it takes considerable time to evaluate and implement a PFAS alternative in a product, assuming an alternative is available. PTI members' positions as manufacturers of consumer/professional products means they are downstream from where the PFAS is added at the component (i.e. battery, gasket, plastic housing) level. Members are heavily dependent on their suppliers to understand the multitude of places PFAS is used in a product and what, if any, alternatives may be available. If alternatives are not available, end-product manufacturers are dependent on chemical, raw material, and other component suppliers to develop and provide a PFAS-free alternative.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

Stakeholders should request to have a PFAS use considered for CUU determination by product category. As mentioned in item 2 above the power tool industry manufactures products to meet consensus developed safety standards. These standards are developed by industry experts that understand the implications of component modification on the end-product. There is a high level of compliance to these safety standards, while allowing companies to differentiate based on performance, ergonomics, and various other features. Allowing an individual manufacturer or supplier to hold a CUU exemption would give unfair advantage and create differences in the market that may impact product safety. Allowing CUU exemption by product category also keeps industries in alignment when PFAS alternatives are identified and implemented into consensus safety standards.

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

PFAS is essential to the function of power tools in two distinct ways, the cell construction of a rechargeable battery (if the tool is cordless) and the overall construction of the tool.

A. Rechargeable Lithium-ion Batteries and their Chargers

Rechargeable lithium-ion cells are the building blocks of the power tool battery pack design. PFAS are used in the manufacture of these battery cells. A technical report from the European Battery Industry Association RECHARGE is attached (Annex B). This in-depth report consists of detailed descriptions of various types PFAS uses in batteries, the emission risks posed by PFAS in batteries, and the availability of alternatives. The below table summarizes the types of PFAS in the RECHARGE report which do not have viable alternatives for their use.[3]

Table 1. RECHARGE Summary on PFAS use in Batteries

PFAS Type	**Why is it used and where**
PVDF	In binders in the active material mass: • Enables a uniform distribution of the slurry • Protects the composite electrode from corrosion and the electrolyte from depletion • Tailors the viscosity of the slurry
PTFE	In binders in the active material mass: • Mechanical cohesion to enable electrode integrity • Lubricant to allow the electrode particles to slide over each other during electrode formation • Hydrophobic properties – Lower water absorption during mixing
Various PFAS including LiTFSI, LICF3SO3 (triflate)	In electrolytes: • Increase electrolyte stability by capturing water and avoiding hydrogen fluoride emissions
PFA, VDF-HFP, FKM	In gaskets: • Very thin high-performance gaskets with chemical and thermal stability and high permeation resistance can be formed to provide stability to high power and high temperature cells
PTFE, PVDF	In coatings on separators: • Separate the negative and the positive electrodes whilst not participating in electrochemical reactions, preventing short-circuit • Ensure 35%-45% porosity with a pore size of 200nm to 1μm
PTFE, FEP, PFA, VDF, HFP, FKM	In valves, gaskets, washers: • Prevent leakage of the electrolyte from the inside and penetration of moisture from the outside

[3] RECHARGE, Application for derogation from PFAS REACH restriction for specific uses in batteries, (April, 2023)

Lithium-ion battery chemistry is needed specifically for power tools because of its high energy density. Lithium-ion cells in power tools must be able to efficiently charge, hold their charge, and discharge efficiently with varying loads. Users expect to charge a battery within the time it takes to discharge a fully charged battery. This could consist of longer periods of low power use or short bursts of high power. Battery performance is expected to be maintained throughout a variety of thermal operating conditions, such as the natural temperature variations throughout the year. In addition, sufficient safety and mechanical robustness of the cells must be ensured as hand-held and transportable power tools are operated near the human body. Energy to weight ratio is also key for hand-held power tools, as the tool must be able to be handled ergonomically and safely for extended periods of time (e.g., when working on rooftops). There is currently no alternative cell technology that can compete with these performance requirements and is available for large scale production.

B. Power Tool Construction

The second way PFAS is essential to power tools is in their construction. The following is a non-exhaustive list of power tools that use PFAS: Band Saws, Belt Sanders, Circular Saws, Cut-off Tools, Detail Sanders, Disc Sanders, Drywall Sanders, Drill/Drivers (Powered), Finishing Sanders, Impact Drivers, Jigsaws, Jointer Planers, Mitre Saws, Mixer/Vibrator, Nail Guns, Nibblers/Shears, Oscillating Multitools, Reciprocating Saws, Rotary Multitools, Rotary Saws, Routers, Screw Guns, Screwdrivers (Powered), Staplers (Powered), Straight/Die Grinders, Surface Grinders, Surface/Thickness Planers, Table Saws, Tappers, Wall Slotter (Powered), Chain Saws (Powered). Many power tools also incorporate Electric Torches/Flashlights as accessories.

Power tools frequently contain fluoropolymers(PVDF, PTFE, or FKM) in components due to the tools' expected long lifespans. Fluoropolymers are used in high-performance plastics, such as those in gaskets and O-Rings. These sealing components prevent leaks of air, oil, grease, and ensure water, dirt, dust, shavings, and other debris stays out of the equipment.

PFAS also have applications in lubricants. Fluoropolymers have a low coefficient of friction, making them ideal for reducing the frictional forces within power tools. These forces are found in various moving parts on the tool such as gears, bearings, and sliding mechanisms. Ensuring power tools are operating smoothly means better overall performance, better energy efficiency, a reduction in the likelihood of mechanical blockages, and reduced heat generation. A reduction in heat lowers the likelihood of overheating and ensures component life is not shortened due to heat stress.

Power tools are exposed to harsh environments such as those that are damp, dusty, oily, salty, contain other corrosive substances, or are directly in ultra-violet(UV) light. They are frequently used on materials that generate dust, such as wood, concrete, and metal. A power tool must be able to handle the environmental stresses placed on it during normal operation. Fluoropolymers provide a protective layer on metal and plastics. This safeguards the internal components and extends the lifespan ensuring that power tools remain reliable and durable, even in challenging working conditions. This protective layer also facilitates easy cleaning and maintenance of power tools. The non-stick properties of PFAS prevent debris, dust, and other contaminants from adhering to the tool's surface, simplifying the cleaning process. Power tools with PFAS coatings are easier to wipe down, increasing their overall lifespan. Power tools must also be capable of withstanding impacts and long periods of vibration during normal use. The addition of fluoropolymers to the housing and components make them resilient to these effects.

PFAS are also used in the electrical systems of power tools beyond batteries. They ensure that plastics around high-temperature parts such as the battery and electric motor are heat-resistant and flame-retardant. They are regularly used in used in electrical insulation on wires and cables.

8. **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

Yes, the MPCA should make CUU determinations certain product categories as a part of this initial rulemaking. These CUUs should not be time limited due to the essential nature of certain product categories and the lack of PFAS alternatives, due to limited scalable production options and/or ongoing research.

9. **Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.**

In future collection of CUU or other PFAS information, manufacturers should be held to the EPA definition of "known to or reasonably ascertainable by", when evaluating sources of PFAS in complex supply chains. The definition is as follows:

> "*means all information in a person's possession or control, plus all information that a reasonable person similarly situated might be expected to possess, control, or know*" [4]

In closing, PTI is grateful to the Minnesota Pollution Control Agency for the opportunity to comment on new rules governing determinations of CUU of PFAS in power tools. Please feel free to contact us with any questions regarding our comments.

The concept of essential use for determining when uses of PFASs can be phased out

Ian T. Cousins, †*[a] Gretta Goldenman,[b] Dorte Herzke,[c] Rainer Lohmann,[d] Mark Miller,[e] Carla A. Ng,[f] Sharyle Patton,[g] Martin Scheringer,[h] Xenia Trier,[i] Lena Vierke,[j] Zhanyun Wang[k] and Jamie C. DeWitt[l]

Received 8th April 2019
Accepted 27th May 2019

DOI: 10.1039/c9em00163h

rsc.li/espi

Because of the extreme persistence of per- and polyfluoroalkyl substances (PFASs) and their associated risks, the Madrid Statement argues for stopping their use where they are deemed not essential or when safer alternatives exist. To determine when uses of PFASs have an essential function in modern society, and when they do not, is not an easy task. Here, we: (1) develop the concept of "essential use" based on an existing approach described in the Montreal Protocol, (2) apply the concept to various uses of PFASs to determine the feasibility of elimination or substitution of PFASs in each use category, and (3) outline the challenges for phasing out uses of PFASs in society. In brief, we developed three distinct categories to describe the different levels of essentiality of individual uses. A phase-out of many uses of PFASs can be implemented because they are not necessary for the betterment of society in terms of health and safety, or because functional alternatives are currently available that can be substituted into these products or applications. Some specific uses of PFASs would be considered essential because they provide for vital functions and are currently without established alternatives. However, this essentiality should not be considered as permanent; rather, constant efforts are needed to search for alternatives. We provide a description of several ongoing uses of PFASs and discuss whether these uses are essential or non-essential according to the three essentiality categories. It is not possible to describe each use case of PFASs in detail in this single article. For follow-up work, we suggest further refining the assessment of the use cases of PFASs covered here, where necessary, and expanding the application of this concept to all other uses of PFASs. The concept of essential use can also be applied in the management of other chemicals, or groups of chemicals, of concern.

Environmental significance

PFASs are manmade organic contaminants that can be found everywhere in the global environment, largely as a result of their high persistence and wide use. Based on concerns regarding their high persistence and other hazardous properties, it has been argued that the production and use of PFASs should be limited to essential uses only. In this paper, we translate the concept of "essential uses" or "essentiality" into three criteria to determine when uses of PFASs are essential, or not, and demonstrate how the criteria can be applied to different use cases of PFASs. This approach can inform and encourage manufacturers, retailers and end users to consider phasing out and substituting uses of PFASs. Thus, the uses and related emissions of PFASs can be systematically limited and the long-term harm to human health and the environment can be avoided.

Introduction

Per- and polyfluoroalkyl substances (PFASs) are a group of more than 4700 substances[1] that have been produced since the 1940s and used in a broad range of consumer products and industrial applications.[2] The multiple uses of PFASs have been well-illustrated by the FluoroCouncil.[3] PFASs can be broadly divided into low molecular weight and high molecular weight (polymeric) substances. The polymeric PFASs can be further subdivided into side-chain fluorinated polymers, fluoropolymers and perfluoropolyethers.[2] The review of Buck *et al.*[2] and the FluoroCouncil website[3] should be consulted for a detailed description of the structures, classes and uses of low and high molecular weight PFASs as that background will not be provided here.

Since 2000 there have been a number of voluntary industry phase-outs and regulatory actions to cease the manufacture and use of long-chain perfluoroalkyl acids (PFAAs; defined as including perfluoroalkane sulfonic acids (PFSAs) with perfluoroalkyl chains containing 6 carbons or more, and perfluoroalkyl carboxylic acids (PFCAs) with perfluoroalkyl chains containing 7 carbons or more) and their precursors, which can transform in the environment or within organisms to long-chain PFAAs. The most common replacements for the above defined long-chain PFAS chemistries are shorter-chain PFASs, *e.g.* PFAAs with fewer fluorinated carbons than long-chain PFAAs, and perfluoroether-based substances (PFASs with perfluoroalkyl segments joined by ether linkages).[4] Although some of these replacement PFASs are less bioaccumulative, they are all similarly highly persistent in the environment as their predecessors.[5,6] PFAAs which are considered short-chain and non-bioaccumulative may also lead to high internal concentrations if people are continuously exposed to high levels. Moreover, short-chain PFAAs, such as perfluorobutanoic acid (PFBA) and PFHxA, tend to be highly mobile and to move readily into ground and surface waters once released to the environment where they can reside for decades to centuries.[7–10] As a result of their high environmental persistence, widespread use and release of any PFAS, even polymeric PFASs,[11] will lead to irreversible global contamination and exposure of wildlife and humans, with currently unknown consequences.[12–14]

Based on concerns regarding the high persistence of PFASs and the lack of knowledge on chemical structures, properties, uses, and toxicological profiles of most PFASs currently in use, it has been argued by more than 200 scientists in the Madrid Statement that the production and use of PFASs should be limited.[12] Indeed, in the textile sector, some brand names and retailers have recognized the problems associated with PFASs and have already taken significant steps to phase out all uses of PFASs in their consumer products.[15–18]

It is neither practical nor reasonable to ban all uses of PFASs in one step. Some specific applications may serve a critical role for which alternatives currently do not exist. However, if some uses of PFASs are found not to be essential to health, safety or the functioning of today's society, they could be eliminated without having to first find functional alternatives providing an adequate function and performance. Elimination of non-essential uses of PFASs could form a starting point for a process that leads to a global phase-out (*e.g.* through the Stockholm Convention on Persistent Organic Pollutants). To critically evaluate the idea that PFASs are essential in modern society, the essentiality of PFASs should be carefully tested against the available evidence for each of their uses. Given the thousands of PFASs on the market and their many uses, this is a formidable but necessary task. Before proceeding in this task, a definition of essentiality, or essential use, is needed. If PFASs are considered non-essential in a given use, then a phase-out of PFASs from that use can be implemented. The aims and structure of this paper are therefore to: (1) define the concept of essential use or essentiality, (2) apply the concept to various use categories of PFASs to determine the feasibility of limiting use, as showcases of the concept, and (3) outline the remaining challenges for phasing out uses of PFASs in society and provide recommendations for further work. It is not our intention to conduct conclusive assessments for our selected use cases of PFASs on the individual use level. Follow-up work may be needed to cover each use case in more detail, where necessary, and to expand the application of the concept to all other uses of PFASs.

The concept of 'essential use'

This approach is based on the example of the Montreal Protocol, which phased out the use of ozone-depleting chlorofluorocarbons except for certain 'essential' uses, and which defined the concept of 'essential use' in Decision IV/25.[19] The two elements of an essential use are that a use is "necessary for health, safety or is critical for the functioning of society" and that "there are no available technically and economically feasible alternatives". To identify uses of PFASs that are non-essential, we combine the definition of essentiality with several categories of PFAS uses. Overall, this leads to the three categories summarized in Table 1.

For uses in category 1 ("non-essential" uses), a phase-out *via* a ban or restriction of PFASs can be prepared because these uses are not necessary for the betterment of society in terms of health, safety and functioning. The technical function of the PFAS (if it has one) in the use case could be considered "nice to have" (*e.g.* non-stick frying pans) but it is not essential. In many cases the "nice to have" function can be fulfilled through substitution with fluorine-free alternatives. Even where there are no alternatives to PFAS for providing the "nice to have" function, the use case can be banned or phased out because it is not essential.

Uses in category 2 ("substitutable" uses) fulfill important functions but are assessed to be non-essential because there are alternatives available that can be substituted into these products or applications and provide the necessary technical function and performance. It may be needed to make the alternatives more well-known and more easily available, but there is no fundamental obstacle to removing PFASs from these uses. Upon increased market uptake, the costs can be expected to decrease.[20,21]

Table 1 Three essentiality categories to aid the phase out of non-essential uses of chemicals of concern, exemplified with PFAS uses

Category	Definition	PFAS examples
(1) "Non-essential"	Uses that are not essential for health and safety, and the functioning of society. The use of substances is driven primarily by market opportunity	Dental floss, water-repellent surfer shorts, ski waxes
(2) "Substitutable"	Uses that have come to be regarded as essential because they perform important functions, but where alternatives to the substances have now been developed that have equivalent functionality and adequate performance, which makes those uses of the substances no longer essential	Most uses of AFFFs, certain water-resistant textiles
(3) "Essential"	Uses considered essential because they are necessary for health or safety or other highly important purposes and for which alternatives are not yet established[a]	Certain medical devices, occupational protective clothing

[a] This essentiality should not be considered permanent; rather, a constant pressure is needed to search for alternatives in order to move these uses into category 2 above.

Uses in category 3 ("essential" uses) are considered necessary and currently have no established alternatives to PFASs that provide the necessary technical function and performance. Innovative research and development may be needed to identify chemical or engineering alternatives and to make them technically and economically feasible. By identifying these opportunities, strong market incentives will be created for industry to develop such alternatives. In support of this approach research and innovation funding could be made available specifically for this purpose, and to support start-up companies that intend to develop and market new alternatives.

Implementation of this conceptual framework could give rise to 'grey zones' where it may not be straightforward to assign a use to a particular category. For example, a grey zone might appear between categories 1 and 2 because some uses of PFASs may be considered as nice-to-have by some (stain-proof and waterproof outdoor jacket for everyday use) and as necessary by others. Similarly, a grey zone could turn up between categories 2 and 3 because the availability and performance of alternatives is being debated (*e.g.* AFFFs used by the military for extinguishing fuel fires). In order to avoid/minimize such 'grey zones' in the implementation of this conceptual framework, clear criteria and relevant processes need to be pre-defined. This would require follow-up work that is beyond the scope of the present paper.

Technical performance standards may play a role in defining whether the use of PFASs is or is not considered "essential" in certain cases. Technical performance standards are detailed specifications concerning how a product should perform in certain circumstances and are often voluntary. However, they may be used to define whether a product is of sufficient quality to be placed on the market or to be purchased through public procurement. For example, some European Union product-related legislation sets so-called "essential requirements" for certain products and then delegates the task of defining how to meet those requirements to European standard-setting bodies, such as the European Committee for Standardization (CEN). The International Standardization Organization (ISO) and national bodies such as the German Technischer Überwachungsverein (TÜV) may also set certification requirements that may be important in the design of the product performance, and how to demonstrate it. The case studies below provide several examples of how technical standards may affect whether a use of PFASs is "essential" or not.

Case studies of uses of PFASs

Below we provide descriptions of several ongoing uses of PFASs. We discuss whether the uses of PFASs are essential or non-essential based on the categorization in Table 1.

Personal care products and cosmetics. PFASs have been found in a range of different cosmetics and personal care products including hair products, powders, sun blocks, and skin creams.[22] The fluorinated ingredients in some of the products that have been chemically analyzed are listed in Schultes *et al.*[22] and include a range of fluorosurfactants and in some cases the fluoropolymer, polytetrafluoroethylene (PTFE). The use of certain PFASs in these products may lead to direct human exposure and potential health effects following dermal or oral uptake. It is not clear whether any technical function provided by the PFASs is truly necessary. After a recent campaign by a Swedish NGO publicizing the presence of PFASs in certain cosmetics, it was relatively easy for several major retailers and brands of cosmetics to quickly announce phase outs of PFASs, for example, L'Oréal, H&M, Lumene, The Body Shop, Isadora, and Kicks.[23] If PFASs in these products were needed for their technical function (possibly liquid repellency and/or to aid spreading over and into the skin) then drop-in alternatives appear to have been readily available given the rapid phase out by retailers. The use of PFASs in personal care products falls under category 1 in Table 1.

Ski waxes. Whereas most skiers use hydrocarbon-based glide waxes, fluorinated glide waxes are also available, though much

Open Access Article. Published on 28 May 2019. Downloaded on 2/28/2024 5:50:12 PM.
This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

more expensive. The fluorinated waxes are favored by competitive skiers because they are highly water repellent and result in better glide compared to hydrocarbon-based waxes. The PFASs used in fluorinated ski waxes are diblock semifluorinated *n*-alkanes (SFAs) mixed with normal paraffins.[2] PFCAs, including perfluorooctanoic acid (PFOA), have also been found in fluorinated ski waxes provided as solids or in powder form.[24] The presence of SFAs in snow and soil samples from a ski area in Sweden was recently demonstrated[25] and professional ski wax technicians working for the Swedish national cross-country ski team were shown to be highly exposed to PFCAs.[26]

From July 2020 onwards, PFOA and related substances (*e.g.* substances which might form PFOA in the environment) will be banned in all products sold in the EU, including ski waxes, due to its recent addition to the REACH Annex XVII list of restricted substances (entry 68). No essential use of PFASs in ski waxes was found in the restriction process and this use category is therefore clearly non-essential. Functioning hydrocarbon-based ski waxes were in use before the fluorinated waxes were introduced. The development of fluorinated waxes was driven by their exceptional technical performance and market opportunity. Fluorinated waxes provide a "nice to have" function that is not essential, and therefore this use case falls under category 1 in Table 1. However, European ski teams are continuing to use fluorinated waxes. The exception is Norway which in Oct 2018 announced that it has banned the use of fluorinated ski waxes in U16 categories in national competitions.[27]

Fire-fighting foams. Class B firefighting foams are formulated to extinguish fires of flammable liquids, such as liquid hydrocarbon fuels. Those currently available are either; (i) aqueous film-forming foams (AFFF), fluoroprotein foams (FP), or film-forming fluoroprotein foams (FFFP), all of which contain fluorosurfactants (*i.e.* they contain PFASs) and (ii) fluorine-free class B foams (F3) using proprietary mixtures of hydrocarbon or silicone surfactants.[28] PFAS-containing AFFFs historically contained long-chain PFAAs (and their precursors),[29] but since 2015[30] the foam manufacturers have eliminated long-chain PFAAs (and their precursors) from their products. Current fluorotelomer-based AFFF formulations contain fluorosurfactants that may transform to short-chain PFAAs (primarily PFHxA and shorter-chain PFAAs) in the environment, which are thought to be less bioaccumulative and less toxic than their longer-chain predecessors. However, short-chain PFAAs are extremely persistent and mobile, and if clean-up of soil or water is later needed, it will be extremely expensive and time-consuming, if at all possible.[13,31]

Fluorine-free class B foams were first developed in the early 2000s by the 3M Company and since then many other companies have marketed fluorine-free class B foams.[28] Many of the currently available fluorine-free foams meet the standard firefighting performance certifications applicable to PFAS-containing AFFF and related foams.[28]

Though some debate continues concerning whether PFAS-containing foams remain necessary for certain scenarios, *e.g.*, fires at refineries or involving very large fuel tanks, in recent years, a number of commercial airports, chemical industry facilities, oil and gas platforms, fire brigades and some national defense forces around the world have switched to using fluorine-free foams based on demonstrated operational performance in extinguishing fuel fires. However, US military forces are currently prevented from switching to fluorine-free foams because the applicable technical standard MIL-F-24385F(SH) – though revised in 2017 to reduce PFOA and PFOS in AFFFs – still requires fluorinated chemistry in addition to setting a performance-based requirement. Note that in October 2018, the US Congress enacted a bill[32] permitting civilian airports across the US to use non-fluorinated alternatives. Hydrocarbon-based foams have been shown to be biodegradable with only localized, short-term problems associated with their release during extinguishing fires or spillages. The silicone-based foams may contain low residual amounts of cyclic siloxanes (*e.g.* decamethylcyclopentasiloxane or D5), which have been judged to be persistent and bioaccumulative.[33] Both D5 and D4 (octamethylcyclotetrasiloxane) are listed as Substances of Very High Concern under REACH, primarily because of their vPvB (very persistent, very bioaccumulative) properties.[34]

In summary, the fluorine-free foams that have been developed and improved since the early 2000s are promising from an operational perspective[35–37] and also from an environmental and human health perspective. Some military maintain that only PFAS-containing AFFF can provide the necessary performance requirements, particularly in the case of large fuel fires. Because of ongoing debate, this use category therefore currently falls under category 2 or 3 in Table 1.

Durable water and stain repellency in textiles. Liquid repellency in textile products can range from an optional "nice-to-have" property in leisure jeans to an essential protection needed in occupational protective clothing.[38] The textile sector often refers to these chemistries as durable water repellents (DWRs), but the leading market technology repels more than just water. Since their introduction in the 1950s, the highest level of repellency for both oil/stain and water has been achieved with side-chain fluorinated polymers. Substitution to 'short-chain' side-chain fluorinated polymers (typically C^6 or C^4 perfluoroalkyl chains) has taken place in recent years. However, there is concern regarding the extreme persistence and lack of human health data for short-chain PFAAs.

A variety of new non-fluorinated DWR alternatives has been developed to create repellent textile surfaces, with a variety of polymer architectures, including linear polyurethanes, hyperbranched polymers and nanoparticles.[38] The functional moieties in terms of liquid repellency consist of either saturated alkyl chains (*i.e.* hydrocarbons) or polydimethylsiloxane (PDMS) chemistry (*i.e.* silicone polymers).[38] Although hazards associated with non-fluorinated DWRs are not yet fully understood, the development of biodegradable alternatives is an important step. Similar to the silicone-based surfactants used in firefighting foams, the silicone-based DWRs may contain residual amounts of persistent cyclic siloxanes (*e.g.* D4 and D5).

Non-fluorinated DWRs have been shown to provide high water repellency equal to short-chain fluorinated polymers and are suitable substitutes for consumer outdoor clothing.[39]

Indeed, a number of leading brands already provide water-repellent outdoor jackets marketed as *e.g.* "fluorine-free".

However, in the case of both non-polar and polar liquids with very low surface tension (such as olive oil or gastric fluid), so far only short-chain fluorinated polymers have been shown to provide effective protection.[40] Such protection may be important in certain occupational settings where a specified level of performance is required.

Medical textiles are an example of where technical standards to protect human lives require a certain performance that may be difficult to meet without the use of PFASs. The European standard EN 13795 defines how the essential requirements set forth in the EU Medical Devices Directive (93/42/EEC)[41] should be met with respect to surgical gowns, drapes and clean air suits. Along with setting performance requirements aimed at preventing the transmission of infectious agents between patients and medical staff, EN 13795 also stipulates the test methods for evaluating whether the performance requirement is met. The test method EN 20811[42] – resistance to liquid penetration – measures the pressure at which water will penetrate the fabric and is used to determine whether the fabric will provide sufficient protection against contamination from penetration by *e.g.* bodily fluids. Current non-fluorinated DWRs may not provide sufficient liquid repellency for non-polar bodily fluids with low surface tension. An alternative is to use surgical gowns coated with a plastic laminate, which offer sufficient protection against biological fluids containing potentially harmful viruses and bacteria but may not be sufficiently breathable for longer operations.

Similarly, performance standards set by the US National Fire Prevention Association for protective clothing for firefighters and other emergency responders for water repellency, oil/stain repellency and breathability are currently not possible to meet without fluorinated chemistry. Other types of occupational clothing, *e.g.* in the oil and gas sector, may require a similar combination of water and oil/stain repellency as well as breathability. At least for now, these uses of PFASs may be considered essential and are, therefore, in category 3, until effective and safer alternatives are available.

In summary, non-fluorinated DWRs are available that provide good water repellency (and certain stain repellency) meeting consumer requirements and expectations for most outdoor apparel, casual wear, and business attire (category 2). In some cases, the use of fluorinated DWRs in textiles is "nice to have" (*e.g.* water-repellent surfer shorts), but is non-essential and falls under category 1. Only a few uses of PFAS in textiles, *e.g.* the occupational protective clothing market, where repellency of a wider range of liquids as well as breathability are necessary, fall under category 3 in Table 1. In those cases, innovative solutions are needed to provide non-fluorinated alternatives.

Food contact materials. Food contact materials (FCMs) cover a range of materials that at some stage come into contact with food. This includes (industrial) food-production equipment and machinery, food packaging, and kitchen utensils like non-stick forms and pans. Growing consumer concern over environmental and health impacts of plastic packaging has led to an increasing market pressure for alternative packaging, including paper.[43] This may result in increasing exposures to PFAS-containing paper-based materials.

The types of fluorochemistry used to protect paper and board have changed over time.[44] Initially, long-chain PFASs were used and were phased out in the 2000s.[44] Current fluorinated paper and board products are largely based on "short-chain" fluorotelomer-based polymeric products, which are side-chain fluorinated polymers containing perfluoroalkyl side chains, typically with six perfluorinated carbons,[44] and poly- and perfluoropolyethers.[45–48]

Despite reassurances by the chemical manufacturing industry that short-chain fluorinated products are safe, there is concern that PFASs will migrate into food and cause harm to human health.[44] Non-fluorinated alternatives have subsequently entered the market in recent years. For example, COOP Denmark A/S, a Danish consumer goods retailer, has succeeded in completely removing PFASs from all its products since September 2014.[49]

Although the current polymer chemistry used in paper and board in food contact materials is similar to that used in textiles, paper and board are often made for single use, whereas textiles (*e.g.* outdoor jackets) need to be durable over the lifetime of a garment. However, some paper and board products need to provide repellency to oil for weeks to months (*e.g.* butter wrappers), whereas others (*e.g.* fast-food wrappers) only require oil repellency for a matter of minutes. The substitution strategies for paper and board are therefore different than for DWRs in textiles given the difference in materials and performance requirements, and may even be different among food contact applications.

There are generally two types of barriers against grease or fat for paper and board, a physical or a chemical barrier.[44] A physical barrier preventing penetration of a liquid into the paper may be sufficient in certain types of single use applications. The chemical barrier, which is the approach used in fluorinated products, repels the grease in the food due to the very weak physico-chemical interaction between grease and paper surface. Two of the most common types of paper that provide a physical barrier against grease are Natural Greaseproof paper[50] and vegetable parchment,[51] providing a dense cellulose structure that prevents the grease from soaking into the paper. There are also various non-fluorinated chemical barriers that can provide similar repellency to grease as fluorinated repellents, including hydrocarbon- and silicone-based alternatives.[52] A third alternative is to add physical barriers such as aluminum or plastic coatings to the paper to provide protection.[53]

In food production, PFASs are mainly used as non-stick fluoropolymer (*e.g.* PTFE) coatings of (metal) surfaces to lower friction (which protects the equipment from abrasion), to minimize adhesion (which allows better cleaning of surfaces), as non-stick- or heat- and acid-resistant fluoroelastomer membranes on conveyor belts, and as lubricant oils and greases in machinery.[54–57] Many of the same uses exist in household kitchen utensils and appliances. These uses are described in

Open Access Article. Published on 28 May 2019. Downloaded on 2/28/2024 5:50:12 PM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

industry patents and commercial materials,[54] but the levels and types of PFASs have been studied only to a limited extent.[58,59]

Non-stick kitchenware is normally produced by either spraying or rolling layers of PTFE onto the surface of the kitchenware. One could argue that the non-stick is a "nice to have" function rather than an essential function given that it is possible to cook food without the non-stick functionality. If the non-stick coating is considered an essential function in a modern society, then other possible non-stick coatings are available, including: enamelled iron-, ceramic-, and anodized aluminium coatings.[60]

In summary, non-fluorinated alternatives have been historically available for all applications of paper-and-board food packaging and the use of fluorinated protective coatings has never been essential (category 1). For example, COOP, a major grocery retailer in Denmark, has found alternatives for all products that previously used PFASs.[49,61] For non-stick cookware there are also non-fluorinated non-stick alternatives which work well in households and this is also not an essential function (category 1). In the food production industry non-fluorinated conveyor belts, lubricants and greases exist, but it is not clear currently whether functional alternatives to fluoropolymer protection against abrasion exist (categories 2 or 3).

Medical devices. Another use of fluoropolymers is as coatings in catheters, stents and needles to reduce friction and improve clot resistance and to provide protein-resistance in filters, tubing, O-rings, seals, and gaskets used in kidney dialysis machines and immunodiagnostic instruments.[3,54,62] The safety evaluation of these devices for use in humans was discussed by Henry *et al.* (2018).[63] After review, multiple regulatory agencies have concluded that the use of PFASs in these products, including in devices implanted into patients' bodies, does not pose an appreciable risk because the fluoropolymers are not bioavailable.[63–65] It is however unclear whether impurities of fluoropolymer processing aids such as PFOA and HFPO-DA were included in the regulatory reviews.

In summary, the inclusion of fluoropolymers into medical devices confers several benefits and does not appear to pose substantial health risks to those who are exposed to these devices through procedures or who have received implants. However, the production and disposal of these devices will continue to lead to the release of PFASs into the environment unless steps are taken to eliminate environmental releases. The use of PFASs in medical devices falls under categories 1–3 in Table 1 (depending on specific use). However, due to limited information in the public domain, it is currently unclear if all medical devices need fluoropolymers or only certain types of medical devices need fluoropolymers.

Pharmaceuticals. There are a wide range of fluorine-containing pharmaceuticals.[66] Since the first fluorine-containing drug was approved by the U.S. Food and Drug Administration (FDA) in 1955, nearly 150 fluorinated drugs have reached the market and about 30% of newly approved drugs contain fluorine constituents including fluoroalkyl groups (a smaller subset can be defined as PFASs). According to Zhou *et al.* (2016),[66] fluorinated drugs encompass all therapeutic areas, are structurally diverse, and are among the most-prescribed and/or profitable in the U.S. pharmaceutical market.

Fluorination of pharmacological agents is often used to enhance their pharmacological effectiveness, increase their biological half-life, and improve their bioabsorption.[66] Some agents are analogous to the long-chain PFASs, such as several types of artificial blood formulations and drugs for the lungs of prematurely born children (for example: perfluorooctyl bromide, an eight-carbon bromine-substituted PFAS[67]). However, most fluorine-containing pharmaceuticals have only one or two fluorine atoms. A smaller number of drugs contain one or two trifluoromethyl groups ($-CF_3$), or the perfluoroalkyl moiety C_nF_{2n+1} as defined by Buck *et al.* (2011).[2] As these agents become more widely produced, prescribed, and used, disposal of these fluorinated drugs (*e.g.* through municipal wastewaters) is likely to lead to increasing environmental releases of various PFASs. A transformation product of nearly all of the anesthetics is trifluoroacetic acid (TFA or CF_3COOH), which can arise from several metabolic or atmospheric degradation pathways[68] and has been a cause of environmental concern.[69–71]

In summary, the addition of 1–3 fluorine atoms or trifluoromethyl groups to various pharmaceutical agents has improved their efficacy, half-lives, and bioabsorption and does not appear to pose substantial health risks to those who take them, relative to analogous non-fluorinated drugs. However, their production and disposal will continue to lead to the release of PFASs into the environment unless steps are taken to eliminate environmental releases. Releases of human metabolic excretion products may pose an additional environmental concern (contamination of water and greenhouse gases) as these drugs become more widely used. The uses of $-CR_2F$, $-CRF_2$, and $-CF_3$ groups in pharmaceuticals should not be evaluated for essentiality as a single group, as specific applications will likely fall under either categories 2 or 3 in Table 1; there are functional non-PFAS alternatives for some pharmaceutical applications, whereas for other uses the pharmaceuticals have life-saving functions.

Laboratory supplies, equipment and instrumentation. PFAS-containing products, in particular fluoropolymers, are also ubiquitous in laboratories, laboratory supplies and analytical instrumentation. Initially this caused major concerns regarding PFAS contamination of environmental and biological samples during PFAS analysis and maintaining quality control in PFAS analysis.[72,73] The PFASs are used because they have high resistance to chemicals and heat, weak interaction with other substances and low permeability, which prevent chemicals/analytes from being adsorbed to the surface and absorbed into the material.

In the laboratory, there are easily identifiable fluoropolymer (*e.g.* PTFE) and fluoroelastomer-based products (*e.g.* Viton). Examples include the use of fluoropolymer-based vials, caps and tape, and fluoropolymers in the solvent degassers of liquid chromatography (LC) instruments. Non-PFAS replacements may be available, depending on the purpose. Personal protective equipment can also contain PFASs, including protective gloves and protective mist/anti-fog coatings of glass (*e.g.* PFPE). These applications can in general be substituted without major

Open Access Article. Published on 28 May 2019. Downloaded on 2/28/2024 5:50:12 PM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

loss of functionality or performance; recommendations for PFAS-free alternatives are often provided as part of guidance to prevent cross-contamination when sampling or analyzing environmental matrices for PFAS.[74–76]

As part of field or laboratory collection of particles of different sizes, some filters are made of or are coated with PFASs to minimize sorption of compounds to the filter itself, such as glass fiber filters, or ultrafiltration filters. As an alternative plastic filters/vials with a low solid surface energy can be used (*e.g.* polypropylene (PP), polytetramethylene oxide (PTME) and polyamide (nylon)).[46,77]

More difficult to replace are fluoropolymer and fluoroelastomer seals (O-rings), and fluoropolymer-based tape within internal components of existing instrumentation. As a result of advances in analytical instrumentation, in particular ultra high-performance liquid chromatography (UHPLC), the use of fluoroelastomers is widespread as seals and membranes and PTFE as inert surfaces inside analytical instruments and in some cases as tubings. The tubing can be replaced by polyetheretherketone (PEEK) or stainless steel tubing without a loss of performance in most applications. Some applications rely on fluorinated solvents (*e.g.*, trifluoroethanol) and acids (trifluoroacetic acid, pentafluorobutanoic acids *etc.*) added to reversed phase LC-MS solvents, and specialty LC-columns are based on fluorinated materials. Non-fluorinated alternatives exist for both these uses.

Perfluoropolyether-based lubricants are also used as oils and greases in pumps and equipment; this can cause laboratory background contamination. Oil-free pumps exist and are reducing the laboratory background contamination, which is beneficial for both the analyses and workers' health. To address concerns related to instrument contamination by PFASs, manufacturers offer a delay column to keep the instrument-borne PFASs from eluting with target analytes during the same time window.

For the vast majority of laboratory applications, PFAS alternatives have been used historically or have been newly developed. Therefore, most applications fall within categories 1–2 in Table 1 and *i.e.*, they are non-essential and replaceable. A small number of current laboratory applications may fall within category 3 as being essential and without appropriate alternatives, and thus further innovation for effective substitution is required.

Perfluorosulfonic membranes. These are fluoroelastomers that exist in many forms and are used in a wide range of chemical synthesis and separation operations and in analytical instrumentation. These membranes are often used in processes that displace less efficient historical methods that use more energy and/or generate hazardous materials and byproducts.[78,79] Nafion® (CAS Number 66796-30-3) is the brand name for a perfluorosulfonic acid membrane from Chemours (formerly DuPont) that consists of a perfluorosulfonic acid copolymer with pendant sulfonic acid groups. It is stable in strongly oxidizing conditions and high temperatures. The density of sulfonic acid groups can be controlled during synthesis to select for variable ion exchange capacity, electrical conductivity, and various mechanical properties.

One of the earliest principal uses of Nafion was as a membrane in the chlor-alkali process, which is the large-scale industrial process that uses brine and electricity to produce the common chemical feedstocks, chlorine gas and sodium hydroxide.[80] Historically these high-volume chemical commodities were prepared with brine in either asbestos diaphragm cells or mercury electrode cells. Both methods generate substantial quantities of hazardous wastes through either the mining and the fabrication of suitable asbestos membranes or the release of aqueous and volatile mercury wastes. Use of Nafion copolymer as a membrane in the electrochemical cell allows for excellent conductance of ions necessary for the process, while maintaining separation of the two parts of the cell under highly caustic conditions.

Perfluorosulfonic acid membranes are also used in high-efficiency fuel cells where, in one example, hydrogen and oxygen are pumped into different chambers within a cell that are separated by the membrane, giving rise to a continuous supply of electricity for various specialty applications. Perfluorosulfonic acid membranes are also used as an acid catalyst in a wide range of chemical conversions leading to decreased energy inputs and higher-purity products.

While it can be argued that perfluorosulfonic acid membranes have made many chemical preparation processes more efficient and cleaner, it is also important to acknowledge that the impacts from their production and use are still poorly understood. Research at one fluorochemical production site in Bladen County, North Carolina has documented that Nafion-related wastes have been released into the nearby Cape Fear River since at least 2012.[81] Moreover, the relatively advanced drinking water treatment plant in the city of Wilmington, North Carolina, has been unable to remove these Nafion-related wastes[82,83] giving rise to a situation where approximately 99% of the residents of Wilmington now have measurable concentrations of Nafion Byproduct 2 in their blood.[84] No human health data are currently available for Nafion Byproduct 2, and the human half-life of this material is likely to be on the order of months to years.[83] The production of perfluorosulfonic acid membranes has provided great utility by improving the efficiency of large-scale chemical syntheses while also reducing the emissions of other known hazardous byproducts (asbestos and mercury), but the current production process leads to the release of at least one persistent byproduct with near universal exposure in a downstream community.

The use of perfluorosulfonic acid membranes is currently judged to be category 3 (essential) in the chlor-alkali process. Before the use of Nafion, there were concerns for worker safety and the environment associated with mercury and asbestos. The use of Nafion as an alternative was the direct result of the chlor-alkali industry addressing these concerns. In the case of the use as a proton exchange membrane (PEM) in fuel cells, there are alternatives to perfluorosulfonic acid membranes,[85] but these are under development and not used as commonly as Nafion (category 2). Although there is a lack of functional alternatives for certain applications, it is reasonable to insist that emissions of persistent and potentially toxic wastes from

Open Access Article. Published on 28 May 2019. Downloaded on 2/28/2024 5:50:12 PM.

the production and use of perfluorosulfonic acid membranes be quantitatively determined and minimized.

Discussion

The Montreal Protocol has provided a successful blueprint to assess the essentiality of a class of widely used persistent chemicals found to have significant human and environmental health risks. Because of their extreme environmental persistence, and increasing data on their adverse effects including human health-related endpoints, PFASs are a prime opportunity for applying a similar approach to protect human health and the environment through the removal of these chemicals from non-essential uses. Our review of several key uses of PFASs demonstrates that currently a global phase-out of PFASs will be complicated, but it also indicates a number of starting points. In particular, different phase-out strategies will be required for each essentiality category. The essentiality of PFASs in the different use categories, based on our three categories in Table 1, is summarized in Table 2. Within a few of the larger use categories (*e.g.* textiles) certain uses of PFASs appear to be easier to phase out (*e.g.* leisure rain jackets) than others (occupational protective clothing) due to different technical performance requirements.

Alternatives assessment

Even if PFASs are assessed, according to the criteria in Table 1, to be non-essential in a particular use, and functional alternatives are available, this is only a first step to phase out and responsibly substitute PFASs. It cannot be generally assumed that non-fluorinated alternatives will be less harmful to human health and the environment than the PFASs they are replacing. The scientific discipline of alternatives assessment has established processes and best practices for identifying, evaluating, comparing, and selecting safer alternatives to chemicals of concern based on hazards, performance, and economic viability.[86–88] This process can be applied to PFASs used in material components, finished goods, manufacturing processes, or technologies. Not all substitutions require direct replacements of a fluorinated compound with a non-fluorinated alternative (*i.e.* chemical alternative); a technological or engineering innovation (*i.e.* functional alternative) can be equally successful[4] and should always be encouraged/prioritized over chemical alternatives. Multiple alternatives should be assessed for a given PFAS until an acceptable substitution is found. Often, once an alternative is found for one use case, it may be easily adapted for other use cases of that chemical as well. In the assessment, once possible non-hazardous alternatives are identified, it is also important to consider multiple endpoints[89] such as energy use, material use (incl. food waste, water use, packaging/machinery use and durability), and land-use (*e.g.* paper *vs.* plastic *vs.* glass), to avoid burden-shifting between different environmental and human impacts.

When considering chemical alternatives for PFASs, the focus should be on the service the product should deliver. The compound should therefore be evaluated for performance using the specifications required for the product, as opposed to comparing directly to the PFAS being replaced. Additionally, the potential for health hazard and potential for exposure – combined, these elements establish the health risks associated with the alternative – must be considered for the general public and vulnerable populations. Finally, additional considerations such as product longevity, persistence in the environment, and sustainability may be considered. Currently there are several established frameworks and evaluation metrics available for conducting alternative assessments.[86,90] In the absence of a thorough evaluation, regrettable substitutions can occur.

Table 2 Essentiality of PFASs in selected use categories

Use	Table 1 Category[a]
Personal care products including cosmetics	1
Ski waxes	1
Fire-fighting foams (commercial airports)	2
Fire-fighting foams (military)	2 or 3
Apparel (medical: long operations)	3
Apparel (protective clothing oil and gas industry)	3
Apparel (medical: short operations, everyday)	2
Apparel (military: occupational protection)	2 or 3
Waterproof jacket (general use)	2
Easy care clothing	1
Food contact materials	1, 2 or 3
Non-stick kitchenware (fluoropolymers)	1 or 2
Medical devices (fluoropolymers)	1, 2 or 3
Pharmaceuticals	2 or 3
Laboratory supplies, equipment and instrumentation	1, 2 or 3
Perfluorosulfonic membranes in fuel cells	2
Perfluorosulfonic membranes in chlor-alkali process	3

[a] Note that the categories in the above table represent the current evaluation and may change in the future.

Challenges and opportunities in chemical regulation

The Madrid Statement[12] recommends limiting the use of PFASs in society. Although all PFASs are highly persistent (or lead to highly persistent transformation products), many of them do not comply with the usual concerns considered in international chemical regulation. It can be argued that their extremely high persistence alone should be cause for regulation and substitution,[13,14] but the practical regulatory tools to implement this approach are currently lacking.

Within the context of the EU REACH Regulation, it has been argued[91] that the most effective way of regulating short-chain PFASs (as with the regulation of long-chain PFASs) is to identify them as Substances of Very High Concern under REACH Article 57, followed by a REACH Annex XVII restriction. Indeed, the EU has considered (*e.g.* in the case of the restriction of PFOA and its related chemicals), and is continuously considering ways to group PFASs in recognition of the impossibility of regulating more than 4700 PFASs individually.

Another relevant regulatory framework is the UN Stockholm Convention on Persistent Organic Pollutants, which includes

Open Access Article. Published on 28 May 2019. Downloaded on 2/28/2024 5:50:12 PM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

exempted uses similar to the essential-use exemptions under the Montreal Protocol. Under the Convention, the Conference of the Parties (COP) considers listing new persistent organic pollutants for elimination (Annex A), or restriction (Annex B), and/or involuntary production (Annex C) based on a recommendation from the Convention's Persistent Organic Pollutants Review Committee (POPRC). The Convention requires that the COP, "taking due account of the recommendations of the Committee, including any scientific uncertainty, shall decide, in a *precautionary* manner, whether to list the chemical, and specify its related control measures, in Annexes A, B and/or C" (Art. 8, Para. 9). As part of its deliberation of whether to list a chemical, the COP also considers whether to allow for any "specific exemptions" and/or "acceptable purposes". "Specific exemptions" is time-limited with one period of five years with the possibility of one extension for another five years, whereas the time period for the applicability of "acceptable purposes" is more open-ended.

Currently, there is no clearly defined criteria for identifying "specific exemptions" and "acceptable purposes" set in the text of the Stockholm Convention. Such "essential use-like" exemptions are primarily identified through the work of the POPRC on a case-by-case basis. However, the COP has subsequently adopted detailed criteria for consideration of requests to extend specific exemptions. For production exemptions, the requesting party must have submitted a justification for the continuing need for the exemption that establishes that the extension is necessary for health or safety, or is critical for the functioning of society; included a strategy in its national implementation plan aimed at phasing out the production for which the extension is requested as soon as is feasible; taken all feasible measures to minimize the production of the chemical and to prevent illegal production, human exposure and release into the environment; and the chemical must be unavailable in sufficient quantity and quality from existing stockpiles. Finally, in the case of a party with an economy in transition, the party must have requested technical or financial assistance pursuant to the Convention, in order to phase out as soon as feasible the production for which the extension is requested (see COP Decision SC-2/3, "Review process for entries in the Register of Specific Exemptions"[92]).

We are convinced that having clear legal guidelines for what constitutes an essential use (a process started in this present work) will benefit the Stockholm Convention and other regulatory frameworks by providing guidelines for determining how to apply the essential use-like exemptions, *i.e.*, by balancing costs *versus* the societal benefits of the use of a substance or product. A clear definition of essential use ensures that only those applications that are necessary for health or safety (or other purposes highly important to society as a whole) and for which non-fluorinated alternatives are not yet available could receive exemptions when chemicals are listed under the Convention. Further, this approach would protect those uses that are legitimately deemed essential until appropriate substitutions can be identified.

The way forward

Innovation in the development of alternatives to PFASs is ongoing and many functional alternatives that provide adequate technical performance have been developed and put into practice for some use categories. However, in other use categories little innovation is under way, due to lack of financial or regulatory drivers to change methods/production, significant technical challenges, lack of awareness of the market opportunities, or the small size of the market. Innovation is being encouraged in countries like Denmark (*e.g.* substitution of PFASs in textiles) and in Sweden through the availability of government funding for industry-academic partnerships (*e.g.* the POPFREE project[93] to encourage small companies to develop non-fluorinated alternatives to PFASs). Furthermore, one of the four key areas in ECHA's 2018 strategy on substitution[94] is to 'Develop coordination and collaboration networks between all stakeholders, ranging from institutions, member states, industry, academia and civil society'.

In some cases, the PFASs in a product or use will be determined as the only compound capable of delivering the required level of performance for that application. In these cases, it is recognized that immediate phase out will not be feasible. But this assessment is only based on current technologies. With clear legislative incentives, new technologies will typically be developed, and consequently PFAS uses in category 3 should continue to be reviewed for potential removal or replacement by new entrants to the market. In fact, use cases identified as category 3 should be the targets of industry and academic programs to develop innovations that may succeed in removing or replacing the PFAS with more sustainable functional alternatives. This system creates a market pressure to be the first to develop new technologies.

Chemical regulation on the other hand progresses slowly compared to product innovation, and assessment of individual PFASs is not feasible for protecting public health. It is simply unlikely that society and industry will spend the money and time to generate adequate data to risk assess >4700 PFASs. Therefore, we strongly recommend a grouping approach be employed, and for PFASs to be regulated as a group. Since regulation of the many thousands of PFASs by authorities is likely to be time consuming, it is important for industry (in particular product designers and manufacturers) to take voluntary measures that will contribute substantially in reducing the emissions of PFASs and their presence in products. There have already been several examples of retailers who through private procurement have phased out PFASs from their supply chains (*e.g.* IKEA, Lindex, and H&M in Sweden,[15,17,95] COOP in Denmark,[61] Vaude in Germany,[96] L'Oreal in France[97]), which in turn puts pressure on chemical manufacturers to find safer alternatives.

We are convinced that our criteria on essential use can inform and encourage other retailers to consider phasing out and substituting PFASs in their products. These types of voluntary measures will in turn help regulators by demonstrating that functional alternatives exist. When policy makers face stakeholder groups from both sides, they can use data-

driven essentiality assessments to support their decision making, *e.g.*, to show why certain uses are not necessary and therefore can be restricted. This will speed up regulatory actions in support of phasing out non-essential uses of PFASs, without risk to health or safety applications.

It is a formidable task to apply the essential use concept to all use cases of PFASs in detail. We have made a start here by illustrating how the concept can be applied to several use cases of PFASs, but to have a conclusive assessment for each use case described in this review, follow-up work may need to be covered in more detail (expanded, subdivided and refined) and engage relevant stakeholders with the necessary in-depth knowledge, where necessary. Although here we have focused on PFASs, the concept of essential use can also be applied in the management of other chemicals, or groups of chemicals, of concern.

Conflicts of interest

Executive Summary

The PFAS (Per and polyfluoroalkyl substances) REACH restriction proposal will have a major impact on the battery industry. This document provides RECHARGE’s feedback to the public consultation and the latest proposal of 22 March. For specific applications where PFAS are used in batteries, RECHARGE is **requesting derogations and additional transition times to provide sufficient time for the battery industry to identify and implement alternative non-PFAS solutions**.

Batteries are a main enabler for the transition towards low-emission mobility, decarbonised energy generation and digitalisation. Batteries power a wide range of general public applications such as smartphones, tablets, power tools, hearing aids, defibrillators, safety lighting in public buildings, and provide many services to industry such as back-up power for mission critical industrial assets (from nuclear power plants to data centres), energy storage systems for electrical grids, traction power to forklift trucks and AGV’s, and deliver energy to a wide variety of machines such as drones, rockets, satellites and IoT objects. Batteries also provide power to an increasing number of mobility solutions such as e-bikes, e-scooters and electric vehicles. They generate significant economic growth and provide jobs for millions of people.

This document details what types of PFAS are used in batteries and why, whether there are non-PFAS alternatives available, what are the tonnages of PFAS consumed and emitted, the socio-economic impact assessment of the proposed PFAS restriction for the battery value chain and finally proposes best practices that the battery industry and legislators could implement to further minimise emissions. All statements provided in this document are supported by scientific evidence.

Contents

1 Introduction and scope

RECHARGE represents over 60 organisations spanning all aspects of the battery value chain. The scope of this document as feedback to the ECHA consultation includes the following types of high performance, advanced rechargeable and lithium batteries:

- Lithium-ion rechargeable batteries (also known as Li-ion batteries)
- Lithium (Li) primary batteries (also known as primary Lithium batteries)
- Nickel–based rechargeable batteries (Ni-Cd and Ni-MH)
- Metal air batteries
- Zinc oxide batteries
- Silver oxide batteries
- Sodium-ion (Na-ion) rechargeable batteries
- Zinc-ion (Zn-ion) rechargeable batteries
- Solid-state batteries
- Lithium metal rechargeable batteries
- Other battery technologies currently under research

The only type of rechargeable battery which does not use PFAS is lead-acid batteries. However, lead-acid batteries have a low energy density. Lead-acid batteries cannot be used as suitable alternatives for the technologies presented above and applications they serve. These technologies serve applications where a variety of performances are required, amongst which are high energy, high power, very long life, superior reliability, ability to withstand extreme temperatures. Lead-acid batteries have limited capacity in these respects and cannot be considered as suitable alternatives. In addition, lead compounds used for battery manufacturing and lead metal have been recommended by ECHA for inclusion on Annex XIV respectively in the 6th and 11th recommendations.

Batteries are a main enabler for the transition towards low-emission mobility, decarbonised energy generation and digitalisation. Batteries power a wide range of **general public** applications such as smartphones, tablets, power tools, hearing aids, defibrillators, safety lighting in public buildings, and provide many services to **industry** such as back-up power for mission critical industrial assets (from nuclear power plants to data centers), **energy storage systems** for electrical grids, traction power to forklift trucks and AGV’s, and deliver energy to a wide variety of machines such as drones, rockets, satellites and IoT objects. Batteries also provide power to an increasing number of **mobility** solutions such as e-bikes, e-scooters and electric vehicles. They generate significant economic growth and provide jobs for millions of people. Batteries are essential to ensure the sustainable development of society and provide critical environmental and social benefits.

This document has been produced using information provided by our members, company reports, governmental publications, patent reviews and academic articles. All statements provided in this document are supported by scientific evidence.

This is a first submission. RECHARGE will update this document with additional information during the public consultation.

2 Why are PFAS used in batteries and where?

Batteries are comprised of two electrodes, a separator and an electrolyte, as schematized in Figure 1. Each electrode consists of an active material mass which is coated onto a current collector.

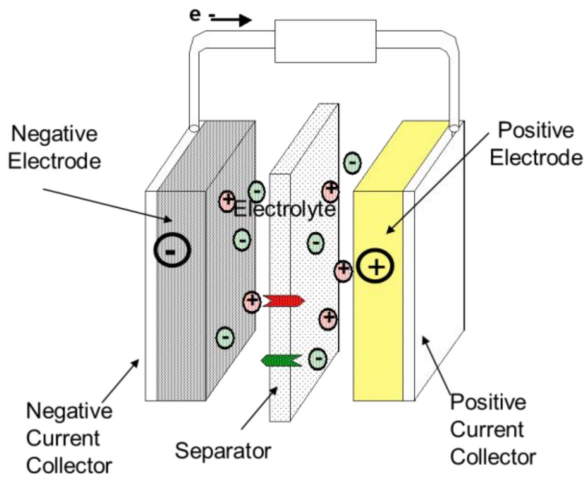

Figure 1. Components of a battery

PFAS have very unique properties:

- Water, oil and dirt repellent
- Durable under extreme conditions (high temperature, pressure, and aggressive chemicals)
- Electrical and thermal insulation.

As chemical resistance and tolerance to a high range of working temperatures are crucial for batteries, PFAS are used in key components for all high performance and lithium battery technologies. PFAS are used in key components in:

- Active material masses
- Electrolytes
- Valves, gaskets, washers & membranes
- Coatings

2.1 PFAS used in active material mass of electrodes

Each electrode is a composite which is manufactured by coating an active material mass onto a current collector (as shown in Figure 2). The active material mass comprises an active material, conductive additives (when needed) and a binder material.

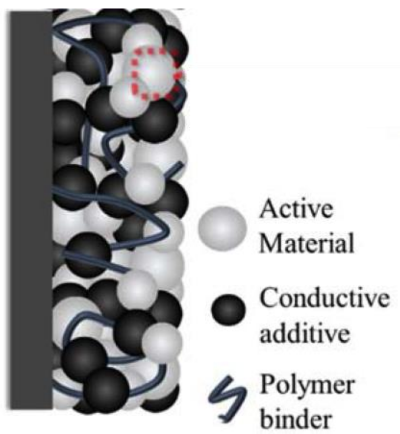

Figure 2: Composite electrode materials

Binder material is used to hold the active material particles together within the composite electrode and to provide a strong connection between the electrode and the current collector. The binder material plays an important role in the manufacturability of the battery and in the battery performance.

Due to their unique properties, both Polytetrafluroethylene (PTFE) and Polyvinylidine difluoride (PVDF – both homopolymer and copolymer) are used as binder materials in the active material masses in electrodes in a wide range of battery technologies, as detailed in Table 1.

Table 1. Binders used in active material masses for different battery technologies

Battery technology	Positive electrode	Negative electrode	Electrolyte
Li-ion (wet-process)	**PVDF** with NMC, NCA, LCO, LMO, LFP active masses	SBR/CMC with graphite anode, **PVDF** with LTO anode	Liquid organic electrolyte
Li-ion (dry process)	**PTFE** with NMC active mass	SBR/CMC with graphite anode	Liquid organic electrolyte
Na-ion	**PVDF** with PBA, Na-NFM and phosphate based active masses	**PVDF** with hard carbon anodes	Liquid organic electrolyte
Solid-state LMP	PEO with LFP active mass	No binder required for metallic lithium anode	Polymeric layer including PEO and **PVDF**
Ni-based rechargeable batteries	**PTFE** with Ni(OH)2 foam active mass	**PTFE** with Cd or MH electrode	Liquid alkaline electrolyte
Primary Li-SOCl2	**PTFE** with carbon anode	No binder required for metallic lithium	SOCl2 electrolyte
Primary Li-SO2	**PTFE** with carbon anode	No binder required for metallic lithium	SO2 electrolyte
Primary Li-MnO2	**PTFE** with Mn02 active mass	No binder required for metallic lithium	Liquid organic electrolyte
Primary Zn-Air	**PTFE** with MnO2 active mass	**PTFE**-membrane	Liquid alkaline electrolyte
Lithium metal rechargeable	**PVDF (and PTFE), with** with NMC, NCA, LCO, LMO, LFP	No binder required for metallic lithium	Liquid organic electrolyte, PE/PP or cellulose separator

2.1.1 PVDF used in active material mass of electrode

Although the PVDF binder comprises only a small portion of the composite electrode (typically 2–5% of the mass of the electrode[1]), the binder plays four important roles in battery performance. The PVDF binder:

- helps to disperse the active material and the conductive additive in the solvent during the fabrication process, enabling a homogeneous distribution of the slurry,
- holds the active material and the conductive additive together and connects them to the current collector, ensuring the mechanical integrity of the solid electrode without significantly impacting electronic or ionic conductivity (see Figure 2),
- acts as an interface between the composite electrode and the electrolyte. In this role, the PVDF binder protects the composite electrode from corrosion and the electrolyte from depletion while facilitating ion transport across this interface,
- tailors the viscosity of the slurry to allow a smooth coating onto the current collector during electrode manufacturing.

PVDF has several unique properties that enable it to fulfil these critical roles:

- **Mechanical properties**, including stiffness, toughness and hardness as well as good adhesion to the active material, the conductive additive, and the current collector. PVDF ensures the flexibility of electrode for cylindrical designs. The positive electrode binder must be able to withstand the forces that result from the expansion and contraction of active materials during charge/discharge cycles,
- **Thermal properties**, particularly thermal stability, are also important, both for the high temperatures commonly used for curing and drying during electrode fabrication and also for operation of the battery at various temperatures,

[1] Cholewinski, A., Si, P., Uceda, M., Pope, M., & Zhao, B. (2021). Polymer Binders: Characterization and Development toward Aqueous Electrode Fabrication for Sustainability. *Polymers*, *13*(4), 631–. https://doi.org/10.3390/polym13040631

- **Good dispersive capabilities** are important to help distribute the slurry evenly over the current collector during fabrication,
- **Chemical and electrochemical stability** are essential properties to enable the binder to function for long periods and over numerous cycles without degradation of the battery. The positive electrode binder must not react with any other components or intermediates formed during operation. In particular, the positive electrode binder must remain stable at the high and low voltage potentials experienced by the cathode. PVDF is the only proven material that can sustain a large voltage range from 0 to 5V at industrial scale for various battery designs (cylindrical, prismatic and pouch cell) and high-capacity cells. This stability guarantees its safe use in the electrochemical environment of the lithium cell.

All Lithium-ion battery manufacturing processes use PVDF as the binder material for all types of positive electrodes. Many other binder materials have been evaluated as replacements for PVDF, however all other materials have been found to oxidise at the high voltage at the positive electrode.

PVDF was previously also used as the binder material for all negative electrodes, however companies using graphite negative electrodes have successfully substituted PVDF with water-based CMC/SBR binder materials. For other types of negative electrodes using higher voltage materials such as lithium titanate oxide (LTO), NTO (Niobium Titanate Oxide)[2] the use of PVDF binder material is required because no research on alternative non-PFAS binders has proved sufficiently conclusive for transfer to industrialization to date.

For Sodium-ion rechargeable batteries, some research is ongoing regarding non-PFAS SBR/CMC binder materials for some hard carbon/PBA cells but this research work has not yet been scaled up. PVDF is preferred with some other PBA materials[3] and with hard carbon[4].

[2] Next-Generation SCiB™ supporting smart mobility in the age of MaaS, Using Niobium Titanium Oxide (NTO) as a next-generation anode material. (n.d.). https://www.global.toshiba/ww/products-solutions/battery/scib/next/nto.html
[3] Wessels, C., D., Motallebi, S., (2020). Electrolyte Additives for Electrochemical Devices. Patent No.: US 10 862 168 B2. https://app.dimensions.ai/downloads/patents?ucid=US-10862168-B2
[4] Barker, J. & Heap, R., (2020). Metallate Electrodes. United States Patent. Patent No.: US 10 756 341 B2. https://patentimages.storage.googleapis.com/4e/07/f0/c9dd46a4691e63/US10756341.pdf

Next generation Lithium-ion battery developments are focussed on producing cathodes using a dry process which avoids the need for NMP solvent. This dry process will significantly reduce energy consumption and lower environmental footprint. However, the dry process requires the use of PTFE or PVDF as the cathode binder material[5,6].

2.1.2 PTFE used in active material masses of electrode

Industry outreach has confirmed that all leading manufacturers of primary batteries based on the technologies listed in Table 1 use PTFE, or another fluoropolymer, as the binder material for the positive electrode. PTFE is used as the binder material for the positive electrode in Lithium primary batteries to provide three main functions:

1. Mechanical cohesion between the positive electrode particles to enable electrode integrity during cell assembly and throughout the lifecycle of the battery storage and use,
2. Lubricant to allow the electrode particles to slide over each other during electrode formation (compression) giving uniform electrode density that is important to consistent battery performance and longevity,
3. Lower water absorption during mixing (PTFE is a hydrophobic material) and more complete drying during electrode baking - low moisture content is critical in Lithium chemistry.

PTFE provides a unique combination of properties that are essential for the performance and durability of Lithium primary batteries:

- **High chemical stability** against the solvents used in Lithium primary batteries (such as thionyl chloride, sulphur dioxide and organic solvents),
- **High electrochemical stability**, which is necessary due to the high voltages (up to 3.9 V),
- **High temperature stability** to withstand the temperature necessary for drying the electrodes and provide stability in high temperature applications,
- **Good adhesion properties** to hold the active mass together in the electrode and provide adhesion to the current collector,
- **Good dispersion properties** to ensure the uniformity during the manufacturing of the electrodes,
- **Unique fibrillation properties**, very low concentrations are needed to hold the active mass in place without covering the active mass surface, this provides excellent porosity, which is needed for good penetration of the electrolyte,
- **Mechanical flexibility** to allow the winding of the electrode during cell assembly.

Polyvinyl alcohol (PVA, CAS 9002-89-5) or Poly(acrylic acid) (PAA, CAS 9003-01-4) may be added to the positive electrolyte binder material to create void volume after baking, this helps with electrolyte absorption.

PTFE is also used as the binder material for the positive and negative electrodes in industrial stationary Ni-Cd and Ni-MH rechargeable batteries.

2.2 PFAS used in electrolytes

PFAS is used in the electrolytes for Lithium-ion rechargeable, Lithium primary, Lithium metal rechargeable, and Sodium-ion rechargeable batteries.

In rechargeable batteries, LiPF6 (which is not a PFAS) has been widely used in older battery technologies for many years. However, recent advances in battery technology have established the use of PFAS substances as state-of-the-art for high performance batteries today, including as additives and as Lithium salt with PFAS anion. These include Lithium salts of PFAS monomers such as Li-Triflate

(CAS 33454-82-9), LiTFSI (CAS 90076-65-6), LiBETI (CAS 132843-44-8), LiFAP (LiPF3(CF2CF3)3n and LiTDI (CAS 761441-54-7). Examples of PFAS additives include Tris(2,2,2-trifluoroethyl)borate (TFEB CAS 659-18-7) and Trifluorotoluene (TFT CAS No. 98-08-8). PFAS substances are also used as gelifiers for Lithium-ion polymer batteries. Sodium bis(trifluoromethylsulfonyl)imide (NaTFSI CAS 91742-21-1) may be used for Na-ion batteries.

These advanced PFAS substances have properties which increase the electrolyte stability through chemical mechanisms such as capturing water and avoiding hydrogen fluoride emissions. The increased stability of the electrolyte provides significant increases in lifetime duration of the battery and battery operating temperature range. The PFAS substances are widely used in next generation Lithium-ion rechargeable batteries and particularly in the case of solid-state batteries.

For Lithium metal rechargeable batteries, polyfluorinated ether solvents, such as 1,1,2,2-Tetrafluoroethyl 2,2,3,3-tetrafluoropropyl ether, are essential to ensure adequate battery cycling lifetimes. This chemically inert solvent (in particular to Li metal) has unique properties that can reduce the viscosity of the cell and therefore the conductivity of the Lithium metal rechargeable batteries.

For Lithium primary batteries, the lithium manganese dioxide (Li-MnO2) electrochemical system is widely used in coin cells and cylindrical consumer cells such as CR2 and CR123A (one of the main electrochemical systems used for Lithium primary batteries), as well as in many cylindrical Lithium primary cell types for industrial applications. Li-MnO2 cells contain an electrolyte composed of organic solvents and a lithium salt. Lithium perchlorate (CAS 7601-90-3) has traditionally been used as the lithium salt, however lithium perchlorate has been found to act as an endocrine disruptor. Lithium perchlorate is the subject of ongoing regulatory management options analysis (RMOA) and is expected to become restricted. As a result, many manufacturers of primary Lithium batteries have already transitioned to using Li-Triflate (CAS 33454-82-9) and LiTFSI (CAS 90076-65-6) for cylindrical Li-MnO2 cells in general, and LiBETI (CAS 132843-44-8), LiFAP (LiPF3(CF2CF3)3n and LiTDI (CAS 761441-54-7) especially for high power Lithium primary cells (similar to the substitution observed in in rechargeable Lithium-ion cells). The use of the PFAS salts instead of lithium perchlorate also provides increased stability and performance as well as higher safety levels. Perchlorates in dry form are explosive materials which can explode in case of a thermal runaway of the battery or a fire.

2.3 PFAS used in valves, gaskets, washers, permeable membranes

PFAS is used in valves, gaskets, washers, and permeable membranes for Lithium-ion rechargeable, Lithium primary, solid-state batteries, Lithium metal rechargeable and Zinc air batteries.

Gasket sealings and washers, shown in Figure 3 for cylindrical cells and Figure 4 for prismatic cells[7], are critical components in batteries to prevent leakage of the electrolyte from the inside and penetration of moisture from the outside. Electrolyte leakages can cause short circuits and severe safety issues.

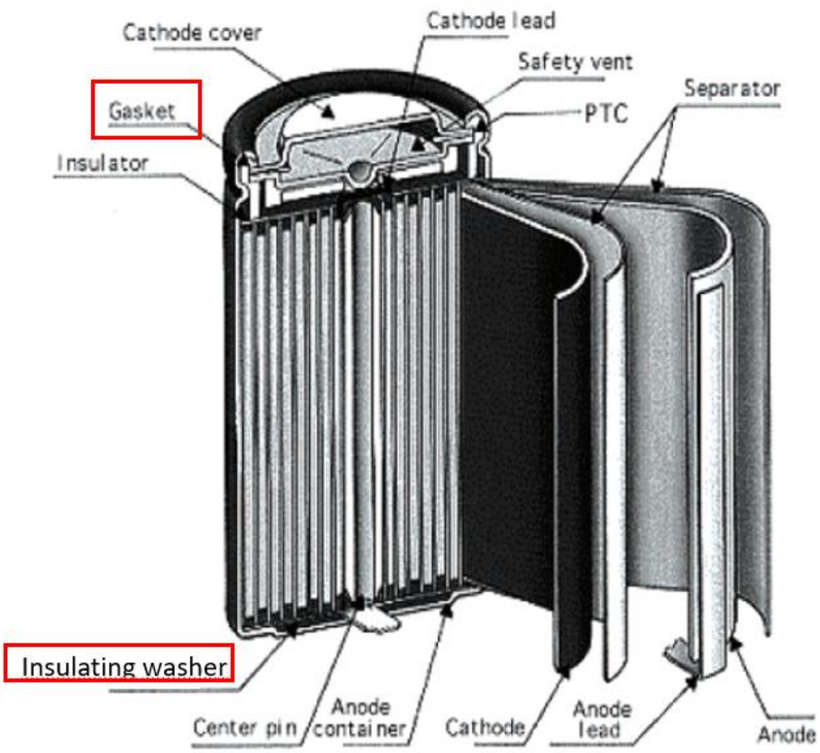

Figure 3. Gasket and washer in a cylindrical cell

[7] Arora, P., & Zhang, Z. (John). (2004). Battery Separators. *Chemical Reviews*, *104*(10), 4419–4462. https://doi.org/10.1021/cr020738u

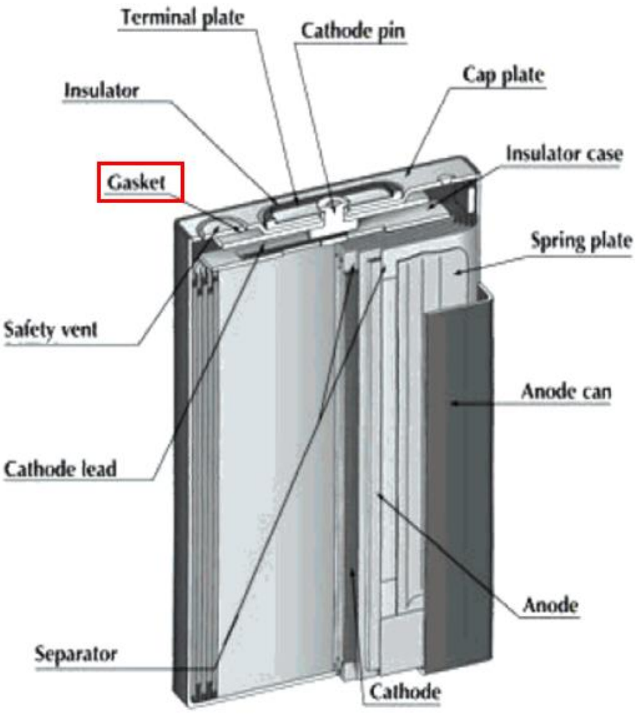

Figure 4. Gasket in a prismatic cell

For some applications used in mild temperature ranges, non-PFAS gasket sealing materials like PBT or PEI provide an adequate sealing performance. However, in high energy density Lithium-ion rechargeable and Lithium metal rechargeable batteries (e.g., high power batteries for automotive, industrial applications and power tools) it is crucial to employ very thin high-performance gaskets with high chemical and thermal stability, and high permeation resistance. This stability for high power and high temperature cells can only be provided by PFAS-based materials such as PTFE, PFA, FEP, VDF, HFP and FKM.

PTFE is not used for sealing gaskets in Li-MnO2 primary Lithium batteries. However, some industrial primary Lithium batteries use Li-SOCl2 and Li-SO2 electrolytes which are much more aggressive materials. SOCl2 is highly reactive and can violently release hydrochloric acid upon contact with water and alcohols. Sealing gaskets and washers for these much more aggressive materials require the use of PFAS-based materials such as FEP, PTFE, glass fiber with PTFE coating. These PFAS-based materials are critical to ensure the long lifetime of the battery, typically around 20 years. FEP is the preferred material for use in internal washers of high-power spiral primary Lithium Li-SOCl2 batteries because it provides excellent insulating properties and prevents internal shorts, thereby ensuring safe design and operation.

PTFE glass fiber washers are also used in Li-MnO2 and Li-SO2 industrial batteries to increase safety, especially in high temperature applications and safety-sensitive applications such as aviation. However, it may be possible to replace PTFE with another high-temperature non-PFAS polymer in these applications.

Zinc air batteries have the highest energy density of any practical battery system and operate by allowing oxygen to access the battery and react with the zinc. The oxygen is reacted on a catalytic surface inside the cell. Air permeable PTFE membranes are necessary to allow air to enter the battery whilst also preventing the release of the alkaline electrolyte from the battery. PTFE has unique hydrophobic properties and air permeability properties to achieve this critical function.

2.4 PFAS used in separator coatings

The separator is an indispensable part of batteries which separates the negative electrode from the positive electrode to prevent internal short circuits, whilst not participating in electrochemical reactions. At present, the most commonly used commercial separators are polyolefin separators, such as polypropylene (PP), polyethylene (PE) and multi-layer composite separators (PP-PE-PP)[8]. The layer materials are processed to make them porous by including tiny pores or voids at 35-45% porosity. The typical pore size is 200 nm - 1 μm which is large enough for the lithium ions to move smoothly through the separator.

Commercial tri-layer PP/PE/PP separators take advantage of the difference in the melting point of PP (165°C) and PE (135°C), using PE as the shutdown layer and PP to protect structural integrity. When the cell temperature rises near the melting point of the PE layer, the PE layer will melt at a temperature of 135°C and close the pores in the separator to stop the current flow while the PP layer, which has a

[8] Costa, C. M., Lee, Y. H., Kim, J. H., Lee, S. Y., & Lanceros-Méndez, S. (2019). Recent advances on separator membranes for Lithium-ion battery applications: From porous membranes to solid electrolytes. *Energy Storage Materials*, *22*, 346-375. https://doi.org/10.1016/j.ensm.2019.07.024

higher melting temperature than PE, remains solid. However, such protection is only effective below the melting point of PP.

To provide better thermal and mechanical stability, commercially available ceramic coated separators have been developed. Ceramic particles, such as alumina, silica, or zirconia can be mixed with polymeric binders and slurry-coated onto the polyolefin separators. In comparison to PP layers, ceramic coatings offer a better electrolyte wettability, which translates into better Li-ion transport through the separator and therefore a better performance of the battery. Although ceramic coatings have proven effective in improving the thermal stability of separators, the effectiveness of the protection is still limited by the thermal stability of the polymeric binder used.

Some companies use PVDF as the binder material for the ceramic coating to provide good adhesion to the electrolyte/composite electrode, as well as providing good adhesion of the ceramic coating to the separator. Other companies have developed non-PFAS binders which also provide good levels of adhesion to the separator and the electrolyte/composite electrode. Some organisations are researching the use of binder-free, thin-film ceramic-coated separators which may be able to provide improved safety for Lithium-ion batteries[9].

2.5 PFAS used in solid-state batteries

Several technical solutions are considered as fundamental to solid-state batteries, particularly for the development of solid-state electrolytes:

a. Polymer
b. Ceramic Sulfide
c. Ceramic Oxide

Polymer electrolyte is used in Lithium-metal-polymer (LMP) solid-state batteries and is already in production. Another solid electrolyte is based on ceramic sulfide. A third category of solid-state batteries are based on ceramic oxides. The last two are still under development at present.

[9] Gogia, A., Wang, Y., Rai, A. K., Bhattacharya, R., Subramanyam, G., & Kumar, J. (2021). Binder-Free, Thin-Film Ceramic-Coated Separators for Improved Safety of Lithium-ion Batteries. *ACS Omega*, *6*(6), 4204–4211. https://doi.org/10.1021/acsomega.0c05037

The architecture of LMP batteries is illustrated in Figure 3 and is based on using polymers as electrolytes and managing their chemical interfaces.

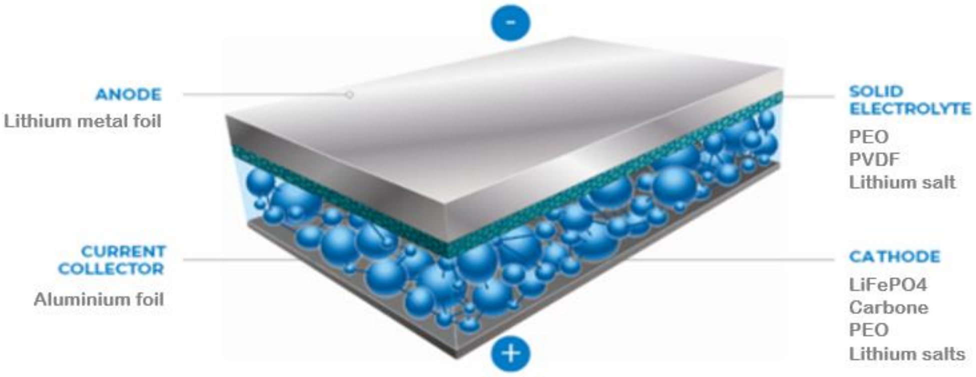

Figure 5. Schematic diagram of an LMP solid-state battery

The Lithium salt LiTFSI is used for the electrolyte and the cathode because it:

- has good conductivity allowing high power performance,
- is compatible with water (it does not hydrolyze and since there is water within the process, a salt that is stable in water is needed)
- is compatible with Lithium (also needed given the anode is Li-Metal)

PVDF is used as a binder in the electrolyte to provide mechanical strength and to act as an interface between the electrolyte and the electrodes.

These PFAS represent less than 5% of the cell's weight, but their role is crucial for the battery. PFAS are foreseen as even more important for the next generation of solid-state batteries. TFSI will be part of the cell recipe for its superior conductivity performances. PVDF is also expected to be a key component to ensure good adhesion between the cathode and the current collector.

3 Missing uses – analysis of alternatives

Table 2. Summary of derogation/transition period requests for various PFAS types, used in different types of batteries depending on current alternatives or alternatives in development

PFAS type	Where used in the battery	Type of battery	Alternatives available today?	Alternatives in development?	Derogation / transition period
PVDF	Binder in active material mass	Li-ion wet process (except for the graphite anode), Na-ion, Lithium metal rechargeable, solid-state	No	Preliminary research programmes funded by EU and Germany Govt	13.5 years
PTFE	Binder in active material mass	Li-ion dry process and semi-dry process, Lithium primary, Ni-Cd, Ni-MH, Zinc oxide, Metal air, Silver oxide, Zinc-ion rechargeable, Lithium metal rechargeable, solid-state	No	No	13.5 years
Various PFAS including LiTFSI, $LICF_3SO_3$ (triflate)	In electrolytes	Li-ion rechargeable, Lithium primary, Lithium metal rechargeable, Na-ion rechargeable batteries	Not for high performance/ next generation batteries	No - PFAS prevents 20% degradation of battery life.	13.5 years

PFAS type	Where used in the battery	Type of battery	Alternatives available today?	Alternatives in development?	Derogation / transition period
PTFE, FEP	Gaskets, washers	Chemically aggressive environments where PFAS is needed for electrochemical stability such as Lithium primary batteries using Li-SO_2 and Li-$SOCl_2$	No	No	13.5 years
PFA, VDF, HFP, FKM	Gaskets	High energy density batteries which require very thin high-performance gaskets such as Lithium-ion rechargeable batteries, Lithium metal rechargeable batteries	No other polymers have required mechanical properties and electrical insulation properties.	No	13.5 years
PTFE	Oxygen permeable membrane	PFAS hydrophobic properties are needed to facilitate air permeation and prevent alkaline electrolyte leakage in Zinc air batteries	No	No	13.5 years
PVDF, PTFE	Solid electrolyte/ gel polymer electrolyte	Solid-state batteries	No	No	13.5 years

PFAS type	Where used in the battery	Type of battery	Alternatives available today?	Alternatives in development?	Derogation / transition period
PTFE, PVDF	In coatings on the separator	Li-ion rechargeable, Lithium primary	Yes	Yes	Transition time of 6.5 years
PTFE, FEP, PFA, VDF, HFP, FKM	In valves, gaskets, washers	Li-ion rechargeable, Lithium primary, solid-state batteries where specific PFAS properties identified in section 3.1.4, 3.1.5 are not required	Yes	Yes	Transition time of 6.5 years

3.1 Uses where alternatives are not yet available

For the below uses where there are no alternatives available today, the chemicals industry will need to invest in research and development to build up the capacity and value chain for new innovative chemistries. The chemicals industry will need to make significant changes to existing research and development roadmaps which will be driven by industry demand for these new chemistries in Europe. In addition to research and development efforts, there is an immediate need for industrial investments to secure the manufacturing and the supply of chemicals to sustain the battery value chain in Europe. There is considerable uncertainty about the future of industry demand in Europe and therefore the timelines for these investments by the chemicals industry are not known. As a result, the battery industry requires derogation periods of at least 13.5 years for each of the below applications. If after the end of 13.5 years there are still no alternatives for specific applications, then the battery industry will need to apply to renew the derogation period for these specific applications.

3.1.1 Use of PVDF as the binder of the active material masses

PVDF is used as the binder material in the active masses for electrodes for Li-ion wet process (except for the graphite anode), Na-ion, Lithium metal rechargeable, and solid-state batteries. For the positive electrode, all attempts to replace PVDF binder materials with other polymers have caused cell performance and manufacturability issues. For the positive electrode, the degradation of alternative binder systems in the electrolyte has been demonstrated.

PVDF binder material is expensive (about 8-10 Euro/kg) and wet processes require the use of n-methyl-pyrrolidone (NMP) solvent (which is also expensive at about 2-6 Euro/kg) to dissolve the PVDF so that the slurry containing the binder material, active material and conductive additive can be dispersed evenly across the metal current collectors. NMP is classified in the EU as toxic to reproduction and its use is restricted under entry 71 of REACH Annex XVII. As a result, the use of NMP requires expensive solvent extraction and recovery systems. NMP also has a high boiling point of 210°C and so the curing and drying process has a high carbon footprint.

In view of the costs of PVDF and the health and safety concerns around the use of NMP solvent, many organisations have carried out research to try to find alternatives to PVDF as a binder material and NMP as the solvent. A peer reviewed academic article[10] indicates that PVDF as a latex can be used as the binder for the positive electrode with water as the solvent instead of NMP. Next generation Lithium-ion battery developments are focussed on producing positive electrodes using a dry process which avoids the need for NMP solvent. This dry process will significantly reduce energy consumption and lower the environmental footprint. However, the dry process still requires the use of PTFE or PVDF as the binder material for the positive electrode.

For Lithium-ion rechargeable batteries, PVDF was previously also used as the binder material for the negative electrode as well as for the positive electrode. For graphite negative electrodes, companies have successfully substituted PVDF with water-based CMC/SBR binder materials. CMC/SBR is now the most common commercially used binder material for the graphite negative electrodes due to its good

[10] Li, J., Lu, Y., Yang, T., Ge, D., Wood, D. L., & Li, Z. (2020). Water-Based Electrode Manufacturing and Direct Recycling of Lithium-ion Battery Electrodes—A Green and Sustainable Manufacturing System. *iScience*, *23*(5), 101081–101081. https://doi.org/10.1016/j.isci.2020.101081

cell performance, lower cost and reduced environmental impact[11]. For other types of negative electrodes using higher voltage materials such as Lithium titanate oxide (LTO), NTO (Niobium Titanate Oxide)[12] the use of PVDF binder material is required because no research on alternative non-PFAS binders has proved sufficiently conclusive for transfer to industrialization to date.

For Sodium-ion rechargeable batteries, some research is ongoing regarding non-PFAS SBR/CMC binder materials for some hard carbon/PBA cells but this research work has not yet been scaled up. PVDF is preferred with some other PBA materials[13] and with hard carbon[14].

The European Commission has recently funded the GIGAGREEN research project on dry alternatives and water-based binder systems for the positive electrode which propose to utilise a range of polymers including CMC/SBR, poly(acrylic acid), sodium alginate, polyurethanes and catechol-bearing polymers[15]. Whilst these initial research studies have indicated that these aqueous binder systems may have good adhesion properties, further research and development is required to investigate whether these alternatives have adequate chemical, mechanical, and electrical properties[16]. There are significant concerns about whether water-based CMC/SBR technology will have the necessary rheology and stability to match with today's positive electrode active materials such as LCO, NMC, NCA, LNMO, LFP. There are specific concerns about the use of water in the slurry production and the electrode coating, drying and calendaring processes, particularly if the water is not completely removed before the battery is assembled.

The Germany Government has funded the DigiBatt Pro 4.0[17] research project which also includes development of water-based binder systems for positive electrodes. As part of this research project, positive electrodes of around 100 metres in a lab scale with roughly 1/100 to 1/50 the scale of mass production have been produced using a nickel rich NCM cathode active material, $LiNi_{0.83}Co_{0.12}Mn_{0.05}O_2$. The cells could be successfully charged and discharged 1,000 times at 25°C before they fall below 80% of initial capacity. Whilst this research project appears to show promising results for very high nickel content batteries, correspondence with the project partners highlights that:

- Positive electrodes manufactured using water-based binder materials show increasing impedance/resistance with increasing numbers of charging and discharging cycles,
- The stability of the charging and discharging cycles is substantially lower than state-of-the-art positive electrodes using PVDF binder materials,
- The rapid increase in pH alkalinity of the water-based binder materials results in a very short shelf life for the mixed slurries, this would be very challenging for an industrial process as the mixture would go out of specification very quickly.

Further investigation of this research project confirms it focussed on a very specific high nickel NCM cathode active material at a moderate cell voltage of 4.2V. There is no evidence that this water-based binder material could be developed to meet the performance targets for positive electrodes with LCO chemistries operated at higher voltages, which is what many electronic devices use today.

It is also important to note that this research project focussed on a very specific cylindrical 21700 cell form factor used in certain automotive and power tool applications. Performance in this specific form factor is not directly transferrable to other cell form factors used in other applications. There are many unknowns which would need to be investigated before this technology could be adopted in other chemistries and other form factors, including:

- cycle life and calendar life and impedance growth under wide range of temperatures

---

[17] "*DigiBattPro 4.0 - BW*" - Digitized Battery Production 4.0 - Fraunhofer IPA. (n.d.). Fraunhofer Institute for Manufacturing Engineering and Automation IPA. https://www.ipa.fraunhofer.de/en/reference_projects/digibattpro.html

- swelling, fast charge cycling is unknown,
- electrode processibility for multilayer pouch cells and uniformity of coating is unknown,
- correspondence with the project partners highlighted that the positive electrodes manufactured using water-based binder materials show higher cell resistance and faster growth in resistance with increasing numbers of charging and discharging cycles with the high nickel NCM cathode active material. This trend is anticipated to become worse when industry moves to cathode active material operating at higher voltage, higher energy and higher power.

Furthermore, replacing the PVDF cathode binder likely requires the development of new cathode active material and Aluminium current collectors that are compatible with a new binder and solvent system. Water is known to cause poor cycle life and increased impedance growth in Lithium-ion cells. A new grade of active cathode powder may need to be developed to increase particle surface protection against water.

Replacing the PVDF cathode binder with new binder and solvent also requires development of a compatible electrode and cell manufacturing process and equipment. The necessary process and equipment change at mass production scale is unknown at this point and will be different for different companies depending on which alternative technology they pursue. The performance of mass production line produced PVDF free battery may have significant performance gaps compared with current batteries. Addressing these performance gaps may require a significant number of iterations of materials improvement, production process change and cell performance testing.

Given the above, we estimate that efforts to develop and commercialise high performance non-PFAS cathode binder, Al foil, active materials and corresponding cell manufacturing processes would take at least 10 years, followed by 5 years to commercialise the new technologies.

3.1.2 Use of PTFE as the binder of the active material masses

PTFE is used as the binder material in the active masses for electrodes for Li-ion dry process and semi-dry process, Li primary, Ni-Cd, Ni-MH, Zinc oxide, metal air, Silver oxide, Zinc-ion rechargeable, Lithium metal rechargeable and solid-state batteries.

There are currently no alternatives to PTFE due its unique combination of properties that are essential for the performance and durability of these batteries, especially for the:

- **fibrillation properties**, which produce an excellent mechanical electrode surface without covering the surface of the active material,
- **chemical properties**, including chemical stability in very aggressive environments,
- **hydrophobic properties**.

Alternative non-PFAS materials such as Polyvinyl alcohol (PVA, CAS 9002-89-5) and Poly(acrylic acid) (PAA, CAS 9003-01-4) have been tested as potential binder materials for the positive electrode and have been found to fail due to performance and manufacturability issues. The degradation of these alternative binder systems in the electrolyte has been demonstrated.

No research has been concluded on whether some of non-PFAS alternatives that are being investigated as potential replacements for PVDF as binders in Lithium-ion rechargeable batteries (see 3.1.1) may also be applicable to Lithium primary batteries. As a consequence, the timescale needed to investigate, develop and qualify alternatives for PTFE binder of the active material mass for Lithium primary batteries would be even longer than in the case of Lithium-ion rechargeable batteries.

3.1.3 Use of PFAS in electrolytes

Various PFAS substances are used in the electrolytes for Lithium-ion rechargeable, Lithium primary, Lithium metal rechargeable, and Sodium-ion rechargeable batteries. LiPF6 (which is not a PFAS) has been widely used in older battery technologies for many years. However, LiPF6 has been found to cause degradation in Li-ion cells, primarily from its thermal decomposition or hydrolysis to form acidic species. Recent advances in battery technology have established the use of PFAS substances as state-of-the-art for high performance batteries today, including as additives and as Lithium salt with PFAS anion.

PFAS electrolytes are used in advanced batteries to provide higher stability, increased performance and higher safety levels. This stability is provided by the high strength of the carbon-fluorine bond in the PFAS which is not present in the older electrolytes. As a result, the PFAS electrolytes provide 20% more battery life compared to $LiPF_6$ electrolytes. This increased battery life provides sustainability benefits by extending the lifetime of the product.

In rechargeable batteries, Lithium salts of PFAS monomers such as Li-Triflate (CAS 33454-82-9), LiTFSI (CAS 90076-65-6), LiBETI (CAS 132843-44-8) and LiFAP ($LiPF_3(CF_2CF_3)_{3n}$ are used to provide stability, performance and higher safety levels. There are no non-PFAS alternatives available today which provide similar stability, performance and safety levels. We estimate that research and development efforts to identify non-PFAS alternatives would take at least 10 years, followed by 5 years to commercialise the new electrolyte chemistry.

For Lithium primary batteries, Lithium salts based on monomolecular PFAS have been developed to replace the endocrine disruptor Lithium perchlorate and to improve the performance and durability of Lithium primary batteries (especially Lithium manganese dioxide batteries). Non-PFAS alternatives for Lithium perchlorate are currently not known and would have to be newly developed.

For Lithium metal rechargeable batteries, polyfluorinated ether solvents, such as 1,1,2,2-Tetrafluoroethyl 2,2,3,3-tetrafluoropropyl ether, are essential to ensure adequate battery cycling rates and lifetimes. This chemically inert solvent (in particular, inert to Li metal) has unique properties that can reduce the viscosity of the cell and therefore the conductivity of the Lithium metal rechargeable batteries. Non-fluorinated solvents can be used in combination with fluorinated ones, but not as a complete replacement primarily due to their lower chemical stability in conjunction with a metal Lithium electrode. There are no non-PFAS alternatives available today.

We estimate that research and development efforts to identify non-PFAS alternatives for electrolytes would take at least 10 years, followed by 5 years to commercialise the new electrolyte chemistries.

3.1.4 Use of PTFE & FEP in gaskets & washers in chemically aggressive environments

There are no alternatives to use of PTFE and FEP in gaskets and washers used in chemically aggressive environments such as the SO_2 and $SOCl_2$ substances used in electrolytes in primary Lithium batteries. SO_2 and $SOCl_2$ are very powerful oxidising agents which degrade almost all polymer types except PFAS materials. Degradation of the gasket and washer would result loss of battery component properties and release of the electrolyte. These primary industrial batteries using these electrolytes are required to operate for 20 years, significant research and development efforts will be needed to identify suitable alternatives which can provide the needed safety and long-term performance.

Polyimidazoles and fully chlorinated PVC may be some potential non-PFAS alternatives which may provide sufficient chemical stability against thionyl chloride in some applications. Thick bound fiberglass materials may also provide possible solutions. However, for chemically aggressive environments, more research on alternative materials is needed before the testing and final qualification can start, so that a derogation of 13.5 years is considered to be necessary.

3.1.5 Use of PFA, VDF, HFP, FKM in gaskets in high performance batteries which require very thin high performance gaskets

There are no alternatives to use of PFA, VDF, HFP, FKM in gaskets in high performance Lithium-ion rechargeable and Lithium metal rechargeable batteries (e.g., high power batteries for automotive, industrial applications and power tools) which require very thin high performance gaskets.

High power and high energy density batteries require very thin high performance gaskets[18]. Gaskets provide insulation between the positive and negative sides of the housings, a proper thermal functionality of the gasket is essential. This application needs a stable and compressive polymer which provides high levels of insulation to withstand the very high currents up to 280 amps which are found in these high performance batteries. Figure 6 compares the compressive properties of PFAS compared to other resins[19].

[18] Lui, J., Aoyama, T., Tsuda, H. & Sukegawa, M., (2019). Long-term reliability evaluation of fluororesin gasket for electrode of automotive lithium-ion battery using simulation. *VIII International Conference on Computational Methods for Coupled Problems in Science and Engineering*. https://upcommons.upc.edu/bitstream/handle/2117/190005/Coupled_2019-24-Long-term%20reliability%20evaluation.pdf

[19] Battery materials, Fluorochemicals, Daikin Global. (n.d.). https://www.daikinchemicals.com/solutions/products/battery-materials.html#anchor04

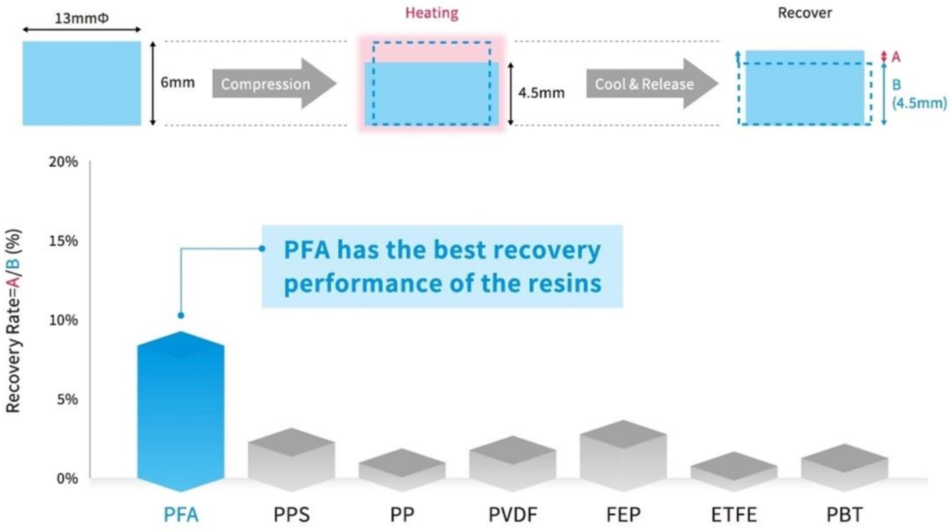

Figure 6. Compressive properties of polymer resins

PFAS provide a unique combination of electrical insulation and hydrophobic properties. Figure 7 compares the moisture permeation properties of PFAS compared to other resins[20]. As a result, the efficiency of the gasket performance is improved because of the reduced humidity absorption even when used at very low thickness.

[20] Ibid

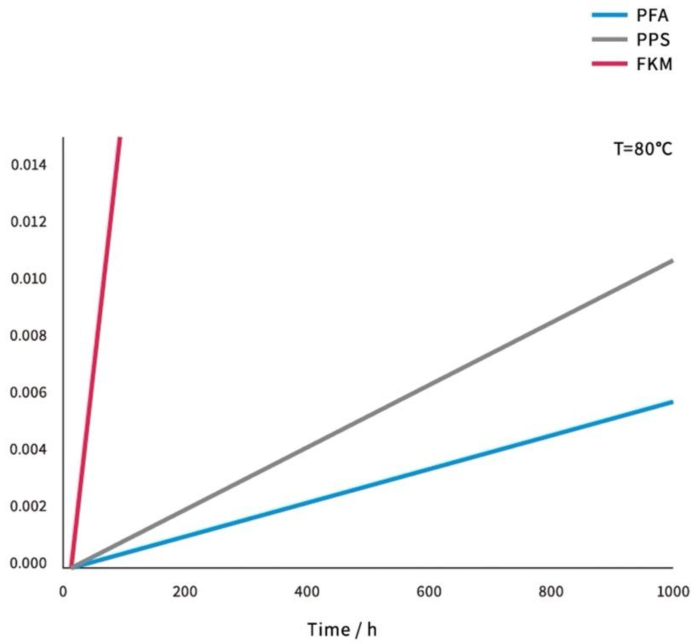

Figure 7. Moisture permeation of polymers

It will take significant time and effort for industry to investigate whether there are alternative polymers that can be used instead of PFAS in these gaskets. We estimate that research and development efforts to identify non-PFAS alternatives would take at least 10 years, followed by 5 years to commercialise the alternatives.

3.1.6 Use of PTFE in oxygen permeable membranes in Zinc air batteries

There are no known alternatives for use of PTFE in oxygen permeable membranes in Zinc air batteries or other types of alkaline metal-air batteries.

Zinc air batteries operate by allowing oxygen to access the battery and react with the zinc. The oxygen is reacted on a catalytic surface inside the cell. Air permeable PTFE membranes are necessary to allow air to enter the battery whilst also preventing the release of the alkaline electrolyte from the battery.

PTFE has unique hydrophobic properties and air permeability properties which allow gas molecules to pass through the membrane whilst at the same time preventing the release of the alkaline electrolyte. Extensive research would be needed to find alternatives. We estimate that research and development efforts to identify non-PFAS alternatives would take at least 10 years, followed by 5 years to commercialise the alternatives.

3.1.7 Use of PTFE / PVDF in solid electrolyte/ gel polymer in solid-state batteries

There are no available alternatives to the use of PVDF / PTFE as a binder in the solid electrolyte/ gel polymer in solid-state batteries. The PVDF / PTFE has unique properties that provide mechanical strength and act as an interface between the electrolyte and the electrodes in solid.

PVDF and co-polymers of PVDF are uniquely placed to enable solid electrolyte/gel polymers in batteries due to the presence of strong electron-withdrawing functional group (–C–F)[21]. These properties include high polarity, excellent thermal and mechanical strength, compatibility with organic solvents and chemical stability[22].

Extensive research would be needed to find alternatives. Research and development efforts to identify non-PFAS alternatives would take at least 10 years, followed by 5 years to commercialise the alternatives.

3.2 Uses where substitution is technically feasible but more time is required

As highlighted below, where substitution is technically feasible, the steps involved in substituting new materials into several subcomponents in a company's battery manufacturing process are considerably more complicated than in other industry sectors and therefore the battery industry requires a longer transition period of 6.5 years. Each new subcomponent needs to be developed and tested separately, and then the combination of the new subcomponents needs to be tested in the new battery and the product applications. Each company's battery manufacturing equipment and process lines also have unique aspects which are specific to that company's products and applications. Some companies may

[21] Manuel Stephan, A. (2006). Review on gel polymer electrolytes for lithium batteries. *European Polymer Journal*, *42*(1), 21–42. https://doi.org/10.1016/j.eurpolymj.2005.09.017

[22] Barbosa, J. C., Dias, J. P., Lanceros-Méndez, S., & Costa, C. M. (2018). Recent Advances in Poly(vinylidene fluoride) and Its Copolymers for Lithium-Ion Battery Separators. *Membranes (Basel)*, *8*(3), 45–. https://doi.org/10.3390/membranes8030045

need to make significant changes to their manufacturing equipment and process lines to accommodate the new subcomponents.

The below consecutive steps 1 to 4 are representative of the battery industry and present an optimistic scenario where no complications arise such as additional certification requirements or unforeseen customer validation requirements. For example, a significant amount of R&D resource will be needed to carry out the development of new subcomponents and the battery industry may face a shortage of qualified technical staff to carry out this work. In addition, a large amount of battery models and finished products containing batteries which are on the market today will need to be recertified and there may not be sufficient third-party certification companies available in the market today to provide these needed recertification services.

The battery industry will make every effort to work within a 6.5 years transition time. However, there may be some types of subcomponents where industry experience finds that it is not possible to achieve substitution within the 6.5 years and so the battery industry may need to apply for an extension to this transition period.

Step 1: Substitute material identification for one subcomponent: up to 12 months

Each company's battery manufacturing process is customised to meet the needs of that company's products. In many cases there are a range of chemistries that could be considered as alternatives for a specific subcomponent. The first step is assessment and laboratory verification to identify which target substitute material is likely to provide the best combination of properties for the specific subcomponent in the company's products. The identification of a target substitute material for one subcomponent alone can take up to 12 months. For example, in the case of the binder for the ceramic coating on the separator, companies which are currently using PVDF will need to evaluate several different alternatives to identify the best material for their application. There are several alternatives in use today which will need to be considered.

Step 2: Separate development of each new subcomponent: 14 - 21 months

This is the process of using the target substitute material to develop the new subcomponent and then to test it in a cell with an existing, already proven chemistry. This step is necessary to isolate the new subcomponent as the only variable that has changed in the cell. Once the cells are built, the testing of the cell cycling process can begin. It takes about 7 months to carry out 1000 test cycles of the cell build containing the new subcomponent, to check that it can meet swelling, impedance, capacity retention and other technical requirements after 1000 cycles. Some companies also need to carry out environmental testing of the subcomponent such as long-term storage at elevated temperatures. A cell build can fail the cycles tests, therefore most companies assume at least one additional iteration of the cell build will be required to refine the specific chemistry of the target substitute material. Therefore, this stage can take several multiples of 7 months, at least 14 to 21 months.

Step 3: Combination of all new subcomponents and chemistry development: 18 - 36 months

This is the process of integrating and developing all the new subcomponents into a next generation cell chemistry package. Each new subcomponent would need to be qualified as part of this larger chemistry package.

The integration and development process requires several cell builds to find a combination of components and process conditions that meets all electrochemical and safety requirements. Depending on the testing capacities at the company, some companies may need to carry out between 3 and 6 cell builds, as some cell builds may fail testing. It takes about five months to develop each cell build and carry out tests of the initial 250 cycles so that sufficient data can be collected to accurately inform the development of the next cell build. The final cell chemistry needs to be tested at 1000 cycles which takes 7 months. Therefore, it may take around 18 - 36 months to arrive at a validated battery chemistry which is ready to be integrated into a new product.

Step 4: Integration into existing product design and new product designs, and into manufacturing processes: 24 - 48 months

The next step is to integrate the new validated battery chemistry into existing product designs and new product designs, and to carry out testing on finished assembled products to ensure they meet all electrochemical, process, safety and reliability requirements and certifications. This requires requalification of the new battery in all existing products which are already in production in Europe. Companies will need to make changes to their manufacturing equipment and process lines to qualify the manufacturing of the new subcomponents, the integration of the new subcomponents into the cell and the integration of the new battery into existing and new products. These changes to manufacturing equipment and process lines may be significant and require extensive time and capital investment.

Product requalification is a very time-consuming exercise which will require extensive resources over many years. The completion of this task will require sufficient test house capacity and transition time to requalify all battery-powered products which are used in Europe for safety, performance and lifetime. Additionally, the process of re-certifying batteries for existing product designs may trigger other regulatory updates unrelated to the new subcomponents that could otherwise have been avoided. For a company with a wide range of existing product designs, this can take around 24 - 48 months.

4 PFAS consumption in tonnes and emissions during battery life cycle

4.1 PFAS consumption in tonnes

Further information will be provided in subsequent submissions.

4.2 Emissions during the battery life cycle

NOTE: This text repeats the information already provided by RECHARGE in the second call for evidence submitted in October 2021. Updated information will be included in subsequent submissions.

4.2.1 Emissions during battery manufacturing

For technologies using PVDF as binder

PVDF is mixed with its organic solvent NMP and other electrode components. A PDVF latex can also be used. This wet mix is then coated on a metallic foil. This electrode is further heated below the degradation temperature of PVDF. The dried electrode is then further used for cell manufacturing. Empty bags of PVDF, PVDF containing residues from the processes as well as scrap cathodes are collected as chemical wastes and disposed of according to applicable European regulations.

For technologies using PTFE as binder

PTFE dispersion is mixed with electrode components and carbon black. This wet mix is then processed and heated below the degradation temperature of the PTFE. The dried mix is then further used for cell manufacturing.

Empty drums of PTFE dispersion, PTFE containing residues from the processes as well as scrap cathodes are collected as chemical wastes and disposed of according to applicable European regulations.

Potential residues of PFAS from binders or electrolyte (either empty packaging or cleaning solutions) are always collected as chemical wastes and disposed of according to applicable European regulations. **No unintended and uncontrolled PFAS emissions are foreseen during battery manufacturing.**

4.2.2 Emissions during battery use

During battery manufacturing, active substances, binders (like PTFE and PVDF) and additives are embedded in a mechanical substrate to form electrodes. These electrodes are then further assembled with the other battery components such as separator, electrolyte, connectors, gaskets, washers and casing to obtain a finished battery. This battery is defined in the REACH regulation as "an article with no intended release" meaning that, **under normal and reasonably foreseeable conditions of use, no end-user of this battery will be exposed to any chemical substances. No PFAS emissions are foreseen during battery use.**

4.2.3 Emissions during battery recycling

Battery recycling is mandatory in Europe since 2006 according to the Battery Directive and will remain mandatory with higher recycling targets in the upcoming Battery Regulation. Fluoropolymers are totally decomposed (as compounds), during the pyrometallurgical recycling processes. The fluorine reports to the flue dust. Flue dust is further processed in a hydro-metallurgical process to extract specific remaining metal content. Also, the PFAS containing waste streams and product streams from the hydrometallurgical recycling process may be treated in high temperatures where fluoropolymers are totally decomposed (as compounds). **No unintended and uncontrolled PFAS emissions are foreseen during battery recycling.**

Further information will be provided in subsequent submissions.

5 Socio economic impact assessment for battery value chain

Further information will be provided in subsequent submissions.

6 Why RECHARGE seeks derogations and additional transition times, and industry best practices

Further information will be provided in subsequent submissions.

Glossary

FEP	Fluorinated ethylene propylene
HFP	Hexafluoropropylene
LiCF3SO3	Lithium trifluoromethanesulfonate
Li-ion	Lithium ion battery
LiSO2	Lithium sulfur dioxide battery
LiSOCl2	Lithium-thionyl chloride
LiTFSI	also known as TFSIL,i Lithium bis(trifluoromethanesulfonyl)imide
LMP	Lithium-metal-polymer
LTO	Lithium titanate oxide
Na-ion	Sodium ion rechargeable battery
NFM	Layered oxide of Ni, Fe, Mn (for Na-ion)
Ni-Cd	Nickel Cadmium battery
Ni-MH	Nickel metal hydride battery
NTO	Niobium Titanate Oxide
PBA	Prussian Blue Analogues
PFAS	Per and polyfluoroalkyl substances
PTFE	Polytetrafluoroethylene
PVDF	Polyvinylidine difluoride (both homopolymer and copolymer)
VDF	Vinylidene fluoride
Zn-ion	Zinc-ion rechargeable batteries

RE: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), ID Number R-4837

Dear Minnesota Pollution Control Agency:

On behalf of the Fluid Sealing Association,[1] Hydraulic Institute,[2] the Valve Manufacturers Association,[3] and Water and Wastewater Equipment Manufacturers Association[4] (collectively, the "Flow Control Coalition"), we respectfully submit these considerations for the Minnesota

[1] Founded in 1933, the FLUID SEALING ASSOCIATION® (FSA) is an international trade association. Member companies are involved in the production and marketing of a wide range of fluid sealing devices primarily targeted to the industrial market. The Fluid Sealing Association membership includes a number of companies in Europe and Central and South America, but is most heavily concentrated in North America. Fluid Sealing Association members account for a majority of the manufacturing capacity for fluid sealing and containment devices in the Americas market.

[2] Founded in 1917, the Hydraulic Institute spent much of the past century playing a leading role in development and implementation of pump standards on behalf of manufacturers, system engineers and end-users. As the nationally and internationally recognized representative of the US pump industry, the Hydraulic Institute works with rulemaking bodies such as the US Department of Energy (DOE) as well as standards setting organizations such as ISO, API, AWWA, *etc*.

[3] Founded in 1938, the Valve Manufacturers Association of America is the only North American trade association that represents the interests of manufacturers, suppliers and distributors of valves, actuators, and controls. VMA's mission is to serve the growth and innovation of the U.S. and Canadian industrial valve industry globally by providing the forum which enhances a positive business operating environment, increases knowledge and education, advances technology innovations, and facilitates business and government connections.

[4] The Water and Wastewater Equipment Manufacturers Association (WWEMA) is a trade association representing water and wastewater technology and service providers since 1908. We advocate, inform, and connect our members with key policy and decision-makers and help our members increase their competitiveness and profitability in the U.S. and abroad. Our members supply the most sophisticated leading-edge technologies and services, offering solutions to every water-related environmental problem and need facing today's society.

Pollution Control Agency (MPCA) during the rulemaking process regarding the Currently Unavoidable Use (CUU) determination. These comments provided from the industrial flow and pressure control industry represent the best information available at this time, however as the process progresses the Flow Control Coalition will continue to review and provide additional information as requested. The Flow Control Coalition appreciates the opportunity to provide this information and applauds Minnesota's efforts to implement common sense reforms that enable the State to better understand and regulate PFAS in products.

The Flow Control Coalition represents industrial industries that are vibrant, innovative and responsible. The member companies of the Coalition play an integral role in supporting the production of products essential to improving the quality of daily life of the public and protecting the planet. Industrial flow control equipment is relied on in many industries, most notably power generation (traditional and new energy sources); national defense; construction and data centers; semi-conductor production; mining; pharmaceutical; pulp and paper; water and wastewater; oil and gas; chemical; transportation; food and beverage and many others.

Certain Fluoropolymers are Essential for Many Critical Applications

The Flow Control Coalition supports Minnesota's efforts to address PFAS shown to meet environmental and human health toxicity criteria, such as perfluorooctanoic acid (PFOA) and perfluorooctane sulfonic acid (PFOS). However, restricting all substances that contain a fully fluorinated carbon atom (or are captured by a similarly expansive definition of "PFAS") is excessively broad and would have significantly *negative* impacts on the economy, environment, safety, national defense, and our way of life.

Many PFAS polymers are of low toxicological concern and are indispensable to countless industrial processes that support the safe production and processing of oil and gas, chemicals, pharmaceuticals, semi-conductors, electrical/nuclear power, and food, as well as numerous other important industrial applications. For many of these applications, PFAS are essential for health and safety reasons, and necessary to enable the functioning of critical industrial operations.

High molecular weight fluoroelastomers and fluoropolymers (*e.g*., PTFE, PTFE, FKM, FFKM, ePTFE, PCTFE, mPTFE, PFA, eTFE, FEP, PVDF, PFPE, FEPM, and ECTFE) are used in the manufacture of gaskets, seals, pumps, coatings, chemical piping and industrial valves, all of which are integral to the production of products core to maintaining modern life. These solid, molded products have negligible potential for worker or consumer exposure or other safety concerns while handling the product. The use of these fluoroelastomers and fluoropolymers enables production of a wide range of everyday products used by almost every American, including semiconductors, cell phones, food and beverages, pharmaceuticals, renewable energy systems, transportation, pulp and paper products, and more. They are also integral in the technology used in efforts to achieve zero carbon goals and in the production, transportation, and storage of hydrogen.

When present in the products manufactured by our member companies, PFAS are used due to their unique properties that provide for effective sealing, creating barriers for emissions, reducing energy use, and performance in highly corrosive or high temperature environments. Highly reliable performance is particularly important when access to the production system is difficult and dangerous, and to provide a safe and reliable production process.

The decision to use PFAS substances in these applications is the product of highly complex and costly engineering determinations. In the flow control industry, highly skilled engineers work to design the entire flow control system to meet detailed specifications required by accepted standards and regulations designed to protect health, safety, the environment, and efficient operations.

Simply put, if there were reasonably available alternatives that delivered the same level of performance in these critical applications, they would be used. In fact, given the cost of PFAS chemicals, the industry would welcome effective alternatives. Unfortunately, such alternatives are not available at this time for the critical applications our industry serves.

Accordingly, the Flow Control Coalition recommends that MPCA adopt a CUU determination for industrial flow and pressure control products, for the reasons discussed further below.

Considerations for Evaluating Currently Unavoidable Use Determinations

In the following section, we address the specific questions posed by MPCA regarding considerations in evaluating CUU determinations. As detailed below, there would be a significant number of CUU determinations for a wide variety of fluid handling and flow control products for which PFAS are essential for proper and safe performance. In the following discussion and attached list, we identify the products and the reasons why the use of PFAS currently (and for the foreseeable future) is unavoidable. Because of the extensive number of products, and the many properties for which PFAS may be utilized, we have attempted to be as efficient as possible in explaining why a CUU designation is appropriate. The Flow Control Coalition would be happy to provide further detail if that would be helpful to Minnesota throughout the rulemaking process.

1. <u>Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?</u>

Yes. "Essential for Health, Safety or the Functioning of Society" means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies.

Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations. Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction.

"Critical infrastructure" specifically should include the industrial flow and pressure control equipment that ensures the safety and effectiveness of the applications noted above.

2. <u>Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?</u>

Yes. A reasonable cost threshold of 'comparable' should be set and should, at a minimum, meet the following criteria:

- The alternative material should **be safer**, perform **comparable to PFAS,** and be considered a **drop-in replacement** (i.e. no redesign of the product is required to accommodate performance deficiencies or vulnerabilities).
- The alternative material should be at a **comparable cost** to the existing PFAS material.
- The alternative material should be **commercially available at-scale** and from multiple suppliers.

If any of the three criteria is not met, the material should be considered a "not reasonable" alternative. An exact quantifiable definition of 'comparable' is difficult to set as cost varies significantly by product and application.

Given those criteria, an "alternative" should mean a substance or chemical that, when used in place of PFAS, results in a functionally equivalent product and that, when compared to a PFAS that it could replace, would reduce the potential for harm to human health or the environment, or has not been shown to pose the same or greater potential for harm to human health or the environment as that PFAS. Alternatives include reformulated versions of products, including versions reformulated by removal or addition of one or more chemicals or substances, that result in the reduction or removal of intentionally added PFAS from the product. Alternatives also include changes to the manufacturing process that result in the reduction or removal of PFAS from a product.

To our knowledge, there are no known commercially available alternatives at this time that provide the same level of protection to health, safety and the environment, or that deliver the same efficiency in manufacturing or service.

Further, even if a new alternative can be identified, or if an existing, older material is to be reintroduced, it will still need to be tested and certified for use in the specific application, and product designs would need to be reengineered. This entails testing the materials regarding functionality (*i.e.*, performance, stability and quality) and obtaining certifications from or adoption by the appropriate regulatory or standard-setting bodies. This is a drawn-out, time-consuming process, and it is difficult to estimate the number of years that it would take to find viable alternatives to current PFAS uses.

3. Should unique considerations be made for small businesses with regards to economic feasibility?

Not applicable.

4. What criteria should be used to determine the safety of potential PFAS alternatives?

Due to the complexity of the question, this needs further evaluation. An additional request for comments should be issued so that further comments on this question can be submitted with the time needed to develop a submission response.

5. How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

Despite the substantial financial incentives to replace PFAS, we are not aware of companies offering new materials as a drop-in replacement and capturing this valuable market, which is a strong indication that, in many cases, especially in industrial applications, that no alternatives exist.

Consequently, an **estimated** time period for a granted CUU should be set at a minimum of 10 years **after** a safe and reasonably available alternative (as defined above) is identified. This timeframe would allow for identification of alternatives and verification and validation testing, which can be upwards of 10 years in highly regulated industrial environments. This estimate assumes that a suitable alternative will be identified within the first few years of the CUU time period.

6. How should stakeholders request to have a PFAS use be considered for currently unavailable use determinations by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Due to the complexity of the question, this needs further evaluation. An additional request for comments should be issued so that further comments on this question can be submitted with the time needed to develop a submission response.

7. In order to get a sense of what type of and how many products may seek a currently unavailable uses determination, please share what uses and products you may submit a request for in the further and briefly why.

Fluid handling or flow control is a complex process that requires numerous components including but not limited to industrial pumps, motors, drives, pipes, seals, gaskets, coatings, piping, and valves. These components work in unison to handle a variety of fluids each with different characteristics and in a variety of situations or use cases. While each type of system cannot be listed here because of the wide array of products used in the processing and production in so many industries, we have attached a list of critical products that contain PFAS (e.g., PTFE, FKM, FFKM, ePTFE, PCTFE, mPTFE, PFA, eTFE, FEP, PVDF, PFPE, FEPM, ECTFE) that are commonly used to handle difficult materials in very specific environments and situations. The attached list includes relevant GPC/HTS product category codes and provides generic uses of PFAS in the product. While we attempted to be as inclusive as possible to provide a general idea of how many applications are currently unavoidable uses and do not have alternatives available, it should be noted that there could be additions to this list.

8. Should MPCA make some initial currently unavoidable use determination as part of this rulemaking using the proposed criteria?

The Flow Control Coalition recommends that MPCA adopt an initial CUU determination for the industrial flow and pressure control products identified in the attached list.

* * * *

The member companies of the Coalition play an integral role in supporting the production of products essential to improving the quality of daily life of the public and protecting the planet. Industrial flow control equipment is critical to many industries, most notably oil and gas; chemical;

national defense; construction; power generation (traditional and new energy sources); mining; pharmaceutical; pulp and paper; water and wastewater; semi-conductor production; construction and data centers; transportation; food and beverage and many others. These industries are found in every state and globally. Because of the breadth of the industry, there must be consistency among all 50 states and the federal government when CUU determinations and approaches to these determinations are made.

The Flow Control Coalition appreciates the opportunity to submit these comments. For further information or to discuss these comments, please contact:

RE: Request for Comment on PFAS in Products Currently Unavoidable Use Rule

Commissioner Kessler,

Medical Alley and our network of more than 800 partners represent one of the most diverse and influential healthcare communities in the world. We are a critical partner and connection point between companies, talent, and the broader Medical Alley community, which employs more than half a million Minnesotans.

We are responding to the Minnesota Pollution Control Agency's Request for Comment on the PFAS in Products Currently Unavoidable Use Rule.

Under the Products Containing PFAS statute, the term "currently unavoidable use" appears four times – once under Subdivision 1(j) for definitional purposes and three times under Subdivision 5(c) for enforcement purposes.

Subdivision 8(b) states:

> Subdivisions 4 and 5 do not apply to a prosthetic or orthotic device or to any product that is a medical device or drug or that is otherwise used in a medical setting or in medical applications regulated by the United States Food and Drug Administration.

Medical Alley interprets this rulemaking to exclude medical devices, medical drugs, medical products, orthotic devices, or prosthetic devices, pursuant to the language under Subdivision 8(b), which includes the materials necessary to manufacture the aforementioned products. Medical Alley supports this exclusion.

Please reach out to Medical Alley Senior Director of Policy and Advocacy Peter Glessing (PGlessing@medicalalley.org) with any questions.

Sincerely,

Roberta Antoine Dressen
President/CEO Medical Alley

Re: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Dear Commissioner Kessler,

On behalf of the Association of Home Appliance Manufacturers (AHAM), I would like to provide our recommendations regarding the rules governing currently unavoidable use determinations for products containing PFAS.

AHAM represents manufacturers of major, portable and floor care home appliances, and suppliers to the industry. Nowadays, American families are spending even more time in their homes, and they need to help ensure that their home is safe, sanitary, able to prepare and preserve food, and that they have access to clean water. Our industry believes that home appliances, whether it is a major, portable or a floor care appliance, are essential to everyday life, adding a life enhancing benefit and keeping people healthy and nourished. These benefits allow people to focus on family time, spend additional hours on work, and gain hours back into the day. The comments below cover all major, portable, and floor care appliances.

AHAM's members produce hundreds of millions of products each year. They design and build products at the highest levels of quality and safety. As such, they have demonstrated their commitment to strong internal safety design, monitoring, and evaluation/failure analysis systems. AHAM supports the intent to protect consumers against all unreasonable risks, including those associated with the exposure to potentially harmful chemicals. AHAM also firmly supports the appropriate use of PFAS chemicals in appliances. Together with industry design practices, test requirements, and redundant safety mechanisms, PFAS chemicals play an important role in the safety of household appliances.

AHAM conducted a member survey in a good faith effort to determine the extent to which PFAS is used in home appliances and the estimated time needed to phase out PFAS in those use cases. To the best of AHAM members' knowledge, appliances contain PFAS chemicals but in low amounts. PFAS are used for their self-lubricating properties and great resistance to high temperature, chemical aggression, and pressure. In the table below is detailed information about applications of specific PFAS chemicals found in appliances. It is important to note that they are often confined to internal components and parts, such as bolts, washers and gaskets, plastic brackets, and wire terminals. This material is added during the manufacturing process, which reduces the potential for any consumer exposure during use or transmission to the environment.

Examples of PFAS Applications in Home Appliances

Applications	Parts containing PFAS	PFAS	PFAS properties
Parts	Insulation on cables, wires, connectors, etc.	PTFE, PFA, FEP, PVDF	Electrical insulation, heat resistance, flame retardancy
	Rubber seals, gaskets	PVDF, PTFE	Heat resistance, chemical resistance, gas barrier
	Gears, ball bearings	PTFE, PVDF	lubrication, heat resistance
	Interior coatings of cookware	PTFE	Corrosion resistance, heat resistance, self-lubricating
	Flame retardants of plastic parts	PTFE, KFBS	Flame retardancy
Battery materials	Binder of Lithium-ion batteries, gaskets	PVDF	Heat resistance, chemical resistance, gas barrier
Chemicals	Refrigerant for Refrigerators, air conditioner, chillers, Foam Blowing agents	Hydrofluoroolefins (HFO/HCFO's)	Refrigerant, cooling
	Greases, lubricants	PTFE, PFPE[1]	Lubrication, chemical resistance, gas barrier

In addition, a number of AHAM member respondents also indicated limited testing solutions are currently available, making it challenging to identify and discriminate different PFAS and determine concentrations. As such, AHAM member respondents stated it is not easy to find laboratories capable and willing to test and/or verify the absence/presence of PFAS, and such testing could be prohibitively expensive and may require several repeat tests for accuracy. Manufacturers rely on accurate information from their suppliers. As a result, regulators should consider these challenges in currently unavoidable use determinations.

AHAM urges the State of Minnesota to take a more robust and complete approach for assessing alternatives, which considers overall safety, performance, innovation, and sustainability factors. Proposals to regulate PFAS should be narrowed to consider the level of use within appliances, and whether the chemicals are accessible to the user. Therefore, a universal PFAS restriction in appliance in such a short period would not be feasible and PFAS applications to internal

[1] PTFE: Polytetrafluoroethylene, PFA: Perfluoroalkyl polymer, FEP: Fluorinated ethylene propylene, PVDF: Polyvinylidene fluoride, PFPE: Perfluoropolyether, KFBS: Nonafluorobutanesulfonates

components of appliances should be separated from potential risks of any consumer exposure during use.

Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Yes- In 2021, the State of Maine became the first state to enact a comprehensive PFAS ban[2], and the Maine Department of Environmental Protection is currently undergoing rulemaking around Currently Unavoidable Uses. In their submission requirements, the Department of Environmental Protection has requested how PFAS is essential for health, safety, or functioning of society. By establishing this definition, manufacturers and suppliers can provide real life examples of how PFAS is essential to human health and the environment. Some specific uses of PFAS's would be considered essential because they provide vital functions as established by federal law and are currently without established alternatives that provide the same fire and heat suppression needed for safety reasons. For example, refrigerant gases play a crucial role in maintaining the comfort and convenience we enjoy in our day-to-day lives in food preservation from our home to our favorite restaurant. These PFAS have been mandated into federal law based on their less global warming potential and to their necessity to society in achieving environmental objectives, including the mitigation of climate change.

More generally, the concept of "essential" must be interpreted broadly to be workable. Under a narrow definition, refrigeration would not be essential since society can theoretically continue to function without these refrigeration products. However, this narrow interpretation ignores the critical role that refrigeration plays in supporting good health by preventing food spoilage and preserving pharmaceuticals.

Maine defines "Essential for Health, Safety or the Functioning of Society,"

> Means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or **significantly interrupt the daily functions on which society relies**. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations. Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction.

---

2 An Act To Stop Perfluoroalkyl and Polyfluoroalkyl Substances Pollution
https://www.mainelegislature.org/legis/bills/display_ps.asp?ld=1503&PID=1456&snum=130

Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Yes- It is expected that these PFAS prohibition requirements will result in additional costs to manufacturers, sellers, and distributors of priority consumer products containing PFAS chemicals in Minnesota. Transitioning to alternatives could have a different price for each appliance as one manufacturer may use one alternative while other manufacturers may use alternatives to meet specific product requirements. Considerations around the availability of the alternative should include a.) what is the approximate cost and availability of other materials that may be required for use of the potential alternatives including required product design changes, b.) what will be the approximate costs and supply chain implications for redesigning the product, including product testing and recertification, and c.) how long would it take a manufacturer to transition.

The costs would occur because manufacturers would have to reorient their production and investment patterns, and some would have to integrate or develop new chemistries, redesign, or reformulate the product, and recertify new products to meet safety standards, performance requirements, and aesthetic preferences. Such complex recertification and re-qualification procedures are very time-consuming, both because of the lack of testing bodies and their technical complexity. Ceasing production of their already third-party safety certified product would be the only option if there are no viable and non-burdensome alternatives. These cost and access considerations could have a dramatic effect for Minnesota consumers.

Another important thing to consider in this prohibition are older service parts that are no longer in serial production. Manufacturers and suppliers should not be forced to retool/redesign obsolete parts that are used to service appliances. There should be determinations made around older service parts.

What criteria should be used to determine the safety of potential PFAS alternatives?

Electronics are certified to end-product safety standards. The National Electrical Code requires all electrical products to be listed which requires certification to the appropriate safety standard. If the revised products meet the Minnesota requirements but do not meet the safety requirements required for certification and listing, then these appliances will not be approved for use in the State of Minnesota. The reality is that the use of potential substitutes could significantly deteriorate the quality, safety, and durability of the products. If regrettable substitutes were used, there would be increased safety risks, including the danger of flammability with many products.

Federal regulations should also be considered. For example, in 2020 the American Innovation and Manufacturing (AIM) Act was signed into law which authorizes the Environmental Protection Agency to address hydrofluorocarbons (HFCs) by providing new authorities in three main areas: to phase down the production and consumption of listed HFCs, manage these HFCs and their substitutes, and facilitate the transition to next-generation technologies through sector-based restrictions. A new alternative refrigerant with lower global warming potential would be considered a PFAS under this law and would have to be removed under the law. Further information below on HFO's.

Ultimately, switching to PFAS-free materials is critical in terms of effort and cost. However, in some cases there are not technically available alternatives to date. Therefore, all PFAS laws should include methods to apply for exemptions for critical uses. We appreciate this rulemaking process. New critical use cases may occur in the future as we receive information from suppliers and PFAS testing methods change/improve, so there should be an open-ended application process for exemptions to cover future discoveries.

Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Yes- AHAM supports the MPCA proposing initial CUU determinations as part of the rulemaking process. This will help create greater market certainty and ensure more of the products Minnesotans rely on for daily life can remain accessible. Even for prohibitions many years away, manufacturers are already working through their global supplies to find alternatives. It is critical for the MPCA to offer exemptions to spur the search for alternatives. A manufacturer of an appliance may have upwards of 5,000 suppliers for potentially 100,000 components across product lines. Also, there may not be sufficient third-party certification companies available to provide these required recertification services in a timely manner. Once an alternative is found, manufacturers have expected 3-5 years to switch over to new parts as quality and products often require recertification and re-qualification procedures which are very time-consuming and can take several years. We would request that MPCA initiate initial CUU determinations in the next stages of the rulemaking process.

In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why.

Below are several requests for Currently Unavoidable Use Determinations:

Hydrofluroolefins (HFO's)/Hydrochlorofluoroolefins (HCFO)

HTS Code- SOLSTICE LBA 290379

As mentioned earlier, under this prohibition, hydrofluroolefins (HFO's) and hyrdochlorofluoroolefins (HCFO's) would be included. This includes an environmentally friendly foam blowing agents that are used in refrigeration and environmentally friendly refrigerants used in air conditioning. HFO/HCFO's are also essential as lubricants and anti-drip agents. These specialized gases are an integral part of various cooling systems, including refrigerators, air conditioners, and heat pumps. Refrigerant gases play a crucial role in maintaining the comfort and convenience we enjoy in our day-to-day lives. It is important for MPCA to work with stakeholders when the requirements could conflict with federal law (AIM Act[3]) which authorizes EPA to

[3] "American Innovation and Manufacturing Act of 2020" https://uscode.house.gov/view.xhtml?req=granuleid:USC-prelim-title42-section7675(a)&num=0&edition=prelim

facilitate the next generation of foam blowing agents, which are captured under the statutory definition, to combat climate change. The Department of Defense recently identified refrigeration, air conditioning, cooling, and electronics thermal control as a mission critical application in their recent report on the Critical Uses of PFAS report.[4]

HCFOs are ultra-low Global warming, climate friendly alternatives for use as refrigerator insulation foam blowing agents. Other states have also acted to ban HFC use, and the U.S. Environmental Protection Agency (EPA) encouraged and effectively drove a transition to these and other low global warming potential (GWP) refrigerants through ozone depletion and climate focused phase-out's of CFC's, HCFC's, and HFC compounds. This HCFO chemical was approved under EPA's Significant New Alternatives Policy (SNAP) program, which included an environmental review. EPA's new definition functionally excludes foam blowing agents and refrigerants from the definition. By deeming HFO blowing agents "acceptable," EPA has determined that HCFO and foam blowing agents "reduce overall risk to human health and the environment compared to other substitutes for the particular end-use."[5] These newer refrigerants have a lower impact on the ozone layer, reducing the potential for ozone depletion and contributing the energy efficiency and sustainability. Additionally, they have lower global warming potential (GWP) compared to their predecessors, making them less harmful to the Earth's climate. Prohibition or restriction of HCFOs would require a total re-design of models and retooling of entire appliance manufacture facilities at significant cost. MPCA should consider a definition of PFAS in accordance with EPA's definition, as established under Toxic Substances Control Act (TSCA)[6]. AHAM proposes that HFOs and HCFOs be identified as Currently Unavoidable Use.

PFAS found in Electronic Components/Wiring and Cables

PFAS are often used throughout the appliance industry at different points within the supply chain. Electronic components like transformers, relays, connectors, buzzers, semiconductors, encoders, printed circuit boards, switches, NTC sensors, capacitors often contain PFAS. PFAS in these components offer a number of key properties, such as flame retardancy, chemical inertness, and dielectric strength, which make them desirable for applications in electronic products because these typically involve high temperatures and voltages. It has been noted by industry that for existing designs, PFAS cannot be easily substituted in printed circuit/wiring boards without a complete redesign of the equipment (including the mechanical dimensions of the product) thus it is difficult to substitute PFAS for spare parts. Importantly, most of these uses are internal to the product where the consumer would not come into contact with PFAS.

Another electronic product category is wiring and cables. Many household electrical appliances have a cable for the power supply. Cable sheaths must be resistant to flying sparks so that they are

---

[4] Department of Defense "Report on Critical Per- and Polyfluoroalkyl Substance (PFAS) Uses" https://www.acq.osd.mil/eie/eer/ecc/pfas/docs/reports/Report-on-Critical-PFAS-Substance-Uses.pdf, p.14

[5] https://19january2017snapshot.epa.gov/snap/overview-snap_.html

[6] https://www.epa.gov/assessing-and-managing-chemicals-under-tsca/risk-management-and-polyfluoroalkyl-substances-pfas#:~:text=Overview%20of%20PFAS%20Actions%20under,fighting%20foams%2C%20and%20wire%20insulation.

not set on fire. The insulating layer around the outside of each wire or cable can be made from a variety of plastic or rubber materials and are often made from fluoropolymers due to their resistance to heat and fire, corrosion, moisture, and cracking. Due to lack of potential alternatives and threat to consumer safety, we would request a determination around electronic components found internally, not in contact with human touch.

Cookware

The law also establishes prohibition on cookware with intentionally added PFAS within Minnesota by 2025. This is the first in the nation prohibition of PFAS in cookware which includes durable houseware items that are used to prepare, dispense, or store food. With this comes a very short timeline, January 1, 2025, where time is of the essence when retailers need months in advance to get products on shelves. Although this is not part of the rulemaking process, we do want to ensure compliance with the law is clear and feasible. Two states- California[7] and Colorado[8] have instituted cookware labeling requirements, but no state has enacted an outright prohibition. Under Minnesota law:

> "Cookware" means durable houseware items used to prepare, dispense, or store food, foodstuffs, or beverages. Cookware includes but is not limited to pots, pans, skillets, grills, baking sheets, baking molds, trays, bowls, and cooking utensils.

Regarding appliances, these products are very complex products with wirings, circuit boards, & many internal components. The products in the 2025 prohibition involve products (cosmetics, dental floss, ski wax) that have direct human contact and most of them are simple, single-material products including pots and & pans under the cookware definition unlike appliances which have hundreds of components with internal electrical components that are inaccessible to human touch. We understand the need to address PFAS released from landfills, but major appliances are recycled at a high rate and at end of life often take on new value as an important manufacturing raw material, including scrap steel. In major appliances, ferrous material can account for 40 to 60 percent of the product's total weight. For smaller portable appliances, there have been studies around recent waste characterization in several states and the quantities of appliance related materials found in the waste stream during the course of these studies and it ranged from as low as 0.11 percent in Maine to 2.49 percent in Michigan.[9] Specifically to Minnesota which has the first in the nation to have an electronics take-back law, there is data to show that appliances are recycled appropriately. According to MPCA data, electronics were only at 1.2% of waste steam.[10]

With the "includes but not limited to" language, it opens the door to unclear product scope. In the deliberation around the California law, an amendment was adopted that removed "but is not limited to" language so that cookware is only the items listed in the bill. Minnesota should work with other

---

8 https://leg.colorado.gov/bills/hb22-1345

9 Analysis of Appliance Recycling in the U.S. and Canada Portable and Floor Care Appliances, Burns & McDonnell, 2017.

10 https://www.pca.state.mn.us/sites/default/files/w-sw1-60.pdf

states to clarify and harmonize the cookware definition to include only products that meet all the following criteria: contain intentionally added PFAS; intended for cooking because the product is "cookware;" and only surfaces that are in contact with food during the cooking process. With a very tight timeline for this cookware prohibition, manufacturers are still working to understand the law to ensure full compliance because products are sold to a national marketplace providing economies of scale resulting in lower costs and more product availability to consumers. Ultimately, any prohibition requires redesign and potentially pulling items off shelves which could lead to less consumer choice and consumers potentially going to neighboring states to buy cookware products. **We would request enforcement discretion for cookware products with internal electronic components containing PFAS because these components are not in contact with human touch and are necessary for safety and/or fire suppression.**

Fluoropolymers

HTS Code- HTS 3904.61 & 3904.69

Another category that falls under the current definition of PFAS used in the home appliance industry is fluoropolymers. Fluoropolymers includes but is not limited to PVDF, FEP, PFA, PTFE, etc. They are used because of their specific and critical properties applied to electrical, and mechanical components, such as washers, plastic brackets, pipes, flexible connections, filters, wire terminals and insulations, lithium-ion batteries, gaskets, gears, packings, bearings, and lubricants. Fluoropolymers are used due to their unique combination of self-lubricating, resistance to high temperature, resistance to high pressure, durability, resistance to abrasion, and resistance to friction. Unlike non-polymeric PFAS, which are mobile, can bioaccumulate, and can have toxicity concerns, fluoropolymers have not been demonstrated to have negative health concerns and are a material of choice for sensitive applications such as medical devices. It is important to note that there is no guarantee that alternatives can be found that will not compromise the high performance, durability, and functionality of household appliances and the continuity of supply for spare parts.

Below are tables to illustrate that fluoropolymers are in most appliances to provide sealing & insulation as well as used for specific parts in contact with food such as high-performance pipes, and connections.

Product	GPC Code
Wine Chillers	10001939
Ovens	10001950
Microwave Ovens	10001952
Dishwashers	10001964
Range Cookers/Stoves	10003690
Refrigerators	10003694

Product	HTC Code
Food Processors	85094000
Water Kettle	85161080
Electric Oven	85166090
Coffee Makers	85167100

Toaster	85167200

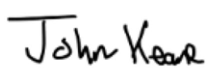
Specifically, regarding coffee makers, PFAS substances only come into contact with food/water for a short time. The use of PFAS in greases in the food and drinking water sector, such as water taps, ceramic valves, are there to decrease friction and wear. Of note, these greases meet the performance requirements of several regulatory standards for drinking water contact, including UBA guidelines, NSF/ANSI 61, ACS, and Water Regulation Advisory Scheme (BS6920:2000).

One of the example fluoropolymers that is used as material in contact with food is Polytetrafluoroethylene (PTFE). Manufacturers use coatings that have a small amount of PTFE for water, scratch resistance, heat resistance, with a good flexibility in manufacturing stage, as well as a long-life durability in use. PTFE pipes for hot water are used because of their unique combined resistance to high pressure, high temperature and high durability under these conditions. Manufacturers and suppliers have reported no feasible substitutes for these coatings.

All these fluoropolymers mentioned here are used to fulfill not only the specific feature needed by the use, but also the electrical and flammability requirements of the product, as well as to maintain the long durability of these parts that reduce the wasting of the product itself. Ultimately, the impact of restriction could potentially lead to significant increases in manufacturing costs which raise costs on consumers.

Thank you for considering our views on this rulemaking and please contact me at jkeane@aham.org or 202-872-5955 if you would like to discuss this in more detail.

Respectfully submitted,



John Keane
Manager of Government Relations

AHAM represents manufacturers of major, portable and floor care home appliances, and suppliers to the industry. AHAM's membership includes over 150 companies throughout the world. In Minnesota, the home appliance industry is a significant and critical segment of the economy. The total economic impact of the home appliance industry to Minnesota is $3.6 billion, more than 20,000 direct and indirect jobs, $468.5 million in state tax revenue, and more than $1.2 billion in wages. The home appliance industry, through its products and innovation, is essential to U.S. consumer lifestyle, health, safety, and convenience. Through its technology, employees and productivity, the industry contributes significantly to U.S. jobs and economic security. Home appliances also are a success story in terms of energy efficiency and environmental protection. New appliances often represent the most effective choice a consumer can make to reduce home energy use and costs.

Submitted via e-Comments as Requested to:
https://minnesotaoah.granicusideas.com
Attention: Minnesota Pollution Control Agency
PFAS Currently Unavoidable Uses Pursuant to §116.943, subdivision 5(c)
Revisor's ID number R-4837

Re: Planned New Rules Governing Currently Unavoidable Use (CUU)

FUJIFILM Holdings America Corporation (FUJIFILM) is a global conglomerate comprised of more than 20 affiliate companies spanning across a broad spectrum of industries including medical and life sciences, semiconductor, electronic, chemical, graphic arts, information systems, motion picture, broadcast and photography. Our relentless pursuit of innovation is focused on providing social value and enhancing the lives of people worldwide.

We submit these comments in response to the Minnesota Pollution Control Agency's (MPCA) solicitation of proposals for currently unavoidable use (CUU) determinations pursuant to Minnesota Statutes §116.943, subdivision 5(c)("Amara's Law") regulating the use of perfluoroalkyl and polyfluoroalkyl substances (PFAS) in products.

To avoid significant adverse socio-economic impacts on Minnesota's economy and the quality of life of Minnesota residents, FUJIFILM requests that MPCA craft a broad CUU exemption that exempts from the 2032 PFAS restriction all uses of PFAS in all materials and processes in the industrial product value chain, including when present in end products. Industrial products that should be considered for exemption include but not limited to:

- **Gas Separation Membranes**
- **Magnetic Tape**
- **Membrane Filters for Microfiltration**
- **Microfilm**
- **Industrial X-Ray Film**
- **Pressure Measurement Film**
- **Medical X-Ray Film**

Industrial Uses of PFAS: Critical Applications Throughout the Supply Chain

1. **Gas Separation Membranes (Apura™):**
    - Enhance natural gas processing efficiency and environmental sustainability.
    - Reduce CO2 emissions by up to 60% compared to traditional methods.
    - Enable carbon capture and storage (CCS) and enhanced oil recovery (EOR) programs.
2. **Magnetic Tape:**
    - Offer reliable, affordable, and sustainable long-term data storage (over 50 years).
    - Reduce e-waste by 80% compared to hard disk drives.
    - Enhance data security with air gap protection against cyberattacks.

3. **Membrane Filters for Microfiltration:**
   - Facilitate the purification of various liquids, including water, beverages, and pharmaceuticals.
   - Contribute to public health and product quality by removing harmful elements.
   - Play a crucial role in diverse industries like electronics and pharmaceuticals.
4. **Microfilm:**
   - Provide a secure and long-lasting (500-year shelf life) archiving solution for invaluable records.
   - Eliminate the need for data migration and ensure future accessibility without reliance on electricity or computers.
   - Contribute to environmental sustainability by reducing e-waste and carbon emissions.
5. **Non-destructive Testing (NDT) using Industrial X-Ray Film:**
   - Ensure the quality and safety of various products across industries.
   - Play a crucial role in advanced manufacturing and cost-saving practices.
   - Offer high reliability, versatility, and permanent information records.
6. **Pressure Measurement Film (Prescale™):**
   - Revolutionize pressure analysis by visualizing pressure distribution for diverse applications.
   - Improve process optimization, quality control, and efficiency in various industries.
   - Reduce material waste, prolong tool life, and ultimately yield higher quality products.
7. **Medical X-Ray Film:**
   - Crucial diagnostic tool in healthcare, facilitating the visualization of internal structures for the identification and assessment of various medical conditions.
   - Non-invasive nature and ability to capture detailed images contribute to accurate and timely diagnoses, supporting effective patient care.
   - The affordability and accessibility of X-Ray Film continue to make it an indispensable resource, ensuring widespread availability and contributing significantly to healthcare delivery in diverse communities.

Shared Commitment to PFAS Alternatives

FUJIFILM has invested significantly in identifying and implementing PFAS alternatives across our supply chain. Given the unique properties, our extensive research and development efforts have yet to identify a suitable alternative that replicates the critical performance characteristics essential for the above-listed industrial products. Should a feasible alternative become available in the short or medium term, we will require extensive lead time extending beyond the 2032 deadline to redesign and revalidate the materials, equipment and production processes.

FUJIFILM respectfully requests that MPCA consider the unique use cases presented above in developing a general exemption for PFAS used in the listed products. We remain committed to finding a suitable alternative and will readily adopt it once available. While actively seeking alternatives, we require a flexible approach to the 2032 deadline to ensure a responsible transition without compromising product performance.

We appreciate the opportunity to contribute to the discussion surrounding MPCA's planned rulemakings. If you have any questions or would like to discuss our position, please contact Nichol Robinson by phone at 312-924-5829 or by email at nrobinson@fujifilm.com.

Sincerely,

Nichol J. Robinson
EHS Manager, Regulatory and Product Compliance

Letter of Support

IDEXX Laboratories Inc. stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.

In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Maine and Minnesota. This proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders. By engaging experts from various industries, Claigan Environmental has adopted a collaborative approach to address this complex issue.

IDEXX Laboratories Inc. actively participated in the consultation process and supports Claigan Environmental's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

Re: MPCA Request for Comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

These comments are submitted by Hussmann Corporation in response to the Minnesota Pollution Control Act (MPCA) request for comment regarding PFAS and Currently Unavoidable Use.

Hussmann, a North American leader in providing display merchandisers, refrigeration systems, installation and service to food retailers around the world would first like to thank MPCA staff for providing stakeholders an opportunity to comment on PFAS and CUU. Hussmann, a member of AHRI, has worked diligently throughout the development of state and federal PFA proposals to better understand the impact on HVACR equipment.

Hussmann supports MPCA's efforts to reduce harm to human health and the environment. However we also recognize the unique challenges to manufacturing associated with the PFAS family of over 12,000 unique chemicals. For our commercial refrigeration regulated product even simple chemical substitutions can take years and cost millions of dollars. The chemical substitution process requires identifying chemicals in a complex, global supply chain, trying to find an alternative (if one is available), and then initiating the complicated, time-consuming, and expensive process of product redesign. Product redesigns include research, development, testing, and implementation which is a lengthy process of several years as this equipment is subject to mandatory testing (e.g., for energy efficiency, safety, earthquake, and food safety etc.) for even a single chemical change. It has taken nearly 18 months to work with our supply chain to search for any occurrence of phenyl isopropylated phosphate (PIP) (3:1).

For these reasons, we urge MPCA to consider not only human health and the environment but also business continuity and survival when proposing new burdensome or potentially unachievable mandates. Government and industry must work together to develop deliberate, effective, thoughtful, and reasonable approaches to PFAS management.

Hussmann supports comments submitted by AHRI. These Hussmann comments in this letter are intended to address only commercial refrigeration equipment applications and provide additional detail and clarity to the AHRI comments.

Hussmann Supports the AHRI Recommendation to Establish HVACR-WH Products as a Category of Currently Unavoidable Uses

In their comments AHRI proposes that MPCA establish a category for "HVACR-WH" which includes heating (including space heating), ventilation, air conditioning, refrigeration (items such as but not all inclusive to display cases, racks, condensing units, evaporative unit coolers, chillers), and water heating equipment and their components and parts including replacement parts, refrigerants, and materials and servicing needs.

Brief Description of the Type of Product – Refrigeration Equipment

Brief Description of Refrigeration Equipment - Typical Product Lines:

"Refrigeration Equipment" [1]

- Refrigeration Equipment products generally include manufactured items such as freezers (commercial, residential, and laboratory/medical), refrigerators, warehouse refrigeration (large storage), coolers, walk-in coolers, walk-in freezers (restaurants, retail food stores), reach-in refrigeration, cold rooms, refrigerated vending machines and icemakers, heat transfer products (including evaporative open towers), and evaporative, adiabatic, and dry coolers and condensers, thermal energy storage units, evaporators and their controls, refrigeration racks, refrigerated cases and merchandizers, prep equipment, condensing units, air cooled condensers, unit coolers, self-contained refrigeration, ice machines, dispensing equipment, blast chillers, mobile/transport refrigeration, refrigeration racks (Low, Medium and High Temp), blast chillers, coolers, and freezers, self-contained cases and merchandizers and similar products
- Replacement Parts generally include manufactured items such as compressors and fans, electric motors, batteries, and parts thereof, original equipment manufacturer (OEM) parts including fans, motors, drive systems, heat exchangers, structural and non-structural framing and panels, compressor parts, filters, valves, seals, gaskets, compressors, thermal expansion valves, heat exchangers, fans and blowers, motors, and similar products.

- Most existing systems use an HFC (or HCFC) refrigerant with lifetimes of up to 25-30 years. This equipment must be serviced and maintained and there are currently no available non-HFC alternatives.
- HVACR Servicing Needs Equipment generally include manufactured items such as vacuum pumps, gage manifolds, refrigerant service cylinders, and similar products.

Refrigeration product is an essential need and critical for the proper preservation of perishable food product, vaccines, medicine, blood plasma, and more. As mentioned earlier refrigeration is a heavily regulated product. And while meeting increasing environmental (Environment Protection Agency AIM as an example) and energy conservation efficiencies (Department of Energy EPCA - Energy Policy and Conservation Act) our industry continues to face challenges in the supply chain, leading to long lead times for many products. Additional burdens and disruption to the supply chain by obsoleting materials is catastrophic to our industry.

Hussmann Corporation, either individually or as part of AHRI, is available to answer any additional questions you may have about refrigeration products. Please feel free to reach out to me directly if you have any questions.

Sincerely,

Ron Shebik

IDEXX Laboratories Inc. Response to Request for Comments on: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Thank you for the opportunity to provide feedback on the planned new rules government currently unavoidable use products.

By way of background, IDEXX manufactures human, animal (pet and livestock), dairy, and water diagnostic products, including complex electronic instruments primarily in Maine. Our products test for, among other things, infectious diseases that can be zoonotic (spreadable from animals to humans, such as SARS CoV2) or cause significant impact to the food supply (such as African Swine Fever and Mad Cow Disease). IDEXX's diagnostic products help enable the health and well-being of people, livestock, and pets, and help ensure the safety of milk and water, here in Minnesota, throughout the United States, and in more than 175 countries globally.

IDEXX offers not only diagnostic solutions to most of the animal production chain but also provides services that, for example, help animal producers manage vaccination more efficiently, reduce the use of antibiotics, re-introduce animals in herds after treatments, optimize reproduction cycles, and ensure early and definitive identification of highly contagious and life-threatening diseases that threaten human and animal populations.

Our focus on human and animal health diagnostic products allies us with the Program's environmental protection goals. Indeed, Reduction of harmful environmental contaminants is at the core of our business. However, it is crucial that that essential products such as IDEXX's remain available and of the same high quality and performance within IDEXX's heavily regulated marketplace. Accordingly, IDEXX submits the following information in support of a CUU designation for its products.

IDEXX requests a currently unavoidable use (CUU) designation for the following categories of products, each of which is essential for human and animal health and safety, as well as the functioning of society:

1. Diagnostic devices and equipment used in veterinary medicine. PFAS are used in the manufacture of such diagnostic devices and equipment, which are essential for the prevention, and detection of animal diseases, including zoonotic diseases, and are critical to the health of pets and livestock, the latter which could affect the supply of food and/or human health. If veterinary diagnostics were unavailable, there would be a significant increase in negative human and animal healthcare outcomes, as well as an inability to mitigate significant risks to human and animal health.

2. Diagnostic devices and equipment used in human medicine. PFAS are used in the manufacture of such diagnostic devices and equipment, which are essential for the prevention, detection, and treatment of disease in humans. If human diagnostics were unavailable, there would be a

significant increase in negative healthcare outcomes, as well as an inability to mitigate significant risks to human health.

3. Diagnostic devices and equipment used for water quality testing. PFAS are used in the manufacture of such diagnostic devices and equipment, which are essential for monitoring of clean potable water, wastewater, and recreational water. If water quality diagnostics were unavailable, there would be a significant increase in negative human and animal healthcare outcomes, as well as an inability to mitigate significant risks to human and animal health.

4. Manufacturing equipment that contains PFAS chemicals. PFAS are used in the manufacturing equipment and raw materials used to manufacture components of diagnostic devices and equipment and diagnostic devices and equipment itself, including (but not limited to) gaskets, O-rings, filters, membranes, tubes, inner layers of chemical reactors, primary packaging materials, tubes in analytical equipment, and tape used to build inert laboratory scale equipment. The manufacturing equipment necessary to make IDEXX's veterinary diagnostic, human diagnostic, and water quality testing products is essential because if unavailable, there would be a significant increase in negative human and animal healthcare outcomes, as well as an inability to mitigate significant risks to human and animal health.

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

IDEXX manufactures human, animal (pet and livestock), dairy, and water diagnostic products that, if unavailable, would result in significant impacts to the health of people, pets and livestock. The products we design and produce in Maine are exported to ~175 different countries and territories, including Minnesota.

Our products test for infectious diseases, including those that spread from animals to humans such as SARS coronavirus 2, and that endanger the food supply, such as African Swine Fever. Our diagnostic solutions help animal producers manage vaccination programs more efficiently and reduce the use of antibiotics.

Veterinarians and pet owners across Minnesota rely on IDEXX Companion Animal products to help our pets lead longer and fuller lives. The relationships IDEXX has with veterinary practices allow us to develop and advance the veterinary standard of care around the world.

IDEXX has a subsidiary company, OPTI Medical Systems that develops and provides human diagnostic products around the world. Our human diagnostics are used in emergency rooms and intensive care units in more than 100 countries to aid in critical care diagnoses. In early 2020, OPTI launched its OPTI® SARS-CoV-2 RT-PCR Covid test.

Our water testing products are relied on throughout Minnesota, including the Minnesota Departments of Health and Agriculture, water utilities of Minneapolis and St. Paul, and more than 500 local public health laboratories, water utilities and wastewater treatment plants across the state. Additionally, more than 2.5 billion people worldwide rely on our test to ensure safe drinking water. We offer solutions for drinking water, wastewater monitoring, and recreational water.

IDEXX products provide significant global support for veterinary care of animals that supply the global markets for food sources and help diagnose and control zoonotic diseases (diseases that can infect both animals and humans). IDEXX's inability to supply our products would result in significant global impacts. For example, transboundary animal diseases (TADs) that could result from the loss of IDEXX products cause livestock production losses (which may be very high if the disease in question spreads very rapidly, particularly if it causes high levels of mortality) and considerable disruption to trade, causing particular concern in countries where export is an important source of revenue for the livestock sector. The prevention and control of TADs add to the cost of livestock production and to the national veterinary budget. Zoonotic TADs (those that can infect humans and cause human disease) cause economic impacts from human sickness and costs to public health systems. Governments spend scarce resources controlling outbreaks of TADs and applying prevention measures, farmers must deal with the impacts in their livestock production systems, and consumers experience the effects of local or widespread market disruptions caused by TADs.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold? And 4) What criteria should be used to determine the safety of potential PFAS alternatives.

MPCA asks questions about the cost and safety aspect of alternatives. Alternatives should be evaluated on a cost/benefit basis. Often costs to determine if there are alternatives to existing product already can outweigh the socio-economic impacts. It is likely the threshold costs will vary considerably among industries and products. Veterinary medicines differ from human medicines in that there are generally no third-party payers in veterinary medicine, meaning the customer/animal owner bears the full cost of the product. Many of our products support disease eradication programs around the world. As such, disruption in animal testing for disease programs can have significant consequences to the health of people and animals on a global scale.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

IDEXX provides no comments on this matter.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

These critical diagnostic tests used to keep our pets, food and water safe are subject to stringent regulatory frameworks around the world, and in the US under the jurisdiction of the United States Food and Drug Administration and the United States Department of Agriculture pursuant to the federal Virus-Serum-Toxin Act, 21 U.S.C. § 151, et seq. Accordingly, our products and their components, including the use of PFAS within our products, cannot simply be switched out for products that do not contain PFAS. Instead, our products are subject to heavily regulated processes that involve years of research and development, regulatory review, and governmental approvals before they can reach market. As one example, the IDEXX diagnostic kit used to test for mad cow disease is written into EU laws. Those laws would need to be changed to change that diagnostic kit.

The length of time to change a regulated health product, either animal or human, needs to be measured in decades, as many of our products have long life cycles. Transitioning to alternatives requires research, followed by generation of data to support the change, followed by regulatory approved from the governing agency.

Our ability to identify PFAS in our diagnostic products is limited to currently available test methods or data provided by our suppliers. Current test methods are developed only in response to national regulations, such as the EPA and pending EU-wide requirements. This means that while Minnesota's legislation calls for identifying all of the more than 10,000 PFAS compounds, internationally recognized labs currently offer screening tests for only about 70 recognized compounds. International test methods are developed as a result of nationally regulated compounds, and it takes years to develop targeted methods that meet the regulations. The Minnesota legislation simply does not account for these practical limitations in PFAS testing capability.
We have invested in multiple systems and technology solutions to monitor regulated lists of chemicals, which includes systems that gather information from more than 100,000 global suppliers. Even still, IDEXX estimates that we have definitive information of PFAS use in only about 1% of our purchased materials. IDEXX buys more than 10,000 unique components or materials sourced from roughly 1,000 global suppliers used to manufacture IDEXX products. A single analyzer that tests for chemistry analytes in animal samples can contain more than 1,000 unique parts.

IDEXX is still investigating our complex supply chain and continue to gather details on use of PFAS in our products. Additionally, we have partnered with Claigan Environmental to better understand the use of PFAS in the electronics sector. Attached hereto as **Appendix A** is IDEXX's letter in support of the Claigan February 29, 2024, CUU submission ("Industry PFAS CUU Project PFAS Currently Unavoidable Uses (CUU) Submission by Industry"), which we incorporate herein by reference.

In conclusion, any human or veterinary diagnostics or water quality testing approved to restore or protect the health and welfare of animals and people and the processes used to produce the products should be considered as necessary for health and therefore considered a currently unavoidable use. This designation should include the entire manufacturing process and not only the final diagnostics. We therefore respectfully request to take this into account when publishing the rule.

Letter of Support

IDEXX Laboratories Inc. stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality and meeting stringent safety standards.

In line with our commitment to finding balanced solutions, Claigan Environmental has developed a comprehensive Currently Unavoidable Uses (CUU) proposal, which is being submitted to the states of Maine and Minnesota. This proposal is founded upon rigorous laboratory testing and incorporates valuable insights gathered from diverse stakeholders. By engaging experts from various industries, Claigan Environmental has adopted a collaborative approach to address this complex issue.

IDEXX Laboratories Inc. actively participated in the consultation process and supports Claigan Environmental's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS while mitigating adverse impacts on businesses, communities, and public health.

re: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per- and Polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Dear Ms. Kessler:

The Outdoor Power Equipment Institute (OPEI) writes on behalf of its members to provide stakeholder comments as MPCA considers new rules pertaining to the currently unavoidable uses of PFAS in products. OPEI strongly believes that MPCA consideration of all stakeholder views, especially when based on technical expertise, sound science, and data, is critical to MPCA's promulgation of this regulation.

The Outdoor Power Equipment Institute (OPEI) is an international trade association representing the manufacturers and their suppliers of non-road gasoline powered engines, personal transport & utility vehicles, golf cars and consumer and commercial outdoor power equipment (OPE). OPE includes lawnmowers, garden tractors, trimmers, edgers, chain saws, snow throwers, tillers, leaf blowers and other related products. OPEI member companies and their suppliers contribute approximately $18 billion to US GDP each year. OPEI members currently distribute their products across all 50 states, through a diversity of retail outlets including independent dealers.

OPEI members manufacture complex durable goods with tens of thousands of component parts. They share common supply chains, in both substance and complexity, with the heavy non-road equipment and automotive sectors. However, unlike those sectors, OPEI members include some small-to-medium size businesses

OPEI and its members understand and appreciate the regulatory consideration of the impacts of PFAS and its uses in society, which is currently occurring across government at the Federal, state and international levels. The following comments, recommendations and requests are contributions to the important process of considering stakeholder input, based on technical expertise and data, to assist in implementing Minnesota state law. We also hope that stakeholder input can assist across governments, to prevent the implementation of disparate regulations which place undue burdens on consumers, businesses, and government alike. The following is responsive to most of the questions posed by MPCA, and where noted OPEI aligns with the *attached* comments submitted by the Association of Equipment Manufacturers, filed with MPCA separately, which OPEI works with in representing shared members and industry sectors.

1. **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**

OPEI supports the comments of the Association of Equipment Manufacturers.

2. **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

OPEI supports the comments of the Association of Equipment Manufacturers.

3. **Should unique considerations be made for small businesses with regards to economic feasibility?**

OPEI supports the comments of the Association of Equipment Manufacturers.

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

OPEI supports the comments of the Association of Equipment Manufacturers.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

OPEI supports the comments of the Association of Equipment Manufacturers.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

OPEI supports the comments of the Association of Equipment Manufacturers.

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

OPEI represents 110 member manufacturers and their suppliers of outdoor power equipment. Our members manufacture and ship approximately 35 million products each year in the U.S., including hundreds of different product lines, and thousands of models. OPE is used in both residential (consumer) and commercial applications, including lawn and garden, construction, agriculture, forestry and tree care, and utility. OPE is powered by gasoline-, diesel-, and propane-powered engines, battery and AC (electric) powered motors, and other sources.

OPE includes the following significant assembled and component product categories:

- Power applications including non-road gasoline and diesel-powered engines, electric motors, batteries, battery packs, and recharge equipment;
- Non-road mobile machinery[1];
- Consumer and commercial lawn & garden equipment and outdoor power equipment (e.g., lawnmowers, garden tractors, trimmers, edgers, chain saws, snow throwers, tillers, leaf blowers, cut-off machines, drills, pressure washers);
- Utility terrain vehicles / all-terrain vehicles / side-by-sides;
- Golf cars, and;

[1] Any mobile machine, item of transportable industrial equipment, or vehicle with or without bodywork or wheels which: 1) is not intended for carrying passengers or goods on the road, 2) includes machinery installed on the chassis of vehicles intended for the transport of passengers or goods on the roads, 3) installed with a combustion engine – either an internal spark ignition (SI) engine, or a compression ignition diesel engine.

- Attachments and implements associated with the above equipment (i.e., mower decks, snow throwers, sprayers).

OPEI member products are broadly used by consumers and businesses across the state of Minnesota, for everyday residential and commercial purposes. In many applications, outdoor power equipment provides essential value and services for societal health and safety. Significant application sectors include:

Lawn and Garden:

Lawn mowers and other wheeled (ground-supported) turf care equipment, handheld products (e.g., trimmers, blowers) and other various forms of outdoor power equipment are essential for safe and healthy managed landscapes, whether it be the backyard or public spaces (e.g., parks, sports fields, commercial properties).

Also included in this broader residential sector, essential for health and safety, are generators for home power in the cases of undue outages, including natural disasters, and pressure washers for general home cleaning and maintenance.

Construction:

The construction sector involves building, repairing, and maintaining infrastructure, including housing, commercial real estate, and public infrastructure. Common OPE uses in these sectors, essential to commercial work, are generators, cut-off saws, and utility vehicles.

Agriculture:

The agricultural sector includes the cultivating of crops and the raising of livestock. Virtually all products manufactured by OPE members can be essential to commercial and residential farm operations, but examples include lawnmowers and turf care equipment, forestry and tree care OPE including chain saws, log splitters, and chipper shredders, utility vehicles, and generators.

Forestry/Tree Care:

The forestry and tree care sector includes commercial and residential applications, to manage forests and woodlands, and the backyard. Common OPE utilized in this sector includes chain saws, pole saws, log splitters, chipper shredders, generators, and utility vehicles.

Utility/Public Safety:

The utility sector includes the maintenance of public infrastructure, both in urban and rural settings, including operations for electric power, natural gas, water supply, and sewage among others. OPE utilized in this sector can include lawnmowers and other various forms of OPE for landscape management in public spaces and on public roadways, and various other maintenance, repair, safety related tasks. Also included here are public safety entities and emergency responders who rely on OPE.

OPEI members design and manufacture a diverse range of assembled whole-good and component products, ensuring their safety and performance in diverse operating environments, which in some cases can be demanding and severe. OPEI members also rely on extensive supply chains which in some cases can be 20 layers deep and include suppliers manufacturing both domestically and abroad. OPE products can also have 10,000 or more unique parts per product, many of which may rely on PFAS for critical functions and characteristics.

Some OPE products can expect prolonged service lives exceeding 10 years, which further increase the need for robust design considerations. To meet these requirements, OPE components rely in many cases on PFAS when they are the only known materials with the technical characteristics to provide the necessary safety functions while withstanding, particularly over extended lifetimes, the following types of physical impacts.

- Pressure up to 500 bar.
- Temperatures as high as 1500°F and cyclical temperatures of -70 to +450°F.
- A high degree of mechanical wear and shear forces.
- Electrical and flammability resistance.
- Vibration up to 45.0mm/s causing alternating stress between joint components.
- Chemical resistance to substances such as fuel, hydraulic fluid, coolant with additives like 2-ethyl hexanoic acid, and carboxylic acids, exhaust gas fumes (highly acidic) and engine oil (highly alkaline).
- Long-term durability (10 years or more) against factors such as ultra-violet (UV) light, mechanical damage, dusty, humid, wet, muddy, damp environments, and exposure to salt spray.
- Lightweight composition to ensure the energy consumption required to operate certain systems is minimized.
- Operation in hazardous or explosive environments.

OPE and its applications are diverse, always with unique considerations, but in consideration of currently unavoidable uses of PFAS, these substances provide important safety and performance characteristics to common components. Among others these include high temperature durability, low friction properties, resistance to sticking, resistance to corrosion, resistance to fuel, water repellency, electrical contact stability, waterproofing, binding characteristics, and evaporative emission protections. Specific OPE components, common to most products are:

- **Seals:** OPE uses fluids to ensure the equipment performs its intended functions. Fluid applications include hydraulic fluid, oil, fuel, refrigerants, coolant, among others. Sealing technology, such as O-rings and gaskets, prevents fluid leaks and ensures water, dirt, dust, and debris stays out of the equipment.

- **Hoses:** Similar to seals, hoses are required and critical to the transmission of fluids from one location to another. Many hoses in the OPE industry use fluoropolymers to safeguard the durability of the machine by protecting its components from various internal pressure, temperature, and chemical stressors.

- **Fluorinated fuel tanks:** Provide a chemical resistance and low permeation barrier that allow federal (EPA) emission standards[2] to be met. PFAS has been found to be an unintentional impurity in these products.

- **Paints:** These coatings protect OPE from natural, chemical, weather, or water erosion and damage. Paint coatings help extend the useful life, and maintenance requirements, for many forms of OPE. Many paint suppliers use PFAS in their paints to improve the flow, spread, and glossiness of the coating, as well as to decrease bubbling and peeling. They are also used in specialty paints to give stain-resistant, and water-repellent properties.

- **Refrigerants/Coolants:** Temperature management is a crucial product design requirement in the OPE industry. Regulating and controlling engine and product temperatures ensures proper operation for peak performance within the temperature limits of the materials used.

- **Hydraulic Fluid:** Hydraulic fluid enables the transfer of power from the engine to end-use hydraulic systems in some forms of OPE. Hydraulic fluid is also heavily used within our manufacturing facilities and is a critical element for functionality in building OPE.

- **Exterior Finishes and Materials:** UV protection is critical for parts and components such as dashboards, handlebar grips, fenders, seat covers, etc. PFAS acts in a way with these pieces, so that

[2] 40 C.F.R Part 1060, Control of Evaporative Emissions from New and In-Use Nonroad and Stationary Equipment

it protects from extended outdoor use and UV exposure by not severely degrading the exterior piece(s) by drying and/or cracking the piece(s) beyond normal wear and tear or safe functionality.

- **Electrical:** Protective coatings on electrical wires and within electrical systems insulate and protect key electronic functionalities for all OPE. PFAS is regularly found within these protective coatings.
- **Batteries:** Batteries utilize chemical binders to hold the internal active materials together to maintain a strong contact between the electrodes and the current collectors. Battery manufacturers use Polyvinylidene Fluoride (PVDF) as a binder in lithium-ion batteries due to its electrochemical and thermal stability, as well as its acceptable binding properties for the cathode. Additionally, certain fluorinated compounds are also used to coat the anodes to prevent unwanted reactions with the electrolyte. Due to their long lasting and chemical stable properties, the fluorinated compounds help extend the useful life of the battery.

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

OPEI supports the comments of the Association of Equipment Manufacturers.

Thank you for consideration of these comments on behalf of OPEI members. I can be contacted as detailed below.

Re: Planned New Rules Governing Current Unavoidable Use Determinations about Products Containing Per- and Polyfluoroalkyl Substances (PFAS)

Revisor's ID Number R-4837
OAH Docket No. 71-9003-39667

Dear Ms. Kessler:

The Association of Equipment Manufacturers (AEM) appreciates the opportunity to comment on the Minnesota Pollution Control Agency's (MPCA) request for comments on the *Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per- and Polyfluoroalkyl Substances (PFAS)*, hereafter referred to as the Planned Rule. We look forward to sharing the expertise and technical knowledge of our industry sectors. We believe it is critically important when developing regulations, that the interest of all stakeholders be considered and understood.

AEM is the North American-based international trade group representing off-road equipment manufacturers and suppliers with more than 1,000 member companies and over 200 product lines in the construction, agriculture, mining, forestry, and utility industries. The equipment manufacturing industry in the United States supports 2.8 million jobs and contributes roughly $288 billion to the economy every year. Our industries remain a critical part of the U.S. economy and represent 12 percent of all manufacturing jobs in the United States. Original Equipment Manufacturers (OEMs) develop and produce a multitude of technologies over a wide range of products, components, and systems that ensure off-road equipment remains safe and efficient, while at the same time reducing carbon emissions and environmental hazards. Finished products have a life cycle measured in decades and are designed for professional recycling of the entire product at the end of life.

The off-road equipment manufacturing industry understands the value and importance of using sound science to inform future policymaking decisions. AEM strives to be a key stakeholder in these policymaking discussions. To ensure that new rules meet their objectives, AEM intends to provide commentary on several MPCA questions listed in the Request for Comments document.

1. <u>Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?</u>

Minnesota statutes 116.943 states that:

> *Beginning January 1, 2032, a person may not sell, offer for sale, or distribute for sale in this state any product that contains intentionally added PFAS, unless the commissioner has determined by rule that the use of PFAS in the product is a*

> *currently unavoidable use. The commissioner may specify specific products or product categories for which the commissioner has determined the use of PFAS is a currently unavoidable use.*

The law goes on to grant the commissioner rulemaking authority to make determinations on what constitutes a *current unavoidable use*, and which products may receive an exemption from the requirements of the regulations.

In the request for comment, MPCA asked for feedback from interested stakeholders on whether the agency should define the term *essential for health, safety, or the functioning of society*, presumably to use this definition as a criterion for determining what does and does not constitute a *current unavoidable use*. Off-road OEMs manufacture a wide variety of complex product types that are sold around the world. The market and compliance requirements are growing in number and complexity in an ever-changing regulatory environment. To ensure that policymakers and effected industry stakeholders meet the overarching objectives of a law, AEM strongly believes that regulations should contain clear, understandable, and achievable compliance criteria for businesses and individuals to follow. This will reduce confusion, save time and money, and foster a better understanding between regulators and the regulated community.

The stated aim of the statute focuses on restricting products that contain intentionally added PFAS. However, the exemption standard utilizes a product function, the term *Current Unavoidable Use,* as the only qualifier. It is not clear what the term *use* means within the context of the larger rule. Is this a reference to the chemical's role in the manufacturing process, or the attributes it conveys to the end product? Or is the term *use* meant for the purpose and function of the product itself? To make sure all stakeholders understand the adopted language, it is important to define the term *Use* and understand how it ties into our product lines, before we define *essential for health, safety, or the functioning of society*. With this in mind, AEM supports a definition similar to the one found in the European Union's Registration, Evaluation, Authorization and Restriction of Chemicals (REACH) law, Article 3 (24) [1]:

> a *use* should refer to any processing, formulation, consumption, storage, keeping, treatment, filling into containers, transfer from one container to another, mixing, production of an article or any other utilization. Furthermore, this use must satisfy the need for the technical function provided by the chemical for a specific end use in a particular setting.

This definition provides clarity on the relationship between identified chemicals of concern and their relationship to the product. It also helps harmonize regulatory definitions in multiple jurisdictions around the world, easing the industry's overall compliance burdens.

With the concept of *use* fully defined, we can address the criteria for determining what products could meet the *essential for health, safety, or the functioning of society* threshold. This term should be divided into two different categories, (1) health and/or safety, and (2) the functioning of society.

(1) Is the *use* of the substance necessary for health and/or safety?
  a. Necessity should be assessed to demonstrating and verifying whether a use is necessary for the following elements:
    i. Preventing, monitoring or treating severe health issues
    ii. Sustaining basic conditions for human life and health

[1] https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=CELEX:32006R1907

iii. Managing and preventing health crises and/or emergencies
iv. Personal safety
v. Public safety
vi. Addressing a danger to animal health which cannot be contained by other means.

(2) Is the *use* of the substance critical for the functioning of society?
   a. Criticality should be assessed by demonstrating and verifying whether a use is critical for any of the following elements:
      i. Providing resources or services which are critical for society (Construction, Agriculture, utility, mining, forestry)
      ii. Managing societal risks and impacts from natural and man-made crises and emergencies.
      iii. Protecting and restoring the natural environment

The final criteria should assess potential alternatives.

(1) Are there alternatives that are acceptable from the standpoint of the environment and human health:
   a. Can alternatives for the specific use be identified?
   b. Are the alternatives safer, technically, and economically feasible, and available at scale?
   c. Do alternatives provide the level of performance which is sufficient from a society point of view?

Assuming the product meets these definitions, the product should receive an exemption from the MPCA. Otherwise, the product exclusions will start to have negative impacts on human health, public safety, and the functioning of society as a whole.

2. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

<u>Should Cost of PFAS alternatives be considered in the definition of "reasonably available"?</u>

As defined in the previous section on establishing criteria for determining *essential for health, safety, or the functioning of society*, economic feasibility is a major component of this consideration. If a product is deemed critical to the functioning of society, the PFAS *use* in that product will likely provide the technical functionality to achieve the identified critical end use. When alternatives either do not exist or are so expensive as to make their purchase unattainable, then cost must be considered when making these determinations, due to that fact cost would be the factor jeopardizing the availability of the product for use in the marketplace.

AEM member companies manufacture products that provide critical functions for our modern world. Off-road equipment grows and harvests food, provides emergency repairs to critical infrastructure, constructs buildings and homes, provides municipal waste processing, among many other critical ends uses. While the work provided by off-road equipment is critical, the machines that work them are heavy capital investments for equipment and fleet owners. For these owners, equipment is cost effective for the work they need to perform, but with change they will become more expensive and less cost effective. As these costs pass on to the customer, contractor, or municipality, the consequences will pass on to the public, which expects and needs the services these machines provide. For these reasons, AEM believes costs should be a consideration when considering the definition of "reasonably available".

Reasonable Cost Threshold:

When developing a reasonable cost threshold, it is important to note that the cost of the new material should not be the only consideration used in making this determination. The next section will define some of these concepts more fully, but for the OEM, the costs associated with identifying, testing, validating, and implementing a new material into a product redesign is an expensive, years long activity. These activities are done to make sure new parts and components meet critical performance, durability, safety, and quality requirements, and may dwarf the extra costs associated with a PFAS alternative.

Consequently, the costs associated with using potential PFAS alternatives extend far beyond the product manufacturer. New materials may require more frequent, and more expensive, maintenance costs. They may not provide the same level of durability, leading to a premature obsolescence of the machine and an increase in societal waste generation. Not to mention the added risks associated with using a new material in a very mature industry used to the safety benefits designed into their components and sub-systems. These later points may be difficult to fully quantify, but they have very real consequences in our industry.

Understanding that the cost associated with adopting new materials in complex industries, such as the off-road equipment sector, is not a simple cost differential between two different substances. The real-world costs are based on a series of complex manufacturing activities, knock-on effects through the value chain, and the customer use experience. AEM recommends that MPCA take these other variables into consideration when developing a reasonable cost thresholds.

3. Should unique considerations be made for small businesses with regards to economic feasibility?

The cost of compliance for chemical regulations is quite high for many industries based on a variety of factors. In particular, the off-road equipment industry has had very little expertise and history regarding the identification, collection and storage of data needed to comply with chemical management regulations. This educational issue, endemic throughout the supply chain, is compounded by the wider compliance environment many of these companies operate in. Smaller manufacturers of components often do not store chemicals above the reporting thresholds required under the EPA's CDR or SARA 313 reporting rules. As a result, many companies in our supply chains and industry-at-large never cultivated the systems or expertise needed to gather and store the relevant chemical data for the components and parts they manufacture and distribute. This means that almost all companies in our industry, and most off-chemical manufacturers in other industries, will need to develop the regulatory expertise and compliance systems from scratch. This undertaking will be immensely expensive for any manufacturer, and prohibitively so for small businesses.

Their task is made more difficult due to the CBI protections many bulk chemical manufacturers utilize to conceal the composition of their products, making downstream identification and reporting extremely challenging to accomplish. Additionally, International suppliers follow various global regulations which differ from U.S. mandated chemical reporting requirements, deepening the data collection obstacles faced by our supply chains. Absent a data reporting system adopted globally across our industry sectors that can track and monitor chemical substances throughout the supply chain, it remains an extraordinarily difficult task for a single OEM to know the chemical composition of the articles they currently market in the U.S.

To illustrate these challenges, some manufacturers possess supply chains that run twenty (20) layers deep, with tens of thousands of unique suppliers scattered throughout the world. Collecting data on the presence of PFAS across hundreds of thousands of individual parts from tens of thousands of different companies is a colossal task. The lack of a *de minimis* reporting threshold ensures that manufacturers will need to collect information for all their parts and components to determine the presence, or lack thereof, of PFAS. The effort and time necessary to coordinate, educate, discipline, and gather useful data throughout the supply chain is a daunting task that will take years to organize and execute.

In comments supplied to the EPA, AEM calculated that the cost of accurately identifying and reporting a single chemical for an OEM would cost over half a million dollars. This estimated cost assumes information provided to the OEM is accurate, complete, and delivered on time. It is also important to note that this estimate does not account for any potential redesign and replacement efforts for phasing the chemical out of use in an off-road machine. For a family of chemicals as large as PFAS, the costs will be an order of magnitude higher.

Assuming a company is looking to identify a single PFAS chemical throughout their product lines, and the industry does not experience any disruptions, obstacles, missing data, or dead ends on their path to gathering the required chemical data, it would take roughly 36 months, or 6240 working hours for a single worker per firm[2] to complete the data gathering process. Using the EPA's estimate of a Technical Professional's wage of $80.50/hour[3], that leads to a total cost of $502,320 per firm. With a supply chain of over 10,000 individual companies, that means the total cost of the data gathering effort for the off-road equipment industry is a minimum of $5 billion dollars in accumulated costs. See Table 1 below:

Table 1: Estimated Costs for Off-Road Equipment Industry to Comply with the Data Collection and Reporting Requirements for a Single Chemical Substance

	COST TO EQUIPMENT MANUFACTURING INDUSTRY
NUMBER OF AFFECT FIRMS	10,000
AVERAGE TIME BURDEN PER FIRM (HRS)	6240
TOTAL TIME BURDEN (HRS)	62,400,000
AVERAGE COST PER FIRM	$502,320
TOTAL COST TO INDUSTRY	$5 Billion

If data collection efforts from industry supply chains produce poor quality information, fail to report information downstream, or prove infeasible to execute, the industry will need to turn to laboratory testing for their parts and components. Due to the lack of a *de minimis* threshold, the product manufacturers will need to test each product down to the detection limit to demonstrate compliance with the Planned Rule. Off-road equipment may contain over 100,000 unique parts in a single product, making testing a time consuming and costly endeavor. Assuming every company in the supply chain only manufactures a single product, uses a GC scan at a cost of $1,000 per part, and receives completely accurate results, testing will cost each company roughly $100 million dollars. With over 10,000 firms, the total cost to the equipment manufacturing industry would be over $1 trillion dollars. Furthermore, testing would create additional constraints on industry, as available time and resources at viable testing laboratories would be overrun with industry PFAS testing requests. These testing bottle necks would extend the compliance timeframe out to well over a decade. Without regulatory relief, this effort would be infeasible to execute on an industry wide level. See cost assumptions for testing in Table 2 below:

[2] Many firms have teams of individuals performing this function, but for the sake of simplicity we will assume a single worker per firm.
[3] EPA (2020). Economic Analysis for the Proposed Rule for Reporting and Recordkeeping Requirements for PFAS. November 2020.

Table 2: Estimated Costs for the Off-Road Equipment Industry to Comply with the Data Collection and Reporting Requirements for a single chemical using Lab Testing of Articles

	COST TO EQUIPMENT MANUFACTURING INDUSTRY
NUMBER OF AFFECT FIRMS	10,000
AVERAGE NUMBER OF PARTS PER FIRM	100,000
TOTAL COST OF GC TEST PER PART	$1,000
AVERAGE COST PER FIRM	$100,000,000
TOTAL COST TO INDUSTRY	$1,000,000,000,000

In reality, the supply chain currently lacks the systems and education required to collect and transmit accurate and complete chemical data to the OEMs. Equipment manufacturers are currently seeing very low quality and inaccurate chemical data from their suppliers. To comply with the data requirements in the rule, most collection efforts will necessitate the use of laboratory testing. Meaning that the cost of compliance in the off-road equipment industry alone will be in the billions of dollars and take years to complete. In this environment, most manufacturers, but small entities in particular, will have an incredible challenge meeting the requirements of the rule. To help these companies survive, AEM suggests that MPCA introduce *de minimis* thresholds, a common universal reporting list of PFAS chemicals, alignment with EPA (and global) chemical rules, simplified reporting requirements, among other administrative changes to reduce the compliance burden.

4. What criteria should be used to determine the safety of potential PFAS alternatives?

When establishing criteria to determine the safety of potential PFAS alternatives it is important to consider an alternative substance under a wholistic approach. It is obvious that when looking at alternatives, policymakers should avoid chemicals that are more persistent, bioaccumulative, and toxic than the PFAS their intended to replace. However, one should also consider the wider safety, environmental, and human health repercussions that potential replacements of PFAS could cause. Generally speaking, policymakers should avoid replacement chemicals that exacerbating existing, or result in new, safety, environmental or health hazards, or eliminate the use of products critical to the functioning of society.

Essential Uses

Off-road equipment must meet highly demanding industry wide technical specifications due to the challenging environments in which these types of machines operate. Manufacturers design their products to operate for decades under extremely harsh, demanding, and arduous work environments. In these environments, materials, parts, and components need to meet rigorous design and testing requirements to ensure the safety of the operator and other workers on the jobsite.

The technical functions of the components and systems help inform the safety and operational design requirements of the machine. These technical characteristics include, but are not limited to, the following variables:

- Pressure - various systems, such as the hydraulic and engine systems, experience extreme pressure environments up to 500 bar.

- Temperature - the engine compartment, regenerative breaking components[4] and exhaust system operate at temperatures as high as 800°C.
    - Off-road equipment must also contend with cyclical temperature cycling due to machine exposure to outdoor conditions; temperatures ranging from as -57°C to 230°C.
- Mechanical – machines expose parts and components to a high degree of mechanical wear and tear. Sealing parts must survive the shear forces due to the mechanical movement of the equipment.
- Chemical resistance - seals interact with various fluids and gases, requiring a high degree of chemical and corrosion resistance to ensure the reliability of exposed parts.
    - Exposure to substances such as fuel, hydraulic fluid, coolant with additives like 2-ethyl hexanoic acid, and carboxylic acids, exhaust gas fumes (highly acidic) and engine oil (highly alkaline).
- Electrical and flammability resistance – the weight, power, and fuel of the machine creates electrical and flammability risks. Components, parts, and systems must include design elements to mitigate these risks.
- Vibration - up to 45.0 mm/s which can cause high frequency fatigue to components due to the repeated strain imposed. The mechanical alternating stress between joint components will make joints undergo cyclic tension and pressure, which may cause the generation, expansion, and extension of cracks.
- UV - Long-term durability against factors such as ultra-violet (UV) light due to exposure to outdoor environments.
- Material Weight – The use of lightweight materials to reduce energy consumption and CO_2 emissions.
- Hazardous Locations - Operation in hazardous or explosive environments requiring ATEX rating (the minimum safety requirements for workplaces and equipment used in explosive atmospheres), such as in chemical plants, mining, and petrochemical applications.
- Durability – Equipment must remain highly reliable over periods of up to, and beyond, 40 years.
- Environmental - Withstand harsh environments, such as:
    - Landfills where machines will experience consistent exposure to a wide variety of substances and mechanical damage.
    - Mining and earth moving equipment where operation in extremely dusty, humid, wet, muddy, and damp environments is necessary. The operation of such equipment is often up to 24 hours a day over extended periods of time. Due to the need to carry heavy payloads over rough terrain, the energy and therefore high temperature requirements of these systems are especially demanding.

[4] Such as break resistors which recover the heat from breaking to decrease the overall energy requirements of the system.

- Exposure to salt spray due to their operation near the sea.

PFAS provides the material properties required to satisfy these various operating conditions. Without a material equivalent that can meet these technical specifications, the equipment and the individual safety and performance systems will fail, causing immediate and dangerous risks for the machine operator and other workers in the vicinity. It is essential that any replacement material meets the necessary performance requirements and still offers the same safety, durability, and quality attributes offered by the original PFAS chemical.

Risk to Public Policy Goals

The off-road equipment industry stands at the intersection between societal environmental goals and the practical commercial requirements of today's end-users. This position requires manufacturers to strike a perfect balance between the work requirements of their customers and the aspirations of the public and global policymakers. Despite this tension, the off-road manufacturing industry remains committed to providing solutions that can satisfy both stakeholders. As our industry looks to the future, PFAS provides crucial attributes manufacturers need in order to develop new technologies, prevent unintended environmental hazards, and ensure our equipment continues to operate safely.

Environmental concerns

Fluid Leaks:

Almost all off-road equipment requires the use of various fluids to enable the operation of specific machine functions. These fluids run in different systems for numerous purposes. Among these functions:

- hydraulic fluid enables power transfers to the hydraulic systems,
- coolant ensures the engine operates within the ideal temperature range,
- fluid coatings work to prevent corrosion, and
- oils reduce friction between moving parts

While these fluids provide useful functionality to our equipment, they also can cause environmental hazards such as leaks and spills. Equipment manufacturers strive to eliminate these leaks to prevent environmental damage, protect worker safety, and ensure the long-term viability of their products.

Fluoropolymers, such as PTFE and fluoroelastomers, provide crucial characteristics that prevent hose and seal failures throughout the machine. These chemicals possess high temperature, chemical and mechanical resistance, making them ideal for sealing applications. This combination of traits helps ensure the long-term viability of various hoses, seals, gaskets, O-rings, and valves placed throughout the machine. Without fluoropolymers, end-users would likely experience much higher rates of fluid leaks, environmental spills, safety issues, component failures, damage to the machine, and premature obsolescence of the machine itself. Currently there are no known technically, or economically, feasible alternatives to these substances.

Climate Change & Ozone Depletion

Various international stakeholders are working to mitigate the impact that humans have on the climate. Like many other sectors, the off-road equipment industry continues to develop new strategies and solutions to reduce its environmental footprint. These efforts may include replacing current refrigerant options with lower GWP alternatives, developing zero-emission powertrains, or working to build new system efficiencies within the equipment to reduce fuel burn. Fluorinated gases will remain a critical substance in these efforts, without which the path to more environmentally friendly technologies will be much more difficult to achieve.

- Refrigerants: Refrigerants and refrigerant systems are already highly regulated for their contribution to atmospheric ozone depletion, and, more recently, their global warming potential. Recently, our organization successfully concluded an application for the use of HFO-1234yf as a refrigerant in off-road equipment through the EPA's Significant New Alternatives Policy (SNAP) program. Commonly used in the automotive sector, HFO-1234yf not only delivers zero ozone depleting potential (ODP), but also provides a greatly reduced global warming potential (GWP) when compared to its immediate predecessor, HFC-134a.

  Unfortunately, many governmental jurisdictions incorrectly identify these fluorinated refrigerants as PFAS chemicals based on the adoption of overly broad regulatory definitions. For this reason, any family wide restriction on PFAS would invariably restrict the use of this substance as a refrigerant in off-road equipment and eliminate the associated environmental gains.

- Alternative Power: Regulatory bodies have a decades long history of looking at on-road and off-road engines to address air quality criteria pollutant concerns. With a growing focus on climate change, policymakers are also looking at engines to help address concerns over GHG emissions. Manufacturers will need to develop new low carbon powertrain technology solutions to achieve the criteria pollutant and GHG reduction levels set by regulators. Within the off-road sector, manufacturers are researching new alternative power technologies, such as lithium-ion batteries, hydrogen fuel cells, and alternative fuels to provide low carbon solutions to their customers and markets they serve. Once again, PFAS provide the functional characteristics required to help foster the maturity and adoption of these new technologies across the market. Without access to certain PFAS, none of these technologies will remain viable in the future.

Waste Streams

Certain PFAS provide advantageous properties that ensure the long-term functionality of off-road equipment. Preserving the useful life of hoses, seals, gaskets, coatings, and electrical components ensures the machine continues to operate for an extended period under severe conditions. Without the use of certain PFAS, machinery in the field will prematurely fail requiring an accelerated need for new parts and components, thus increasing the generation of waste.

Additionally, future broad-based prohibitions or restrictions of PFAS could jeopardize the off-road industry sector's general recycling and remanufacturing efforts. The off-road sector invests a lot of time and money to ensure their equipment is responsibly recycled, remanufactured, and resold into secondary markets. These efforts reduce the amount of wasted materials the industry produces, prevents equipment from going to landfills, and avoids the premature obsolescence of our products. Any restriction of materials needs to protect against endangering these recycling efforts, and the associated unintended environmental consequences.

Safety Concerns

Safety concerns are perhaps the most important issue the off-road industry attempts to mitigate in their design processes. Heavy equipment, operating in hazardous environments, and under severe stress with various workers on the job site provides ample safety challenges for equipment manufacturers to consider. Under these conditions, machine operators look for reliable and durable equipment with the appropriate safety standards designed into the machine. Several PFAS play a key role in ensuring the products continue to operate safely:

- Fluoropolymers in seals and hoses ensure hydraulic systems maintain pressure. Sudden pressure losses due to hydraulic hose failures can cause loads to drop suddenly on a jobsite, significantly increasing potential harm to workers.
- Heavy equipment operates at very high temperatures, requiring unique chemical solutions to mitigate any potential fire issues. Due to the pressure and temperature stability some PFAS chemistries are used to decrease the potential for fire, thereby protecting worker safety.

<u>Undesirable Alternatives</u>

Any transition to a PFAS alternative must avoid regrettable substitutions. Materials must satisfy national and international legal and regulatory requirements. Furthermore, they must not present an even greater risk to the environment, human health, or present new safety risks to the work site and operator.

Off-road equipment manufacturers require thorough testing and validation of new materials prior to their integration into a final product design. Substance specifications vary based on their intended purpose within the larger machine. Due to the nature of the work, manufacturers often require highly durable and robust materials that can operate consistently under very extreme conditions. Replacing proven materials with alternative substances can, under the right circumstances, produce desirable environmental outcomes. However, transitioning away from irreplaceable or highly specified materials can often lead to higher environmental and human health risks, as well as suboptimal product performance outcomes.

For example, FKM materials provide high chemical, temperature and pressure resistance in gaskets, seals, and hoses. This material performs so well, that it is widely considered to be irreplaceable for the continued operation of most modern equipment. Its closest alternative, ethylene propylene diene monomer (EPDM), also known as synthetic rubber, does not perform well in the high pressure and temperature environments found in modern equipment. More troubling, synthetic rubber utilizes N-methylpyrrolidone (NMP) during its synthesis, which is a regulated Substance of Concern (SoC) in a variety of regulatory jurisdictions.

It is important to ensure that OEMs receive enough time and support when transitioning away from regulated substances. Companies struggle with making informed and responsible decisions when faced with short implementation timeframes, discordant regulatory requirements, and overprescribed rulemakings. Policymakers need to provide appropriate exemptions, time, resources, and public-private collaboration necessary to ensure manufacturer stakeholders can identify and adopt desirable alternatives for their SoC**.**

With this in mind, AEM recommends that MPCA make sure that, when establishing criteria for PFAS alternatives, the new material must meet the safety, durability, quality, and performance requirements of the original PFAS materials, and must satisfy the need to avoid regrettable substitutions.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

Off-Road Equipment Challenges and Assumption to Finding Alternatives for PFAS

For most PFAS use cases, there are no currently known technical alternatives available for use in off-road equipment that does not compromise the safety, durability, or reliability of the finished product. AEM members produce equipment designed to consensus safety standards and subject to third party certifications, customer requirements, and regulatory testing obligations. Changes to materials and formulations which affect fit, form, function, performance, or safety must undergo extensive testing to ensure any new designs meet internal quality benchmarks, design specifications, and regulatory requirements.

Due to the challenges inherent to the off-road industry, it is extremely difficult to estimate the time needed to identify, test, and qualify alternative chemical substances for each end use. The estimates from AEM and their member companies are based on the following assumptions:

- A suitable and viable technical alternative material exists (although as described above, there are no known current technical alternatives for most PFAS use cases).
- Manufacturers do not encounter dead ends during their material assessments, and suitable characteristics are identified the first-time test are completed.
- Supply chain issues throughout the world do not hamper shipping and transportation timelines.
- The total number of PFAS substances used in off-road equipment is a manageable size (roughly 10-20 chemicals at a time). Manufacturers will try to conduct simultaneous redesign work wherever possible, but they cannot implement changes across all product lines simultaneously as test cells, qualified staff, and other resources are all limited. The higher the number of PFAS substances used in the components and systems of the end-product, the longer the timeline will be.

Any transition away from PFAS requires significant time and resources to simply identify and qualify any PFAS-free material for use in the off-road equipment sector. AEM's member companies estimate that this effort would require a complete re-direction of all engineering resources within each member company to accomplish this task alone. Global engineering resources are extremely limited, with almost all companies facing severe staffing and human resource challenges. As such, off-road equipment manufacturers will need significant additional resources and time to address the qualification requirements for PFAS-free components, due to the fact that any individual company is highly unlikely to have the resources on hand to accomplish this task. This type of activity will impact all other R&D projects and other internal development programs. It is likely that all these activities would pause in order to focus enough resource on PFAS qualification activities. If no exemption were granted, it is highly likely that all product sales, manufacturing activities, and service actions in the state of Minnesota would stop until suitable alternatives are identified, tested, designed, and qualified.

Off-Road Equipment PFAS Replacement Timeline

Off-road equipment operates in some of the most demanding and severe environments over a product life cycle measured in decades. The equipment are highly complex pieces of machinery requiring each manufacturer to undertake component and system level qualifications to ensure the necessary performance characteristics are met.

Working under these design requirements, and the assumptions listed in the previous section, AEM member companies estimate that replacing a manageable number of PFAS substances at one time would take at least 15 years for new equipment and 30 years for replacement parts and components. This estimate assumes the timeline starts at the date at which an alternative has been identified to ensure the OEM can maintain the systems in the machine which safeguard the operator, maintenance personnel, the worksite, and the environment.

These product re-design and validation assumptions have precedence in other chemical management and environmental rulemakings. In their recently published, *Decabromodiphenyl ether and Phenol, Isopropylated Phosphate (3:1); Revision to the Regulation of Persistent, bioaccumulative, and toxic Chemicals Under the Toxic Substances Control act (TSCA)*[5] proposed rule, EPA granted the off-road equipment industry, along with other similar industries, a 15 year transition period for new equipment and 30 year transition period for replacement parts for a single chemical substance; Phenol, Isopropylated Phosphate (3:1) (PIP 3:1). Furthermore, during engine emission rulemakings[6], which focus only on the engine and aftertreatment system redesigns, regulators like EPA, California Air Resource Board (CARB), and the EU Commission provide a 7-13 year transition (depending on the power category) to produce new certified engines. While these two rules are different from the requirements promulgated in Amara's Law (HF2310), the reality is that these two other rules are simpler to comply with and grant the off-road equipment industry extended timelines to implement the design changes needed to meet the requirements of the law.

Criteria for Establishing Timelines for Unavoidable Use Determinations:

The off-road equipment industry provides a useful case study in adopting a cautious approach to establish unavoidable use determination timelines. Off-road machines are large, highly complex products, with specific design requirements, and extremely long supply chains, making large scale design changes impossible to implement in short periods of time. If a suitable alternative exists, it is unlikely that all industries require the same timeline to transition their products away from the use of PFAS. Assuming this is true, it is important to establish certain criteria for determining a timeline.

Speaking on behalf of off-road equipment, MCPA should grant a current unavoidable use determination when there are no PFAS alternatives that are technically suitable, economically feasible, commercially available, legally compliant, and safe. We understand that overtime these conditions may change and will require careful consideration on behalf of industry stakeholders to determine what an appropriate timeline looks like. That said, AEM strongly believes that the any PFAS alternative must satisfy these listed criteria prior to ending a current unavoidable use determination:

- Technically suitable: The PFAS alternative meets or exceeds the technical properties associated with the PFAS equivalent. This ensures that any replacement material provides the safety, quality, durability, and performance characteristics needed for the machine to operate successfully. If the new substance does not meet these technical requirements, the machine is likely to experience elevated safety risks, performance failures, premature obsolescence, and increased waste.

[5] https://www.federalregister.gov/documents/2023/11/24/2023-25714/decabromodiphenyl-ether-and-phenol-isopropylated-phosphate-31-revision-to-the-regulation-of
[6] https://www.epa.gov/regulations-emissions-vehicles-and-engines/final-rule-control-emissions-air-pollution-nonroad

- Economically Feasible: The PFAS alternative is reasonably priced. If the new alternative is too expensive, the increase in price will threaten the long-term viability of the entire construction, agricultural, mining, utility, and forestry industry.
- Commercially Available: The PFAS alternative is available for purchase at scale. When developing new substances, chemical manufacturers and material processors require time to commercialize these products and distribute enough material for use throughout the global supply chain. OEMs, in turn, require their own time to test and validate new materials prior to adoption.
- Legally Compliant: The PFAS alternative is legally compliant with domestic and international law. Many components in off-road equipment are regulated under other regulatory frameworks. For instance, emissions-related components cannot be altered without notifying and, in many cases, re-certifying the engine with EPA, CARB, the EU, and other regulators. This process takes a substantial amount of time and resources to complete.
- Safe: The PFAS alternative is safe for handling, storage, manufacturing, and use. If the new material does not meet this requirement, it should not be used in the marketplace. This requires extra time and resources to prove.

Off-road equipment manufacturers produce machines to meet a host of different requirements. These include safety, regulatory, environmental, and customer requirements. Validating new components, parts, and systems takes time and cannot be accelerated without sacrificing important features. To achieve a successful outcome and with safe and durable results, a change of this magnitude should be validated and substantiated on an industry level. Other industries operate under similar types of demands. Therefore, it is crucial to keep these criteria in mind when establishing unavoidable use determination timelines.

6. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

The off-road equipment industry manufactures safe equipment using consensus safety standards with decades of experience using components and materials that satisfy well-tried safety principles. Companies in these sectors will innovate and differentiate themselves on performance, efficiency, functionality, and a host of other features, but prefer to move together when it comes to safety. Therefore, to maximize worker safety and avoid largescale market disruptions, it is important that current unavoidable use determinations apply to the industry as a whole and consider industry wide acceptance and approval of potential PFAS alternatives, rather than on a company-by-company basis. This process will mitigate safety risks on the workplace and guarantee a smoother transition when viable PFAS alternatives are identified.

7. In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

AEM represents off-road equipment manufacturers and suppliers with more than 1,000 member companies and over 200 product lines in the construction, agriculture, mining, forestry, and utility industries. Off-road equipment encompasses a large variety of products and product types. While many of these products use similar components, parts and systems, their intended function and use cases may differ substantially between equipment types; requiring a more complete definition to fully encompass the off-road sector. Generally, off-road equipment includes the following types of machines:

- Mobile off-road equipment,
- Large scale fixed installation,
- Large scale stationary industrial tools,
- Alternative power applications, and
- Attachments and implements.

The definitions of each of these categories are as follows:

- <u>Off-road mobile machine:</u> any mobile machine, item of transportable industrial equipment, or vehicle with or without bodywork or wheels which:
  - Is not intended for carrying passengers or goods on the road,
  - Includes machinery installed on the chassis of vehicles intended for the transport of passengers or goods on the roads,
  - Installed with a combustion engine – either an internal spark ignition (SI) engine, or a compression ignition diesel engine,

- <u>Large Scale Fixed installations:</u> cover a combination of several types of machines which include, but are not limited to, tower cranes, light towers, crushers, and screeners:

  - A combination of several types of apparatus and, where applicable, other devices;
  - Assembled, installed and de-installed by professionals;
  - With the intention to be used permanently in a pre-defined and dedicated location;
  - And it has to be large-scale.

- <u>Large scale stationary industrial tools:</u> include, but are not limited to, cranes and blow-out preventers.

  - An assembly of machines, equipment and/or components, functioning together for a specific application;
  - Permanently installed and de-installed by professionals at a given place;
  - Used and maintained by professionals in an industrial manufacturing facility or R&D facility;
  - And it has to be large-scale.

- <u>Alternative power applications:</u> Products intended to power off-road equipment, such as batteries, battery packs, and recharge equipment.

- <u>Attachments & implements associated with the above equipment</u> (i.e., towed mowers, sprayers, buckets, forks)

<u>PFAS Use Cases in Off-Road Equipment</u>

The off-road equipment industry, defined by its diverse end-use applications, harsh working environments, and extremely long product lifecycles, demands unique material solutions to meet the safety, environmental and performance requirements of the marketplace. Future regulatory, customer, and societal pressures will continue to push this sector to develop and adopt new technologies to tackle global policy concerns, especially issues around climate change, engine emissions, circular economy concepts, enhanced recycling, energy usage, and sustainable supply chain issues. This complex mixture of impending market conditions requires industry access to distinctive material chemistries to accomplish these goals. Due to their highly specialized and unique properties, PFAS chemicals help provide a critical building block for OEMs to meet these objectives. While some industries may find alternatives to specific PFAS applications with sufficient research and development, there are many critical uses which cannot be replaced. Broad restrictions on PFAS will damage product innovation and could render future technology development goals impossible to achieve.

PFAS Essential Use Cases

Manufacturers design their products to operate for decades under extremely harsh, demanding and arduous work environments. Equipment materials, parts, and components need to meet rigorous design and testing requirements to ensure critical product functions continue to operate safely and effectively on the jobsite. With their many useful chemical and physical traits, PFAS provide crucial characteristics necessary to meet various equipment design challenges.

- Seals: All off-road machines use fluids to ensure the equipment continues to perform their intended functions. Fluid applications include hydraulic fluid, oil, fuel, refrigerants, coolant, among others. Sealing technology, such as O-rings and gaskets, prevents fluid leaks and ensures water, dirt, dust, and debris stays out of the equipment.

  Properly designed seals must meet various design characteristics to ensure they operate in a reliable, continuous, and efficient manner. The mechanical functions inside a off-road vehicle exposes parts and components to various stressors:

  - Pressure - various systems, such as the hydraulic and engine systems, experience extreme pressure environments up to 500 bar.
  - Temperature - the engine compartment and exhaust system operate at temperatures as high as 800 °C.
  - Chemical - seals interact with various fluids, requiring a high degree of chemical and corrosion resistance to ensure the continued operation of exposed parts.
  - Mechanical – machines possess a high degree of mechanical wear and tear, sealing parts must survive the shear forces due to the mechanical movement of the equipment.

  PFAS are the only chemical family known to provide the combination of thermal stability, chemical resistance, low frictional characteristics, and sealing capabilities required to operate in this harsh machine environment. Several PFAS chemicals, known broadly as fluoropolymers, which include Polytetrafluoroethylene (PTFE), Fluoroelastomer (Viton), and Polyvinylidene fluoride (PVDF) possess many of these crucial chemical traits and have no known substitutes, making them irreplaceable for the heavy equipment off-road industry.
  Replacing PFAS with inappropriate material substitutes would compromise the functionality of corresponding parts and components, ensuring increasing failure rates, fluid leaks, safety issues, and shorter vehicle lifetimes.

- Hoses: Similar to seals, hoses are required to transport fluids from one location to another, prevent fluid leaks, and maintain the cleanliness of the equipment's components and systems. Many hoses in the off-road industry use fluoropolymers to safeguard the durability of the machine by protecting its components from various internal pressure, temperature, and chemical stressors.

  Under these conditions fluoropolymer lined hoses, especially those with PTFE, provide a necessary level of protection to ensure the durability and long-term reliability of the component. There are no known viable alternatives for PTFE used in hoses. Alternatives, such as rubber hoses, provide less durability, as well as decreased flexibility and strength over time. Inappropriate alternatives will result in increasing fluid leaks, damage to the machine, loss of fluid power, and increasing safety risks for the operator.

- PTFE Tape: Over the operational lifetime of a machine, leaks will inevitably occur. Operators looking to fix fluid leaks from seals and hoses require the appropriate materials to withstand the normal operating conditions found inside off-road equipment. PTFE tape provides this level of assurance.

- Hydraulic Fluid: Hydraulic fluid enables the transfer of power from the engine to end-use hydraulic systems. The vast majority of off-road equipment rely on hydraulic systems to carry, push, dig or lift heavy loads. Without this important technology, much of the work performed today would require radically different, and less efficient, technology solutions. Prominent examples of machines and systems that use hydraulic power include excavators, cranes, forklifts, lifts, dozers, graders, loaders, shovels, trenchers, and concrete pumping systems, among others.

  Hydraulic fluids must possess a variety of crucial properties to protect the longevity of the hydraulic system and its components. In turn, the durability of these systems helps ensure that the machine continues to operate in a safe and efficient manner. Pin hole leaks, sudden drops in pressure, or contamination of the fluid can all cause serious safety issues for the operator or maintenance team. To avoid these types of safety concerns, hydraulic fluid producers utilize certain PFAS based chemicals to provide the corrosion, chemical, temperature and wear resistance needed for the system to operate smoothly.

- Refrigerants: Temperature management is a crucial product design requirement in the off-road sector. Many machines have enclosed operator cabins near large diesel engine exhaust systems, with few options for ventilation due to environmental concerns. Ensuring equipment operators remain comfortable while working is an important safety and comfort feature needed in modern machines.

  Ideal refrigerants need to possess off-corrosive and off-toxic characteristics with a low global warming potential (GWP), zero ozone depleting potential (ODP) and a low boiling point. Most widely adopted refrigerants, such as hydrofluorocarbons (HFCs), hydrofluoro-olefins (HFOs), and hydrochlorofluoroolefins (HCFO's) are used extensively in the automotive, aerospace, and off-road sectors. These substances break down quickly in the atmosphere into substances that naturally occur in the environment. Unlike most PFAS chemicals of concern, which may last thousands of years without breaking down, most modern refrigerants have an atmospheric lifetime measured in days, months and in some cases years.

  Due to the inconsistencies in defining what is, and what is not, a PFAS chemical, refrigerants sometimes find themselves included with this larger group. Refrigerants, such as HFC-134a and HFO-1234yf, may find themselves in scope of certain PFAS regulatory requirements despite possessing none of the chemical attributes or risk profiles which make PFAS a concern to policymakers. An accurate assessment of these substances using scientifically accurate definitions would help exclude them from the broader definition of a PFAS seen in recent legislative and regulatory actions.

- Paints: Coatings protect off-road equipment from chemical, weather, or water erosion. Well-designed coatings can help extend the useful life, and maintenance requirements, for off-road products, and are highly valued by OEM's and their customers. Many coating providers use PFAS in their paints to improve the flow, spread, and glossiness of the coating, as well as to decrease bubbling and peeling. They are also used in specialty paints to give stain-resistant, graffiti-proof, and water-repellent properties.

- Alternative Power: Policymakers have long sought to reduce the emissions of criteria pollutants and decarbonize the off-road sector. OEMs and engine manufacturers are looking at many new alternative power sources and technology solutions to meet their ESG goals. While the industry will continue to innovate and experiment in this space, it is clear that PFAS chemistries will play a crucial role in many of these future developments. Two of the most widely discussed technology solutions, batteries, and hydrogen fuel cells, use PFAS to fulfill crucial functionality.

    - Batteries utilize chemical binders to hold the internal active materials together to maintain a strong contact between the electrodes and the current collectors. Battery manufacturers use Polyvinylidene Fluoride (PVDF) as a binder in lithium-ion batteries due to its electrochemical and thermal stability, as well as its acceptable binding properties for the cathode. Additionally, certain fluorinated compounds are also used to coat the anodes to prevent unwanted reactions with the electrolyte. Due to their long lasting and chemical stable properties, the fluorinated compounds help extend the useful life of the battery.

      Under standard industry practices, batteries are manufactured in clean-room conditions, preventing the release of any PVDF into the surrounding environment. These closed conditions make it impossible for any PFAS materials to escape. Furthermore, battery recycling operations recover the PVDF through hydrometallurgical treatment processes. The collected PVDF is further broken down and captured by gas scrubbers, preventing any further release.

    - Hydrogen fuel cells use a proton exchange membrane (PEM) to separate the anode and the cathode. The PEM uses fluoropolymers to separate the protons from the electrons at the membrane surface, allowing only the protons to permeate to the cathode. In this technology, the fluoropolymers provide crucial properties that enable the fuel cell to produce electricity. The fluoropolymers used in the fuel cell PEM have no known alternative replacement.

Other examples: fire retardants, electrical insulation (Equipment), personal protection equipment including gloves/shielding/aprons (e.g. Nitrile, Viton)

Based on the critical benefit of the off-road equipment industry to society, the complex nature of these machines and their supply chains, as well as the fact that PFAS provides crucial safety functions and has no known alternatives, AEM recommends MPCA grant off-road equipment a current unavoidable use determination.

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria.

AEM supports the criteria outlined in this comment when considering current unavoidable use determinations as well as the criteria needed to establish realistic timelines for these classifications. Assuming these criteria are adopted and used by MPCA when making their determinations, AEM supports making some initial current unavoidable use determinations as part of this rulemaking.

AEM appreciates your consideration of these comments.

Please feel free to contact me at Jmalcore@aem.org if you have any questions or require any further information.

Best Regards,

Jason Malcore
Senior Director, Safety & Product Leadership
Association of Equipment Manufacturers (AEM)

By E-Mail

Katrina Kessler
Commissioner
Minnesota Pollution Control Agency
520 Lafeyette Road North
St. Paul, Minnesota 55155-4194

Subject: Request for Comments on Planned New Rules Governing Currently Unavoidable Use (CUU) Determinations for Products Containing per-and Polyfluoroalkyl Substances (PFAS)

Dear Ms. Kessler:

Emerson Electric Co. appreciates the opportunity to respond to the State of Minnesota's Pollution Control Agency's (MPCAs) request for comments on criteria and processes by which CUU determinations will be made. We commend MPCA for giving industry the opportunity to participate in this important process.

Emerson Electric Co., headquartered in St. Louis, Missouri, is a global technology and engineering company with significant operations in Minnesota, including more than 2,900 staff and 15 sites, and is fully committed to making industrial products that are safe for end-users and the environment, consistent with MPCA's objectives.

Pursuant to the request for comments guide, answers to most questions are provided herein, highlighting considerations that we believe are essential to the CUU process. Please note that our comments represent the perspective of a downstream user of fluoropolymers in high-performance Industrial Automation Monitoring and Control (IAMC) products.[1]

1. **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**

[1] ***The statements, responses, commentary, and estimations made in this request are based on Emerson's good faith effort, research and knowledge Emerson is aware of at this time this request is submitted to Minnesota. Emerson intends to continue to research and acquire knowledge regarding PFAS and may at a future time have updated information and analysis regarding the subject matters in this request. However, Emerson does not undertake to update any such statements, responses, commentary, and estimations submitted in this request to reflect later developments. Emerson has issued these statements, responses, commentary, and estimations in this request to solely address this request for industry comments. Emerson's statements, responses, commentary, and estimations in this request should not be read, construed, or applied as to speaking to matters beyond what Minnesota has requested under this comment request. Emerson encourages industry to continue to find and/or develop PFAS alternatives. Emerson reserves all its rights and interests under this Minnesota law. Nothing in this submission shall be viewed as waiving any of its rights.***

Yes, with the caveat that MPCA should be open to re-evaluating the criteria based on potential technological progress and innovations on which society may be reliant on in the decades to come.

The MPCA could consider leveraging the extensive work and stakeholder input completed for the European (EU) Commission by WSP. The EU Commission contracted with WSP to support the development of the "essential use concept" to satisfy the requirements defined in the Chemical Strategy for Sustainability (CSS) under the EU Green Deal. Below is relevant information extracted from WSP's report:

Criteria # 1: Necessary for health or safety if one or more are met:

- Preventing, monitoring or treating illness and similar health conditions.
    - Provide healthcare (including monitoring and diagnosing), such as uses for and in medical devices, test and measurement equipment, and for producing medicines.
    - Ensure hygiene and cleaning in hospitals where disinfection is required.
    - Prevent transmission of and control diseases.
- Sustaining basic physical conditions for human life and health.
    - Secure sufficient clean water, food and air.
    - Secure heat and shelter
- Managing health crises and emergencies
    - Mitigate the effect of disease outbreaks.
    - Ensure the functioning of emergency and ambulance services.
- Ensuring personal safety
    - Ensure the functioning of personal safety equipment.
    - Ensure lubrication in vehicle brakes, fire resistance in products, or corrosion protection.
- Ensuring public safety
    - Ensure safety of infrastructure, such as road, rail and air safety and building safety.
    - Ensure the functioning of emergency services to prevent danger to the public.
    - Customs control

Criteria # 2: Critical for the functioning of society if one or more are met:

- Providing resources or services critical to society
    - Enable installation, maintenance and transmission of infrastructure and services critical to society, such as energy supply and transport, water treatment and water supply, waste treatment, digital communication and healthcare infrastructure.
- Managing societal risks and impacts from natural crises and disasters
    - Repair damage to infrastructure from natural disasters such as floods, fires, earthquakes.
- Protecting and restoring the natural environment
    - Reduce greenhouse gas emissions, such as use for renewable energy technologies.
    - Reduce air pollutants, such as use in scrubber technologies and similar uses.
    - Protect ecosystems and biodiversity, such as use for control of invasive species.
    - Analyze and monitor pollutants
    - Remediate pollutants in the environment.
- Performing scientific research and development
    - Perform laboratory analysis, measurement and testing.
    - Perform laboratory experiments.
- Protecting cultural heritage

- o Conservation of cultural heritage.

2. **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

An assortment of analysis should be included in this alternative contemplation. Below are some preliminary concepts that Minnesota could consider in its drafting phases. A factor analysis process, along with the preliminary concepts below, for industry to weigh when making these future product determinations may be a practical solution to help MPCA ponder this open question.

1. The alternative material should **be safer**, perform **comparable to PFAS,** and be considered a **drop-in replacement** (i.e. no redesign of the product is required to accommodate performance deficiencies or vulnerabilities).
2. The alternative material should be at a **comparable cost** to the existing PFAS material.
3. The alternative material should be **commercially available at-scale** and from multiple suppliers.

MPCA could consider convening a roundtable of companies to discuss additional concepts for quantifying a reasonable cost threshold.

3. **Should unique considerations be made for small businesses with regards to economic feasibility?**

Not Applicable

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

Industry requests additional time to provide meaningful comments on this question and request this question comment be extended.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?**

Despite the substantial financial opportunity to replace PFAS, Emerson is not aware of companies offering new materials as a drop-in replacement and capturing the prosperous market, which is a strong indication that, in many cases, especially in industrial applications, that no alternatives exist. Consequently, the time period for a granted CUU should be set at **greater than 15 years for industrial applications**. This timeframe would allow for identification of alternatives and verification and validation testing, which can be upwards of 10 years in highly regulated industrial environments such as those called for in nuclear applications. This estimate assumes that a suitable alternative will be identified within the first few years of the CUU time period.

Industry needs timeframes that are predictable and can be managed without disruption to fulfillment of orders and critical product development projects. With the changing technological landscape, re-evaluations seems reasonable.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be**

determined to be currently unavoidable? What information should be submitted in support of such requests?

6a. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA?
For the initial CUU determination, MPCA could issue a formal request for CUU proposals, with detailed instructions and examples, for release to the public with a response timeline of up to six (6) months.

For future requests, an online submission form could be created to streamline requests for new or a renewal of a CUU. An official procedure that defines the requirements, review process, frequency of CUU considerations, and response time should be developed.

6b. Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable?
No comment.

6c. What information should be submitted in support of such requests?
Consider harmonizing with the State of Maine's CUU Request for Proposal (RFP) with further consideration given to item number 1, per the following:

1. Provide a brief description of the type of product including, if applicable, the Global Product Classification (GPC) brick category and code, or if GPC is not applicable than the Harmonized Tariff System (HTS) code.

   Alternative Consideration: Given the complexity and number of products used in the marketplace that would require evaluation, MPCA could consider convening a task force, including industry representatives, to develop alternative ways to identify products.

2. Describe the intended use of the product and explain how it is essential for health, safety or the functioning of society.
3. Describe how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, provide citations to that requirement.
4. Describe whether there are alternatives for this specific use of PFAS which are reasonably available.
5. Provide contact information for the submission.

7. In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Emerson is anticipating requesting a CUU designation for 24 Industrial Automation Monitoring and Control (IAMC) products. This submission was developed with the assumption that MPCA's submission requirements align with the State of Maine's published CUU Request for Proposal (RFP). Below are potentially future analysis based on what we understand today and what Minnesota has published in the context of the rule.

IAMC products are the control systems and associated instrumentation, including the devices and controls used to automate industrial processes. The scope of equipment consists of interdependent, high-performance electromechanical products that measure a variety of parameters such as temperature, humidity, pressure, corrosion, and density as well as process control products such as valves, actuators, flow measurement devices and regulators, as outlined in Table 1 below:

TABLE 1. IAMC PRODUCTS

1. Pressure, Flow, Level and Temperature Measurement (4)	9. Distributed Control Systems (1)
2. Corrosion, Erosion & Heat Trace Monitoring (3)	10. Hygienic & Sanitary Measurement (1)
3. Energy Monitoring & Management (1)	11. Vibration Sensors & Welding Machines (2)
4. Industrial Test & Measurement Instruments (1)	12. Electrical Power Distribution & Control (1)
5. Density & Viscosity Measurement (2)	13. Valves (1)
6. Liquid, Flame & Gas Detection (3)	14. Regulators (1)
7. Machinery Monitoring, Protection & Maintenance (1)	15. Actuators (1)
8. Marine Measurement & Analysis (1)	

In 2022, IAMC products generated revenues of ~$200 billion globally. However, IAMC products are used as a critical component in a wide range of downstream uses where the socio-economic footprint is several times larger. The fluoropolymers used in IAMC products are discrete solid plastic parts that meet the OECD's definition of a polymer of low concern (link) and are contained within enclosures throughout the long life of the product emitting negligible emissions.

IAMC's fluoropolymer-containing products are key to fulfilling many critical-to-society applications:

The comprehensive scope of uses and products are difficult to list, but key examples and additional details are provided below, with additional details provided in Table 3.

- Chlorine production - drinking water and food processing disinfectant
- Semiconductor manufacturing
- Critical chemical processing – feedstocks, pharmaceuticals, pulp & paper, etc.
- Medical procedures - Invasive cyogenic tumor removal
- Pressure vessel – relief valves are required in all pressure vessels by law
  - 46 CFR § 54.15-10 - Safety and relief valves
- Control of sustainable energy applications – wind, H2, solar, mobility, etc.
- Other examples of uses include critical infrastructure sectors, as defined by the United States government, forest products, rail and other mass transportation, and construction operations.

The operating profile of these uses, and to which IAMC products are exposed, are defined by the industrial sectors that leverage the technology. These applications often involve exposure to multiple extreme environmental conditions simultaneously. The IAMC environmental parameters often include the following:

- Hazardous environments are prevalent and include fire, explosion, and toxic chemical threats. These environments often mandate equipment certifications, namely UL/IEC 60079.
- Broad chemical exposure is common due to the massive number of chemicals processed every day. These chemicals span the entire pH range and are processed at different temperatures and pressures. Example harsh chemicals include sulfuric acid, hydrofluoric acid and chlorine.
- Low temperatures near -76°F. Beyond this for cryogenic processing, IAMC products can be exposed to temperatures down to -328°F.
- High temperatures near 500°F.
- High pressures near 2,200 PSI to accelerate and influence reaction rates and to increase volume-time efficiencies. Pressures up to
- 14,500 PSI bar exist in some chemical processes. These environments often mandate equipment certifications, specifically ASME Boiler Pressure Vessel Code (BPVC).

IAMC products frequently operate in harsh environments where only fluoropolymers can deliver the performance needed for safe and efficient operations.

TABLE 2. THESE EXAMPLES ILLUSTRATE THE ESSENTIALITY OF IAMC PRODUCTS, THEIR CONTRIBUTION TO HEALTH, SAFETY, AND THE FUNCTIONING OF SOCIETY, AND THE ESSENTIALITY OF PFAS AS AN ENABLING MATERIAL.

APPLICATION	IAMC INTENDED USE	ESSENTIALITY FOR HEALTH, SAFETY AND/OR THE FUNCTIONING OF SOCIETY (SECTION 2.0)	ESSENTIALITY OF PFAS (SECTION 3.0)
Water treatment & Provision of Safe Food Supply	**Chlorine production** 1. Measurement equipment and valves are used for containment and control of the chlorine production process. 2. Solenoid valves for control of potable water and clean-in-place systems.	Chlorine is the most common type of drinking water disinfectant. It is able to reduce the chance of pathogen regrowth in water storage tanks or distribution systems and oxidizes iron, manganese, taste and odor compounds, remove color in the water, destroy hydrogen sulphide, and aid other water treatment processes, such as sedimentation and filtration. Chlorine is also used to clean and sterilize food processing equipment to prevent bacteria growth.	PTFE & PFA liners in measurement equipment and valves for the production of chlorine. Highly concentrated chlorine is corrosive and highly toxic to people and the environment. PTFE & PFA liners can withstand the corrosive environment, are lightweight and have a relatively low carbon footprint associated with their manufacturing processes. Exotic metals that might withstand the corrosive environment are not viable due to the high weight and increased CO2 associated with their manufacturing processes.
Semiconductors	**Semiconductor manufacturing** 1. Pressure regulators are used to control the pressure of media used in etching and chemical vapor deposition processes. 2. Industrial test & measurement instrumentation to detect organic impurities in air during µ-Processor manufacturing.	The rapid vertical and horizontal expansion in chips applications means the market for semiconductors is expected to multiply in Maine and around the globe.	Use in semiconductors and microchips manufacturing ensuring that highly corrosive chemicals do not contaminate ultra-clean fabrication environment. Pressure regulators utilize PTFE and PCTFE in valve seats to control the pressure of media used in etching and chemical vapor deposition processes for semiconductor manufacturing, providing high purity and compatibility with the processed gases to prevent a reaction with the media. PCTFE also delivers an ideal compressive modulus and creep resistance for maintaining sealability.
Chemical Feedstocks, Pharmaceuticals, Petroleum, Hydrogen, Pulp & Paper	**Critical chemical processing** 1. Measurement equipment and valves for containment and control during chemical production.	Chemical feedstocks are the essential building blocks for items such as building materials, appliances, clothing, pharmaceuticals & personal care items, and everyday items such as laundry detergent and toothpaste.	Control and isolation valves utilize PTFE valve packing in the production of pharmaceuticals, chemicals, hydrogen processing, etc. ▪ PTFE valve packing is better at sealing gases than graphite, is inert and delivers performance at extreme temperatures, -200°C to +260°C ▪ PTFE waveguides are used in non-contact, radar level measurement applications for safe storage of harsh chemicals. ▪ PTFE and PFA liners are used in flow meters to control process conditions. Liners protect metal from corrosive media.
Medical	**Invasive tumor removal procedures** 1. Solenoid valves for control of cryogenic fluids	Tumor removal procedures can be very painful and dangerous, often requiring the use of a cryogenic fluids and accompanying equipment.	Solenoid valves use PTFE, FKM & FFKM in o-rings at cryogenic temperatures (-328°F)
Pressure Vessels	**Pressure vessel** 1. Relief valves to prevent pressure vessel rupture. 2. Welding machinery for automated and consistent fabrication.	Across all pressure vessels – from a heat exchanger to a three-story pressurizer in a nuclear reactor – a relief valve is required by law for safety. Pressure vessels include boilers, chemical tanks and reactors, etc.	Industrial relief valves use PTFE, FKM & FFKM in valve seats at high temperatures (300°F) and high pressures (1,500 PSI). Alternative materials do not provide adequate properties for reliable seals on these devices.
Sustainable energy/ mobility: Batteries/Solar/ Wind/Hydrogen	**Sustainable energy applications** 1. Distributed Control Systems for automation, monitoring & control of processes.	The proliferation of sustainable energy applications are key enablers of decarbonization initiatives across the globe. Automation of these processes, including data collection, is a highly complex but necessary activity to maintaining an efficient and safe manufacturing operation.	Fluoropolymers such as PTFE are utilized in most decarbonization activities such as H2 production and storage, mobility, wind and solar. Fluoropolymers are used as protective films in solar, coatings, for offshore wind turbines, and membranes for transportation activities involving H2 and battery manufacturing.

No Suitable Alternatives Exist Today that can Deliver the Necessary Performance for challenging IAMC operating environments:
The challenging IAMC end uses demand the use of high performance and high reliability materials like fluoropolymers, which are vital as an engineering material class, not because of one particular characteristic, but because of the multiple properties any of them simultaneously possesses. Fluoropolymers' most commonly leveraged properties include:

- Broad chemical resistance to virtually all chemicals
- High and Low temperature performance down to -328°F/ up to 500°F
- High pressures near 2,200 PSI nominally and 14,500 PSI for certain chemical processes
- Intrinsic flame resistance with a limiting O_2 index
- Low friction and Excellent electrical properties

GPC and HTS codes for the proposed 24 CUUs are provided in Appendix A.

8. **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

Yes, CUUs deemed critical to safety, health and critical to the functioning of society should be provided as soon as possible to give industry time to plan next steps, if any.

9. **Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.**

Emerson respectfully submits the following considerations:

- Permit a category of products to be exempted as a CUU. For example, medical devices or Industrial Automation Monitoring & Control (IAMC) products can be categorized as a single CUU.
- Exempt all CUUs from reporting requirements.
- Provide an exemption for fluoropolymers in industrial applications that meet the criteria for critical for health, safety and functioning of society.
- Focus efforts on the beginning and end of life phases by demanding responsible manufacturing by the chemical producers and investing in safe end-of-life emission control strategies. Industrial downstream users deploy fluoropolymers that satisfy the OECD's polymer of low concern criteria (link).

We appreciate the opportunity to provide this information and invite you to reach out for additional information or discussion regarding these comments. We look forward to your response and any potential follow-up.

PERFORMANCE
FLUOROPOLYMER
PARTNERSHIP

March 1, 2024

Katrina Kessler
Commissioner
Minnesota Pollution Control Agency

Re: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837[1]

Submitted via https://minnesotaoah.granicusideas.com/

On behalf of the American Chemistry Council's Performance Fluoropolymer Partnership,[2] thank you for the opportunity to submit comments on planned new rules governing currently unavoidable use (CUU) determinations about products containing per- and polyfluoroalkyl substances (PFAS). The Partnership's members are some of the world's leading manufacturers, processors, and users of fluoropolymers, including fluoroelastomers, and polymeric perfluoropolyethers. The Partnership's mission is to promote the responsible production, use, and management of fluoropolymers, while also advocating for a sound science- and risk-based approach to regulation. We hope the Minnesota Pollution Control Agency (hereafter "MPCA") will find our comments useful in crafting proposed regulations. First, we provide general comments on the proposed regulation, followed by responses to the specific questions raised in the request for comments.

General Comments

When determining whether the use of a PFAS in a product or product component is a CUU, MPCA should recognize that not only is it regulating current uses, but it is also making important decisions about the economic viability of substances critical to future innovations that promise to deliver tremendous societal benefits in a range of fields from healthcare to mitigating the negative effects of climate change. Only by applying a risk-based approach to determining whether a particular substance is unavoidable can MPCA balance the economic and social needs of Minnesotans with the goal of protecting the state's citizens and environment from potentially harmful PFAS.

By using criteria for identifying polymers of low concern to human health or the environment,[3,4] MPCA can avoid using its resources to analyze the essentiality of fluoropolymers in particular uses and instead focus on other PFAS substances that may present a higher risk. Fluoropolymers are large, stable molecules that have been demonstrated to meet multiple criteria developed within chemical regulatory frameworks around the world to identify

polymers of low concern.[5,6] As demonstrated in the references provided, fluoropolymers are insoluble substances and therefore do not present concerns about mobility in the environment, in contrast to certain highly water soluble PFAS substances. In addition, fluoropolymers are neither bioavailable nor bioaccumulative, are not long-chain non-polymer PFAS, such as PFOA and PFOS, and do not transform into non-polymer PFAS in the environment.

Because of their unmatched combination of properties, fluoropolymers are used in thousands of products and product components (see responses to questions 7 and 8). Because of their favorable health and environmental safety profiles, as well as their irreplaceability in a wide range of products and applications that are essential to the daily lives of Minnesota's residents and businesses, fluoropolymers and uses of fluoropolymers should be designated as CUUs. Determination of CUUs across the entirety of Minnesota's economy will be exponentially more complex and burdensome if fluoropolymers are not excluded.

We strongly recommend that MPCA consider four other factors where CUU determinations are concerned:

1. Affirmative CUU determinations should extend to the entire supply chain necessary for the substance in the use. A CUU cannot exist in the economy if the manufacturers and processors involved in bringing the CUU to market do not have adequate regulatory certainty.

2. The 2032 ban may not allow sufficient time for manufacturers acting in good faith to adequately test and document the performance of fluoropolymers versus potential substitutes at scale. While such information is being generated, certain uses could be banned, which could lead to shortages or disruptions of supplies critical to the health, safety, and functioning of society. Implementing regulations should have a mechanism for extensions for manufacturers acting in good faith to generate information to support a CUU determination. Therefore, MPCA should create a continuous process for CUU applications and determinations.

3. Similarly, advances in technology and/or the emergence of new societal threats and challenges may result in new CUUs of fluoropolymers being recognized after 2032. MPCA should ensure that the regulatory process under development will allow those "new" CUU applications to be designated as such and allowed in commerce in Minnesota after January 1, 2032.

4. In order to avoid opinion-based criteria, MPCA should employ methods such as risk assessment, life cycle assessment, and socio-economic analysis and include

Integr Environ Assess Manag, https://doi.org/10.1002/ieam.4646.

transparent stakeholder engagement in their process. MPCA should obtain broad stakeholder and expert input and carefully consider the uses under consideration.

More specific comments on MPCA's nine questions appear below.

1. Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Yes, criteria should be defined for "essential for health, safety and functioning of society." An "essential" assessment should only be initiated when there is deemed to be a risk to human health or the environment from the use of an intentionally added PFAS in a product. Products that do not present an unacceptable risk to human health or the environment should be presumed to be "essential for health, safety and functioning of society." On this point, we reiterate that fluoropolymers have been demonstrated to satisfy criteria for identifying polymers of low concern. If there is no concern about risk during the use of an intentionally added fluoropolymer, MPCA and stakeholder time and resources should not be wasted on an essentiality analysis. Neither should residents of Minnesota be denied access to a myriad of products important to their daily lives simply because those products contain fluoropolymers.

When considering the essentiality of a substance in a use, MPCA can look to the Maine Department of Environmental Protection's (DEP) most recent regulatory proposal,[7] which says:

> ***"Essential for Health, Safety or the Functioning of Society"*** *means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations.*
>
> *Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction.*

More generally, the concept of "essential" must be interpreted broadly in order to be workable. Under a narrow interpretation of "essential" it may be argued that products such as cell phones, laptop computers, or automobiles are not "essential to the functioning of society" since society can continue to function without these conveniences. This narrow and inappropriate interpretation fails to properly account for the fact that these types of products are highly beneficial and are an essential feature of our society. Similarly, under a narrow interpretation of "essential" it could be argued that products such as refrigeration units are not "essential to health" since people can live healthy lives without refrigeration. However, this narrow interpretation ignores the critical role that refrigeration plays in supporting good health by preventing food spoilage and preserving pharmaceuticals. These are a few examples of the types of products that, if they became unavailable, would likely cause massive social and

[7] Maine Department of Environmental Protection. PFAS in Products: Currently Unavoidable Uses. https://www.maine.gov/dep/spills/topics/pfas/PFAS-products/cuu.html

economic dislocation. To avoid this type of disruption we strongly urge MPCA to adopt a broader interpretation of "essential".

Three recent federal efforts provide examples of how to evaluate the concept of "essential." First, the Cybersecurity and Infrastructure Security Agency (CISA) has identified 16 critical infrastructure sectors "whose assets, systems, and networks, whether physical or virtual, are considered so vital to the United States that their incapacitation or destruction would have a debilitating effect on security, national economic security, or national public health or safety."[8] Those sectors are:

- Chemicals
- Commercial facilities
- Communications
- Critical manufacturing
- Dams
- Defense industrial base
- Emergency services
- Energy
- Financial services
- Food and agriculture
- Government facilities
- Healthcare and public health
- Information technology
- Nuclear reactors, materials, and waste
- Transportation systems
- Water and wastewater systems

While not inclusive of all uses that would meet the criteria for "essential", the CISA's list demonstrates the need for broad interpretation to mitigate against potential unforeseen adverse impacts to critical end uses and the people who rely on them.

Secondly, a new report from a committee of the National Science and Technology Council identifies critical and emerging technologies (CETs) and advises federal departments and agencies to use the list to "inform future efforts that promote U.S. technological leadership; cooperate with allies and partners to advance and maintain shared technological advantages; develop, design, govern, and use CETs that yield tangible benefits for society and are aligned with democratic values; and develop U.S. Government measures that respond to threats against U.S. security."[9] The CETs identified in the report are:

- Advanced computing
- Advanced engineering materials
- Advanced gas turbine engine technologies
- Advanced and networked sensing and signature management
- Advanced manufacturing
- Artificial intelligence
- Biotechnologies
- Clean energy generation and storage
- Data privacy, data security, and cybersecurity technologies
- Directed energy
- Highly automated, autonomous, and uncrewed systems, and robotics
- Human-machine interfaces
- Hypersonics

---

[9] National Science and Technology Council, Fast Track Action Subcommittee on Critical and Emerging Technologies. *Critical and Emerging Technologies List Update*. February 2024. https://www.whitehouse.gov/wp-content/uploads/2024/02/Critical-and-Emerging-Technologies-List-2024-Update.pdf.

- Integrated communication and networking technologies
- Positioning, navigation, and timing technologies
- Quantum information and enabling technologies
- Semiconductors and microelectronics
- Space technologies and systems

The report identifies multiple sub-sectors in each of the CETs.

Finally, the Department of Defense (DoD) recently released a report highlighting the criticality of certain PFAS chemistries across a broad swath of applications of strategic and national importance.[10] Based on an extensive survey of known uses of PFAS chemistries, DoD concluded as follows:

> *PFAS are critical to DoD mission success and readiness and to many national sectors of critical infrastructure, including information technology, critical manufacturing, health care, renewable energy, and transportation. DoD relies on an innovative, diverse U.S. industrial economy. Most of the structurally defined PFAS are critical to the national security of the United States, not because they are used exclusively in military applications (although a few are) but because of the civil-military commonality and the potentially broad civilian impact.*

DOD went on to warn that:

> *Emerging environmental regulations focused on PFAS are broad, unpredictable, lack the specificity of individual PFAS risk relative to their use, and in certain cases will have unintended impacts on market dynamics and the supply chain, resulting in the loss of access to mission critical uses of PFAS. These market responses will impact many sectors of U.S. critical infrastructure, including but not limited to the defense industrial base.*

The DoD report specifically mentions the importance of fluoropolymers for energy storage and battery technologies, microelectronics, semiconductors, resins for specialty materials, specialty filters and membranes, munitions, and tactical and protective textiles. In addition, the report notes the importance of fluoropolymers in lines, hoses, o-rings, seals, gaskets, tapes, cables, and connectors in civil and military aircraft, space systems, vehicles, weapon systems, utility systems, and other applications, where "[a]lternatives are not as resistant to embrittlement and break-down and have a much shorter useful life, leading to more frequent part replacement, which is not feasible for space or satellite uses."

In developing regulations interpreting the concept of "essential" MPCA should heed DOD's warning and ensure that the term is interpreted broadly enough to encompass uses of PFAS—fluoropolymers in particular--that are critical to national infrastructure and supply chains. MPCA should also consider whether a PFAS is required to meet a specific performance standard or legal requirement. Some examples include meeting air or water emission controls, occupational safety requirements, product purity/contamination regulations, or in-life product performance and safety standards like performance specifications for the multiple components

---

[10] Report on Department of Defense's Per- and Polyfluoroalkyl Substances Task Force Activities, September 2022. https://media.defense.gov/2022/Oct/13/2003095518/-1/-1/1/REPORT-ON-DEPARTMENT-OF-DEFENSE'S-PER-AND-POLYFLUOROALKYL-SUBSTANCES-TASK-FORCE-ACTIVITIES.PDF

of automobiles, airplanes, and electronic devices of all types. Similarly, MPCA should acknowledge that in most instances, the durability and reliability of an "essential" product is itself an essential function, and, therefore, materials such as fluoropolymers that help to assure the reliable functioning of an essential item are themselves essential.

2. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Yes, the cost of PFAS alternatives should be considered in the definition of "reasonably available." However, the evaluation of the cost of an incumbent material or product relative to potential alternatives involves much more than just comparing the relative unit costs of materials. There are costs associated with testing and qualifying potential alternatives, redesign of production lines, added laboratory expenses, and costs related to training workers, among others. Potential human and environmental risks must be considered as well.

Furthermore, evaluating "availability" should account for the extent to which an alternative is already proven in a particular application and whether existing supply chains for the potential alternative can support increased demand. This includes demonstrating, using objective, quantifiable data, that a proposed alternative performs a required function at least as well as the incumbent substance. It also requires a determination that the proposed alternative will not substantially increase the cost of the product at issue. In other words, an alternative cannot be considered "reasonably available" if: (i) it does not perform a required function as well as the PFAS substance; (ii) it is not available at scale; or (iii) implementation of the alternative will appreciably increase the cost of the product. At a minimum, if those criteria are not met, an alternative cannot be considered "reasonably available".

Fluoropolymers are generally more expensive than other alternatives and are therefore used when potential alternatives cannot meet specific performance requirements. Fluoropolymers are used to improve the functionality, reliability, and durability of products. In many cases, not only do the materials used to make the products undergo rigorous testing and qualification, but the article or assembled product must also meet performance specifications that are not possible without fluoropolymers. Thus, where questions of "essential for health, safety, or the functioning of society" are concerned, MPCA should also investigate performance and reliability.

Therefore, consideration of "cost" must consider a suite of factors beyond the cost of the fluoropolymer and a potential alternative on the open market, and MPCA should not assume that the adoption of an alternative will be cost neutral in terms of the manufacturing process. For product (or product component) users, there may also be substantial costs to replace or repair the product more frequently because of relatively less durability. There may also be societal costs due to reduced product performance or safety.

Finally, MPCA should consider what effect the adoption of an alternative might have on the price of the final good and whether such a price increase would affect the ability of disadvantaged communities in Minnesota to access or maintain important products like mobile phones, computers, automobiles, household appliances, and others. For some, even minor cost increases can be significant, and regulators should take this fact into account.

3. Should unique considerations be made for small businesses with regards to economic feasibility?

Small businesses will be disproportionately affected by costs associated with testing and qualifying potential alternatives, the costs of redesigning products or production processes, and the replacement of any equipment (plus associated training costs). The significant effort required to determine which materials or products a business is using and whether the market is offering alternatives to them has a cost of its own. Such costs may represent an even larger burden on small enterprises that lack the resources to perform the research. MPCA should consider some form of relief for small businesses.

4. What criteria should be used to determine the safety of potential PFAS alternatives?

An alternative should not be considered “reasonably available” unless it is demonstrated, through scientific data, to present less risk under intended conditions of use than the incumbent substance. As a threshold matter, this would require MPCA to determine that the product containing the incumbent substance presents an appreciable risk to human health or the environment. Furthermore, any comparison of potential risks must include an assessment of the risks associated with any increased potential for product or product component failure, including the waste that would be associated with product replacement or repair.

MPCA should articulate clearly and transparently the criteria or information that will be used for comparative evaluations of potential risk and adopt a weight of evidence approach to assessing risk. In addition to the hazard and exposure profiles of incumbent PFAS and potential alternatives, MPCA should also consider impacts such as water use, consumption of raw materials, emissions, energy efficiency, reliability/safety during use, and useful life. The use of landfill capacity or other end of life disposal options should be considered in the cost of replacement.

5. How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

Affirmative CUU determinations should last until demonstrably safer and more sustainable alternatives are discovered and can reasonably be implemented at scale in the economy. Significant changes in available information should trigger a re-evaluation. Re-evaluation should apply not only to the use with an affirmative CUU determination, but to any alternative that was identified as the basis for denying a CUU determination. In other words, if new information about the safety or performance of an alternative becomes available, the denied CUU determination should be re-opened.

In no case should re-evaluations take place more frequently than 10 years. MPCA should consult with potentially affected industries to determine if a longer re-evaluation period may be necessary to evaluate alternatives or otherwise provide information for the re-evaluation process.

For any CUU petition that is declined (including CUUs that were granted and then subsequently declined on re-evaluation), MPCA must give manufacturers adequate time to transition to the alternative. We cannot provide a specific timeframe, as the time required to test and qualify an alternative may be quite different for different product or product component applications.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

MPCA will need to establish a process by which manufacturers and users (or their representatives) can request a CUU determination from MPCA. The process should be flexible enough to accommodate multiple uses of a substance instead of going use by use. The latter would pose a huge time burden on both MPCA and stakeholders.

A manufacturer that makes a timely submission of a request for a CUU determination should not be penalized if MPCA is unable to process the request by the statutory deadline of January 1, 2032, for identifying CUUs. In such cases, the manufacturer should be exempt from the ban until MPCA makes a final determination that the use is not a CUU. The converse process creates even more challenges in terms of allowing adequate time to respond to a request to a “not a CUU” request. At a minimum, the information requirements for either request should be identical. No party in the process should have a relatively higher or lower bar for substantiating its request. If a stakeholder argues against the establishment of a CUU designation, the manufacturers or users of those products should be given a clear and meaningful opportunity to rebut.

Any process around the granting or re-evaluation of a CUU must protect trade secrets. As noted in our November 28, 2023, comments on the Planned New Rules Governing Reporting by Manufacturers Upon Submission of Required Information about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor’s ID Number R-4828:

> *Some types of proprietary information the Agency will request derive independent economic value and are the subject of efforts to maintain its secrecy. Such information may also be recognized as confidential by federal or other state agencies, and trade secrets that are inadvertently disclosed may compromise national security and infrastructure. Therefore, in the proposed rule, the Agency must provide clear instructions regarding the specific steps that must be taken to officially assert and/or substantiate a trade secrets claim for information submitted that qualifies as a trade secret under Minnesota law, including the timeline by which such claims must be made relative to the reporting deadlines.*
>
> *The Agency also should define in regulation a process whereby a manufacturer is to be notified if its trade secret is subject to a public records request or is inadvertently disclosed by the Agency or any organization with which the Agency collaborates or contracts in the administration of the reporting program, including other states and any organization that designs, operates, or otherwise administers the reporting platform. The*

Agency should not enter into data sharing agreements with any organization, including but not limited to other states, if the Agency cannot assure that those organizations possess equivalently protective policies for trade secrets submitted to Minnesota. As we have previously noted in comments to the State of Maine, we are particularly concerned about how commercially valuable trade secret information will be managed by the Interstate Chemicals Clearinghouse (IC2) of which the Agency is a member.

7. In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

We would like to take this opportunity to draw MPCA's attention to a recent report from the Fluoropolymers Product Group of Plastics Europe. The report, *Socioeconomic Impact Assessment for Fluoropolymers,* contains extensive information about the uses of and alternatives for specific fluoropolymers in multiple sectors, including:

- Transport, including automotive and aerospace
- Chemical processing
- Construction materials
- Energy, including batteries and hydrogen
- Petroleum and mining
- Electronics and semiconductors
- Water and wastewater treatment
- High performance lubricants
- Medical devices and pharmaceuticals
- Architectural and professional textiles
- Metal plating and manufacturing of metal products
- Industrial coatings

The report is publicly available.[11] The information in the report about fluoropolymer uses and alternatives is relevant to the United States (as opposed to the economic information).

In addition, we have produced a white paper on the use of fluoropolymer resins in architectural and infrastructure applications.[12] The report compares fluoropolymer resins against potential substitutes in five end-use applications: building facades and protection; roofing and roofing structures; bridges and walkways; water towers; and solar panels. The white paper provides compelling evidence of the unmatched performance of fluoropolymer-based products in elements of the critical infrastructure.

[12] https://fluoropolymerpartnership.com/wp-content/uploads/2023/12/PFP-White-Paper-on-Fluoropolymers-in-Infrastructure-and-Construction.pdf

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Yes, MPCA should make some initial CUU determinations as part of the rulemaking process using the proposed criteria. As noted previously, an "essential" assessment should only be initiated based on an assessment of risk to human health or the environment from the use of an intentionally added PFAS in a product. To start, MPCA could determine that products in which the use of a fluoropolymer enhances health, safety, and functioning of society should be granted CUU status or otherwise exempted from the requirements under the PFAS in products statute. Fluoropolymers have been shown to meet criteria for identifying polymers of low concern for human health and the environment. MPCA can maximize the use of its resources and can avoid the disruption of many product supply chains by giving fluoropolymers affirmative CUU determinations.

A non-exhaustive list of fluoropolymer uses that support significant societal benefits are provided as a starting point:

- Medical applications, pharmaceutical precursors, medical devices, and equipment that is deemed necessary to protect society from disease or otherwise reduce morbidity and mortality;
- Military and national defense uses (see the CSIA and DoD report referenced under question 1);
- Safety and critical functioning of chemical manufacturing processes and the storage of hazardous, corrosive, or explosive substances.
- Multiple systems that rely on fluoropolymers to enhance the safety of trains, airplanes, automobiles, heavy motorized equipment, ocean-going vessels, and other passenger and cargo transport vehicles;
- Navigation and communication systems that rely on fluoropolymers' unique combination of optical, thermal and dielectric properties;
- Semiconductor manufacturing that relies on high-performing fluoropolymers and fluoroelastomers to achieve and maintain the required levels of purity and clean manufacturing;
- Lubrication systems and sealing systems operating under harsh conditions;
- Water purification and treatment systems that utilize fluoropolymer membranes, resins, or filtration media;
- Analytical standards, testing equipment, and monitoring systems required for health, environmental, and safety measurements, detection, signaling, and monitoring;
- Exploration, conservation, research, and harvesting in all segments of the energy industry (e.g., hydrogen, solar, wind, oil, hydroelectric, and gas);
- Protective coatings used in construction, original equipment manufacturing, and factory applications;
- Fluoropolymers used in research and development in the uses described above or for uses that receive affirmative CUU determinations; and

- A product for which federal law governs the presence of a fluoropolymer in the product in a manner that preempts state authority.

9. Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

Some CUU determinations will require MPCA to determine whether reasonably available alternatives exist. The bases for such determinations must be consistent, fair, transparent, and well-defined. MPCA should propose objective criteria for determining when alternatives are or are not “reasonably available,” taking into consideration factors such as performance, safety, total cost of ownership, and reduced potential for risk to human health or the environment when compared to products or product components made with alternatives to fluoropolymers.

****

Thank you for the opportunity to provide these comments. Please contact me if you or your colleagues have any questions.

Re: MPCA Request for Comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Dear Commissioner Kessler:

The Air-Conditioning, Heating, and Refrigeration Institute (AHRI) appreciates the opportunity to submit comments to the Minnesota Pollution Control Agency (MPCA) for its planned new rules governing currently unavoidable use (CUU) determinations for products containing Per-and polyfluoroalkyl substances (PFAS).

Regulatory bodies should adopt basic principles to provide stability and certainty to the regulated community. Adopting the basic principles outlined in these comments will help MPCA meet its PFAS management goals, while supporting industry in preparing to meet these new challenges.

In the following proposal, we will provide responses to MPCA's request for information on various points that will help the agency develop regulations that will protect human health and the environment as well as jobs, businesses, and products that are essential to societal well-being. We ask that MPCA consider these comments carefully to prevent AHRI members' essential products from being banned from distribution in Minnesota commencing January 1, 2032.

Background on AHRI

AHRI represents more than 330 manufacturers of heating, ventilation, air conditioning, refrigeration, and water heating (HVACR-WH) equipment. It is an internationally recognized advocate for the HVACR-WH industry and certifies the performance of many of the products manufactured by its members. In North America, the annual economic activity resulting from the HVACR-WH industry is more than $211 billion. In the United States alone, AHRI member companies, along with distributors, contractors, and technicians employ more than 704,000 people. In Minnesota, the HVACR-WH industry supports more than 16,000 jobs.[1] AHRI and its members are committed to reasonable PFAS management that supports human health and the environment while protecting the jobs and the products that are essential to our society's well-being.

Introduction

AHRI supports MPCA's efforts to reduce harm to human health and the environment. We recognize there is precedent among controlling agencies at the international, federal, and state level for providing "critical use" or "currently unavoidable use" exemptions as these entities recognize the unique challenges associated with the PFAS family of over 12,000 unique chemicals.[2]

For the regulated community, even simple chemical substitutions can take years and cost millions of dollars. The chemical substitution process requires identifying chemicals in a complex, global supply chain, trying to find an alternative (if one is available), and then initiating the complicated, time-consuming, and expensive process of product redesign. Product redesigns include research, development, testing, and implementation which is a lengthy process process of several years as this equipment is subject to mandatory testing (e.g., for energy efficiency, safety, earthquake, and in some cases, food safety etc.) for even a single chemical change. Please see Appendix III for the assessed schedule for the steps and timing to replace phenyl isopropylated phosphate (PIP) (3:1).

For these reasons, we urge MPCA to consider not only human health and the environment but also business continuity and survival when proposing new burdensome or potentially unachievable mandates. This is especially true for vulnerable small businesses who have labor and financial constraints which cannot support the proposed compliance timelines and mandates. Government and industry must work together to develop deliberate, effective, thoughtful, and reasonable approaches to PFAS management.

Specific Comments in Response to MPCA's Request

1) Should criteria be defined for "essential for health, safety, or the functioning of society?" If so, what should those criteria be?

Response: Yes, criteria should be defined for "essential for health, safety, or the functioning of society" as well as other key terms and concepts which are detailed here. MPCA should also provide guidance and examples whenever possible. Please consider our responses here:

A. "Essential," "Essential for health, safety, or the functioning of society," and "Reasonably available alternatives"

Under MN Section 21, Subsection 116.943, Subdivision 1(j), "'Currently unavoidable use' means a use of PFAS that the commissioner has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available." Therefore, it is critical for the regulated community to have a clear understanding of these terms.

To lessen the burden on the regulated community, AHRI asks MPCA to harmonize with other enacted laws and regulations as much as possible. For example, MPCA could consider using the definition found in Maine's Section 1614 of Title 38, which defines "Essential for Health, Safety or the Functioning of Society" to mean:

> products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations. Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction.[3]

Again, for harmonization, AHRI asks MPCA to consider using the definition found in Maine's Section 1614 of Title 38, which defines "reasonably available" to mean "a PFAS alternative which is readily available in sufficient quantity and at a comparable cost to the PFAS it is intended to replace and performs as well as or better than PFAS in a specific application of PFAS in a product or product component."[4]

B. "Product Categories"

Once the MPCA has established the criteria for CUUs, AHRI recommends establishing Product Categories to lessen the burden on the regulated community. AHRI proposes that MPCA establish a category for "HVACR-WH" which includes heating (including space

[3] Maine Title 38, Section 1614, Enacted October 25, 2023.
[4] Maine Title 38, Section 1614, Enacted October 25, 2023.

heating), ventilation, air conditioning, refrigeration (including transport), refrigerants, and water heating equipment and their components and parts including replacement parts, materials, and manufacturing and servicing needs. Please see our response to "Question 7" for additional information.

C. “PFAS Definition”

Under MN Section 21, Subsection 116.943, Subdivision 1(p), PFAS are defined as “’Perfluoroalkyl and polyfluoroalkyl substances’ or ‘PFAS’ means a class of fluorinated organic chemicals containing at least one fully fluorinated carbon atom.” However, no definitive list of chemicals is provided. This makes it difficult if not impossible for product manufacturers (who are not chemicals experts and who often have complex, international, multi-tiered supply chains) to identify which of these substances are used in their products.

The grouping of thousands of PFAS creates regulations that are too complex to comply with or to enforce and thus not reasonable, practical, or achievable. Targeted PFAS should be identified by its unique Chemical Abstract Service Registry Numbers (CASRN). CASRN are unique numerical identifiers assigned by the Chemical Abstracts Service (CAS) to every chemical substance described in the open scientific literature from 1957 through the present. At present, the EPA has compiled a list of over 12,000 PFAS.[5]

In today’s multi-tiered global supply chains, CASRN are the accepted nomenclature for identifying chemicals, and an essential accepted method of communication for chemical disclosure information. Without the CASRN to pinpoint the chemical in question, it would be difficult (if not impossible) to comply with any impending regulatory action.

Despite not providing the clarifying CASRN in the statute, however, in MN Section 21, Subsection 116.943, Subdivision 4(a) “Testing required and certificate of compliance” provides that the commissioner can “direct the manufacturer of the product to, within 30 days, provide the commissioner with testing results that demonstrate the amount of each of the PFAS, identified by its *chemical abstracts service registry number* [emphasis added], in the product…” This statement indicates that MPCA is aware of how difficult it would be to identify chemicals without its CASRN yet expects the regulated community to do so. AHRI requests that MPCA provide a list of targeted PFAS along with their associated CASRN.

Furthermore, it should be noted that currently there are no common methods of testing for PFAS in products.

D. “Intentionally added”

Under MN Section 21, Subsection 116.943, Subdivision 1(l), “‘Intentionally added’ means PFAS deliberately added during the manufacture of a product where the continued

[5] https://comptox.epa.gov/dashboard/chemical_lists/pfasmaster. (Last accessed on Feb. 13, 2024).

presence of PFAS are desired in the final product or one of the product's components to perform a specific function."

AHRI recommends that MPCA clarify to what level a substance is considered "intentionally added" and provide *de minimis* exemptions for articles containing less than 0.1% (by weight) of PFAS. (Please see "AHRI urges MPCA to Grant Certain Exemptions" below for more information pertaining to the *de minimis* concept.)

The intentionally added concept is separate from the concept of concentration in the product. A substance is intentionally added if it serves a technical function in the final product or component. Depending on how Minnesota determines concentrations, it is likely that having a *de minimis* threshold will not exempt many intentionally added PFAS, but rather will further exempt PFAS that are already considered unintentionally added.

E. <u>"Substantially Equivalent" and "Additional Time"</u>

MN Section 21, Subsection 116.943, Subdivision 3(a) states that "[t]he commissioner may waive all or part of the information requirement under subdivision 2 if the commissioner determines that substantially equivalent information is already publicly available" and 3(d) states that "[t]he commissioner may extend the deadline for submission by a manufacturer of the information required under subdivision 2 if the commissioner determines that more time is needed by the manufacturer to comply with the submission requirement." AHRI asks that MPCA provide clarification and guidance as to what will be considered "substantially equivalent" information and what criteria the commissioner will use to determine if "more time is needed."

F. <u>AHRI urges MPCA to Grant Certain Exemptions.</u>

In addition to an exemption to a ban on PFAS, the heating, cooling, water heating, and refrigeration equipment industry asks that policy makers provide additional relief through three additional exemptions. AHRI asks to receive *de minimis* exemptions for articles containing less than 0.1% (by weight) of PFAS, replacement parts exemptions, and large-scale manufacturing equipment exemptions.

a. <u>MPCA Must Grant *De Minimis* Exemptions</u>

Due to the complexities of the international, multi-tiered supply chain, determining a presence below the threshold of 0.1 % by weight is nearly impossible. Manufacturers must rely on the accuracy of reporting from every supplier throughout the entire supply chain on trace amounts of a chemical, even those that are present unintentionally. There is little, if any, evidence to suggest that the presence of trace amounts of a chemical in an article can contribute to *exposure*, which must be considered in any risk determination. Furthermore, there has been much scientific debate over whether it is actually possible to achieve 100% confidence in any formulation.

Lastly, and possibly most importantly, international and federal law has precedent for providing *de minimis* exemptions.[6] The *de minimis* exemption allows covered facilities to disregard certain minimal concentrations (0.1% or below) of chemicals in certain situations. Although this exemption is limited, it shows that the Agency understands the difficulties associated with tracking and managing chemicals below this threshold. Therefore, we urge MPCA to extend that relief to this application as well. We urge other regulatory bodies to follow this precedent. Not having a *de minimis* exemption puts an unreasonable burden on manufacturers and therefore, should be provided to allow permanent regulatory relief.

b. MPCA Must Grant Replacement Parts Exemptions

Another exemption the MPCA should provide relates to replacement parts. Many manufacturers are required to maintain replacement parts for years to ensure that consumers' products can continue to remain operational and meet warranty demands. It is not economically feasible for manufacturers to redesign and produce replacement parts years after they were originally made, because many of these parts are no longer being actively manufactured. So that companies can meet legal and consumer requirements, we request that MPCA provide a fifteen-year exemption for all replacement parts.

c. MPCA Must Grant Large-Scale Manufacturing Equipment Exemptions

MPCA should also exempt large-scale manufacturing equipment. This is equipment that exists at manufacturing facilities that does not enter into commerce, is often legacy equipment, and provides essential functions for which there is no known replacement. Existing equipment should not need to meet new compliance requirements. Accordingly, replacement parts for such equipment should also be exempted.

AHRI asks MPCA to consider these terms and ideas and to provide additional opportunities for stakeholders to work cooperatively with the agency to develop rulemakings that achieve goals to protect human health and the environment while protecting the jobs and the products that are essential to our society's well-being.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available?" What is a "reasonable" cost threshold?

Response: Yes. The standards for reasonably available alternatives should consider both the *technical and economic* feasibility of alternatives. Here we examine the *economic* feasibility of alternatives; please see the "No Technically Feasible Safer Alternative to PFAS Is Reasonably

[6] 40 CFR §372.38(a), https://ofmpub.epa.gov/apex/guideme_ext/f?p=GUIDEME:GD-TITLE:::title:deminimis. (Last accessed on Feb. 13, 2024).

Available for the Entire HVACR-WH Category of Products" section for information on *technical* feasibility of alternatives.

A. Economic Considerations for *Finding* Feasible Alternatives

TSCA Section 6(g)(1) directs EPA to consider whether a "technically and economically feasible safer alternative is available." In addition to our comments above about the lack of a technically feasible alternative, we also wish to provide MPCA with information on economic feasibility, both in finding an alternative and implementing an alternative. Substantial costs would be incurred to conduct an adequate alternatives analysis. Such costs might include those for performance and reliability testing and additional information gathering to fill data gaps and ensure an informed decision. If no viable alternatives are readily identified, producers must invest in research and development of new chemistries, with subsequent process development and scaling up necessary to evaluate feasible options.

Estimates for conducting evaluations of alternative technologies range from the hundred-thousand-dollar range (with minimal new data acquisition) to several million dollars (if the evaluation requires extensive testing and acquisition of data). The US EPA, for example, is aware of the enormous expenses required to evaluate chemicals. The Agency's *initial* fee for a manufacturer-requested risk evaluation on a single chemical included requires a $1,250,000 up-front payment; full costs are undoubtedly much higher.[7]

Furthermore, if no viable alternatives are readily identified, the next likely step may be to invest in exploring entirely new technologies.

B. Economic Considerations for *Implementing* a Feasible Alternative

The expense imposed on companies – small and medium-sized enterprises as well as large, multinational corporations – affected by a ban on the use of PFAS would be substantial enough to disrupt the market and impact the national economy. Implementation costs include manufacturing infrastructure redesigns, inventory loss, new formulation acquisition costs, product redesign costs, and many other expenses—both foreseeable and unforeseeable.

Even simple chemical substitutions can be very expensive. A great example is the relatively "simple" substitution of a new chemical for methanol in windshield washer fluid in Finland. The ECHA Committee for Socioeconomic Analysis (SEAC) reported this cost as $4 million dollars.[8] More difficult substitutions, such as implementing a new

---

[7] https://www.epa.gov/tsca-fees/tsca-fees-table. (Last accessed on Feb. 13, 2024).
[8] https://echa.europa.eu/documents/10162/cc415549-cac9-4784-97dc-2170d0bf8f25. (Last accessed on Feb. 13, 2024).

material or a new fluid across an HVACR product line, can quickly run into the tens of millions of dollars.[9]

Manufacturing facility redesign costs tend to be incredibly costly. Introducing a new chemical into the manufacturing process would result in "retooling" the manufacturing infrastructure as an unavoidable by-product of implementing new technology. These major changes require sufficient capital investment. Employees would need training.

Furthermore, disruptions in production schedules to engage in parts reformulation and conducting testing to meet safety standards would have adverse downstream impacts and possibly broader repercussions across related markets. This process could shut down businesses across our industry in the United States, making our nation more reliant on imports, which would consequently cause sharp cost increases for domestic manufacturers. That in turn could cause decimation of important manufacturing sectors of the nation, including public safety, food and agriculture, transportation, and national defense.

Due to the complex nature of the production process, product reformulations or facility redesigns can be extremely costly and can easily run in the tens of millions of dollars.

MPCA should also consider that costs would be passed on to the consumer or business owner. For instance, how costs could impact an average consumer to replace an HVAC system when typical prices range from $8,000 - 12,000. For a retail food store or restaurant business these costs could range from $40,000 – 150,000. For large, refrigerated warehouse storage facilities the cost easily be up to $1 million or more. For larger supermarkets, this will necessitate retrofits for each refrigeration rack, and each rip-out would require considerable investment – an estimated $1 million per rack – and result in significant downtime and store closures across the state.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

<u>Response</u>: Yes. For all the points made in response to Question 2, small businesses face these same challenges.

---

[9] For example, see costs for substituting another chemical for BPA in thermal paper as reported by the ECHA Committee for Socioeconomic Analysis (SEAC), https://echa.europa.eu/documents/10162/7f8d2988-fad4-4343-bef3-4518336db109. (Last accessed on Feb. 13, 2024).

4) What criteria should be used to determine the safety of potential PFAS alternatives?
<u>Response</u>: MPCA should use a scientifically sound, risk-based approach when making determinations of the safety of PFAS alternatives.

A. <u>Best Available Science</u>
Determinations should be based on sound science. Any regulatory action addressing PFAS should be based on sound, peer-reviewed science and a transparent and well-informed record. Agencies should identify sources of uncertainty and the research needed to reduce those uncertainties, and regulations should remain flexible to accommodate emerging science.

B. <u>Risk-Based Approach</u>
Determinations should apply a risk-based approach to consider both hazard and exposure. To best protect human health and the environment, a risk-based approach focuses limited agency resources on the highest priorities based on actual environmental, health, and safety risk of particular chemistries, not just the mere presence of a substance. Please see additional information about this in the "No Technically Feasible Safer Alternative to PFAS Is Available for the Entire HVACRHVACR-WH Category of Products" section.

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?

<u>Response</u>: AHRI recommends that MPCA look for guidance on this question from the precedents set at the national and international levels. For example, recent EPA rulings have set a precedent for providing manufacturer exemptions to chemical bans that do not have a time limit (and other regulatory bodies should follow suit).[10] If MPCA determines that any exemptions granted must sunset, they should consider federal guidelines. For example, the EPA is required under TSCA Section 6(g)(3) that the period of exemption must be "reasonable."

The controlling federal statute provides additional clarification. TSCA Section 6(d) states that the Administrator shall, "specify mandatory compliance dates for the *start* [emphasis added] of ban or phase-out requirements under a rule under subsection (a), which shall be as soon as practicable, but not later than 5 years after the date of promulgation of the rule…" and furthermore states the Administrator shall "specify mandatory compliance dates for full implementation of ban or phase-out requirements under a rule under subsection (a), which shall be as soon as practicable; and provide for a *reasonable transition period* [emphasis added]." Therefore, EPA has the authority to provide five years for the start of any ban or required phase-out of any chemical, and further allow for a reasonable amount of time for manufacturers to

[10] 86 Fed. Reg. 894, January 6, 2021, "Phenol, Isopropylated Phosphate (3:1) (PIP 3:1); Regulation of Persistent, Bioaccumulative, and Toxic Chemicals Under TSCA Section 6(h)", https://www.regulations.gov/document/EPA-HQ-OPPT-2019-0080-0588. (Last accessed on Feb. 13, 2024).

transition to alternatives. Therefore, we expect MPCA to provide a similar number of years to allow manufacturers a reasonable time period for addressing this complex issue.

Further, there is global precedent for allowing reasonable phase-out periods for complying with chemical bans. The European Union's "RoHS Directive"[11] allows for several years for manufacturers to eliminate substances that are being restricted. For example, RoHS II Amendments under Directive 2015/863 provided for four to six years to implement restrictions and recently the European Commission stated in their RoHS Review report[12] that the current exemption time periods are too short, stating "[t]he evaluation found that the validity periods for time-limited exemptions and transition periods in case of expiry are too short for EEE, which requires long development, testing and validation time (e.g. for certain medical devices). Both periods are currently limited. Time-limited exemptions cannot exceed a seven-year validity period and where an exemption is revoked, a transition period of at least 12 months but no more than 18 months applies."

Moreover, European authorities routinely have granted "exemptions" to the RoHS thresholds for restricted substances in designated uses. The maximum time allowable under the RoHS Directive for such exemptions extends to seven years for certain categories of products. The European authorities recognize the complexities of the chemical management process and accordingly grant sufficient time for affected entities to implement change. Recently, EPA provided an additional 10 years for processing and distribution in commerce certain PIP (3:1) containing articles and PIP (3:1) used in manufacturing equipment and provided an exclusion for PIP (3:1) used in wire harnesses and circuit boards. MPCA should follow suit to provide sufficient time based on each particular substitution, which some manufacturers estimate could take up to 20 years. This time will allow manufacturers to determine the presence of PFAS throughout its supply chain and manufacturing processes, find a suitable alternative, and begin to implement the alternative. Alternatively, it is reasonable to suggest that MPCA should keep any CUU exemptions in place until a suitable alternative can be found and implemented, the complexities of which are explained below.

A. Determining the Presence of PFAS in the Supply Chain and in the Manufacturing Processes

The modern network between a company and its suppliers to produce and distribute a specific product consists of a global, nonlinear, multi-tiered supply chain. The system is vastly broad and complicated and includes levels starting with the raw materials supplier, moving on to a material formulator, to an article producer, to a component assembler, to an end producer, and to, finally, an original equipment manufacturer. And the network is not linear as portrayed in this simple example and is instead a complicated web of dealers, contractors, and sellers at any one tier in the chain. Further, suppliers can be found in any country throughout the world—often a product crosses many national borders several times before ultimately reaching a US consumer.

[11] Directive 2011/65/EU of The European Parliament and of The Council of 8 June 2011 on the restriction of the use of certain hazardous substances in electrical and electronic equipment. (Last accessed on Feb. 13, 2024).
[12] European Commission, "Report from the Commission to the European Parliament, the Council, the European Economic and Social Committee and the Committee of the Regions," December 7, 2023.

To comply with a chemical regulation, AHRI members must first navigate the complexities of the international supply chain to determine the presence of a chemical in their supplier network. Next, they must determine the presence of a chemical in their manufacturing processes. Since MN controlling law does not provide a *de minimis* exemption, this process must be conducted for even trace amounts of a chemical, even for those that are not added intentionally. To do so, there must be reliance on the accuracy of reporting from every supplier throughout the entire supply chain. It can take months (if ever, due to confidential business information (CBI) claims), lack of resources and expertise, and other factors to get responses from suppliers deep within the supply chain.

Manufacturers must devote considerable effort and divert resources from other immediate activities to comply with an unnecessarily and artificially short regulatory timeframe. It is almost impossible to get internal approval to divert time and money towards this endeavor in advance of an actual ban. Businesses cannot proactively begin this process for hundreds or even thousands of chemicals that might someday be banned. And MPCA must recognize that although these comments focus on PFAS, manufacturers are also dealing with PFAS and non-PFAS regulations from international treaties to local ordinances. Small businesses are especially disadvantaged.

Further, a process must be developed to track and manage chemicals throughout the entire supply chain to ensure compliance beyond any regulations' effective date. AHRI is actively working with its members to support their development of materials management processes, and although some AHRI members have robust internal processes, many are still in development.

A conservative estimate is that the process of determining a single chemical's position in the supply chain and developing a tracing program to ensure continued compliance would take at least 24-36 months to achieve. Emerging regulations should allow manufacturers essential time to undertake proper review of their supply chains to adequately ensure compliance.

B. *Finding* a Technically and Economically Feasible Safer Alternative

Because currently there are no reasonably available, known-to-be-suitable, PFAS alternatives for the *entire* HVACR-WH category, manufacturers would need to identify an immediate substitution of alternate formulations for companies to maintain production. But finding a suitable chemical requires significant investment of time and resources, with no guarantee of success within a planned timeline.

To find an alternative chemical, a conservative estimate of time to complete a *preliminary* screen for possible alternatives to PFAS can take months to years, depending on the complexity of the product. A more in-depth alternative analysis including stakeholder surveys to collect additional information on safety, performance, availability, and economic feasibility could take many years.[13]

Based on our experience, an additional one to two years to conduct adequate performance testing is needed before manufacturers can commit to using a particular alternative. This step brings the entire process of finding a suitable alternative to a total timeline of two to three years, if not longer.

C. *Implementing* a Technically and Economically Feasible Safer Alternative

Once an alternative formulation has been identified, additional time is needed for implementation. A conservative estimate of the time needed to implement a *single* alternative to PFAS is three to five years. When products contain multiple PFAS, this timeline increases (especially if the substitution of many PFAS are happening concurrently), as different PFAS perform different functions in products. That is, an alternative for PFAS "A" may not function as an alternative for PFAS "B."

The process requires redesigning and testing new parts that contain PFAS alternatives for compliance with applicable standards – a resource-intensive and time-consuming process. Similar tests and evaluations likely would be needed to eliminate PFAS use in industrial machinery. Sufficient volumes of any alternative formulations would need to be made available in the market to meet demand. Given that PFAS are used in multiple heating, cooling, water heating, and refrigeration equipment industry applications, these activities would disrupt and delay production schedules.

Specific tasks required to phase out existing products and introduce alternatives typically include:

- Procurement of appropriate alternative components
- Compliance assessments
- Quality assessments and certifications
- Safety assessments and certifications
- Supplier coordination
- Manufacturing modifications
- Shipment, import, and distribution
- Replacing existing systems
- Retrofitting equipment
- Investing in new technologies
- Retraining and reskilling workers to adapt to the changes in technology for the manufacturing, installation, maintenance, and servicing of these critical heating and cooling systems

[13] For more information about the complexities of a chemical alternatives analysis, please see the California Department of Toxic Substances Control (DTSC) 302-page guide: https://dtsc.ca.gov/wp-content/uploads/sites/31/2016/01/AA-Guide-Version-1-0_June-2017.pdf. (Last accessed on Feb. 13, 2024).

D. Minnesota Should Create a Safe Harbor for Supplier Chemical Disclosure

Obtaining information from suppliers remains difficult. AHRI members continue to face difficulty in obtaining information on whether chemicals are contained in articles and the many components used in their products.

AHRI's Directory of Certified Product Performance lists over four million products with over nine million new products sold and installed annually in homes and businesses. Members continue parsing through tens of thousands of stock-keeping units (SKUs), each having hundreds of associated components and spare parts, to better understand whether their products will be affected by this regulation. Suppliers, especially small businesses, struggle to provide chemical data information to their OEM customers. Some suppliers will not disclose the chemical makeup of components as the composition due to CBI constraints.

AHRI and its members urge MPCA to consider these points and create an allowance for safe harbor provided best efforts are made to obtain this important information.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

Response: For harmonization and a lessened burden on the regulated community, MPCA should look to prevailing federal law for guidance. MPCA should use its authority to meet its legal obligations while still providing manufacturers with an ability to obtain compliance without undue encumbrance. For example, under TSCA Section 6(g)(1), EPA has authority to grant an exemption from a risk management rule if the Agency finds that:

> (A) the specific condition of use is a critical or essential use for which no technically and economically feasible safer alternative are available, taking into consideration hazard and exposure;
>
> (B) compliance with the requirement, as applied with respect to the specific condition of use, would significantly disrupt the national economy, national security, or critical infrastructure; or
>
> (C) the specific condition of use of the chemical substance or mixture, as compared to reasonably available alternatives, provides a substantial benefit to health, the environment, or public safety.[14]

When a member of the regulated community can successfully show these criteria are met, EPA has the obligation to use its authority under TSCA Section 6(g) to grant the exemption. We urge MPCA to adopt similar criteria.

---

[14] US Toxic Substances Control Act, Section 6(g)(1).

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Response: AHRI members will likely request a CUU for the heating, ventilation, air conditioning, refrigeration, refrigerants, and water heating equipment (HVACR-WH) category of products, based on the intended use of these products, as well as the criticality for health, safety, and the functioning of society.

A. Brief Description of HVACR-WH Category Typical Product Lines:

"HVACR-WH" includes heating, ventilation, air conditioning, refrigerants, refrigeration, and water heating equipment and their components and parts including replacement parts, materials, and manufacturing and servicing needs. Here are brief descriptions of the types of products that generally comprise each associated product line within the HVACR-WH category. This list is meant to provide examples of product types and individual products and is not meant to be exhaustive (please see Appendix I for more information):

- "Heating"
  - Heating products generally include manufactured items such as: space heaters, room heaters, ventless room heaters, heat pumps, furnaces, boilers, heating elements, burners, boiler equipment and associated parts and accessories, anti-scaling agents, filters, venting, and their associated spare parts, and similar products. These examples are meant to be representative, not exhaustive, of heating products.
- "Ventilation"
  - Ventilation products generally include manufactured items such as: louvers dampers, energy recovery ventilators, air exchangers, air filters, air filtration equipment, residential and commercial air filters, air filter media in general (and their associated manufactured equipment), and similar products. These examples are meant to be representative, not exhaustive, of ventilation products.
- Air Conditioning and Heat Pumps"[15]
  - Air conditioning products generally include manufactured items such as residential, commercial, and industrial products which heat and cool air or fluids, air conditioning machines comprised of motor-driven fans and elements for changing the temperature and humidity (including those machines in which the humidity cannot be separately regulated), cooling towers and similar plants for direct cooling (without a separating wall) by means of recirculated water, evaporative air coolers, thermal energy storage tanks, and similar products. These examples are meant to be representative, not exhaustive, of air conditioning and heat pump products.

[15] https://www.hts-code.com/code/hts_result?code=8415, https://www.hts-code.com/code/hts_result?code=8418&submit=Search.

- "Refrigerants" [16,17,18]
    - Refrigerants products generally include manufactured items such as: single component refrigerants and blends, refrigerants and non-mechanical heat transfer fluids, items defined by ASHRAE34 and approved by the EPA Significant New Alternatives Policy (SNAP) Program used in air conditioning, heat pump, refrigeration or other refrigerant containing equipment, specific refrigerants (for example, R125, R134a, R143a, R227ea, R1234yf, R1234ze(E), and any R400 or R500 series blends containing one or more refrigerants with a fully fluorinated carbon atom), and similar products.. These examples are meant to be representative, not exhaustive, of refrigerants products.
- "Refrigeration Equipment" [19]
    - Refrigeration Equipment products generally include manufactured items such as freezers (commercial, residential, and laboratory/medical), refrigerators, warehouse refrigeration (large storage), coolers, walk-in coolers, walk-in freezers (restaurants, retail food stores), reach-in refrigeration, cold rooms, refrigerated vending machines and icemakers, heat transfer products (including evaporative open towers), and evaporative, adiabatic, and dry coolers and condensers, thermal energy storage units, evaporators and their controls, refrigeration racks, refrigerated cases and merchandizers, prep equipment, condensing units, air cooled condensers, unit coolers, self-contained refrigeration, ice machines, dispensing equipment, blast chillers, mobile/transport refrigeration, refrigeration racks (Low, Medium and High Temp), blast chillers, coolers, and freezers, self-contained cases and merchandizers and similar products. These examples are meant to be representative, not exhaustive, of refrigeration equipment products.
- "Air Conditioning and Refrigeration Equipment Components"
    - Refrigeration Equipment Components generally include manufactured items such as plastic wire insulation, plastic electrical components, contactors, relays, overloads, and molded parts such as fan guards, fans, blowers, compressors, thermal expansion valves, heat exchangers, motors, plastic wire insulation, plastic electrical components, contactors, relays, overloads, and molded parts such as fan guards, fans, and similar components. These examples are meant to be representative, not exhaustive, of air conditioning and refrigeration equipment components.
- "Water Heaters"
    - Water heating products generally include manufactured items such as residential, commercial and industry products which heat water for potable uses, residential and commercial water heating equipment that utilizes gas, oil, or electric (via electric resistance heating elements or a heat pump), storage water heaters, tankless water heaters, heat pump water heaters, and others. Water heater products utilize oil, gas, or electricity to heat potable water for use outside the heater upon

[17] American Society of Heating, Refrigeration and Airconditioning Engineers 34, Designation and Safety Classification of Refrigerants.
[18] https://www.epa.gov/snap.
[19] https://www.hts-code.com/code/hts_result?code=8418&submit=Search.

demand, and similar products. These examples are meant to be representative, not exhaustive, of water heater products.

- "HVACR-WH Monitoring and Controls Equipment"
  - Water heating products generally include manufactured items such as residential, commercial and industry products which heat water for potable uses, residential thermostats, other controllers, leak detectors, and similar products. These examples are meant to be representative, not exhaustive, of HVACR-WH monitoring and controls equipment products.
- "HVACR-WH Parts"
  - Parts generally include manufactured items such as o-rings, gaskets, heat exchangers, cabinets gas burners, air filters, fluid filters, filter driers, compressors, thermal expansion valves, heat exchangers, fans/blowers, motors, and similar products. These examples are meant to be representative, not exhaustive, of HVACR-WH parts.
- "HVACR-WH Replacement Parts"
  - Although HVACR-WH Replacement Parts will generally mirror the list for HVACR-WH Parts, it is important to recognize replacement parts as a separate category as there are precedents at the federal level and other jurisdictions where chemical laws and regulations exempt replacement parts in recognition of the long life of complex durable goods and the need to continue to provide repair and service for products already sold.
  - Replacement Parts generally include manufactured items such as compressors and fans, electric motors, batteries, and parts thereof, original equipment manufacturer (OEM) parts including fans, motors, drive systems, heat exchangers, structural and non-structural framing and panels, compressor parts, filters, valves, seals, gaskets, compressors, thermal expansion valves, heat exchangers, fans and blowers, motors, and similar products. These examples are meant to be representative, not exhaustive, of HVACR-WH replacement parts.
- "HVACR-WH Servicing Needs"
  - Most existing systems use an HFC (or HCFC) refrigerant with equipment lifetimes of up to 25-30 years. This equipment must be serviced and maintained and there are currently no reasonably available alternatives.
  - HVACR Servicing Needs generally include manufactured items such as vacuum pumps, gage manifolds, refrigerant service cylinders, and similar products. These examples are meant to be representative, not exhaustive, of HVACR-WH servicing needs parts.
- "HVACR-WH Manufacturing Processes"
  - Manufacturing Processes generally include processes for equipment, components, parts, and materials such as brazing, soldering, and welding tools, equipment, and supplies; machining, cutting, and grinding tools and others. These examples are meant to be representative, not exhaustive, of HVACR-WH manufacturing processes parts.

B. Intended Use of HVACR-WH Category Products

The HVACR-WH Category products that are manufactured with and through the use of PFAS[20] provide substantial benefits to health and public safety. Heating, cooling, water heating, and refrigeration products serve and support nearly every major sector in the nation, providing life critical products and services for medical facilities and hospitals; government agencies; the US military; law enforcement, first responders, and public safety; food and medicine preservation; energy; public works and infrastructure support services; critical manufacturing; defense industrial base; and conservation. Often, the health, safety, and the functioning of society depends on AHRI member products for which alternatives are not reasonably available. Burdensome regulations could impair our sector's ability to meet these critical needs.

C. HVACR-WH Category Products' Essentialness for Health, Safety, and the Functioning of Society

Many PFAS are integrated into critical components in numerous residential and commercial heating, cooling, water heating, and refrigeration products and systems that contribute not just to provide comfort, but to ensure public health and safety. Other important services include cold chain procedures that ensure the systematic coordination of activities for ensuring essential temperature-control for food preservation and processing and for critical health and life sciences. Services dependent on refrigeration include everything from the prevention of dangerous food spoilage to life-giving medicines, vaccines, proteomics, therapeutics, blood plasma, and other temperature-dependent elements in the life sciences and pharmaceutical sectors. Collectively these constitute a vital part of the economy, at all levels, including for public safety.

"To ensure our economic prosperity and national security,"[21] President Biden's Executive Order 14017, "America's Supply Chains," recognized the need to strengthen and secure critical supply such as the HVACR-WH supply chain which has been recognized as essential. As noted earlier, the HVACR-WH industries provide critical lifesaving ventilation, climate control, and transportation and storage of food and medicines (including vaccines). The United Nations has also declared that access to cooling is a fundamental human right.[22]

Domestic and foreign manufacturing would be substantially disrupted by a ban on use of PFAS in manufacturing facilities, given the current lack of technically feasible alternatives for many applications. In 2018, PFAS materials and products generated $2.1

---

[20] PFAS" as it is currently defined by the state of Minnesota: "'Perfluoroalkyl and polyfluoroalkyl substances' or 'PFAS' means a class of fluorinated organic chemicals containing at least one fully fluorinated carbon atom." MN Section 21, Subsection 116.943, Subdivision 1(p); under other, more targeted definitions, these same chemicals may not be considered PFAS.

[21] Amidst Rising Heat Waves, UN says cooling is a Human Right. https://thewire.in/environment/un-cooling-human-right-not-luxury

[22] Amidst Rising Heat Waves, UN says cooling is a Human Right. https://thewire.in/environment/un-cooling-human-right-not-luxury

billion in direct economic activity and supported 13,500 jobs indirectly.[23]

Because PFAS are used ubiquitously throughout the heating, cooling, water heating, and refrigeration equipment supply chain and in its manufacturing processes, and because currently there are no reasonably available, known-to-be-suitable, PFAS alternatives for the *entire* HVACR-WH category, a ban on all PFAS would substantially disrupt provision of these critical societal services as well as the industry's business sustainability and continuity.

As mentioned earlier, the heating, cooling, water heating, and refrigeration industry has a $211 billion impact on the nation's annual economy and in communities across the country, with more than 704,000 American jobs.

In conclusion, a ban on HVACR-WH Category PFAS products and uses would disrupt societal access to lifesaving cooling and heating as well as the entire heating, cooling, water heating, and refrigeration industry and therefore, the national economy at a time when our nation's manufacturers continue to struggle with other supply chain disruptions and economic hardships due to the recent pandemic and current inflation, as well as expending all available resources to respond to new and pending environmental and efficiency regulations. Now is the time for the government to initiate actions to support continued equitable access to heating and cooling and to support businesses and foster economic recovery, rather than impose additional regulation for which it would be impossible for companies to comply.

D. PFAS Are Essential to the Function of HVACR-WH Category Products

In the HVACR-WH Category products sector, common uses for PFAS include: electronics, computer chips, bearings, gaskets, air filters, grommets, washers, PTFE tape used on joints, O-rings, hoses, wiring, wiring insulation, sealant, foams, packaging, cloth, textiles, chrome plating, paints, pigments, coatings, and waxes, among many others (please see Appendix I for more information).

However, it should be noted that we are considering "PFAS" here as it is currently defined by the state of Minnesota: "'Perfluoroalkyl and polyfluoroalkyl substances' or 'PFAS' means a class of fluorinated organic chemicals containing at least one fully fluorinated carbon atom."[24] And under other, more targeted definitions, these same chemicals may not be considered PFAS. AHRI and its members do not support this definition and urge the state of Minnesota and MPCA to adopt a new definition that better reflects a PFAS family representative of high-risk chemicals (please see more information about prioritization in our "MPCA Should Adopt a Risk-Based Chemical Management Approach" section below).

Here are some specific examples of how products in the HVACR-WH category are essential for the well-being of society but this is meant to be illustrative and not

---

[23] https://fluoropolymerpartnership.com/fluoropolymer-facts/socioeconomic-importance/.
[24] MN Section 21, Subsection 116.943, Subdivision 1(p).

exhaustive (please also see Appendix I for more information):

i. PTFE in Tape and Paste: This product is used for the proper assembly of pipe fittings. PFAS are used in the manufacture of these materials and trace amounts are potentially left in the products. There are currently no other products on the market that will properly seal pipe fittings The lack of availability of this product would lead to inadequately assembled hot water piping causing risk to the health and safety of the consumer due to increased scalding risk and damage to property from water leakage. These materials are considered Polymers of Low Concern (PLC's).[25]

ii. PTFE in Bearing Material in Compressors: Historically, compressor technologies applied bearings made of aluminum. In general, the performance was poor, leading to limited compressor lifetime and an inadequate ability to support large loads. Recently, bearing technology has evolved with the introduction of PTFE into their composition. Because there is no other technology available to replace PTFE at this time, manufacturers would be forced to return to an aluminum composition. Consequently, compressor lifetime would be reduced, creating a significative impact on sustainability. Additionally, the limited ability to support higher loads would create limitations within heat pumps to achieve desired temperatures, such as sanitary hot water or operation in very low ambient temperatures without a complementary electrical heater.

iii. Fluoropolymer Gaskets and O-rings (PTFE, FKM): These products are used to seal flange fitting and ensure leakless connections. PTFE, a fluoropolymer, and FKM, a fluoroelastomer, are used in the manufacture of these products. PFAS are used in the manufacture of these materials and trace amounts are potentially left in the products. Fluoropolymer gaskets are required to meet the high temperature and chemical resistant requirements of these products. There are currently no replacement products that can adequately meet the required specifications of these gaskets. Replacement with an unsuitable alternative would lead to similar concerns to health and safety as described above. These materials are considered Polymers of Low Concern (PLC's).[26]

iv. HFO Blowing Agent in Foam Insulation: Is used because it has the best performance/cost ratio. HFO is being used as a blowing agent in foam insulation for our industry as a replacement for cyclopentane. HFO can provide a 10 – 15% improvement in performance in K-factor thermal conductivity as compared to cyclopentane.[27] Alternatives would be vacuum insulation panels (VIP),

[25] "A Critical Review of the Application of Polymer of Low Concern and Regulatory Criteria to Fluoropolymers," Barbara J Henry, *et al.* Integrated Environmental Assessment and Management, Volume 14, Number 3, pp. 316–334, January 30, 2018.

[26] "A Critical Review of the Application of Polymer of Low Concern and Regulatory Criteria to Fluoropolymers," Barbara J Henry, *et al.* Integrated Environmental Assessment and Management, Volume 14, Number 3, pp. 316–334, January 30, 2018.

[27] https://pmt.honeywell.com/us/en/about-pmt/newsroom/featured-stories/the-blowing-agent-alternative-enabling-key-improvements-in-the-household-appliance-industry

cyclopentane blowing agent, or thicker insulation. VIP is very difficult to handle without damage and is ~ 2x+ cost. Cyclopentane is highly flammable (HFO is non-flammable) and less effective.[28] Additionally, current HFO equipment cannot support cyclopentane and would need to be retrofitted. Thicker insulation would affect the product fit in current locations for replacement.

Therefore, many complex, high-value products and services are provided from the use of select PFAS, which are essential to the manufacturing or installation processes and in incorporation into articles or products. Because PFAS molecules have unique properties, including very strong chemical bonds, they are employed in a myriad of applications. PFAS are used to make fluoropolymer coatings and products that resist heat, oil, stains, grease, and water. Fluoropolymers withstand high temperatures and resist interference from other substances, which increases reliability, prevents fires, and keeps consumer costs low.

The presence of PFAS in heating, cooling, water heating, and refrigeration product components ensures that the parts perform appropriately and contribute to product safety and reliability. Without some PFAS (or an effective alternative, yet to be identified), many products and processes would not function as intended and would experience a decrease in performance, safety, and longevity. Thus, simply eliminating PFAS from these uses is not an option for this sector.

E. No *Technically* Feasible Safer Alternative to PFAS Is Reasonably Available for the Entire HVACR-WH Category of Products[29]

Currently, there are no reasonably available, known-to-be-suitable, PFAS alternatives for the *entire* HVACR-WH category. Due to the unique characteristics of this class of chemicals, few other substances have been shown to meet the rigorous standards applicable to these applications.

Because PFAS molecules have unique properties, they are employed in a variety of applications. Some PFAS are used to make fluoropolymer coatings and products that resist heat, oil, stains, grease, and water.[30] Fluoropolymers withstand high temperatures and resist interference from other substances, which increases reliability, prevents fires, and keeps consumer costs low. In HVACR-WH equipment, substituting fluoropolymers with lower performing alternatives would result in products that are less safe, require more maintenance, have shorter service lives, and are less efficient.

---

[28] https://pmt.honeywell.com/us/en/about-pmt/newsroom/featured-stories/the-blowing-agent-alternative-enabling-key-improvements-in-the-household-appliance-industry.

[29] AHRI acknowledges that there are a few potentially available alternatives for a small number of select products within the broad HVACR category that have been identified, however, the implementation and testing process could take years before the substitution could take place. Also, for the vast majority of products within the HVACR category, no alternatives have yet even been identified.

[30] https://www.cdc.gov/biomonitoring/PFAS_FactSheet.html. (Last accessed on Feb. 13, 2024).

Consideration should also be given to the technical standards that illustrate why fluoropolymers are critical in these HVACR-WH systems and components. Alternative materials are not reasonably available to simultaneously satisfy all required properties, such as low flammability, high service temperature, low dielectric constant, electric arc tracking resistance, mechanical strength and elasticity, and chemical resistance/inertness to even the most aggressive chemicals.

MPCA Should Adopt a Risk-Based Chemical Management Approach

Another point to consider here is that certain chemicals that fall within the scope of the broad structural definition used by Minnesota to define the term PFAS represent a low risk to human health and the environment. For example, most fluoropolymers that meet Minnesota's structural definition meet the Organization for Economic Cooperation and Development's criteria to be polymers of low concern which means that they are "deemed to have insignificant environmental and human health impacts."[31] Current research supports this:

> Per- and polyfluoroalkyl substances (PFAS) are a group of fluorinated substances that are in the focus of researchers and regulators due to widespread presence in the environment and biota, including humans, of perfluorooctane sulfonate (PFOS) and perfluorooctanoic acid (PFOA). Fluoropolymers, high molecular weight polymers, have unique properties that constitute a distinct class within the PFAS group. Fluoropolymers have thermal, chemical, photochemical, hydrolytic, oxidative, and biological stability. They have negligible residual monomer and oligomer content and low to no leachables. Fluoropolymers are practically insoluble in water and not subject to long-range transport. With a molecular weight well over 100 000 Da, fluoropolymers cannot cross the cell membrane. Fluoropolymers are not bioavailable or bioaccumulative, as evidenced by toxicology studies on polytetrafluoroethylene (PTFE)…[32]

AHRI and its members recommend that MPCA apply a *risk-based approach* to consider both hazard *and* exposure. To best protect human health and the environment, a risk-based approach focuses limited agency resources on the highest priorities based on actual environmental, health, and safety risk of particular chemistries, not just the mere presence of a substance.

The mandate to evaluate both hazard and exposure in any risk assessments is well established in the controlling federal statutory law. As outlined in 15 U.S.C. Section 2605

---

[31] "A Critical Review of the Application of Polymer of Low Concern and Regulatory Criteria to Fluoropolymers," Barbara J Henry, et al. Integrated Environmental Assessment and Management, Volume 14, Number 3, pp. 316–334, January 30, 2018; "A critical review of the application of polymer of low concern regulatory criteria to fluoropolymers II: Fluoroplastics and fluoroelastomers," Stephen H. Korzeniowski, *et* al. Integrated Environmental Assessment and Management, Volume 19, Issue 2, pp. 326 – 354, June 9, 2022.

[32] "A Critical Review of the Application of Polymer of Low Concern and Regulatory Criteria to Fluoropolymers," Barbara J Henry, *et al.* Integrated Environmental Assessment and Management, Volume 14, Number 3, pp. 316–334, January 30, 2018.

(b)(1)(A), "The process to designate the priority of chemical substances shall include a consideration of the hazard *and exposure* potential of a chemical substance" (emphasis added). Similarly, 15 U.S.C. Section 2605 (b)(4)(D) states a requirement to "Integrate and assess available information on hazards *and exposures* for the conditions of use of the chemical substance" (emphasis added). The requirement is also stated repeatedly throughout the Lautenberg Chemical Safety Act because it is a logical way to approach complex chemical management. We urge MPCA to prioritize high-risk use and grant exemptions for low-risk uses such as those found in the HVACR-WH category.

Comparative Analysis of Substitutes

We urge MPCA to follow the Significant New Alternatives Policy (SNAP) program[33] process of a mandatory, comparative analysis of alternatives to ensure that no regrettable substitutes are deemed acceptable in replacing PFAS chemicals.

Under Section 612 of the Clean Air Act (CAA), SNAP program reviews substitute within a comparative risk framework examining overall risk to human health and the environment of both existing and new substitutes including toxicity, flammability, occupational and consumer health and safety, local air quality, and ecosystem effects. This careful analysis ensures that currently used chemicals, necessary for the efficacy of this equipment are not prohibited unless EPA has determined that there are other available substitutes that pose less overall risk to human health and the environment.

Fluorinated Refrigerants Are Not Persistent and Are Not a Concern to Human Health or the Environment.

A perfect example of low-risk PFAS can be seen in refrigerants. Fluorinated refrigerants do not present a hazard to human health or the environment. This is due both to their inherent properties and the way they are used. Unlike certain fluorinated substances, fluorinated refrigerants are not persistent in the environment. These refrigerants readily break down to a degradation product, trifluoroacetic acid (TFA), which has been shown to pose a low risk of toxicity to human health and the environment.[34] For instance, a study prepared for the Norwegian Environment Agency on fluorinated refrigerants concluded in 2017 that "the consensus amongst academic experts is that TFA will have a negligible effect on the environment."[35] In addition, unlike previous generations of refrigerants, fluorinated refrigerants have low global warming potential (GWP). Finally, due to the use of these refrigerants in closed loop systems, exposure to humans and the environment is low.

Another example can be found in various national legislations which place restrictions on where refrigerant alternatives can be installed. From that perspective, carbon dioxide, for example, may

---

[33] EPA Significant New Alternatives Policy (SNAP) program https://www.epa.gov/snap

[34] UNEP EEAP, Environmental Effects of Stratospheric Ozone Depletion, UV Radiation, and Interactions with Climate Change: 2022 Assessment Report, 25 (March 2023) – "[Furthermore,] [t]rifluoroacetic acid has biological properties that differ significantly from the longer chain polyfluoroalkyl substances (PFAS) and inclusion of TFA in this larger group of chemicals for regulation would be inconsistent with the risk assessment of TFA."

[35] Norwegian Environment Agency, Study on Environmental and Health Effects of HFO Refrigerants (2017).

appear to be a good alternative to a fluorinated refrigerant, but carbon dioxide is not always a good alternative in terms of energy efficiency or safety. For larger stores using carbon dioxide for refrigeration applications, the overall energy efficiency can be good, but for small facilities where the need for heat recovery is small, the overall energy efficiency can be insignificant, and the carbon dioxide systems therefore burden the external environment more in the form of a greater need for purchased energy--thus also defeating Minnesota's additional efforts to become a climate leader in the future. Carbon dioxide systems must also operate at extremely high pressures often exceeding 2,000 psig which compared to traditional HVAC systems is ~ 5 times greater and thus requires special design considerations.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Response: Yes. AHRI recommends that MPCA make a CUU determination for the HVACR-WH category of products, according to the information we provided in response to Question 7.

Conclusion

The decisions made during this formative period will set the precedent for years and perhaps decades to come. To ensure the smoothest path forward for all affected parties, we need to work together now.

MPCA should continue to engage the regulated community, by convening workshops, by providing comment opportunities (and with sufficient notice), by disseminating information, and by providing timely, regular updates. AHRI proposes that formal government-industry councils be established, similar to those found in other areas of government. This would provide an ongoing opportunity for regulators and regulated parties to confer as issues develop. Government and industry could work together to find reasonable, workable solutions to the challenge of balancing jobs and the economy while ensuring chemicals are managed appropriately for human health and the environment.

Thank you for allowing us to provide our information. Please feel free to contact us directly if you have questions or need additional information.

Sincerely,

Stacy Tatman, MS, JD
AHRI Senior Director, Regulatory Affairs

Commercial Air-Cooled Condensers used with chillers									
Commercial Gas Boilers			A device that uses combustion to heat water that provides heating to a commercial building such as a resturant, office, school, or other establishment.	Commercial heating	Safety and comfort of building occupants	Sealing, low friction, insulation, fire retardant	No known alternative at this time		
Commercial Split Systems									
Commericial Oil Boilers			A device that uses combustion to heat water that provides heating to a commercial building such as a resturant, office, school, or other establishment.	Commercial heating	Safety and comfort of building occupants	Sealing, low friction, insulation, fire retardant	No known alternative at this time		
Compressors									
Cooling Towers (Open, Closed, Wet, Hybrid)				Commercial and Industrial Heat Rejection	Safety and comfort of building occupants, Heat Rejection for industrial processes	Electrical insultaion, electronics, grease and lubricants, possibly in some plastics	No known alternative at this time		
Dedicated Outdoor Air Systems									
Dehumidifiers									
Dry Coolers				Commercial and Industrial Heat Rejection in the absence of available water	Safety and comfort of building occupants, Heat Rejection for industrial processes	Electrical insultaion, electronics, grease and lubricants, possibly in some plastics	No known alternative at this time		
Ductless Systems									
Electric Instanatneous Water Heater	10005479		A tankless water heater uses a resistive heating element to heat domestic hot water for home usage such as sinks and showers.	Residential water heating	Safety and comfort of building occupants	Sealing, insulation	No known alternative at this time		
Electric Tank Water Heater	10002658		A tank product that used resistive heating elements to heat water for domestic usage such as sinks and showers.	Residential water heating	Safety and comfort of building occupants	Sealing, insulation	No known alternative at this time		
Evaporator Coils									
Fan Coils									
Furnace	10002658		Furnaces		Sealing, insulation, low friction, electronic components		No	Flouropolymer	not known
Furnace spare parts	10007005		Replacement Parts/accessories		Sealing, insulation, low friction, electronic components		No	Flouropolymer	not known
Gas Furnaces									
Geothermal Heat Pumps									
Heat Pumps									

Product Type	GPC Code	HTS Code	Brief Description	Intended Use	Reason PFAS are Essential	PFAS Function	Alternatives	PFAS Used Name	PFAS Used CASRN
Heating		8514 8416 8417	Heating products generally include manufactured items such as furnaces, boilers, heating elements, burners, and others.						
Heating Equipment Accessories	10002660		Water heaters have many components and parts that are often replaced including large components such as valves or motors and small components like sealants or o-rings.	Residential heating	Safety and comfort of building occupants	Sealing, low friction, insulation, fire retardant	No known alternative at this time		
Humidifiers									
HVACR-WH at large				Leadwire Insulation in special applications				Polytetrafluoroethylene (PTFE) (Teflon)	9002-84-0
				Shrink Tubing in some special applications				Polytetrafluoroethylene (PTFE) (Teflon)	9002-84-1
				Grease in some special bearings for special motor applications.				Perfluoropolyalkyl Ether (Krytox, Braycote 601EF)	60164-51-4
HVACR-WH Servicing Needs			HVACR Servicing Needs generally include manufactured items such as vacuum pumps, gage manifolds, refrigerant service cylinders, and others. Only 2% of retail stores comprise new installations, while the others are existing systems. Most existing systems use an HFC (or HCFC) refrigerant that have lifetimes of up to 25-30 years. This equipment must be serviced and maintained and there are currently no reasonably available alternatives.						
HVACR-WH Manufacturing Processes		8454-8468	Includes processes for equipment, components, parts, and materials such as Brazing, soldering, and welding tools, equipment, and supplies; machining, cutting, and grinding tools						
HVACR-WH Monitoring & Controls Equipment		8414	Parts generally include manufactured items such as compressors, thermal expansion valves, heat exchangers, fans/blowers, motors, and others.						
		4016	O-rings and gaskets						
		8415	Heat exchangers						
		8416	Cabinets gas burners						
		5911	Air filters						
		8421	Fluid filters/filter driers						
HVACR-WH Replacement Parts			Although HVACR-WH Replacement Parts will generally mirror the list for HVACR-WH Parts, it is important to recognize replacement parts as a separate category as there are precedents at the federal level and other jurisdictions where chemical laws and regulations exempt replacement parts in recognition of the long life of complex durable goods and the need to continue to provide repair and service for products already sold						
		8414	Compressors and fans						
		8501-8507	Electric motors, batteries, and parts thereof						

Product Type	GPC Code	HTS Code	Brief Description	Intended Use	Reason PFAS are Essential	PFAS Function	Alternatives	PFAS Used Name	PFAS Used CASRN
			Also, original equipment manufacturer (OEM) parts including fans, motors, drive systems, heat exchangers, structural and non-structural framing and panels, compressor parts, filters, valves, seals, gaskets, compressors, thermal expansion valves, heat exchangers, fans and blowers, motors, and others						
Hyrbid Electric Water Heater (heat pump)	10002658		A tank product that uses resistive heating elements and a heat pump with refrigerants to heat water for domestic usage such as sinks and showers.	Residential water heating	Safety and comfort of building occupants	Sealing, low friction, insulation, fire retardant	No known alternative at this time		
Indirect Hot Water Tanks	10002658		Hot water tanks that use a boiler as its heating source. The product uses a foam insulation and tank to store the hot water	Residential water heating and heating	Safety and comfort of building occupants	Sealing, insulation	No known alternative at this time		
Magnetic Filter	10002649		A filtration system used to maintain water in a boiler system. Without the filter, products are prone to a higher rate of corrosion and less efficient heating	Residential heating	Safety and comfort of building occupants	Sealing	No known alternative at this time		
Oil Furnace									
Packaged Outdoor Units									
Packaged Water-cooled Indoor Units and Heat Pumps									
Panel Radiators	10002654		A radiator that can be mounted to a wall that provides radiant heating in combination with a hydronic heating system such as a gas or oil boiler	Residential heating	Safety and comfort of building occupants	Sealing	No known alternative at this time		
Printed Electronic Control Board Spare Part	10007005		A refrigerant that is commonly used in hybrid electric water heaters	Residential water heating and heating	Safety and comfort of building occupants	Insulation, fire retardant	No known alternative at this time		
Refrigerantion Equipment		8418 8476	Refrigeration Equipment products generally include manufactured items such as freezers (commercial, residential, and laboratory/medical), refrigerators, warehouse refrigeration (large storage), coolers, walk-in coolers, walk-in freezers (restaurants, retail food stores), reach-in refrigeration, cold rooms, refrigerated vending machines and icemakers, heat transfer products (including evaporative open towers), and evaporative, adiabatic, and dry coolers and condensers, thermal energy storage units, evaporators and their controls, refrigeration racks, refrigerated cases and merchandizers, prep equipment, condensing units, air cooled condensers, unit coolers, self-contained refrigeration, ice machines, dispensing equipment, blast chillers, mobile/transport refrigeration, refrigeration racks (Low, Medium and High Temp), blast chillers, coolers, and freezers, self-contained cases and merchandizers and similar products.						
		2903	Single component refrigerants and blends						
		3827	Single component refrigerants and blends						
Refrigerants		2903	Refrigerants and non-mechanical heat transfer fluids[3]: Refrigerants products generally include manufactured items defined by ASHRAE[4] 34 and approved by the EPA Significant New Alternatives Policy (SNAP) Program[5], used in air conditioning, heat pump, refrigeration or other refrigerant containing equipment as defined above, Specific examples include: Refrigerants such as R448A, R449A, R404A, R410A, R454A, R454B, R454C, R455A, R1234ze, R1234yf, and others						

Product Type	GPC Code	HTS Code	Brief Description	Intended Use	Reason PFAS are Essential	PFAS Function	Alternatives	PFAS Used Name	PFAS Used CASRN
			Various fluorinated gases, including hydrofluorocarbons ("HFC"), hydrochlorofluoro-olefins ("HCFO"), hydrofluoroolefins ("HFO") refrigerants and their mixtures ("Blends").						
Replacement parts	10002660				Sealing, insulation, low friction		No	Flouropolymer	not known
Residential Oil Boilers	10002658		A device that uses combustion to heat water that provides heating (often the only source) to the home	Residential heating	Safety and comfort of building occupants	Sealing, low friction, insulation, fire retardant	No known alternative at this time		
Residential Gas Boilers	10002658		A device that uses combustion to heat water that provides heating (often the only source) to the home	Residential heating	Safety and comfort of building occupants	Sealing, low friction, insulation, fire retardant	No known alternative at this time		
Residential Gas Instantaneous Water Heater	10005479		A tankless water heater uses combustion to heat domestic hot water for home usage such as sinks and showers.	Residential water heating	Safety and comfort of building occupants	Sealing, low friction, insulation, fire retardant	No known alternative at this time		
Thermal Energy Storage Equipment				Commercial and Industrial thermal energy storage for energy efficiency or load balancing	Safety and comfort of building occupants, requred for heat rejection in industrial processes	Electrical insultaion, electronics, possibly in some plastics	No known alternative at this time		
Thermostats	10004002		Device for controlling air conditioning equipment		Sealing, insulation, low friction, electronic components		No	Flouropolymer	not known
Thermostats and Outdoor Reset Accessory for Boilers	10004002		Replacement and accesory parts for water heaters and boilers such as pressure relief valves, manifolds, spare parts for plumbing, etc.	Residential heating	Safety and comfort of building occupants	insulation, fire retardant	No known alternative at this time		
Transport Refrigeration									
UV Lights									
Variable Refrigerant Flow Units (VRF)									
Ventilation		8414 8481	Ventilation products generally include manufactured items such as louvers dampers, energy recovery ventilators, air exchangers, and others						
Ventilators									
Venting Kit	10002660		Kit used for concentric venting that includes sealant to ensure a safe path for flue gas.	Residential water heating and heating	Safety and comfort of building occupants	Sealing	No known alternative at this time		
Water heaters	10002658 10005479		Water heating products generally include manufactured items such as residential and commercial water heating equipment that utilizes gas, oil, or electric (via electric resistance heating elements or a heat pump) which heat water for potable uses.						

Product Type	GPC Code	HTS Code	Brief Description	Intended Use	Reason PFAS are Essential	PFAS Function	Alternatives	PFAS Used Name	PFAS Used CASRN
Water heater replacement parts	10007005		Boilers have many components and parts that are often replaced including large components such as valves or motors and small components like sealants or o-rings.	Residential water heating	Safety and comfort of building occupants	Sealing, low friction, insulation, fire retardant	No known alternative at this time		

APPENDIX II

	Process	Comment
1	Identify Current Use	Identify all places where chemical is used
2	Identify Alternatives	Need to identify potenial alternative chemicals
3	Source	Source appropriate supplier(s)
4	Formulation	Formulation chemical
5	Chemical Testing	Testing of chemical (flammability, flexibility, corrosion resistance, etc.)
6	Results analysis	Chemical company, parts supplier and OEM review and adjust as needed
7	Formula Adjustment	reformulate / adjust chemicals
8	Retesting	Testing of chemical (flammability, flexibility, corrosion resistance, etc.) as needed
9	Results analysis	Chemical company, parts supplier and OEM review and adjust as needed
10	Test Parts Development	Manunfacture initial sample parts for testing - confirmation of compound will work
11	Testing	Testing of initial samples
12	Analysis	Review results and feedback for adjustment
13	Chemical manufacturing	Chemical company needs to manufacture enough chemical and depending on company, may be doing so for many customers
14	Drawing Updates	OEM needs to update applicable drawings, possible new models numbers, part numbers, etc to control invnetory
15	Modify manufacturing process	As needed, manufacturing processes, tools, etc may need to be changed or new tooling made to allow use of new alternate chemical
16	Tooling Trial	Initial trial for use of new tool; analyze results
17	Modify/improve tooling as needed	If changes needed tool needs to be retested
18	Retrial/test	Retest and analyze results
19	Sample Parts	Receive sample parts off tooling or other more final samples
20	Parts testing	Testing of parts
21	Product Testing	Install and test in product
22	Parts safety approval	Perform applicable safety approval for parts
23	Product safety approval	Perform applicable safety approval for products
24	Order parts for mass production	Order after approvals
25	Produce products	OEM manufacturing and shipping lead time
26	Ship to distribution	OEM's ship from factories to warehouses, inventory
27	Distribution ship to customers	Ship from OEM warehouse to distributor warehouse
28	Customers sell to end users	Distributor inventory and sells to contractor for install

March 1, 2024

Laura Kessler, Commissioner
Minnesota Pollution Control Agency
520 Lafayette Rd. N.
St. Paul, MN 55155-4194

RE: Request for Comments; PFAS in Products Currently Unavoidable Use Rule; Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837; OAH Docket No. 71-9003-39667

Dear Commissioner Kessler:

Panasonic Corporation of North America (Panasonic) appreciates the opportunity to submit proposals seeking currently unavoidable use (CUU) determinations for our various product categories, including appropriate uses of PFAS in electronics and is fully supportive of the intent behind MN HF 2310 to protect the residents of the State of Minnesota from PFAS exposure. Panasonic is a comprehensive electronics manufacturer involved in development, production, sales, and service activities in a broad array of business areas, such as components for home and commercial electronic equipment, as well as equipment in telecommunications, industrial, automotive, aviation, and housing, and more. Panasonic has operated under its business philosophy, "contributing to the progress and development of society and the well-being of people worldwide through its business". We continue to work diligently to create new values and challenge ourselves to remove present and future barriers, by facing head-on global environmental and social issues.

Over many years Panasonic has voluntarily reduced the hazardous chemicals in the products we manufacture. PFAS, however, are a broad class of chemicals and are embedded in many internal components of electronics, thus being more challenging to identify and replace. PFAS commonly used in electronics has a variety of properties including the ability to resist high temperatures, inert chemical resistance, water, and oil repellency for protection against moisture and corrosion, low coefficient of friction, low dielectric constant and its manufacturability, compressibility, flexibility, high stress crack resistance and flame retardant. PFAS is found in semiconductors, wires and cables, printed circuit boards, etc. Namely, a tiny amount of PFAS is used in internal, mechanical components. PFAS in electronics is not likely exposed to humans, unlike food packaging, floss, or water repellent clothing, nor to the environment, due to proper management of electronics product end-of-life implemented in this country.

Specific knowledge of the presence of PFAS in many products is still under review, given that requirements to track and report its use are relatively new. This makes completing the State's questions regarding CUU quite challenging in the limited timeframe provided. We are still surveying our suppliers (tens of thousands) for the presence of PFAS in the materials, components, and subparts they provide for incorporation into our final products. Without adequate time to complete a full investigation of the use of PFAS, and if restrictions or bans of PFAS-containing-products, without derogations or scope exemptions, there will inevitably be massive, negative nationwide impacts as companies are forced to reassess where they sell or manufacture key products, such as batteries. Therefore, Panasonic respectfully requests the State to consider the following:

- Allow adequate time for a thoughtful and thorough review of current uses of PFAS.
- Rely on national standards and requirements set by the U.S. Environmental Protection Agency (EPA) to avoid a national patchwork of requirements for essential products.
- All CUU of PFAS for the best possible protection of health and safety and the functioning of society.

Specific products that Panasonic is requesting a CUU for include batteries, industrial components (e.g., consumer, business-to-business, automotive, and aviation), and refrigerants.

Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Yes. Panasonic requests that the State aligns with the EPA and other U.S. states, such as the State of Maine, for the CUU. In 2021, the State of Maine became the first state to enact a comprehensive PFAS ban. The Maine Department of Environmental Protection (Maine DEP) is currently undergoing rulemaking around CUU. In their submission requirements, the Maine DEP requested how PFAS is essential for health, safety, or functioning of society. By establishing this definition, manufacturers and suppliers can provide real world examples of how PFAS is essential to human health and the environment. Some specific uses of PFASs would be considered essential because they provide vital functions as established by federal law and are currently without established alternatives.

Maine defines "Essential for Health, Safety or the Functioning of Society,"

> Means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or *significantly interrupt the daily functions on which society relies*. Products or product components that are

> Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations. Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction. (Emphasis added.)

Many of the products Panasonic manufactures are included in this definition. For example, our batteries are used to power medical devices and smoke detectors, which save lives, electric vehicles, which are needed to meet the nation's carbon reduction goals, and night vision goggles, which enhance our nation's security. It would be impossible to list every product with a justification of its use. Therefore, we request that the State of Minnesota allows industry to determine more broad ranges of product categories that are deemed essential for health, safety, or the functioning of society, such as batteries.

Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Yes. Potential PFAS prohibition requirements will result in additional costs to manufacturers, sellers, and distributors of priority consumer products containing PFAS in Minnesota. Thus, costs will increase for consumers. At this time, there are no feasible alternatives for many PFAS uses, therefore a cost threshold cannot be determined.

What criteria should be used to determine the safety of potential PFAS alternatives?

Panasonic recommends taking a risk-based evaluation approach to determine the safety of alternatives. First, let us note that many uses of PFAS are in internal components, not accessible to human touch or ingestion, and, due to end-of-life practices, are not likely to leach into the environment. Therefore, the risk of PFAS to human health and the environment may be negligible, for example, from use in the electronic components and parts or in batteries. The first step in the risk-based approach should be to determine if there is a hazard associated with the use of PFAS in the product category. If that is determined to be significant, then alternatives need to be evaluated for their ability to perform to all safety and use tests and have no adverse effects equal to or worse than the PFAS it is replacing. This approach would follow the Safer Products program designed by the State of Washington Department of Ecology, in which priority chemical classes are first selected, followed by identifying which consumer products contain these chemicals and may harm people and the environment. The Department then determines what regulatory action is taken for each priority chemical class and provides a list of feasible alternatives to all stakeholders. The process for determining alternatives will depend on the product and product use, and may take years, through various testing requirements.

Panasonic recommends that the State should defer to the U.S. Environmental Protection Agency, which currently has a reporting requirement for PFAS and then will determine risk-based restrictions.

How long should PFAS CUU determinations be good for? How should the length of the CUU determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?

We acknowledge that new information may arise after appropriate research and development is conducted on risks and alternatives. Panasonic suggests a minimum of 10 years before re-evaluation to adequately assess the situation.

To get a sense of what type of and how many products may seek a CUU determination, please share what uses and products you may submit a request for in the future and briefly why. MPCA notes that there will be a future opportunity to present a full argument and supporting information for a possible CUU determination.

Specific products for which Panasonic will likely request a CUU include batteries, industrial components (e.g., consumer, business-to-business, automotive, and aviation), and refrigerants. This includes the components of already prohibited uses, such as ball bearings in massage chairs, which are classified as upholstered furniture.

How should stakeholders request to have a PFAS use considered for CUU determination by MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

As a global manufacturer, we request harmonization with other nations, the U.S. Environmental Protection Agency, and other states that already implemented similar regulations before Minnesota. We cannot manufacture products specifically for sale in a specific state; and any state-specific prohibitions will simply result ceasing sales into Minnesota.

Under the State of Maine's CUU rulemaking, the following information is requested:

1. Provide a brief description of the type of product including, if applicable, the Global Product Classification (GPC) brick category and code, or if GPC is not applicable than the Harmonized Tariff System (HTS) code.
2. Describe the intended use of the product and explain how it is essential for health, safety or the functioning of society.

3. Describe how the specific use of PFAS in the product is essential to the function of the product. If this use of PFAS is required by federal or state law or regulation, provide citations to that requirement.
4. Describe whether there are alternatives for this specific use of PFAS which are reasonably available.

Should MPCA make some initial CUU determinations as part of this rulemaking using the proposed criteria?

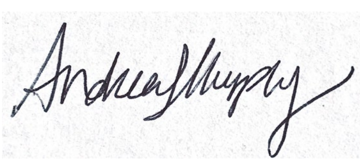
Yes. Many uses of PFAS are CUU. Panasonic would appreciate a determination is made quickly so that our company can focus efforts on surveying our vast supply chains and researching and finding alternatives for uses that have a direct impact on human health or the environment.

Other questions or comments relating to defining CUU criteria and the process MPCA uses to make CUU determinations.

As a global company, Panasonic manufactures and sells products around the world and recommend global alignment with other agencies, such as the European Union, the U.S. EPA, and other U.S. states. It is virtually impossible for a company of our size to manufacture products to individual State standards while maintaining prices that do not negatively impact consumers, affect overall employment, or disrupt the current functioning of society. We are supportive of the risk-based approach that the U.S. EPA is taking regarding PFAS, and alignment with their approach is more feasible.

Thank you for your consideration of these points. If you have further questions or need clarification, my contact information is listed below.

Sincerely,



Andrea Murphy
Director, Environmental Affairs

RE: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS)
OAH Docket No. 71-9003-39667

Dear Commissioner Kessler, Ms. Gilchrist,

WaterLegacy appreciates the opportunity to comment on the above matter, described by the Minnesota Pollution Control Agency (MPCA) as the "PFAS in Products Currently Unavoidable Use Rule." Our comments do not address the full scope of concerns that could be raised regarding PFAS. They highlight the areas with which WaterLegacy is most familiar as a result of our work the past fifteen years and track the sections of the statute to which they correspond. WaterLegacy then provides brief answers to the nine questions in MPCA's December 8, 2023 notice of a comment opportunity. In order to protect water quality and human health, WaterLegacy requests that:

A) MPCA's rulemaking requiring disclosure and prohibition of the use of PFAS must include drilling and mining activities that may use processes and products containing PFAS.

B) MPCA's PFAS rulemaking must require transparency, limit "unavoidable use" exemptions, and fully cover industrial products and applications, including mining.

C) MPCA's PFAS rulemaking must focus on protecting public health from long-term impacts of PFAS not protecting private short-term economic interests.

A. PFAS Rulemaking Must Include Drilling and Mining Processes and Products.

Exploratory drilling for minerals, use of tunnel boring machines, use of surfactants to enhance metal recovery in the ore floatation process, ore leaching, acid mist suppression, use of wetting agents, and use of fluoropolymer in pipes, cables, hoses and conveyor belts are just some of the ways in which the mining industry can introduce PFAS to surface water and groundwater.

(Barfoot *et al*. 2022).[1] Specifically, PFAS may be used in mining for "ore floating" using their property of low surface tension to "[c]reate stable aqueous foams to separate the metal salts from soil." (Gluge *et al*. 2020).[2] PFAS may also be present at mining sites in uses that are ancillary to the mining operation, such as fire suppression and firefighting activities, cleaning of metal surfaces, and use as a foaming agent in drilling fluids, coatings and lubricants. PFAS may end up in effluent or tailings ponds through use in processing as well as in AFFF. *Id*.

Although there have been few efforts to monitor mines as potential sources of PFAS to the environment and little disclosure by the industry, BHP's Mount Whaleback Iron Ore Mine in Western Australia was recently identified as the source of PFAS impacts to groundwater with the potential to threaten a nearby drinking water supply. (Barfoot *et al*., 2022). The Western Australia (WA) Department of Water and Environment Regulation declared the Mount Whaleback mine a dangerous "contaminated site" and ordered BHP to clean it up. (Hunt, 2021).[3] In discussing this finding of PFAS a fire protection company director has cautioned, "There would definitely be residual legacy contamination on a lot of sites, because under WA law all firefighting suppression systems need to be tested annually. . . This means PFAS is being sprayed on the ground, so it makes sense there's ground contamination." *Id*.

Drilling and the use of tunnel boring machines pose risks to health and the environment to the degree that they inject PFAS into groundwater. The media platform for drilling professionals noted that the PFAS contaminant "is found in many of the products, materials and equipment commonly used in the drilling industry." (Rasmussen, 2019).[4] Drilling professionals were advised to review the Manufacturer Safety Data Sheet to ensure that materials used in the field—including PVC casing and sleeve, tubing, grout, bentonite, fuels, oils, and grease—do not contain PFAS substances including the "most commonly found and best studied PFAS" perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS). *Id*.

Chemical formulations for products used in tunnel boring are not publicly available on industry websites. Without specifying the chemical parameters, one company's website promotes the

[3] Hunt, P. (July 2, 2021), PFAS a toxic problem in "wild west" mining industry, *Australia's Mining Monthly*, Exhibit 3, https://www.miningmonthly.com/life-cycle-end-of-life-management/news/1413112/pfas-toxic-problem-in-%E2%80%98wild-west%E2%80%99-mining-industry

[4] Rasmussen, S. (July 22, 2019), PFAS Adds Complexities to Environmental Drilling Jobs, *The Driller*, Exhibit 4, https://www.thedriller.com/articles/91558-pfas-adds-complexities-to-environmental-drilling-jobs

following: "Specific products and lubricants for rock tunnel boring machines: sealants, protection pastes for the main bearing, greases, hydraulic fluids, ground treatments and additives for backfill grouting" including "tail seal greases, main-bearing sealing paste, main-bearing greases, fire-resistant fluids for tunnel boring, foaming agents for rock tunnel boring, grouting additives."[5] Another company's website for tunnel boring fire suppression claims that its product is an alternative to "PFAS based systems that are starting to face regulatory pressure."[6]

Both websites highlight the need for products to which PFAS have frequently been intentionally added. One explains the need for foaming agents to control dust, stating "because of a much higher rotation speed of the cutting head and much drier spoil than earth pressure tunnel boring machines (EPB), create dust. Dust accumulation on the flanks of the disc cutters is a source of wear for the tools: disc cutters, grippers, cutters, etc. . . . Further, it makes the atmosphere on the tunnel boring machine difficult to breathe."[7] The second underscores the need for fire suppression products if a tunnel boring machine is used:

> A fire in a TBM is a catastrophic event to be avoided at all costs. First and foremost, any fire in a tunnel is deadly. . . Then there is the machine itself. As referenced above, TBMs carry an incredible price tag. . . The fire risk on a TBM is real. They are virtually a self-contained city of high-voltage systems that operate an array of mechanisms that cut and support the tunnel . . . The undeniable fire hazard must be recognized and addressed.[8]

The toxic impacts of PFAS in oil and gas drilling and extraction have been analyzed and documented.[9] However, other than the BHP Mount Whaleback Iron Ore Mine in Western Australia, WaterLegacy could find no example of groundwater monitoring proximate to metallic mining to determine PFAS levels. The use of PFAS in exploratory drilling, tunnel boring, mining processes, or mining products is rarely disclosed. MPCA's March 2022 PFAS Monitoring Plan did not discuss the need to monitor exploratory drilling or mining facility sites.[10]

[10] MPCA, PFAS Monitoring Plan, March 2022, https://www.pca.state.mn.us/sites/default/files/p-gen1-22b.pdf. However, Cliffs Erie LLC – Hoyt Lakes is listed as a solid waste management

Given Minnesota's existing taconite mines, extensive exploratory drilling efforts underway for nonferrous metals, and numerous proposals for metallic mining, it is critical that MPCA's upcoming "currently unavoidable use" rules for products containing PFAS mindfully and rigorously address drilling and mining products and processes. Many of the suggested rule clarifications and definitions discussed below arise from this concern.

B. MPCA's PFAS Rulemaking Must Require Transparency, Limit "Unavoidable Use" Exemptions, and Address Drilling, Mining and Other Industrial Uses of Products.

MPCA has previously requested comments tracking the provisions of Minn. Stat. § 116.943. WaterLegacy's comments in this section follow the structure of the statute.

1. ***Definitions in Minn. Stat. § 116.943, subd. 1 should be clarified to ensure that the concept of "currently unavoidable use" is appropriately narrow and the scope of products where the PFAS statute applies is broad enough to include mining and other industrial uses.***

    a. Clarification of "currently unavoidable use" in Minn. Stat. § 116.943. Subd. 1(j) is necessary to prevent exceptions from swallowing the rule.

    - In order to avoid indefinite exemptions and remove any incentive to develop safer alternatives, the rule should state that "Currently unavoidable use" means "a specific use of PFAS that the commissioner has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available within a specified period of time."

    - Any determination that a specific use is currently unavoidable should sunset at the end of the time during which the commissioner has determined that an alternative is not reasonably available. This avoids the need for the commissioner to continually review and update exemptions.

    - The rule should state that there is a rebuttable presumption that use of PFAS is avoidable and that the manufacturer or user bears the burden of proof to demonstrate both that the proposed use is essential and that alternatives are not reasonably available. This clarity will reduce the burden on the agency and reflects the legislative intent.

    - The rule should state that "economic considerations alone" cannot be used to determine that alternatives are not reasonably available. This is consistent with principles and policies in Minnesota's environmental laws.

---

facility at which PFAS monitoring may be implemented. MPCA, Facilities included in the PFAS Monitoring Plan, August 2022, https://www.pca.state.mn.us/sites/default/files/p-gen1-22c.pdf.

b. Clarifications of "intentionally added" in Subd. 1(l) and the term "manufacturer" in Subd. 1(n) are necessary to avoid creating a loophole for industrial users that blend, mix or modify products.

- "Intentionally added" should include "blending, mixing, or modifying" as well as the "manufacture" of a product to avoid creating a loophole where an industrial user could blend, mix, or modify a drilling fluid, lubricant, or other product so that it contains PFAS without a disclosure or unavoidable use requirement.

- "Manufacturer" for purposes of this rule should mean the person that creates or produces a product or a person that blends, mixes, or modifies a product so that it intentionally contains PFAS.

c. Clarification of the term "industrial use" in the definition of "product" in subd. 1(q) is necessary to ensure that various mining uses are covered.

- Where the rule refers to the statutory definition including "product components, sold or distributed for personal, residential, commercial, or industrial use," the rule should further clarify that "industrial use" for purposes of this section includes "all components of mining, including drilling, tunnel boring, construction, mining, processing, containment, storage, or disposal of wastes."

- There may be other uses such in construction or transportation that should also be explicitly identified in the definition of "product."

2. ***Terms in Minn. Stat. § 116.943, subd. 2 should be clarified to avoid placing an undue burden of proof on an agency to prove intent or knowledge and to emphasize disclosure.***

a. The rules should clarify that disclosure of PFAS cannot be evaded by claiming lack of intent or knowledge. Disclosure should be required for Subd. 2 "to the extent that such information is known to or reasonably ascertainable by that person." This is the standard that U.S. Environmental Protection Agency has applied for years in its Toxic Substances Control Act Chemical Data Reporting Rule and recently extended its use to the agency's PFAS reporting rule. *See e.g.*, 40 C.F.R. § 711.15; 88 Fed. Reg. 70516. This creates a reasonable person standard rather than requiring the agency to prove specific knowledge or intention and would make implementation more effective.

b. Clarification is needed to ensure that products containing PFAS used for commercial or industrial purposes are not excluded because there is no sale per se in Minnesota. Products may be sold to a national or even international corporation that will foreseeably use the product in Minnesota. To avoid a potential loophole, the rules should clarify that Subd. 2(a), (c), and (d) apply to "a manufacturer of a product sold, offered for sale, or distributed in such a manner so that its use in the state is known or reasonably foreseeable that contains intentionally added PFAS."

c. The rule should clarify that Subd. 2(b) has a limited scope so that with the approval of the commissioner, a manufacturer may supply the information required in paragraph (a) for a category or type of product rather than for each individual product "only if such a limited disclosure is sufficient to inform consumers, commercial users, industrial users and the public of the purpose for and amount of PFAS in a specific product or application."

d. In addition to clarification of statutory language, the MPCA should emphasize public health and welfare in reporting as follows:

- MPCA should require reporting on all products that contain PFAS in the interest of public health and welfare. If manufacturers wish to protect their formulas for products, they should use safer alternatives to PFAS.

- MPCA should make publicly available and readily accessible at no charge information disclosed under Subd. 2 disclosing the purpose and amount of each PFAS.

- When it is known or reasonably ascertainable that a product contains other toxic chemicals that may have synergistic adverse health effects with PFAS, their purpose and amount should also be disclosed in the interest of public health and welfare.

3. ***Terms in Minn. Stat. § 116.943, subd. 3 should be clarified in rule to restrict the commissioner's ability to provide waivers for disclosure.***

a. The rule should clarify the concept in Subd. 3(a) to specify the findings and disclosures that the commissioner must make in order to grant a waiver so that the exception does not overwhelm the rule. For Subd. 3(a)(i) the rule should clarify: "The commissioner may only waive all or part of the information requirement under subdivision 2 if the commissioner determines that substantially equivalent information is already publicly available, describes how it is substantially equivalent, and specifies where and how that information is readily accessible to the public."

b. The rule should also ensure that Subd. 3(a)(ii) is not the loophole that swallows the rule, as follows: "The commissioner may only grant a waiver under this paragraph to a manufacturer or a group of manufacturers for multiple products or a product category if the commissioner has determined for each manufacturer and product that it meets the requirements in sub-paragraph (i)."

c. WaterLegacy lacks experience with the agricultural statutes cited in Subd. 3(b). However, it seems that the language of the second sentence requires clarification to have a substantive meaning. Text with a more definite meaning would read: "For information that is regulated under chapters 18B and 18C, the commissioner and the commissioner of agriculture ~~must jointly determine whether to~~ will make the information publicly available ~~based on~~ unless such disclosure is clearly prohibited under applicable statutes."

4. ***Prohibitions in Minn. Stat. § 116.943, Subd. 5 are the heart of the recently enacted legislation and require clarification and emphasis in MPCA's rulemaking*.**

   a. MPCA rules implementing Subd. 5(b) should refer back to the definitions provided in WaterLegacy's comments on Subd. 1(l) and (q) above so as to include "products" for "industrial use" including all components of mining in the description of prohibited uses.

   b. The rules implementing Subd. 5(b) should refer back to the scope of covered products provided in WaterLegacy's comments on Subd. 2(a)–(d) above so that products containing PFAS sold or distributed so that their use in Minnesota is known or reasonably foreseeable will be addressed.

   c. Prohibitions of use of products with PFAS implementing Subd. 5 should be drafted to ensure compliance with Minnesota's groundwater rules. The rules should contain a provision specifically stating that discharge, injection, or introduction of a product containing intentionally added PFAS into the saturated or unsaturated zone of groundwater is prohibited. Minn. R. 7060.0600, subp. 1 and subp, 2.[11]

C. MPCA's PFAS Rulemaking Must Focus on Protecting Public Health from Long-Term Impacts of PFAS, Not Protecting Private Short-Term Economic Interests.

WaterLegacy appreciates the opportunity to comment at this early stage of the MPCA's development of the "PFAS in Products Currently Unavoidable Use" Rule. However, we are concerned that the nine questions asked in the MPCA's December 8, 2023 notice seem biased in favor of weakening prohibitions on PFAS. Below, please find WaterLegacy's brief responses to these questions.

1. *Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?*

It is not recommended that MPCA define criteria for "essential for health, safety, or the functioning of society." The word "essential" has a plain dictionary meaning. Rulemaking to set

---

[11] *See In re Denial of Contested Case Hearing Requests and Issuance of NPDES/SDS Permit No. MN0071013 for the Proposed NorthMet Project*, 993 N.W.2d 627, 663 (Minn. 2023) ("under subpart 2, pollution cannot be discharged to the unsaturated zone in a way that may result in pollution to the underground waters.")

criterial for what is "essential" is likely to undermine the legislative purpose, which is to prohibit PFAS products in the state, not to find ways to allow their continued use.

2. *Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?*

Costs of alternatives should not be considered in the definition, other than to say that economic considerations alone should not determine that an alternative is not reasonably available. The statute does not use the term "cost" except in the context of fees to cover agency expenses.

3. *Should unique considerations be made for small businesses with regards to economic feasibility?*

Unique considerations should not be made for small businesses. Nothing in the statute suggests that MPCA would be authorized to apply such considerations.

4. *What criteria should be used to determine the safety of potential PFAS alternatives?*

MPCA should rely on independent scientific evidence of safety or reduced harm of potential PFAS alternatives and should recognize that standards developed either in the (often political) regulatory process or through industry-sponsored research are likely to be insufficient to determine safety. It is recommended that safety be determined by an independent scientific advisory team working with the Minnesota Department of Health. Such a process should remove the determination of the safety of potential alternatives from the conflict-driven question of whether a "currently unavoidable use" of PFAS should be allowed.

5. *How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?*

The applicant for a currently unavoidable use determination should bear the burden of proving the length of time for which the determination should apply. The rules should also state a maximum length that no determination can exceed. After it sunsets, any further "currently unavoidable use" determination should require a new application.

6. *How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?*

Producers or users seeking a "currently unavoidable use" exception from the PFAS prohibition should be required to make an application to MPCA, subject to notice, comment, and judicial review. That application should require the applicant to demonstrate that the particular use is essential to health, safety, or the functioning of society and that no other ways to accomplish that use without PFAS are reasonably available. A financially interested party (for example, a manufacturer of a competing product that does not contain PFAS) and members of the public should be able to apply for an "avoidable use" category determination. Such a category determination could be based on information that products or processes not containing PFAS are reasonably available to accomplish an essential use or that a particular category of products or processes containing PFAS is not an essential use. Such a determination would not sunset.

7. *In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.*

This question does not apply to WaterLegacy.

8. *Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?*

MPCA should not make any "currently unavoidable use" determinations except through a specific application process. Minn. Stat. § 116.943 gave the MPCA clear authority to expand the categories of products with PFAS that are *prohibited*, but provided no comparable authority for MPCA to search out and prove exceptions to the statute.

9. *Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.*

It is recommended that MPCA prioritize determining and prohibiting categories of products containing PFAS that are *not* essential to health, safety, or the functioning of society and those for which there *are* reasonably available safer alternatives without intentionally added PFAS. This approach and the requirement that industries prove any "currently unavoidable use" exceptions would provide clarity and protect health and the environment as the statute intended.

WaterLegacy requests that MPCA take this PFAS rulemaking opportunity to protect public health and clean water and to increase public transparency regarding products containing chemicals with serious health effects. We also request that MPCA work with the Minnesota Department of Health and the Minnesota Department of Natural Resources to monitor both exploratory drilling and legacy mining sites for PFAS and to ensure that environmental review and proposals for permitting require evaluation and avoidance of the discharge or injection of PFAS into groundwater.

Sincerely yours,

Paula G. Maccabee

Abstract

Per- and poly-fluorinated alkyl substances (PFAS) are a group of more than 3,000 man-made chemicals including perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS). This emerging class of contaminants has been the centre of litigation settlements already worth billions of dollars across various US states. Ubiquitous at very low levels in the environment, PFAS have been measured in water supplies across the US. While the focus on PFAS to date has centred around manufacturing facilities and commonly known aqueous film forming foam (AFFF) release sites (airports and military bases), international governments have been starting to consider other types of PFAS impacts associated with a broad range of industries.

Although mining has not yet become a key focus area for concerns related to PFAS impacts, mines are beginning to be identified as sources of PFAS. For example, BHP's Mount Whaleback Iron Ore Mine in Western Australia was recently identified as the source of low level PFAS impacts to groundwater. These impacts have the potential to threaten a nearby drinking water supply, prompting BHP to evaluate PFAS use across its site. The use of PFAS within the mining industry has been long established, including use within industrial processes (e.g., use as surfactants to enhance metal recovery, within the ore flotation process, etc.), as well as use of AFFF for firefighting activities. Consequently, environmental releases of PFAS from mining facilities could occur and require consideration and management.

This paper will provide an overview of the challenges associated with PFAS in the environment, and the implications these challenges may have for the mining industry. It will review PFAS use within the mining industry, site characterization challenges, potentially relevant receptors and exposure pathways, and remedial options, as well as the status of PFAS regulation internationally.

Introduction

Per- and poly-fluorinated alkyl substances (PFAS) are a group of more than 3,000 man-made chemicals including perfluorooctanoic acid (PFOA) and perfluorooctane sulfonate (PFOS). This emerging class of contaminants has been the centre of litigation settlements worth over $5.5 billion across the US. Ubiquitous at very low levels in the environment, PFAS have been measured in water supplies across the US. A variety of adverse health effects have been associated with PFAS exposure, including liver damage, decreased fertility, thyroid disease, cancer, decreased immunity, and more.

Mines are beginning to be identified as potential sources of PFAS release to the environment. The use of PFAS within the mining industry has been long established, including use within industrial processes (e.g., use as surfactants to enhance metal recovery, within the ore flotation process, etc.), as well as use of aqueous film forming foam (AFFF) for firefighting activities. Consequently, environmental releases of PFAS from mining facilities could occur and require consideration and management. As such, this paper will review PFAS use within the mining industry, site characterization challenges, potentially relevant exposure pathways for receptors, and remedial options, as well as the status of PFAS regulation.

PFAS Use within the Mining Industry

As outlined in Gluge et al. (2020), 1400 individual PFAS substances have been identified for more than 200 uses in 64 different categories, including the mining industry. PFAS substances are widely used due to the many properties that make them invaluable to industry, including:

- the ability to lower the aqueous surface tension
- high hydrophobicity
- high oleophobicity
- high non-flammability
- capacity to dissolve gases
- high stability
- extremely low reactivity
- high dielectric breakdown strength
- good heat conductivity
- low refractive index
- low dielectric constant
- ability to generate strong acids
- operation at a wide temperature range
- low volatility in vacuum
- impenetrability to radiation

In mining, PFAS uses include ore leaching in copper and gold mines, ore floating, separation of uranium from ore/minerals, concentration of vanadium compounds, acid mist supressing agent, wetting agents, hydrocarbon foaming agent, and the use of fluoropolymer in pipes, cables, hoses and conveyor belts (Gluge et al. 2020, Wood 2021).

PFAS may also be present at mining sites for uses that are ancillary to the mining operation, such as PFAS-containing AFFF for fire suppression/firefighting activities, cleaning of metal surfaces, and use as a foaming agent in drilling fluids, paints and coatings, and so on. In the case of AFFF, fire suppression systems often need to be tested annually, and traditionally this has involved discharge of AFFF to the ground surface. As noted by Hunt (2020), mining sites typically have fixed fire suppression/fighting systems that can spray suppressants for long distances from a fixed location, meaning impacts can be widespread.

Site Characterization Challenges

The characterization of PFAS at any Site, including mining sites, should consider PFAS fate and transport in the environment, requirements for adjusted field procedures during sample collection, and implementation of appropriate laboratory quality assurance and quality control (QA/QC) processes.

PFAS Fate and Transport

Fate and transport of PFAS in the environment can be highly variable, given PFAS include many compounds with different physical-chemical characteristics that control their behaviour (ITRC 2021a). Carbon-fluorine chain length, functional group, charge and degree of fluorination all influence PFAS behaviour. When PFAS are discharged or spilled to ground surface, the PFAS can adsorb to soil through either hydrophobic or electrostatic interactions and remain close to the source area. PFAS can also show enhanced retention within the vadose zone, given the tendency of PFAS to accumulate at the air-water interface. Alternately, the charged functional group and associated hydrophilic properties can lead to PFAS leaching into groundwater and mobilizing with groundwater flow. Generally, the degree to which PFAS adsorb to solids or mobilize can be approximated by the chain length; longer carbon-fluorine chains tend to adsorb more strongly to solids versus shorter carbon-fluorine chains. Given the high stability of PFAS, once present in groundwater, large plumes can form that remain present for long periods of time. Transformation of commonly assessed PFAS, such as PFOA and PFOS, under typical environmental conditions is limited; however, PFAS precursors or polyfluorinated compounds may transform into more stable PFAS. Uptake of PFAS by plants and animals has been observed, with some PFAS showing bioaccumulation and biomagnification potential. Site-specific considerations cannot be omitted from assessment planning, as they do impact the fate and transport of PFAS, similar to other contaminants (ITRC 2021a).

PFAS can be found in other media, such as surface water, sediment and air (ITRC 2021a). Similar mechanisms as discussed for soil and groundwater dictate how PFAS behave in these media as well, including solid-liquid partitioning, and transformation or uptake. Given the surfactant-like properties of many PFAS and accumulation at the air-water interface, PFAS have been observed to form a foam at the top of surface water bodies when present at high concentrations. Many PFAS have low vapour pressures that limit movement of PFAS from water to air; however, there are some PFAS, such as fluorotelomer alcohols (FTOHs), that show greater volatility. Atmospheric transportation of PFAS can occur through release of volatile PFAS or PFAS adsorbed to air-borne particulate matter (ITRC 2021a).

Field Sampling Procedures and QA/QC

Although standard environmental sampling best practices should be followed, field sampling programs that include PFAS have additional considerations. PFAS are found in many commercial products, which include some of the equipment and supplies typically used to collect environmental samples, creating the potential for sample contamination. Other materials (such as glass) may adsorb PFAS, which would low-bias the collected data. Both cases should be avoided, and this can be facilitated through review of available reference documents regarding PFAS sampling, which notably include the Michigan Department of Environmental Quality (MDEC) *General PFAS Sampling Guidance* (MDEC 2018) and the Interstate Technology Regulatory Council's (ITRC's) *Sampling Precautions and Laboratory Analytical Methods for Per- and Polyfluoroalkyl Substances (PFAS)* (ITRC 2020).

Precautions outlined in MDEC (2018) and ITRC (2020) include avoiding certain clothing, materials, food packaging, and personal hygiene products that may contain PFAS when sampling. Sampling equipment and supplies should not contain Teflon, polytetrafluoroethylene (PTFE), fluorinated ethylene propylene (FEP), ethylene tetrafluoroethylene (ETFE), LDPE, polyvinylidene fluoride (PVDF), fluoropolymers or anything with "fluoro" in the name. Other materials that should be avoided during sampling include Decon-90, post-it notes, waterproof field paper or books, "blue ice" and any type of cooler pack, waterproof markers, sharpies, permanent markers, binders, spiral/ hard cover notebooks, plastic clipboards, adhesive paper products, food packaging and containers and adhesive tapes. Acceptable materials to use during sampling include materials made from high density polyethylene (HDPE), polypropylene or silicone, decontamination solutions like Alconox/ Liquinox, and field supplies that include loose plain paper, metal clipboards, ball point pens, and ice formed by water.

When executing a PFAS sampling program, PFAS sampling materials should be stored separately from sampling supplies for other parameters. Non-disposable field equipment should be decontaminated between each sample location and prior to use at a site where PFAS is being assessed. Sample collection should begin at the location where impacts are least expected (i.e., lowest anticipated PFAS concentrations) and move towards locations where impacts are most expected (i.e., highest anticipated PFAS concentrations). Eating or drinking on site during sampling should be avoided to minimize the potential for cross-contamination. Hands should be washed prior to returning to the site following any breaks.

In order to confirm that field procedures have been effective in inhibiting sample contamination, field QA/QC blank samples should be obtained, including equipment blanks, trip blanks and field blanks. Equipment blanks are collected using laboratory-provided PFAS-free water that is passed through or over equipment used for sampling activities to assess whether the equipment represents a potential source of PFAS to the sample. Field blanks are PFAS-free water samples that are collected in separate laboratory-provided sample containers while conducting sampling in the field to monitor that field activities are not a potential source of PFAS to the sample. Trip blanks are PFAS-free water samples prepared by the laboratory that are transported during the sampling procedure to monitor that PFAS have not been introduced to the samples through laboratory preparation or transportation. The combination of these field QA/QC blank samples will provide confidence that the collected PFAS data are representative of site conditions.

Laboratory QA/QC

Choosing a certified laboratory to complete PFAS analysis is important to maintaining the accuracy and reliability of the data. The laboratory should provide appropriate containers to collect samples (i.e., unlined and made of polypropylene or HDPE); glass containers and certain plastic bags should be avoided, wherever possible. If high PFAS concentration samples are to be submitted for analysis, these samples should be segregated during sampling and shipment, and flagged to the laboratory to support appropriate preparation for analysis. It is noted that there are only a few multi-laboratory validated and published methods for analysis of PFAS, and those released to date have generally been developed for analysis of water samples (drinking water, groundwater, surface water and wastewater). Draft laboratory methods are available for other media, such as soil, sediment, biosolids and tissue; however, these have not been validated by multiple laboratories (ITRC 2021b). Following PFAS analysis, it is important to review the laboratory certificates of analysis to confirm the reported laboratory QA/QC procedures, such as method blanks, spiked blanks and analysis of duplicates, and compare the results to the provided evaluation criteria. This review of laboratory QA/QC may help indicate whether sample matrix interference or laboratory issues could have impacted the reliability of the reported PFAS concentrations.

Relevant Exposure Pathways

Human and ecological receptors can be exposed to PFAS through various pathways both at a mining site, as well as off-site, due to fate and transport mechanisms (e.g., groundwater migration, wind erosion, deposition). The routes of exposure and the receptors exposed, particularly off-site, can be influenced by the physical location of the mining site. Figure 1 illustrates a potential mining site, the surrounding land use, and the potential routes of exposure and receptors (as indicated by the numbers [#], and explained in the text below). The main expected source of PFAS is the use of AFFF (#1). PFAS may also end up in effluent or tailings ponds through use in processing (#2). These waters are unlikely to be treated for PFAS.

Human Health

The most likely potential exposure routes to PFAS for people at a mining site (e.g., workers) are incidental ingestion of soil (#3), potable water ingestion (should the mining site rely on groundwater or nearby surface water as source water) (#4), and, to a lesser extent, direct contact with PFAS-containing products (e.g., AFFF) (#1) and inhalation of PFAS in dust and air (#5). According to ITRC (2021c), exposure via potable water is generally the dominant exposure pathway in comparison to other pathways (e.g., from food), even if PFAS concentrations in the drinking water source are low. If there is an on-site accessible surface water feature, there may also be exposure via incidental ingestion of sediment and surface water (#2).

Figure 1: Potential mining site and surrounding land use (numbers described in text).

Similar routes of exposure to PFAS would also be present for people living near the mining site, including mining workers living in off-site camps, as well as other residential communities, including Indigenous communities. The dominant exposure pathway of concern off-site would still be ingestion of PFAS-impacted potable water (i.e., groundwater or surface water) (#6); however, other routes of exposure could include direct contact with PFAS-impacted soil (due to off-site migration of soil particulates via wind or mining emissions and deposition onto soils) (#7), consumption of food exposed to PFAS through watering (e.g., livestock) (#8), soil up-take or irrigation (e.g., crops) (#9), exposure to PFAS-impacted surface water and sediment (e.g., incidental ingestion of surface water/sediment, ingestion of aquatic biota) (#10), and, to a lesser extent, inhalation of PFAS in dust and in air (#11).

Ecological Health

The routes of exposure for ecological receptors would be similar both at the mining site and off-site. Plants and soil invertebrates could be exposed to PFAS in soil (#12), although exposure off-site may be limited as impacts would only be transmitted via off-site migration of PFAS through wind (e.g., soil particulate) or mining emissions, followed by deposition onto soils. Aquatic biota could be exposed to PFAS in both surface water and sediment in on-site surface features, if present, and from PFAS migration in mining site groundwater to off-site surface water features (#10). Terrestrial and aquatic mammals and birds could be exposed via impacted surface water (e.g., consumption) (#10) and via food (e.g., plants, invertebrates, mammals, birds and aquatic biota) (#10, 12, 13); however, exposure on-site for mammals and birds may be limited if measures are in place that limit their access to the mining site itself (e.g., fencing).

Remedial Options

Remediation depends on the use of treatment technologies that can exploit a contaminant's chemical and physical properties for the purpose of removing or destroying the contaminant from environmental media. PFAS are a challenge to remediate because they are typically found in the environment as mixtures composed of different PFAS with potentially very different properties. The solubility, surfactant properties, stability, and poor adsorption characteristics of different PFAS tend to complicate remediation, as common technologies are ineffective (e.g., air stripping, soil vapor extraction, biostimulation or bioaugmentation) or have limited effectiveness (e.g., chemical oxidation). There are very few field-demonstrated, cost-effective treatment technologies for PFAS on solids or in water; however, there are proven ex situ technologies that could be applicable to the situations typically encountered at a mining site and these will be reviewed here. ITRC (2021d) provides an excellent summary of other emerging technologies currently under development.

Mines typically use local groundwater for drinking water and historical PFAS use may contaminate the drinking water supply to levels above recommended drinking water criteria. Beyond use of AFFF, treatment of process water at most mining sites largely does not address PFAS, meaning PFAS can be discharged to the environment in treated process water and impact drinking water supplies. As the primary concern at mining sites is drinking water, this review will focus primarily on water treatment technologies.

To date, readily available technologies for drinking water treatment have been limited to sorption and ion exchange, whereas treatment of leachates and process waters has included foam fractionation and coagulation (ITRC 2021d), depending on the composition of the solution. When considering remedial options for mining sites, it is important to note these sites are typically remote and operate under harsh environmental conditions, where power generation can be costly. Consequently, transport of PFAS-impacted treatment media off-site is expensive, sensitive specialized equipment has poor longevity, and onsite disposal of highly soluble and potentially mobile contaminants like PFAS is not practical.

Sorption and Ion Exchange

Sorption and ion exchange are two removal technologies that bind PFAS using Van der Waals and/or weak ionic forces, resulting in the accumulation of PFAS on the sorptive media. Granular activated carbon (GAC) and ion exchange resins (IX) are the most common sorptive media available used for PFAS adsorption. Various types of GAC have been tested with most PFAS and manufacturers having developed models to predict mass loading under a variety of solution conditions. Most testing has focussed on the efficacy of

GAC sorption of long-chain PFAS (Appleman et al. 2013; Ochoa-Herrera and Sierra-Alvarez 2008) and has demonstrated that GAC treatment can achieve effluent concentrations below detection limits for United States Environmental Protection Agency (USEPA) Method 537.1 (Shoemaker and Tettenhorst 2018). Although also effective with other organic contaminants such as petroleum hydrocarbons and chlorinated solvents, co-contaminants can displace PFAS from GAC, reducing treatment. Sorption efficiency is dependent on carbon chain length of the PFAS and the ionic functional group, with shorter chain PFAS and carboxylic acids having lower sorption efficiencies than longer chain and sulfonic acid types (e.g., PFOS adsorbs more effectively than PFOA [McCleaf et al. 2017] and both adsorb more effectively than perfluorobutanesulfonate [PFBS] or perfluorobutanoate [PFBA] [Appleman et al. 2013]).

GAC can be regenerated through solvent (methanol) extraction and the material reused for non-drinking water applications. The solvent extracted PFAS can be distilled to remove the solvent and the concentrated PFAS can be treated through incineration in a kiln at temperatures >1,000° Centigrade (°C).

Ion exchange has been shown to effectively sorb and treat a broad suite of PFAS at field scale to below analytical detection limits for influent concentrations in the range of several 100 micrograms per liter (µg/L) total PFAS (Kothawala et al. 2017; McCleaf et al. 2017; Woodard et al. 2017). Resins can be designed to target certain PFAS more effectively, but generally, like GAC, perfluorosulfonic acids (PFSAs) have a greater affinity than perfluorocarboxylic acids (PFCAs) for similar chain length and longer chains have a greater affinity than shorter chain PFAS. IX are also available as single use and regenerable resins, where the solvent extract can be submitted directly for incineration or distilled and the PFAS residue incinerated. Regenerable resins are better suited for removal of higher concentration PFAS (ITRC 2021d).

IX are highly susceptible to fouling and require pre-treatment for pH, inorganic and organic co-contaminants and major anions and cations. Low concentrations of dissolved organic matter, iron or manganese can significantly influence membrane performance and permeability.

Reverse Osmosis and Nanofitration

Reverse osmosis (RO) and, to a lesser extent, nanofiltration (NF) are commonly used in mining and many industrial water treatment processes to remove ions from water by forcing impacted water through a semipermeable membrane. Both techniques can concentrate PFAS in the permeate, which can then be treated using a second technology (such as foam fractionation or advanced oxidation) and have been shown to be effective at removing longer chain (>C5) perfluoroalkyl acids (PFAAs) (Loi-Brugger et al. 2008; Tang et al. 2006). In order to preserve the RO/NF membranes for removal of PFAS, pre-treatment is required to remove interfering anions and cations, optimize pH and remove organic contaminants that might clog the membranes. The effectiveness of RO/NF at removing PFAS has been evaluated extensively in wastewater and drinking water applications where PFAS was not the target contaminant (Tang et al. 2006; Flores 2013;

Glover et al. 2018; Dickenson 2016; Merino et al. 2016). Tang et al. (2006 and 2007) studied PFAS from various wastewaters using various RO and NF membranes and achieved >99% removal at PFOS concentrations ranging from 0.5 to 1,500 milligrams per liter. Although RO/NF have high treatment efficiencies at high PFAS concentrations and reliably remove the bulk of PFAS from highly impacted waters (e.g., PFAS-AFFF impacted groundwater where concentrations can be in the high μg/L range), they still require a polishing treatment using GAC or IX to reliably achieve regulatory criteria for effluent limits.

Foam Fractionation

As a result of their non-polar tail and polar head, PFAS tend to accumulate at the air-water surface which facilitates removal via foam fractionation by bubbling air or reactive gases (e.g. ozone) through a water column to form foam. The foam, which is composed predominantly of PFAS and other similar co-contaminants, is then skimmed off the water surface. One application used by the Australian Department of Defence, Army Aviation Centre Oakey (AACO) (base near Toowoomba, Queensland) is referred to as surface activation foam fractionation (SAFF) and uses hundreds of columns to progressively strip PFAS off the top of the water columns (ITRC 2021d). Various studies have shown that C6 PFAS and greater can be removed effectively with this technology; however, it is less effective on shorter chain PFAS. The treatment rates that can be achieved with foam fractionation depend on the degree of foaming and contaminant load. At high foaming rates, throughput is reduced significantly, but the technology is very useful for removal of longer chain PFAS from concentrated mixed contaminant streams and RO/NF reject.

Developing Destructive Technologies

There are many destructive technologies in development showing promise for the destruction of short and long chain PFAS using oxidation approaches (ITRC 2021d). Ozonation (in combination with persulfate), activated persulfate, electrochemical oxidation, sonochemical oxidation, supercritical water oxidation, photochemical oxidation (UV-Ox) and other advanced oxidation technologies are in various stages of development. While these technologies are promising, the PFAS concentrations need to be in the range where oxidation is cost effective. At remote sites, like mining sites, where disposal of PFAS can be challenging due to transportation costs, these destructive technologies may be better options for onsite destructive treatment of concentrated waste in combination with a GAC or IX polishing post treatment.

Status of PFAS Regulation

To date, internationally, there appears to be no official guidance or guidelines produced regarding PFAS that are specifically directed to the mining industry; however, many jurisdictions have produced screening values for environmental media that would be potentially applicable to mining sites. Standards and guidelines for surface water, drinking water, groundwater, and soil have been developed for up to 20 PFAS in the jurisdictions of Canada, the United States (US), and internationally. The majority of these standards and guidelines are for PFCAs and PFSAs, with only a few jurisdictions preparing standards and guidelines for select fluorotelomer sulfonic acids (FTSAs) and GenX (a trade name for a group of shorter chain PFAS, e.g., less than six carbons). Some of these values are regulated. Select jurisdictions have also developed criteria for other types of media (e.g., sediment, ambient air, fertilizer, fish tissues, eggs, other food products, etc.); however, these values are often unregulated. Given the primary exposure pathway of concern at mining sites is expected to be ingestion of potable water, this review will focus on standards and guidelines that have been produced for water.

North America

In the US, no federal maximum contaminant level (MCL) has been released by the USEPA for any PFAS; however, the USEPA did define a lifetime health advisory for drinking water concentrations of PFOA and PFOS as 70 nanograms per litre (ng/L) in 2016, which applies to PFOA and PFOS individually and as a sum (USEPA 2019a). The USEPA has also released a screening level of 40 ng/L to determine if PFOA and/or PFOS are present in groundwater and warrant further investigation, but the preliminary remediation goal for contaminated groundwater remains as the USEPA drinking water health advisory (USEPA 2019b). In 2020, the PFAS Action Act was passed by the House of Representatives to classify certain PFAS as hazardous substances, which is expected to lead to enforceable MCLs in future (Library of Congress, 2020).

In the absence of federal MCLs, pressure from citizens and politicians has led some states to develop their own standards (Zemba et al. 2019). Many states have developed their own guidelines and criteria, especially for PFOA and PFOS, at a range of values more conservative than the USEPA (ITRC 2021e). Illinois (2 ng/L PFOA and 14 ng/L PFOS) and California (5.1 ng/L PFOA and 6.5 ng/L PFOS) have some of the most conservative values for drinking water (ITRC 2021e). Hawaii has set criteria for the largest number of PFAS parameters, with groundwater protective concentration levels for 18 PFAS. The range of guidelines and standards available from the States for the six PFAS for which standards and guidance values are most commonly defined are summarized in **Error! Reference source not found.**1. Soil guidelines and standards for the protection of drinking water or groundwater have also been released by 12 States for up to 18 PFAS (ITRC 2021e).

In Canada, Health Canada (HC) has established drinking water guidelines (DWGs) for PFOA and PFOS, as well as drinking water screening values (DWSVs) for nine additional PFAS (HC 2019). The DWGs and DWSVs for the same six PFAS included in Table 1 are detailed in Table 2. The DWGs and DWSVs were defined to protect human exposure from drinking water sources. The DWGs for PFOA and PFOS are presented as Maximum Acceptable Concentrations (MACs) that are based on a study that referenced hepatocellular hypertrophy in rats as a result of exposure to PFOA and PFOS (HC 2018a and 2018b). Health Canada suggested that an additive approach using the ratio of PFOA and PFOS to their respective DWG should also be considered in cases where PFOA and PFOS occur concurrently in drinking

Table 1: Sample PFAS Water Guidelines and Standards (United States) (ITRC 2021e)

PFAS Analyte	Drinking Water (ng/L)	Groundwater (ng/L)	Surface Water (ng/L)
PFOA	2 - 667	2 – 40,000,000	70 – 24,000
PFOS	6.5 - 667	2 – 500,000	6 – 300,000
Perfluorononaote (PFNA)	6 - 70	4.4 – 40,000,000	70 – 1,000
PFBS	345 – 667,000	420 - 400,000	400,000
Perfluorohexanesulfonate (PFHxS)	18 - 140	18 – 500,000	700
Perfluoroheptanoate (PFHpA)	20 - 70	2 – 40,000,000	300

water sources (HC 2018a and 2018b). In 2021, the Canadian Council of Ministers of the Environment (CCME) produced a federal environmental quality guideline for PFOS in groundwater protective of ecological receptors and human health (CCME 2021). The CCME value is also summarized in **Error! Reference source not found.**. None of the federal guidelines developed in Canada are currently regulated. The only Canadian province to produce regulated values is British Columbia (BC) (BC 2019); these values are included in Table 2.

Table 2: Sample PFAS Water Guidelines and Screening Values (Canada)

PFAS Analyte	DWG (MAC, ng/L) (HC 2019)	DWSV (ng/L) (HC 2019)	CCME, Groundwater (ng/L) (CCME 2019)	BC Contaminated Sites Regulation, Drinking Water (ng/L) (BC 2019)
PFOA	200			200
PFOS	600		600	300
PFNA		20		
PFBS		15,000		80,000
PFHxS		600		
PFHpA		200		

International

The Australian government completed a literature review for PFAS toxicity and indicated the evidence of human health impacts directly related to PFAS exposure is limited and does not indicate an increase in overall cancer risk (Zemba et al. 2019); however, this government still released health-based PFAS guidelines for drinking water, residential water, and soil for PFOA, PFOS, and PFHxS (ITRC 2021e).

For other areas known for mining sites, such as South America, Indonesia, Asia, Russia and the Middle East, country-specific regulatory frameworks for PFAS are unknown; however, many of the countries in these regions are part of the Stockholm Convention (Brennan et al. 2021) which has been regulating select PFAS as Persistent Organic Pollutants since 2009.

Conclusion

PFAS can be found at mining sites both due to their use in industrial processes, as well as in AFFF. The assessment, management, and remediation of environmental releases of PFAS from mining facilities needs to consider the unique receptors and exposure pathways associated with these remote sites, as well as the related logistical challenges for assessment and remedial approaches. As a number of jurisdictions are advancing regulation around the use of PFAS and its presence in environmental media, mining facilities will need to consider the potential impacts and liabilities associated with PFAS use at their operations.

Per- and polyfluoroalkyl substances (PFAS) are of concern because of their high persistence (or that of their degradation products) and their impacts on human and environmental health that are known or can be deduced from some well-studied PFAS. Currently, many different PFAS (on the order of several thousands) are used in a wide range of applications, and there is no comprehensive source of information on the many individual substances and their functions in different applications. Here we provide a broad overview of many use categories where PFAS have been employed and for which function; we also specify which PFAS have been used and discuss the magnitude of the uses. Despite being non-exhaustive, our study clearly demonstrates that PFAS are used in almost all industry branches and many consumer products. In total, more than 200 use categories and subcategories are identified for more than 1400 individual PFAS. In addition to well-known categories such as textile impregnation, fire-fighting foam, and electroplating, the identified use categories also include many categories not described in the scientific literature, including PFAS in ammunition, climbing ropes, guitar strings, artificial turf, and soil remediation. We further discuss several use categories that may be prioritised for finding PFAS-free alternatives. Besides the detailed description of use categories, the present study also provides a list of the identified PFAS per use category, including their exact masses for future analytical studies aiming to identify additional PFAS.

Environmental significance

Per- and polyfluoroalkyl substances (PFAS) are a large group of more than 4700 substances that are used in a wide range of technical applications and consumer products. Releases of PFAS to the environment have caused large-scale contamination in many countries. For an effective management of PFAS, an overview of the use areas of PFAS, the functions of PFAS in these uses, and the chemical identity of the PFAS actually used is needed. Here we present a systematic description of more than 200 uses of PFAS and the individual substances associated with each of them (over 1400 PFAS in total). This large list of PFAS and their uses is intended to support the identification of essential and non-essential uses of PFAS.

1 Introduction

Per- and polyfluoroalkyl substances (PFAS) are a class of thousands of substances[1,2] that have been produced since the 1940s and used in a broad range of consumer products and industrial applications.[3] Based on concerns regarding the high persistence of PFAS[4] and the lack of knowledge on properties, uses, and toxicological profiles of many PFAS currently in use, it has been argued that the production and use of PFAS should be limited.[5] However, there are specific uses that make an immediate ban of all PFAS impractical. Some specific uses of PFAS may currently be essential to health, safety or the functioning of today's society for which alternatives so far do not exist. On the other hand, if some uses of PFAS are found to be non-essential, they could be eliminated without having to first find alternatives that provide an adequate function and performance. To determine

which uses of PFAS are essential and which are not, the concept of "essential use," as defined under the Montreal Protocol, has recently been further developed for PFAS, including illustrative case studies for several major use categories of PFAS.[6]

PFAS are costly to produce (*e.g.* fluorosurfactants are 100–1000 times more expensive than conventional hydrocarbon surfactants per unit volume[7]) and therefore are often used where other substances cannot deliver the required performance,[1] or where PFAS can be used in a much smaller amount and with the same performance as a higher amount of a non-fluorinated chemical. Examples are uses that operate over wide temperature ranges or uses that require extremely stable and non-reactive substances. The C–F bonds in PFAS lead to very stable substances, a feature that also makes the terminal transformation products of PFAS very persistent in the environment. Furthermore, the perfluorocarbon moieties in PFAS are both hydrophobic and oleophobic, making many PFAS effective surfactants or surface protectors.[8] PFAS-based fluorosurfactants can lower the surface tension of water from about 72 mN m^{-1} (ref. 9) to less than 16 mN m^{-1}, which is half of what is attainable by hydrocarbon surfactants.[8,10] Likewise, the surfaces of fluorinated polymers have about half the surface tension compared to hydrocarbon surfaces. For instance, a close-packed, uniformly organized array of trifluoromethyl ($-CF_3$) groups creates a surface with a solid surface tension as low as 6 mN m^{-1}.[11]

Due to these and other desirable properties, PFAS are used in many different applications. A good overview of the range of uses of PFAS as surfactants and repellents is provided in the monograph by Kissa (2001).[3] It lists 39 use categories, mostly derived from patents, and describes the functions of PFAS in these use categories. However, the work by Kissa (2001) was published nearly 20 years ago, focused on fluorosurfactants and repellents, and it is not clear which of these uses are still relevant today. In addition to Kissa (2001),[3] there are a few other monographs and a number of peer-reviewed scientific articles and reports that have looked into the uses of PFAS.[8,12–22] While these articles and reports provide useful information, each of them focuses on the uses of a specific PFAS group (in specific use categories). This is also the case for the reviews from the Persistent Organic Pollutants Review Committee (POPRC), the focuses of which are on perfluorooctanoic acid (PFOA), perfluorooctane sulfonic acid (PFOS), perfluorohexane sulfonic acid (PFHxS), their precursors, and the PFAS that may be or have been introduced as replacements for these PFAS.[23–29] The FluoroCouncil[30] has provided additional information on uses of PFAS. However, the information is rather generic with limited details about specific uses and substances. Hence, a comprehensive overview that summarizes major current uses is missing.

The present paper, together with the Appendix (Table 4) and the ESI,† aims to provide a broad, but not exhaustive, overview of the uses of PFAS and associated individual substances (note that a working definition of PFAS is used here to define the scope of PFAS considered in this study, which is provided in the Methods section below). The paper addresses the following points: (i) in which use categories have PFAS been employed and for which functions? (ii) Which PFAS have been – and are still – used in a certain category? (iii) What is the extent of the uses in certain parts of the world? Within the European Union (EU), there are discussions underway for restricting PFAS to those uses that are essential,[31] and extensive information on many PFAS uses will be needed in this context. The present work also aims to support this process by showing in which specific applications PFAS are used, and in which functions, as a first step toward differentiating essential and non-essential uses of PFAS.

2 Methods

2.1 Which PFAS are addressed?

A first clear definition of PFAS was provided by Buck *et al.* (2011).[1] They defined PFAS as aliphatic substances containing the moiety $-C_nF_{2n+1}$ within their structure, where n is at least 1. The OECD/UNEP Global PFC Group noted that many substances containing other perfluorocarbon moieties (*e.g.* $-C_nF_{2n}-$) were not commonly recognized as PFAS according to Buck *et al.* (2011), *e.g.* perfluorodicarboxylic acids.[2] Considering their structural similarities to commonly recognized PFAS with the $-C_nF_{2n+1}$ moiety, the OECD/UNEP Global PFC Group proposed to also include substances that contain the moiety $-C_nF_{2n}-$ ($n \geq 1$) as PFAS.[2] However, the exact definition is still under discussion. The present study is in line with the OECD proposal in several, but not all, respects. In contrast to the definition by Buck *et al.* (2011), the present study also includes (i) substances where a perfluorocarbon chain is connected with functional groups on both ends, (ii) aromatic substances that have perfluoroalkyl moieties on the side chains, and (iii) fluorinated cycloaliphatic substances.

More specifically, the present study focuses on polymeric PFAS with the $-CF_2-$ moiety and non-polymeric PFAS with the $-CF_2-CF_2-$ moiety. It does not include non-polymeric substances that only contain a $-CF_3$ or $-CF_2-$ moiety, with the exception of perfluoroalkylethers and per- and polyfluoroalkylether-based substances. For these two PFAS groups, substances with a $-CF_2OCF_2-$ or $-CF_2OCFHCF_2-$ moiety are also included.

2.2 Literature sources

The present inventory was started with the risk profiles and risk management evaluations for PFOA, PFOS, PFHxS and their related compounds to obtain an overview of uses of these chemicals.[23–29] Reports and books that address fluorosurfactants and fluoropolymers in general were also included.[3,8,12,16,20,21,32–43] Literature specific to certain use categories was retrieved for more information either on the substances used, or to understand why PFAS are, or were, necessary for a given use. All specific references are cited in the ESI-1.†

In addition, databases, patents, information from PFAS manufacturers and scientific studies that measured PFAS in products were examined. These additional sources are described in more detail in the following subsections. The

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

searches were not exhaustive in any of the sources described, and there are still many more reports, scientific studies, patents, safety data sheets and databases with information on the uses of PFAS than the ones cited here or in the ESI-1.†

The information in the Tables in the ESI-1† from these sources was marked according to its original source. Information from patents (cited in a book, article or report) was marked with "P", information on PFAS analytically detected in products with "D", and information on uses or information without additional reference with "U" for "use", or "U*" for "current use" (which is defined as a use with public record(s) of use from the last 4 years, *i.e.* 2017 or later).

2.2.1 Chemical data reporting under the US Toxic Substances Control Act. Manufacturers and importers that produced chemicals in amounts exceeding 25 000 pounds (11.34 metric tons, t, per year) at a site in the United States (US) between 2012 and 2015 were obliged to report to the US Environmental Protection Agency (US EPA) in 2016 (data for 2016 to 2019 will be reported in 2020). The data reported in 2016 included for each reported substance: the name, Chemical Abstracts Service (CAS) registry number and product categories for consumer and commercial uses and sectors, as well as function categories for industrial processing and use. The masses (tonnages) used and exported also had to be reported; however, they are in most cases confidential business information (CBI). The reported data were filtered according to chemical names containing the word "fluoro". Non-polymeric substances that did not contain the $-CF_2CF_2-$ moiety and polymeric substances that did not contain the $-CF_2-$ moiety subsequently were removed. This left 39 entries where a specific PFAS was applied in a consumer or commercial use, and around 120 entries where a specific PFAS was applied in an industrial processing or use. The entries are labelled with "U" for "use" in the Tables in the ESI-1 and ESI-3.†

2.2.2 Data from the SPIN database of Denmark, Finland, Norway and Sweden. The Substances in Preparations in Nordic Countries (SPIN) database contains information on substances from the product registries of Denmark, Finland, Norway and Sweden.[44] There are several cases in which substances do not need to be registered. For example, Denmark, Finland, Norway and Sweden exempt products that come under legislation on foodstuffs and medicinal products from mandatory declaration. Furthermore, the duty to declare products to the product registers does not apply to cosmetic products and there is in principle no requirement to declare solid processed articles to any of the registers. There is also a general exemption from the duty to declare chemicals in Sweden, Finland and Norway, if the quantity produced or imported is less than 0.1 t per year (in Finland no exact amount is given). Of the Nordic countries, only Denmark and Norway require information on all constituents for most products for which declaration is mandatory. In Sweden, substances that are not classified as dangerous and that make up less than 5 per cent of a product may be omitted from the declaration. In Finland, information on the composition of products is registered from the safety data sheets. Complete information on the exact composition is consequently not necessarily given.

The data that we used in the present study were extracted for us from the SPIN database by an employee of the Swedish Chemicals Agency (KEMI) and the data included only non-confidential information. However, there is also a substantial amount of confidential information in the SPIN database. This is visible when the substances are accessed *via* the web interface of the SPIN database.[44] It was also pointed out to us that not all substances have available use data due to confidentiality.

The database includes four large data sets with information on uses. Two of the data sets ("UC62" and "National use categories") contain information on specific use categories, while the other two ("Industrial NACE" and "Industry National") contain information on sectors of uses. In addition to the use categories and sectors of uses, the data sets also contain information on the quantities of a chemical used in a certain use category or sectors of uses if the reported mass exceeds 0.1 t. The available data cover the time period 2000 to 2017. The four data sets were merged and then (as with the TSCA Inventory data) filtered for chemicals containing the word "fluoro". Those non-polymeric substances that did not contain the $-CF_2CF_2-$ moiety and polymeric substances that did not contain the $-CF_2-$ moiety subsequently were removed. This left 950 entries. Entries with available data for 2017 were labelled as "current use" (U*) in the Tables in the ESI-1 and ESI-3,† all other entries with "U" for "use".

2.2.3 Patents. Another important source of information is the patent literature. Patents were searched for *via* SciFinder^{n}[45] (which is the newest version of SciFinder) and Google Patents.[46] The patent search in SciFinder^{n} was mostly conducted *via* keywords and the constraint that the patent must contain a substance with the $-CF_2-CF_2-$ moiety. This can be done in SciFinder^{n} by using the "draw" function. Google Patents was mainly used to search for a full patent text (*via* the patent number) when SciFinder^{n} only provided the abstract of the patent. The advantage of SciFinder^{n} (which belongs to CAS) is that experts manually curate the substances described in the patents and provide CAS numbers. All substances identified in the patent are visible in SciFinder^{n} together with the patent. Through the patents it was possible to determine in which applications PFAS may be used. While it is not possible to determine whether licenses for a patent have been obtained, the status of the patent (*e.g.* active, withdrawn, expired, not yet granted) can be determined. Active patents become expensive for their owners over the years. Representatives from CAS informed us that it is very likely that a patent is still in use if it is still paid for after 10 to 15 years.[47] After 20 years, a patent expires, which means that the invention can be used by others free of cost. Note that many patents cover not just a specific substance, but rather a basic structure to which different functional groups can be attached. The SciFinder^{n} experts assign CAS numbers to those substances whose existence has been proven by the registrants. Such a proof can be

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM.
This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

a physical method or the description in a patent document example or claim. Still, it is not always clear which substances are actually used in practice. Patents were found for many uses, and the patented substances are included in the Table in the ESI-1,† labelled with "P" for "patent".

2.2.4 Information from companies that manufacture or sell PFAS. 3M, Chemours, DuPont, F2 Chemicals, Solvay, and other PFAS manufacturers describe on their webpages which products they make and what these can be used for. Separate factsheets are also available for some of the products, for example, for fluorocarbons from F2 Chemicals,[48] 3M™ Novec™ Engineered Fluids[49–52] or Vertrel™ fluids from Chemours.[53] The difficulty with this information is that it often does not specify which substances are contained in the products. Sometimes the safety data sheets provide information about the composition of the products, but in most cases they do not. Dozens of factsheets and safety data sheets were screened for the present study and the information on the PFAS they contained was extracted. However, it was not feasible, in a reasonable amount of time, to examine all factsheets and safety data sheets of the major PFAS manufacturers. The data included in the Table in the ESI-1† are labelled with "U" for "use".

2.2.5 Studies that measured PFAS in products. There are also numerous individual studies that analysed PFAS in products, for example in apparel,[54,55] building materials,[56] hydraulic fluids and engine oils,[57] impregnation sprays,[58,59] fire-fighting foams,[60–65] food packaging materials,[66,67] or various other consumer products.[33,68–75] These studies are important because they show in which products PFAS exist. However, in most studies only a handful of substances were analysed and even for these substances it is not clear whether they were used intentionally, impurities in the actual substances, or degradation products. The data included in the Tables in the ESI-1† are labelled with "D" for "detected analytically".

2.2.6 Market reports. A variety of non-verified commercial market reports exist for PFAS. Examples are the Fluorotelomer Market Report, Fluorochemicals Market Report or the Perfluoropolyether Market Report from Global Market Insights.[76–78] The information from these reports is not included in this study as these reports do not state their information sources and thus cannot be verified.

2.3 Nomenclature

In the present study, a distinction is made between use categories and subcategories. A use category can, but does not necessarily, have subcategories. An example of a use category for PFAS is sport articles; a subcategory under sport articles is tennis rackets.

A distinction is also made between use, function and property. The "use" is the area in which the substances are employed. This can either be the use category or the subcategory. The "function" is the task that the substances fulfil in the use, and the "properties" indicate why PFAS are able to fulfil this function. An example for a use would be chrome plating. In chrome plating, PFAS have the *function* to prevent the evaporation of hexavalent chromium(VI) vapour, because of the PFAS *properties* that lower the surface tension of the electrolyte solution and since the PFAS used are stable under strongly acidic and oxidizing conditions.[3]

In the present study, the term "individual PFAS" always refers to substances with a CAS number, irrespective of whether they are mixtures, polymers or single substances.

2.4 Classification of use categories

The use categories in the present study were developed and refined throughout the course of the project to have as few well-defined use categories as possible that were not too broad. Initially, the use categories as defined by Kissa (2001)[3] were employed, but they are very specific and thus broader categories were needed to cover the identified uses. Examples of use categories from Kissa (2001) which were assigned to broader categories are "moulding and mould release" (in the present study a subcategory under "production of plastic and rubber"), "oil wells" (in the present study a subcategory with a slightly different name under "oil & gas"), and "cement additives" (in the present study a subcategory under "building and construction"). In the course of the project, more use categories were defined as additional uses were added. The use categories in the present study were finally divided into "industrial branches" and "other use categories" to make a distinction between use categories that define broad industrial branches such as the "semiconductor industry" or the "energy sector", and use categories that are more specific such as "personal care products" or "sealants and adhesives". Note that some of the "other use categories" may be applied to several of the "industry branches". For example, "wire and cable insulations" may be applied in "aerospace", "biotechnology", "building and construction", "chemical industry" and others. A detailed overview of the use categories and their subcategories is provided in the Appendix (Table 4) of this paper.

Overall, the use categories defined in the present study are very similar to the categories of the SPIN database, although some categories of the SPIN database are more specific (and correspond to subcategories in the present study). Some of the categories in the SPIN database could not be assigned to any of the use categories in the present study because they were too general. Examples are "impregnation", "surface treatment", "anti-corrosion materials" or "manufacture of other transport equipment". Although the substances from these categories are not included in the present study, their quantities appear in Fig. 3 under "various".

2.5 What kind of information can be found where in this article?

The present study comes with an Appendix (Table 4) that lists the functions of the PFAS in the use categories and subcategories that we identified. In addition, we indicate which properties of the PFAS are important for the identified function. The Appendix thus contains the main results of the present study in a condensed form and is therefore part of the main paper and not part of the ESI.†

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

The ESI† of the present study is divided into three parts. ESI-1† is a comprehensive document with over 250 pages. It is available as a pdf, but can also be provided upon request as an MS Word document. ESI-1† is intended to be used as a reference document and contains a detailed description of all uses that were collected here as well as the PFAS employed in these categories with names, structural formulas and CAS numbers. Before reading sections of the ESI-1,† it is recommended to study the first two pages of the ESI-1,† where some of the specific features of the document are explained.

In addition, there is an MS Excel workbook (ESI-2†) that contains all PFAS that appear in ESI-1.† This workbook has a worksheet for each of the most common PFAS groups such as perfluoroalkyl acids (PFAA), perfluoroalkane sulfonyl fluoride (PASF)-based substances, or fluorotelomer-based substances and, thus, offers a good overview of the described PFAS. A list of what is included in the different worksheets is provided in the first worksheet. ESI-2† is primarily intended as a reference for readers who do not have access to SciFinder^n or other chemical databases or who just want to look up the name or structural formula for a specific CAS number. In addition to name, CAS number, and structural formula, ESI-2† also contains the identified uses of each PFAS. In contrast to ESI-1, ESI-2† assigns the uses to the PFAS (and not the PFAS to the uses).

The third part of the ESI-3† is also an Excel workbook that provides a separate worksheet for each use category. These worksheets list the PFAS from the ESI-1† with the names, CAS numbers, elemental compositions, and exact monoisotopic masses of the substances. Our intention is that the lists can be added to accurate mass spectrometry libraries and thus help to identify unknown PFAS more easily in the future. For this purpose, it would be helpful to connect the CAS numbers in the ESI-3† with *e.g.* the Norman SusDat ID of the NORMAN Substance Database[79] and perhaps to commercial mass spectrometry libraries in the future.

Table 1 Industry branches and other use categories where PFAS were or are employed. The numbers in parentheses indicate the number of subcategories. No parentheses indicate no subcategories

Industry branches	
Aerospace (7)	Mining (3)
Biotechnology (2)	Nuclear industry
Building and construction (5)	Oil & gas industry (7)
Chemical industry (8)	Pharmaceutical industry
Electroless plating	Photographic industry (2)
Electroplating (2)	Production of plastic and rubber (7)
Electronic industry (5)	Semiconductor industry (12)
Energy sector (10)	Textile production (2)
Food production industry	Watchmaking industry
Machinery and equipment	Wood industry (3)
Manufacture of metal products (6)	
Other use categories	
Aerosol propellants	Metallic and ceramic surfaces
Air conditioning	Music instruments (3)
Antifoaming agent	Optical devices (3)
Ammunition	Paper and packaging (2)
Apparel	Particle physics
Automotive (12)	Personal care products
Cleaning compositions (6)	Pesticides (2)
Coatings, paints and varnishes (3)	Pharmaceuticals (2)
Conservation of books and manuscripts	Pipes, pumps, fittings and liners
Cook- and bakingware	Plastic, rubber and resins (4)
Dispersions	Printing (4)

Fingerprint development	Sealants and adhesives (2)
Fire-fighting foam (5)	Soldering (2)
Flame retardants	Soil remediation
Floor covering including carpets and floor polish (4)	Sport article (7)
Glass (3)	Stone, concrete and tile
Household applications	Textile and upholstery (2)
Laboratory supplies, equipment and instrumentation (4)	Tracing and tagging (5)
Leather (4)	Water and effluent treatment
Lubricants and greases (2)	Wire and cable insulation, gaskets and hoses
Medical utensils (14)	

3 Results

In the present study, more than 200 uses in 64 use categories were identified for more than 1400 individual PFAS. This means that the present study encompasses five times as many uses (counted as use categories plus subcategories) than included in Kissa (2001).[3] This shows that our present study goes much further than simply updating this previous work. The following subsections describe the identified use categories and substances, and show and discuss the most important use categories in terms of quantities used, based on the data of the SPIN database and the Chemical Data Reporting database under the TSCA.

3.1 In which use categories have PFAS been employed and for which function?

The Appendix to the present study sets forth the use categories identified and answers the question of why PFAS were employed for a specific use. The use categories identified in this study are divided into "industry branches" and "other use categories", as listed in Table 1. In total, 87 uses within the 21 industry branches and 123 uses within the 43 other use categories were identified. Among the use categories, medical utensils, the semiconductor industry, and the automotive industries have the largest numbers of subcategories. About 15% of the subcategories were identified by patents, and 5% by studies that measured PFAS in products (see ESI-3†). The remaining categories have been mentioned previously in other publications.

The identified uses include many uses not previously described in the scientific literature on PFAS. Some examples of those uses are PFAS in ammunition (ESI-1 Section 2.4†),

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

climbing ropes (ESI-1 Section 2.38†), guitar strings (ESI-1 Section 2.24†), artificial turf (ESI-1 Section 1.17†), and soil remediation (ESI-1 Section 2.37†). Also, additional subcategories of PFAS in already described use categories such as in the semiconductor industry were identified. For example, in addition to the subcategories etching agents, anti-reflective coatings, or photoresists, PFAS may also be employed for wafer thinning (patent US20130201635 from 2013)[45] and as bonding ply in multilayer printed circuit boards (patent WO2003026371 from 2003) in the semiconductor industry.[45] In the energy sector, PFAS are known to be employed in solar collectors and photovoltaic cells, and in lithium-ion, vanadium redox, and zinc batteries. In addition, fluoropolymers are also used to coat the blades of windmills[13] and PFAS can be employed in the continuous separation of carbon dioxide in flue gases (patent CN106914122 from 2017)[45] and as heat transfer fluids in organic Rankine engines.[48] These examples all show that the uses of PFAS are much more extensive than so far reported in the scientific literature.

Altogether, we were able to identify almost 300 functions of PFAS (listed in the Appendix). Examples of those functions are foaming of drilling fluids, heat transfer in refrigerants, and film forming in AFFFs. The properties that led to the use of the PFAS are also identified. These include among others: ability to lower the aqueous surface tension, high hydrophobicity, high oleophobicity, non-flammability, high capacity to dissolve gases, high stability, extremely low reactivity, high dielectric breakdown strength, good heat conductivity, low refractive index, low dielectric constant, ability to generate strong acids, operation at a wide temperature range, low volatility in vacuum, and impenetrability to radiation. In the Appendix (Table 4), these properties are assigned to the specific uses (and functions).

3.2 Which PFAS have been – and are still – used in a certain category?

The ESI-1† to the present study describes or lists those PFAS that have been or are currently employed (or have been patented) for each individual use. In total we have found uses for more than 1400 individual PFAS. About one third of these PFAS are also listed in the OECD list.[2] This shows that many of the PFAS listed in the present study are on the market, and that many more PFAS that are not on the OECD list may be used or are already being used.

Due to the great variety of uses and the large number of PFAS, it is difficult to make generic statements here. Overall, it was found that the number of different PFAS identified for a certain use mostly depends on the properties required for that use. Some properties, or combinations of properties, are only found in specific groups of PFAS. For example, perfluorocarbons seem to be particularly well suited as vehicles for respiratory gas transport due to the high solubility of oxygen therein. Similarly, anionic PFAS (largely those with a sulfonic acid group) are used as additives in brake and hydraulic fluids due to their ability to alter the electrical potential of the metal surface and thus, protect the metal surface from corrosion through electrochemical oxidation. In contrast, there are also properties that are shared by many different groups of PFAS. Many PFAS are very stable and many can reduce the surface tension of aqueous solutions considerably, improving wetting and rinse-off. Therefore, a typical use in which many different types of PFAS have been or are used is in cleaning compositions. The patented, analytically detected and employed PFAS for this use include PFAAs, PASF-based substances, and fluorotelomer-based substances (see ESI-1 Section 2.6.1†). A similar variety of PFAS (87 substances in total) were identified in patents for photographic materials to control surface tension, electrostatic charge, friction, adhesion, and dirt repellency.

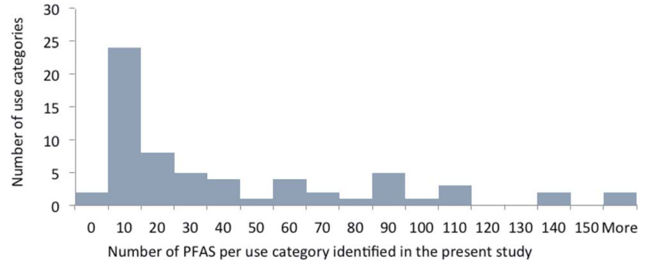

Fig. 1 Use categories grouped according to the number of PFAS identified. The use categories are those mentioned in Table 1 without distinction of subcategories. Identified PFAS included PFAS detected analytically in products, patented and employed PFAS. The data show *e.g.* that 26 use categories contain fewer than 20 PFAS and seven use categories contain more than 100 PFAS.

This array of different PFAS may be surprising, but it shows that some properties of PFAS are shared across many PFAS groups. The large number of patented PFAS for the same use raises the question of whether some of these substances offer better performance than others, or whether it does not really matter which PFAS are employed. The latter would indicate that manufacturers can invent new PFAS quite easily to avoid license fees for patents of other manufacturers.

For the majority of uses, however, far fewer PFAS were identified. Fig. 1 highlights the use categories grouped according to the number of PFAS identified. It should be noted that the number of PFAS reflects the number that we have identified in the present study, and not the number of substances on the market or available for a certain use. For half of the use categories, we have identified more than 20 PFAS, and for seven use categories more than 100 PFAS. The use categories with more than 100 identified PFAS are "photographic industry", "semiconductor industry", "coatings, paints and varnishes", "fire-fighting foams", "medical utensils", "personal care products", and "printing". There are also two categories where no specific substances were identified. These are "ammunition" and "nuclear industry".

The most frequently identified PFAS in our literature search are non-polymeric fluorotelomer-based substances, followed by non-polymeric PASF-based substances and PFAAs. Other identified non-polymeric substances are perfluoroalkyl phosphinic acids (PFPIA)-based substances, perfluoroalkyl carbonyl fluoride (PACF)-based substances,

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM.
This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

cyclic PFAS, aromatic substances with fluorinated side-chains, per- and polyfluoroalkyl ethers, hydrofluoroethers, and other non-polymers. Polymeric substances include fluoropolymers, side-chain fluorinated polymers, and perfluoropolyethers (see also ESI-2†). There is also a variety of substances in the groups themselves, especially among the non-polymeric fluorotelomer-based and PASF-based substances. For many of the substances, only one use (or patent for a use) was identified. For example, one use (or patent) was assigned to 375 fluorotelomer-based substances, two uses (or patents) to 46 fluorotelomer-based substances and three or more uses to 36 fluorotelomer-based substances. The reason why so many PFAS have only one identified use may be that not all the uses were identified for all PFAS. But it also seems that many patents contain "new" PFAS because they work just as well as the established ones.

In contrast to the many PFAS with only one assigned use, some PFAS have many uses. ESI-2† illustrates this point: of the 2400 links between individual PFAS and assigned uses, 16 PFAS have been assigned to 10 or more uses (see Table 2 and Fig. 2). The exact use counts are not important *per se*, because there may be more uses for these PFAS that have not been included in the present study, but they demonstrate that some PFAS are employed more frequently than others. It has to be noted that the three fluoropolymers in Table 2 are quite different from the other PFAS on the list, as they represent possibly dozens or hundreds of technical products with different grades and molecular sizes.

Of the 2400 links between individual PFAS and assigned uses, around 40% were obtained from patents, 26% from studies that detected PFAS in products, and 34% of the links were obtained from publications that reported actual uses.

3.3 What is the extent of the uses in certain areas of the world?

To prioritize PFAS uses in the search for alternatives, it is key to know for which uses PFAS were employed the most. Wang *et al.*[15,17,80] and Boucher *et al.* 2019 (ref. 14) published global emission inventories for C_4–C_{14} PFCAs and C_6–C_{10} PFSAs. For PFSAs and their precursors, the highest amounts were identified for the use in "apparel/carpet/textile", followed by "paper and packaging", "performance" and "after-market/consumers". There is also information on the quantities of individual fluoropolymers used.[40,81] However, a coherent data set with data covering a wide range of uses and at the same time a wide range of PFAS has not been available so far. The following two subsections will show the magnitude of the uses in the Nordic countries and the US based on the data from the SPIN database and the Chemical Data Reporting database under the TSCA, respectively. Data from REACH that would have covered more countries than the data from the SPIN database are not shown, because the tonnage bands in REACH refer to the substances and not to use categories. Accordingly, only in those cases where a substance has only one use would it have been possible to obtain useful information for this study, which would have created a lot of uncertainty in the data.

3.3.1 Data from the SPIN database. Fig. 3 highlights the total, non-confidential amounts of PFAS employed in the different use categories in Sweden, Finland, Norway and Denmark between 2000 and 2017.[44] It should be noted that the data from these Nordic countries may not be representative of other parts of the world. Reasons are that only non-confidential data are included, that substances in foodstuffs, medicinal products, and cosmetics do not have to be declared (see Section 2.2.2) and that there is no fluoropolymer or PFAS production in these

Table 2 PFAS with more than 10 assigned uses. Numbers based on counts of uses and patents, not on detections in products. The structures of these substances are shown in Fig. 2

Substance	CAS number	Assigned uses
Ammonium perfluorooctanoate	3825-26-1	14

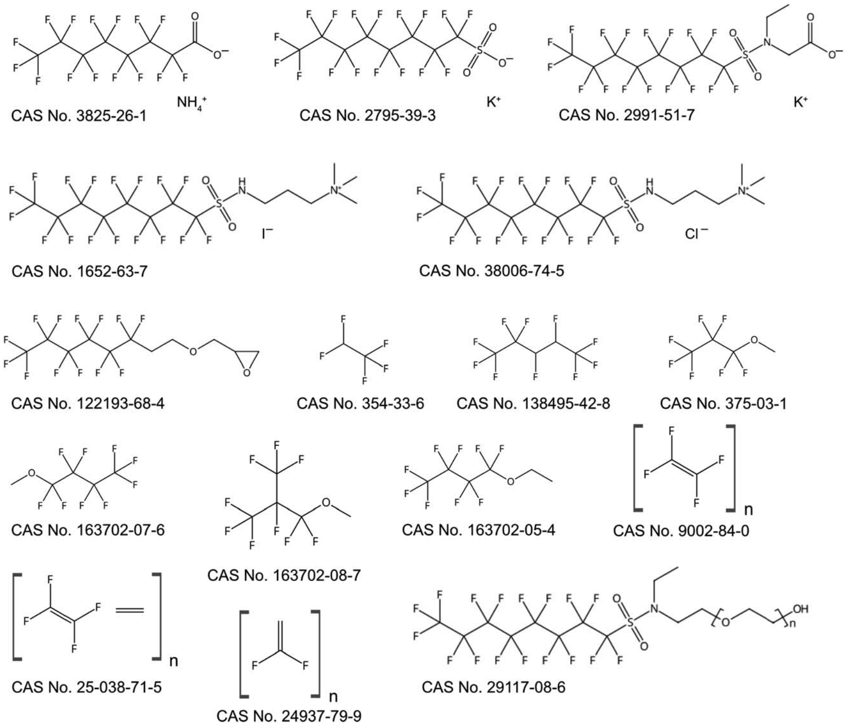

Fig. 2 Structures and CAS numbers of the PFAS with more than 10 assigned uses.

countries. Nevertheless, the data from the SPIN database provide a first indication of which uses of PFAS have been important in the last 20 years in this region.

The data illustrate that a large amount of PFAS was used in the production of plastic and rubber, the electronics industry, and coatings and paints (Fig. 3). The production of plastic and rubber does not include the production of fluoropolymers. Between 2000 and 2017, more than 3000 t of PFAS were used in the three categories previously mentioned. Around 1500 t of PFAS were used in building and construction and in lubricants and greases and around 1200 t of PFAS in the chemical industry, respectively. All other uses were below 1000 t.

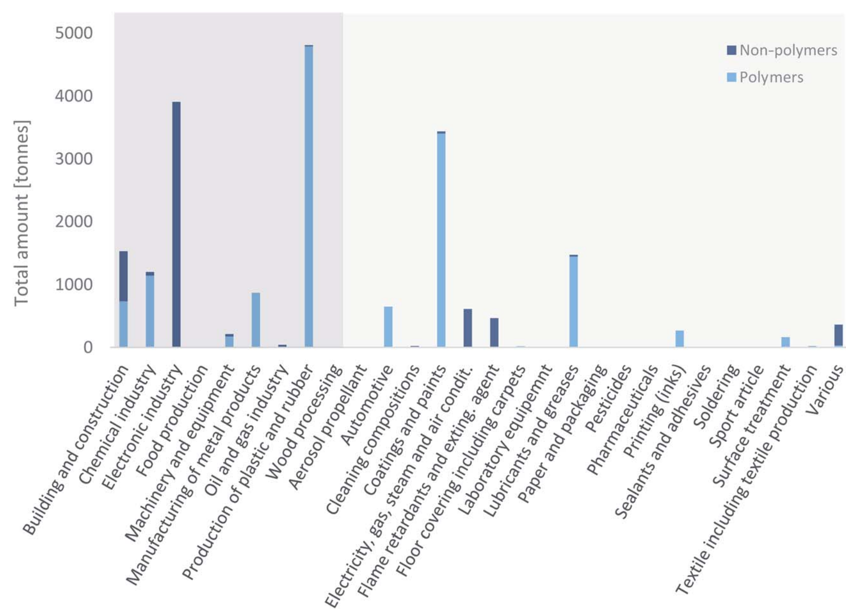

Fig. 3 Amount of PFAS employed in the different use categories in Sweden, Finland, Norway and Denmark from 2000 to 2017, as reported in the SPIN database.[44] Polymers include fluoropolymers and perfluoropolyethers. Side-chain fluorinated polymers have not been used above 0.2 t in any of the uses. Use categories with dark background are industrial branches, use categories with light grey background are other use categories.

Non-polymers were mainly used in the electronic industry, in buildings and construction, electricity, gas, steam and air conditioning supply, and flame retardants and extinguishing agents. Of the 6300 t of non-polymers used in the Nordic countries between 2000 and 2017, 5650 t (90%) were the hydrofluorocarbon (and greenhouse gas) 1*H*-pentafluoroethane (CAS no. 354-33-6). More than 70% (470 t) of the remaining non-polymeric PFAS were used in flame retardants and extinguishing agents. The SPIN database has a combined category for these two use categories, so it was not possible to distinguish them.

Polymers were mostly used in the production of plastic and rubber, coatings and paints, lubricants and greases, and in the chemical industry. At least 13 700 t of polymers were used in the Nordic countries between 2000 and 2017, and 10 000 t (73%) of this was PTFE. This percentage is a bit higher than the numbers published recently by AGC, which stated that 53% of the 320 000 t of fluoroplastics consumed worldwide in 2018 was PTFE.[81]

3.3.2 Data from the Chemical Data Reporting under the TSCA. Under the TSCA, the Chemical Data Reporting lists under "volume" the amount of a substance in a certain sector and function category or product category. However, more than 80% of the volume entries in the Chemical Data Reporting database are CBI. The certainty of the available information is therefore low, but a general statement is still possible. Table 3 highlights the non-confidential data on used and exported amounts of PFAS for the different uses based on the data reported in 2016.

The amount of used and exported PFAS was largest for functional fluids in "electrical equipment, appliance, and component manufacturing" and functional fluids in "machinery manufacturing". The exact same amounts in the two use categories are no coincidence but come from the declaration that 50% of the total amount was used for "electrical equipment, appliance, and component manufacturing" and 50% for "machinery manufacturing". 1*H*-Pentafluoroethane (CAS no. 354-33-6) accounted for 100% of the total amount in both cases. The high amounts of 1*H*-pentafluoroethane employed as functional fluids in "electrical equipment, appliance, and component manufacturing" confirm the data from the SPIN database indicating that the electronic industry is an important purchaser of this hydrofluorocarbon. The high amounts of "functional fluids" in "machinery manufacturing" could be related to refrigerants, air conditioners or other uses, but due to the broadness of the use category, nothing definite can be concluded. Also, as it was found for Europe, no data were available for amounts of non-polymeric PFAS used as processing aids under fluoropolymer production in the US, which may be expected to be a considerable contributor. The same amounts of "finishing agent" in "paint and coating manufacturing" and "paper manufacturing" are again from the declaration of 50% and 50%.

4 Discussion

4.1 Scope of the present study and uncertainties

4.1.1 Scope and uncertainties related to use categories. The present study covers many past and current uses of PFAS. The inventory is not exhaustive and it also contains uncertainties. One area of uncertainty comes from harmonizing entries to one use category that come from different sources. This is especially relevant for the comparison of amounts used, because the reported amounts from the different databases are related to more or less specific use categories that may be defined differently in different databases. Although not quite as critical, this was also a relevant point for the ESI-1.† Here, information on specific uses of PFAS was assigned to subcategories and information on broader uses to the main use

Table 3 Amounts (used + exported) that were not labelled as CBI for the different uses of PFAS from the Chemical Data Reporting under the TSCA from 2016. The rows with bold text are the uses with high amounts indicated by non-confidential data

Sector and function	Amount [t]
Paint and coating manufacturing – adhesive and sealant chemicals	0.001
Industrial gas manufacturing – air conditioners/refrigerations	138
Computer and electronic product manufacturing – solvents for cleaning and degreasing	1.03
Electrical equipment, appliance, and component manufacturing – functional fluids	**2180**
Fabricated metal product manufacturing – solvents for cleaning and degreasing	0.11
All other chemical product and preparation manufacturing – fire-fighting foam agents	190
Machinery manufacturing – functional fluids	**2180**
Miscellaneous manufacturing – solvents for cleaning and degreasing	0.10
Oil and gas drilling – surface active agents	0.022
Paint and coating manufacturing – adhesives and sealant chemicals	0.31
Paint and coating manufacturing – finishing agents	0.005
Paper manufacturing – finishing agents	0.005
Pesticide, fertilizer, and other agricultural chemical manufacturing – surface active agents	0.07
Miscellaneous manufacturing – plating agents and surface treating chemicals	1.96
Printing ink manufacturing – processing aids, not otherwise listed	0.001
All other basic inorganic chemical manufacturing – refrigerants (heat transfer fluids)	450
Rubber product manufacturing – rubber compounding	0.13
Soap, cleaning compound, and toilet preparation manufacturing – surface active agents	0.12
Textile, apparel and leather manufacturing – finishing agents	0.16

categories. Still, there were some use categories (especially from the Chemical Data Reporting database under the TSCA) that were so broad that we were not able to assign them to any category in our list. Examples are "surface active agents in all other basic inorganic chemical manufacturing", or "functional fluids in wholesale and retail trade". The PFAS listed under such categories and their quantities were not, therefore, considered in the present study.

Another area of uncertainty originates from unidentified uses. We found, for example, that PFAS are used in climbing ropes.[82] It therefore cannot be excluded that PFAS are also used in climbing harnesses, but no information was found on this. We did not have the capacity to conduct interviews with industry representatives who might have revealed additional information. We were similarly limited when it came to evaluating the copious amount of information about PFAS uses, for example in reports, scientific papers and patents. Therefore, not all PFAS uses might have been identified in the present study.

In the case of patents in particular, a great amount of information is available, but it should be noted that only some of the PFAS included in patents currently are likely to be used on the market. In addition to these uncertainties, some of the use category-specific information in the SPIN database is CBI, meaning that we may have not seen all categories. It would be desirable if such information was no longer confidential in the future, in order to inform consumers, users, and regulators.

Nevertheless, the SPIN database is a very valuable source of information and it would be much easier to compile such inventories of uses if other countries had product registries like the Nordic countries. Without such product registries, the compilation of uses and the substances used remains difficult and lengthy. It would also be advantageous if the uses under REACH were more precisely named. Current categories like "processing aids at industrial sites" or "manufacture of chemicals" are very broad and thus difficult to include.

An important question is whether the majority of the use categories is covered in the present study or whether important use categories are still missing. It is difficult to answer such a question quantitatively, but a qualitative indication is possible when the use categories of the SPIN database are compared to the categories that were identified independently of the SPIN database. Both categories match very well; only three categories had to be added to accommodate data from the SPIN database in the ESI-1† appropriately. These three categories were "machinery and equipment", "manufacture of basic metals" and "manufacture of fabricated metal products". However, with the exception of these three categories, all specific information from the SPIN database could be classified very well into the existing categories of the present study. Overall, we assume that there are no major gaps in the general use categories. However, it is quite possible that subcategories are missing. Among the uses of which we are aware, there may also be some uses where PFAS are no longer employed.

To improve the list of uses in the future, there are several possibilities. Firstly, one could try to get access to product registries of as many countries as possible. Unfortunately, not all product registries are as easily accessible as those of the Nordic countries and many developing countries do not have such a registry. The list could also be extended with information from REACH registration dossiers. These dossiers include information of uses and tonnage bands expected to be used at the time of registration. Interviews with manufacturers of products could also generate more information. However, we know from experiences with past projects that manufacturers often want the interviewers to sign a non-disclosure agreement before the interview, which prevents using the information obtained in publications. The information from such interviews could still provide some indication as to what kind of information to look for in the public domain. The same is true for market reports. They can only provide a clue of what to look for in the public domain (given that they often contain no references). A discouraging factor for researchers who may want to use market reports as data sources is that the companies who generate them often sell them for extortionate sums (*i.e.* several thousand US dollars) and that most of them are not based on thorough research.[83] Another approach could be to use artificial intelligence to systematically search product sales/industry magazines for words or phrases, such as 'fluor'.

4.1.2 Uncertainties related to substances. Uncertainties also exist regarding the substances identified for a particular use. Some of these uncertainties are already discussed in the Methods section: not all registered patents are used on the market, not all substances included in a patent are used in practice, and substances that have been detected analytically in products might be impurities in or degradation products of the actual substances. In addition, we only looked for examples of certain types of PFAS and the lists are by no means complete. Also, the substances included in the present study from the SPIN database are not substances in articles, but substances in preparations. The substances listed in the ESI-1† under U or U* are also those that were intentionally used in the products. However, impurities, reaction products upon mixing the ingredients, and degradation products of the intentionally added PFAS might also be present in products. Industrial blends are rarely pure, but can be only 80% of the registered substance, so 20% can be impurities, reaction by-products, degradation products *etc.*

In addition, industry tends to evolve around consumer needs, cost savings, and external factors such as regulatory oversight, and substances used today may no longer be relevant tomorrow. A better overview of the substances being used could be obtained if manufacturers had to list which substances are contained in a product in the safety data sheets. However, except for a few instances (*e.g.* when uses are authorized for food contact materials in Germany), this is not the case and patents are therefore often the only way to find out what products (might) contain. A better overview of the substances used would also be possible, at least for the US, if substances with tonnages below the reporting threshold of 11.34 t per year were also included in the TSCA Chemical Data Reporting database. In the EU, it would be helpful if the registration dossiers under REACH as well as other legislations were updated regularly with a more detailed breakdown of which-quantities of the substances are used in which applications.

4.1.3 Uncertainties related to quantities. The third part of the present study – identifying the key use categories in terms of

 This journal is © The Royal Society of Chemistry 2020

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

quantities – also contains various uncertainties. The data from the SPIN database only represent the Nordic countries, and many industry branches have a greater presence in other countries or regions of the world than in the Nordic countries. Additionally, many of the volumes in the SPIN database are CBI. Furthermore, the SPIN database does not include all uses. An example is that foodstuff, and hence food packaging, is not reported to the SPIN database, which possibly could explain why 'packaging', which was significant in the OECD study, did not stand out in the SPIN survey. Similarly, non-polymeric PFAS such as ADONA and the GenX chemicals are used as processing aids during fluoropolymer production. The quantities of these processing aids are not captured in the statistics of the SPIN database since this activity is not ongoing in Scandinavia. However, the significant amounts of fluoropolymers produced in Europe in 2018 of about 51 000 t per year,[81] and globally of about 320 000 t per year suggest that a considerable amount of PFAS is used as processing aids in this use category in addition to what is shown in Fig. 3 under "Chemical industry".

The data from the US are only partly helpful, because a large part of the reported amounts has been claimed as CBI and only substances manufactured or imported at above 11.34 t per year at a single site have been reported. Although in some use categories large quantities of PFAS are employed, it is difficult to compare the amounts, because the unreported amounts due to CBI could be much larger than the non-confidential reported amounts. The extent of the uncertainties in the SPIN database due to the CBI cannot be estimated with the available data, but could be large. It would be helpful if regulatory agencies, such as the US EPA or the national authorities in the Nordic countries, could create a ranking of the PFAS uses (without stating any numbers) based on the entire datasets they have collected.

4.2 Findings of the present study with regard to uses

The present study is a renewed and expanded effort to systematically compile a wide range of known as well as many overlooked uses of PFAS. Besides describing the uses of PFAS, we also endeavoured to explain which functions the PFAS fulfil in these uses (see Table 4 in the Appendix). The descriptions of the functions and properties of the PFAS employed are especially important for determining "non-essential" use categories and identifying alternatives for those uses currently considered "essential".

However, as can be seen from the question marks in the Appendix it was not always possible to determine why PFAS were used or needed in a particular case. In 4% of the cases we could not clarify which function the PFAS fulfil in the use category or subcategory, and in 21% of the cases we could not clarify which property is needed to fulfil the mentioned function. For example, we do not know exactly why PFAS are employed in the ventilation of respiratory airways, in brake-pad additives, and in resilient linoleum. It would be important to engage with product manufacturers to understand what function the PFAS actually have, in order to identify appropriate replacements. Some of the uses might also be judged as "non-essential" and thus could be eliminated or discontinued.

Our study also shows that in several areas where large quantities of PFAS are employed, discussions concerning alternatives are still not underway in the public domain. In general, in recent years the focus in the search for alternatives for PFAS has been on fire-fighting foams,[84,85] paper and packaging,[86,87] and textiles.[88–91] This focus was certainly appropriate, because these are uses where PFAS are in direct contact with the environment (fire-fighting foam) or with humans (food packaging, textiles). However, our results show that PFAS are also used widely in the production of electronics and in machinery manufacturing, and at least in the Nordic countries in the production of plastic and rubber and in paints and coatings. Measuring and/or reporting emissions along the life cycles of these uses, and the search for alternatives in these use categories should therefore also be prioritized. These uses could for instance be included in the activities for which data have to be reported under the European Pollutant Release and Transfer Registry.

It would also be important to look for alternatives in industry branches that use smaller amounts of PFAS or that are not included in the SPIN database or Chemical Data Reporting database, but produce large amounts of wastewater, exhaust gases or solid waste containing PFAS. More information is needed to prioritize the various use categories, but potentially worrisome categories where environmental contamination has been documented are fluoropolymer production,[92–94] the semiconductor industry,[95,96] and metal plating.[97]

Beside the categories mentioned above, there are also uses where humans are in direct contact with PFAS and that have not yet gained much attention regarding alternatives. These include: personal care products and cosmetics (ESI-1 Section 2.28†), pesticides (ESI-1 Section 2.29†), pharmaceuticals (including eye drops) (ESI-1 Section 2.30†), printing inks (ESI-1 Section 2.33†), and sealants and adhesives (ESI-1 Section 2.35†). A search for alternatives would also be important here.

4.3 Findings of the present study with regard to substances

We can ascertain from the SPIN database that two PFAS, 1*H*-pentafluoroethane and PTFE, account for 75% of the quantities used in the Nordic countries. One explanation is that PTFE and 1*H*-pentafluoroethane are not used as additives, but as the main products. For example, entire roof structures or coatings are made out of PTFE.[30] For 1*H*-pentafluoroethane (also known as HFC-125), one of the main uses is as a heat transfer fluid and cooling agent,[44,98] which could explain the large quantities of that substance used.

Other PFAS used as surfactants are utilized in much smaller quantities probably due to their high market price. They may therefore not appear (or at least not in high amounts) in databases such as the SPIN database or the Chemical Data Reporting database, which only report substances (or amounts) above a certain threshold. PFAS used in articles that are manufactured mainly in Asia or other countries outside the EU or the US may also not appear

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

in large amounts in the SPIN or Chemical Data Reporting database, simply because the databases do not contain information on PFAS in articles. The PFAS that we have listed as examples in the ESI-1† are mainly those used in Europe or North America. A recent publication[99] lists *e.g.* seventy PFAS from the Inventory of Existing Chemical Substances Produced or Imported in China (IECSC) that are not in the North American and European chemical inventories. These PFAS are also not in our inventory, because no information on their intended use was provided.

Concerning the currently used PFAS, it was thought – due to the voluntary phase out of all PFAS products derived from perfluorooctane sulfonyl fluoride by 3M[100] and the voluntary PFOA Stewardship Program in which eight companies agreed to phase out 95% of uses by 2015 (ref. 101) – that at least ammonium perfluorooctanoate and potassium perfluorooctane sulfonate are no longer in use in the US. However, other companies have not been prevented from taking over the market, and there has been very limited enforcement of the actual phase-out through regulation. A recent article revealed that PFAS that can break down into PFOA and PFOS are still in use in the US.[102] Those uses include coatings for medical devices, apparel, and other industries, and equipment in pharmaceutical companies. PFAS that can break down into PFOA and PFOS are also still used by semiconductor and electronics companies.[102]

4.4 Prioritisation of use categories

Based on the data from the SPIN database, the Chemical Data Reporting under the TSCA and information on the production of wastewater, exhaust gases and solid waste, we propose that the following use categories need to be prioritized for reducing/eliminating the use of PFAS. At the same time, it must be noted that fluoropolymers and hydrofluorocarbons are produced and used in much larger quantities than PFAAs and their precursors. However, PFAAs and their precursors are more critical from a toxicological point of view. Therefore, the proposal for prioritization is made for each of the three PFAS groups individually: PFAAs and precursors, hydrofluorocarbons, and fluoropolymers.

4.4.1 PFAAs and precursors

4.4.1.1 Fire-fighting foams. PFAS-containing fire-fighting foams are used for extinguishing liquid fires such as fires in oil, jet fuel, other non-water-soluble hydrocarbons, alcohols and acetone. Although relatively small quantities of PFAS are used in fire-fighting foams (class B for extinguishing flammable liquid fires), these foams are an important use category because the foams and the chemicals they contain are released directly into the environment. There are numerous reports about PFAS-contaminated sites where fire-fighting foams have been used (especially for training activities) or spilled.[61,63,103,104] Although PFAS-free class B fire-fighting foams have been developed in the meantime, PFAS-containing fire-fighting foams are still widely in use today.[65,105,106] For more information, see ESI-1 Section 2.14† and the Appendix.

4.4.1.2 Chemical industry with a special focus on processing aids in the polymerization of fluoropolymers. Important uses of PFAS in the chemical industry are their uses as processing aids in the polymerization of fluoropolymers, the production of chlorine and sodium hydroxide, and the production of other chemicals including solvents. PFAS that are used as processing aids in the polymerization of fluoropolymers are of special concern. This is because the surrounding environments at numerous sites have been heavily contaminated due to the release of the processing aids from the nearby manufacturing plants,[92–94] and considerable amounts of fluoropolymers are produced in Europe and worldwide. For more information, see ESI-1 Section 1.4.†

4.4.1.3 Surface protection of textile, apparel, leather, carpets, and paper. Considerable quantities of PFAS, especially of side-chain fluorinated polymers, have been used as surface protectors in textile, apparel, leather, carpets, and paper. These are open and dispersive uses where many consumers come into contact with the PFAS-containing products. It has also been reported that there are high emissions to air, dust, and wastewater from a textile manufacturing plant in China.[107] The side-chain fluorinated polymers contain PFAAs as impurities and they may act as important precursors to PFAAs.[108] For more information, see ESI-1 Sections 2.5, 2.16, 2.20, 2.26, and 2.40.†

4.4.2 Hydrofluorocarbons

4.4.2.1 Electronic industry. PFAS have been used in electronic devices themselves *e.g.* in flat panel displays or liquid crystal displays. However, they have also been used for the testing of electronic devices and equipment, as heat transfer fluids/cooling agents, in cleaning solutions, to deposit lubricants and to etch piezoelectric ceramic filters. Based on data from the SPIN database and the Chemical Data Reporting database under the TSCA, the most widely used substance in the electronic industry in the Nordic countries and the US is the hydrofluorocarbon 1*H*-pentafluoroethane. According to the SPIN database it is mainly used as a heat transferring agent and cooling agent. However, 1*H*-pentafluoroethane is not only of concern due to its high persistence but also because it has a global warming potential that is 3500 times that of carbon dioxide. Therefore, 1*H*-pentafluoroethane is one of the substances regulated by the Kigali Amendment of the Montreal Protocol and efforts are being undertaken to reduce the production and consumption of this substance. The search for PFAS-free alternatives is therefore even more important in this use category.

4.4.2.2 Machinery and equipment. The Chemical Data Reporting database under the TSCA lists also high amounts (more than 2000 t per year) of 1*H*-pentafluoroethane that is used as a “functional fluid” in “machinery manufacturing” in the US. This could be related to refrigerants, air conditioners or other uses, but due to the broadness of the use category, nothing specific can be concluded. Given the high amounts reported, there is an urgent need for more information on where and for which function hydrofluorocarbons, and PFAS in general, are

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

used in this category. For more information, see ESI-1 Section 1.10† and the Appendix.

4.4.3 Fluoropolymers

4.4.3.1 Production of plastic and rubber. The SPIN database reveals that large amounts of fluoropolymers (more than 4000 t between 2000 and 2017) have been used in the production of plastic and rubber in the Nordic countries between 2000 and 2017. PFAS have been used as mould release agents, foam blowing agents, foam regulators, polymer processing aids, in the etching of plastic, as anti-blocking agents for rubber, and as curatives in the production of plastic and rubber. As polymer processing aids, fluoropolymers can increase the processing efficiency and quality of plastic and rubber.[109] The use of PFAS in the production of plastic and rubber may explain why PFAS are found, for example, in artificial turf.[110] For more information, see ESI-1 Section 2.14† and the Appendix.

4.4.3.2 Coatings, paints and varnishes. The data from the SPIN database show that large amounts of fluoropolymers (more than 3000 t between 2000 and 2017) have been used in coatings and paints in the Nordic countries between 2000 and 2017. Fluoropolymers can be used to impart oil- and water-repellency to the paints or coatings, and fluoropolymers are also used as anti-stick and anticorrosive coatings. For more information, see ESI-1 Section 2.8† and the Appendix.

4.5 Use and implications of the present study

The large number of uses that exist for PFAS, together with the large number of individual substances, makes their regulation and eventual phase-out very challenging. The approach of allowing PFAS only in "essential uses", as suggested for example in the EU strategy paper "Elements for an EU-strategy for PFAS",[5] will not be easy to implement if regulators try to assess all uses individually. An alternative approach could be to deem all PFAS uses as "non-essential" unless producers or users make a convincing case for essentiality, and that authorities set a sunset clause on "essential uses".

The number of use categories for both non-essential and essential cases is critical to estimate the amount of work that would need to be done, for example, to prepare a restriction proposal under REACH (as planned by five European countries[31]). The descriptions in the present study of where and why PFAS are used can be used to provide an overview of the uses and may also facilitate an understanding of what alternatives need to be developed and with which priority.

The information in this study may also help regulators and scientists determine which PFAS to measure in contaminated areas, in humans, in surrounding communities, and in products. To facilitate the identification of PFAS in various matrices, we provide the ESI-3 file,† which contains for each use category the name, CAS number, and exact monoisotopic mass of the substance. The ESI-3 file† also includes information on whether PFAS were identified in a patent, detected analytically in products, or reported as employed substances. Laboratories could use modern analytical methods such as suspect-screening analysis utilising accurate mass spectrometry to identify novel and emerging PFAS listed in our ESI-3.†[60,111] Patented substances may be less likely to be on the market and could be excluded or given a lower priority or weighting in suspect screening workflows. Similar lists (such as the ESI-3†) are provided by the OECD/UNEP Global PFC Group,[2] Zhang *et al.* (2020),[99] the US EPA, the NORMAN Substance Database[79] and others. An overview is provided under https://comptox.epa.gov/dashboard/chemical_lists. However, only a few of these lists also contain information on uses.

The ESI-3† may also be valuable for identifying sources of PFAS in the environment. Some uses may impart characteristic PFAS "fingerprints" (*i.e.* PFAS contamination patterns) to environmental samples that could be used to identify a source, *e.g.* through statistical methods.[112] On the other hand, many environments will be impacted by multiple sources and such fingerprinting methods could be challenging in practice.

5 Conclusions

The present study is the first of its kind to systematically compile a wide range of known as well as poorly documented uses of PFAS. The compilation is not exhaustive, but it still demonstrates that PFAS are used in almost all industry branches and in many consumer products. Some consumer products even have multiple applications of PFAS within the same product. A cell phone for example may contain fluoropolymer-insulated wiring, PFAS in the circuit boards/semiconductors, and a screen coated with a fingerprint-resistant fluoropolymer. The search for alternatives is therefore a challenging and extensive task and is important in all use categories. However, it seems particularly critical to us to replace PFAAs and their precursors in fire-fighting foams, processing aids for the polymerization of fluoropolymers and in the surface protection of textiles, apparel, leather, carpets, and paper. Hydrofluorocarbons seem to be used most in the electronics industry and in machinery and equipment. Replacing them in these categories will therefore be an important but challenging task. A search for alternatives to fluoropolymers will be important in the production of plastic and rubber and in coatings, paints, and varnishes.

A matching database of viable alternatives to PFAS would be a logical progression of the present study. It would also be helpful if environmental protection agencies, for example the US EPA, could create a ranking of PFAS uses (without providing tonnages) based on the data they have collected. A ranking without exact figures would still be better than the current situation, in which very little is known about the quantitatively most important use categories due to CBI. The TSCA reform in the US was unfortunately unsuccessful in reducing industry's excessive use of CBI. On the one hand, CBI may protect a specific industry's business, but on the other hand it also results in less protection for consumers, users, and workers from the chemicals. Even regulators are left in the dark about volumes, use categories, and PFAS used, which limits their ability to assess and prevent harm to humans and the environment.

Conflicts of interest

Jamie DeWitt is serving as a plaintiff's expert witness in several cases related to PFAS.

Appendix

Table 4 Overview of the uses of PFAS, the function of the PFAS in the uses and the properties of the employed PFAS that make them valuable for this application

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
Industry branch		
Aerospace		
- Phosphate ester-based brake and hydraulic fluids	Corrosion protection	Altering the electrical potential at the metal surface
- Gyroscopes	Flotation fluids in gyroscopes	?
- Wire and cable	High-temperature endurance, fire resistance, and high-stress crack resistance	Non-flammable polymers, stable
- Turbine-engine	Use as lubricant	Corrosion resistant, stable, non-reactive, operate at a wide temperature range
- Turbine-engine	Use as elastomeric seals	Operate at a wide temperature range
- Thermal control and radiator surfaces	Reject waste heat	Survival over a wide operating temperature range, low solar absorbance, high thermal emittance, and freedom from contamination by outgassing
- Coating	Protect underlying polymers from atomic oxygen attack	Non-reactive, very stable
- Propellant system	Elastomers compatible to aggressive fuels and oxidizers	Non-reactive, very stable
- Jet engine/satellite instrumentation	Use as lubricant	Long-term retention of viscosity, low volatility in vacuum and their fluidity at extremely low temperatures
Biotechnology		
- Cell cultivation	Supply of oxygen and other gases to microbial cells	Great capacity to dissolve gases
- Ultrafiltration and microporous membranes	Prevent bacterial growth	?
Building and construction		
- Architectural membranes *e.g.* in roofs	Resistance to weathering, dirt repellent, light	Oleophobic and hydrophobic, low surface tension, beneficial weight-to-surface ratio
- Greenhouse	Transparent to both UV and visible light, resistant to weathering, dirt repellent	Oleophobic and hydrophobic, low surface tension
- Cement additive	Reduce the shrinkage of cement	?
- Cable and wire insulation, gaskets & hoses	High-temperature endurance, fire resistance, and high-stress crack resistance	Non-flammable polymers, stable
Chemical industry		
- Fluoropolymer processing aid	Emulsify the monomers, increase the rate of polymerization, stabilize fluoropolymers	Fluorinated part is able to dissolve monomers, non-fluorinated part is able to dissolve in water
- Production of chlorine and caustic soda (with asbestos diaphragms cells)	Binder for the asbestos-fibre-based diaphragms	?
- Production of chlorine and caustic soda (with fluorinated membranes)	Stable membrane in strong oxidizing conditions and at high temperatures	Stable, non-reactive
- Processing aids in the extrusion of high- and liner low-density polyethylene film	Eliminate melt fracture and other flow-induced imperfections	Low surface tension
- Tantalum, molybdenum, and niobium processing	Cutting or drawing oil	Non-reactive, stable
- Chemical reactions	Inert reaction media (especially for gaseous reactants)	Non-reactive, stable

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
- Polymer curing	Medium for crosslinking of resins, elastomers and adhesives	?
- Ionic liquids	Raw materials for ionic liquids	?
- Solvents	Dissolve other substances	Bipolar character of some of the PFAS
Electroless plating	Disperses the pitch fluoride in the plating solution	Low surface tension
Electroplating (metal plating)		
- Chrome plating	Prevent the evaporation of chromium(VI) vapour	Lower the surface tension of the electrolyte solution, very stable in strongly acidic and oxidizing conditions
- Nickel plating	Non-foaming surfactant	Low surface tension
- Nickel plating	Increase the strength of the nickel electroplate by eliminating pinholes, cracks, and peeling	Low surface tension
- Copper plating	Prevent haze by regulating foam and improving stability	Low surface tension
- Tin plating	Help to produce a plate of uniform thickness	Low surface tension
- Alkaline zinc and zinc alloy plating		
- Deposition of fluoropolymer particles onto steel	Supported by fluorinated surfactants	Cationic and amphoteric fluorinated surfactants impart a positive charge to fluoropolymer particles which facilitates the electroplating of the fluoropolymer
Electronic industry		
- Testing of electronic devices and equipment	Inert fluids for electronics testing	Non-reactive
- Heat transfer fluids	Cooling of electrical equipment	Good heat conductivity
- Solvent systems and cleaning	Form the basis of cleaning solutions	Non-flammable, low surface tension
- Carrier fluid/lubricant deposition	Dissolve and deposit lubricants on a range of substrates during the manufacturing of hard disk drives	?
- Etching of piezoelectric ceramic filters	Etching solution	Acidic
Energy sector		
- Solar collectors and photovoltaic cells	High vapour barrier, high transparency, great weatherability and dirt repellency	Oleophobic and hydrophobic, low surface tension
- Photovoltaic cells	Adhesives with PFAS hold mesh cathode in place	Lower the surface tension of the adhesive
- Wind mill blades	Coating	High weatherability
- Coal-based power plants	Polymeric PFAS filter remove fly ash from the hot smoky discharge	Stable, non-reactive
- Coal-based power plants	Separation of carbon dioxide in flue gases	Lower the surface tension of the aqueous solution
- Lithium batteries	Binder for electrodes	Almost no reactivity with the electrodes and electrolyte
- Lithium batteries	Prevent thermal runaway reaction	Good heat absorption of first layer and good heat conductivity of second layer
- Lithium batteries	Improve the oxygen transport of lithium–air batteries	Great capacity to dissolve gases
- Lithium batteries	Electrolyte solvents for lithium–sulfur batteries	Bipolar character of some of the PFAS
- Ion exchange membrane in vanadium redox batteries	Polymeric PFAS are used as membranes	Resistance to acidic environments and highly oxidizing species
- Zinc batteries	Prevent formation of dendrites, hydrogen evolution and electrode corrosion due to adsorption onto the electrode surface	Low surface tension, non-reactive

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
- Alkaline manganese batteries	MnO_2 cathodes containing carbon black are treated with a fluorinated surfactant	?
- Polymer electrolyte fuel cells	Polymeric PFAS are used as membranes	Ion conductance
- Power transformers	Cooling liquid	Good heat conductivity
- Conversion of heat to mechanical energy	Heat transfer fluids	Good heat conductivity
Food production		
- Wineries and dairies	Final filtration before bottling with polymeric PFAS	Resist degradation
Machinery and equipment	?	?
Manufacture of metal products		
- Manufacture of basic metals	Inhibit the formation of acid mist during the electrowinning of copper	Lower the surface tension of the aqueous solution
- Manufacture of fabricated metal products	?	?
- Pickling of steel wires	Acid-pickling promoter	?
- Treatment of coating of metal surfaces	Promote the flow of metal coatings, prevent cracks in the coating during drying	Lower the surface tension of the coating
- Treatment of coating of metal surfaces	Corrosion inhibitor on steel	Non-reactive
- Etching of aluminium in alkali baths	Improving the efficient life of the alkali baths	?
- Phosphating process for aluminium	Fluoride-containing phosphating solutions help to dissolve the oxide layer of the aluminium	?
- Cleaning of metal surfaces	Disperse scum, speed runoff of acid when metal is removed from the bath, increase the bath life	?
- Water removal from processed parts	Solvent displacement	Low surface tension
Mining		
- Ore leaching in copper and gold mines	Increase wetting of the sulfuric acid or cyanide that leaches the ore	Low surface tension
- Ore leaching in copper and gold mines	Acid mist suppressing agents	Low surface tension
- Ore floating	Create stable aqueous foams to separate the metal salts from soil	Low surface tension
- Separation of uranium contained in sodium carbonate and/or sodium bicarbonate solutions by nitrogen floatation	Improve the separation	?
- Concentration of vanadium compounds	Destruction of the mineral structure, increases the specific surface area and pore channel thus facilitating vanadium leaching	Acidity
Nuclear industry		
- Lubricants for valves and ultracentrifuge bearings in UF6 enrichment plants	PFAS are used as the lubricants	Stable to aggressive gases
Oil & gas industry		
- Drilling fluid	Foaming agent	Low surface tension
- Drilling – insulating material for cable and wire	Polymeric PFAS are used as insulating material	Withstand high temperatures
- Chemical driven oil production	Increase the effective permeability of the formation	Low surface tension
- Chemical driven oil production	Foaming agent for fracturing subterranean formations	Low surface tension
- Chemical driven oil production	Heavy crude oil well polymer blocking remover	?

 This journal is © The Royal Society of Chemistry 2020

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
- Chemical driven gas production	Change low-permeability sandstone gas reservoir from strong hydrophilic to weak hydrophilic	Hydrophobic and oleophobic properties
- Chemical driven gas production	Eliminate reservoir capillary forces, dissolve partial solid, dis-assemble clogging, increase efficiency of displacing water with gas	Lower surface tension of the material
- Oil and gas transport	Lining of the pipes is made out of polymeric PFAS	Non-reactive (corrosion resistant)
- Oil and gas transport	Reduce the viscosity of crude oil for pumping from the borehole through crude oil-in-water emulsions	Hydrophobic and oleophobic properties
- Oil and gas storage	Aqueous layer with PFAS prevents evaporation loss	Lower the surface tension of the aqueous solution
- Oil and gas storage	Floating layer of cereal treated with PFAs prevents evaporation loss	Low surface tension
- Oil containment (injection a chemical barrier into water)	Prevents spreading of oils or gasoline on water	?
- Oil and fuel filtration	Polymeric PFAS are used as membranes	Non-reactive (corrosion resistant)
Pharmaceutical industry		
- Reaction vessels, stirrers, and other components	Use of polymeric PFAS instead of stainless steel	?
- Ultrapure water systems	Polymeric PFAS are used as filter	Low surface tension
- Packaging	Polymeric PFAS form moisture barrier film	Hydrophobic
- Manufacture of "microporous" particles	Processing aid	?
Photographic industry		
- Processing solutions	Antifoaming agent	Lower the surface tension of the solution
- Processing solutions	Prevent formation of air bubbles in the solution	Lower the surface tension of the solution
- Photographic materials, such as films and papers	Wetting agents, emulsion additives, stabilizers and antistatic agent	Low surface tension, low dielectric constant
- Photographic materials, such as films and papers	Prevent spot formation and control edge uniformity in multilayer coatings	Low surface tension
- Paper and plates	Anti-reflective agents	Low refractive index
Production of plastic and rubber		
- Separation of mould and moulded material	Mould release agent	Hydrophobic and oleophobic properties
- Separation of mould and moulded material	Reduce imperfections in the moulded surface	Low surface tension
- Foam blowing	Foam blowing agent	Low surface tension
- Polyol foams	Foam regulator	10.5.3.1.1.1.1 lower the surface tension of the foam
- Polymer processing aid	Increase processing efficiency and quality of polymeric compounds	Lower the surface tension of the polymeric products
- Etching of plastic	Wetting agent	Low surface tension
- Production of rubber	Antiblocking agent	Low surface tension
- Fluoroelastomer formulation	Additive in curatives	?
Semiconductor industry		
- Photoresist (itself)	Photoresist matrix, changes solubility when exposed to light	?
- Photoresist (photosensitizer)	Increase the photosensitivity of the photoresist	?
- Photoresist (photo-acid generator)	Generate strong acids by light irradiation	Able to generate strong acids
- Photoresist (quencher)	Controlling the diffusion of the acid to unexposed region	?
- Antireflective coating	Provide low reflectivity	Low refractive index

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
- Developer	Facilitate the control of the development process	?
- Rinsing solution	Rinsing the photoresist to remove the developer	Low surface tension
- Etching	Wetting agent	Low surface tension
- Etching	Reduce the reflection of the etching solution	Low refractive index
- Etching	Etching agent in dry etching	Strong acids
- Cleaning of silicon wafers	Etch cleaning	Strong acids
- Cleaning of integrated circuit modules	Remove cured epoxy resins	?
- Cleaning vapour deposition chamber	Remove dielectric film build up	Generation of reactive oxygen species
- Wafer thinning	Non-stick coating composition on carrier wafer	Low surface tension
- Vacuum pumps	Working fluid	Stable, non-reactive
- Technical equipment in contact with process chemical or reactive plasma	Polymeric PFAS are used in inert moulds, pipes and elastomers	Stable, non-reactive
- Multilayer circuit board	Bonding ply composition	Low dielectric constant, low dissipation factor
Textile production		
- Dyeing and bleaching of textiles	Wetting agent	Low surface tension
- Dyeing process using sulphur dyes	Antifoaming agent	Low surface tension
- Dye transfer material	Release agent	Low surface tension
- Textile treatment baths	Antifoaming agent	Low surface tension
- Fibre finishes	Emulsifying agent	Hydrophobic and oleophobic properties
Watchmaking industry		
- Lubricants	Form an oil layer and reduced wear	Non-reactive (do not oxidize, resistant to corrosion)
- Drying as production step after aqueous cleaning	Solvents in solvent displacement drying	Low surface tension
Wood industry		
- Drum filtration during bleaching	The used coarse fabric is made out of polymeric PFAS	Stable
- Coating for wood substrate	Clear coating is made out of polymeric PFAS	Stable, non-reactive
- Wood particleboard	Part of adhesive resin	Low surface tension
Other use areas		
Aerosol propellant	Aerosol propellant	Non-flammable, stable, non-reactive
Air conditioning	Working fluid	Non-flammable, stable, non-reactive
Antifoaming agent	Prevent foaming	Low surface tension
Ammunition	Make the final product rubbery and reduce the likelihood of an unplanned explosion due to shock; enable long-term storage without degradation of the polymer	Long-term stability without degradation
Apparel		
- Breathable membranes	Polymeric PFAS are used as membranes	High permeability to water vapour, but resist passage of liquid water

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
- Long-lasting durable water repellent finish	Provide water and oil repellence, stain resistance and soil release	Lower surface tension of the fabric, hydrophobic and oleophobic properties
Automotive		
- Car body	Weather resistance paint, no-wax brilliant top coat	Low surface tension
- Automotive waxes	Aid spreading, improve the resistance of the polish to water and oil	Lower the surface tension of the wax, oleophobic
- Windshield wiper fluid	Prevent icing of the wind shield	?
- Car body	Light, stable	Beneficial weight-to-surface ratio, stable
- Engine and steering system	Polymeric PFAS are used as sealants and bearings	Operate at a wide temperature range, non-reactive
- Engine oil coolers	Heat transfer fluid	Good heat conductivity
- Cylinder head coatings and hoses	Increase the fuel efficiency	?
- Cylinder head coatings and hoses	Reduce the fugitive gasoline vapour emissions	Low surface tension
- Electronics	Cables and wires	High-temperature endurance, fire resistance
- Fuel lines, steel hydraulic brake tubes	Corrosion protection	Non-reactive, stable
- Interior	Dirt repellent in carpets and seats	Low surface tension, oleophobic
- Brake pad additives	?	?
Cleaning compositions		
- Cleaning compositions for hard surfaces	Enhance wettability	Lower the surface tension of the cleaning product
- Carpet and upholstery cleaners	Provide stain resistance and repel soil	Low surface tension, oleophobic
- Cleaning compositions for adhesives	?	?
- Dry cleaning fluids	Stabilizer, improve the removal of hydrophilic soil	Hydrophobic and oleophobic, low surface tension
- Cleaning of reverse osmosis membranes	Remove calcium sulphate	?
Coatings, paints and varnishes		
- Paints	Emulsifier for the binder, dispersant for the pigments, wetting agent	Hydrophobic and oleophobic, low surface tension
- Paints	Enhance the protective properties of anticorrosive paints	Non-reactive
- Paints	Antifouling on ships	?
- Paints and coatings	Anti-crater, improved surface appearance, better flow and levelling, reduced foaming, decreased block, open-time extension, oil- and water repellency, dirt pickup resistance	Low surface tension, oleophobic
- Paints and coatings	Form second coat on a first coat	Low surface tension
- Coatings	Antistick and anticorrosive coatings	Low surface tension, non-reactive
- Coatings	Highly durable and weatherable	Stable, non-reactive
Conservation of books and manuscripts	Preserve historical manuscripts	Permeability to water vapour, but resist passage of liquid water
Cook- and bakingware	Prevent food from sticking to the pan/baking ware	Low surface tension, non-reactive, stable at high temperatures
Dispersions	Disperse solutions	Low surface tension
Electronical devices		
- Printed circuit boards	Use fibre-reinforced fluoropolymer layer	Low dielectric constant
- Capacitors	Separation of high voltage components (dielectric fluid)	High dielectric breakdown strength, non-flammable

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM.

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
- Acoustical equipment	Provide an electrical signal in response to mechanical or thermal signals	Piezoelectric and pyroelectric properties
- Liquid crystal displays (LCDs)	Provide the liquid crystal with a dipole moment	Dipoles
- Liquid crystal displays (LCDs)	Polymeric PFAS provide moisture sensitive coating for displays	Hydrophobic
- Light management films in flat panel display	Reduced static electricity build-up and dust attraction during fabrication	Low dielectric constant
- Razors	Polymeric PFFAs is used on the razor	?
- Electroluminescent lamps	Polymeric PFAS is used as coating	?
Fingerprint development	Solvent	?
Fire-fighting foam		
- Fluoroprotein (FP) foams	Fuel repellents	Low surface tension
- Film-forming fluoroprotein (FFFP) foam	Film formers, foam stabilizers	Lower the surface tension of water
- Alcohol-resistant film forming fluoroprotein (AR-FFFP) foam	Film formers, foam stabilizers	Lower the surface tension of water
- Aqueous film-forming foams (AFFF)	Film formers	Lower the surface tension of water
- Alcohol-resistant aqueous film forming foam (AR-AFFF)	Foam stabilizers	Low surface tension
Flame retardants		
- Polycarbonate resin	Flame retardants	Non-flammable
- Other plastic	Flame retardants	Non-flammable
Floor covering including carpets and floor polish	Improve wetting and levelling	Low surface tension
- Soil-release finishes for carpets	Provide water and oil repellence, stain resistance and soil release	Low surface tension, hydrophobic and oleophobic
- Aftermarket carpet protection	Provide water and oil repellence, stain resistance and soil release	Low surface tension, hydrophobic and oleophobic
- Resilient linoleum	?	?
- Laminated floor covering	?	?
- Floor polish	Improve levelling and wetting	Low surface tension
Glass		
- Surface treatment	Make glass surfaces hydrophobic and oleophobic	Hydrophobic and oleophobic
- Surface treatment	Prevents misting of glass	Hydrophobic
- Surface treatment	Dirt-repellent	Low surface tension
- Surface treatment	Fire-or weather resistant	Non-flammable, stable
- Etching and polishing	Increase the speed of etching, improve wetting	Low surface tension
- Drying as production step in glass finishing	Solvents in solvent displacement drying	Low surface tension
Household applications		
- Threads and joints	Polymeric PFAS is used for sealing	?
Laboratory supplies, equipment and instrumentation		
- Consumable materials (vials, caps, tape)	Made out of polymeric PFAS	?
- Personal protective equipment (gloves)	?	?
- Particle filters	Minimize the sorption of compounds to the filter itself	Low surface tension
- Solvents	Dissolve other substances	Hydrophobic and oleophobic

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
- LC instruments	Polymeric PFAS are used in the solvent degasser	Non-reactive ?
- LC columns	Some columns are based on polymeric PFAS	?
- Reverse phase LC-solvents	can contain PFAS	?
- Seals and membranes in UPLCs, autoclaves and ovens	are made out of polymeric PFAS	Work over a wide temperature range
- Oils and greases in pumps	Form a thick oil layer and reduced wear	Non-reactive, non-flammable
- Sterilization of an insulated vessel	Sterilization medium	?
- Electro plotting	Protein-sequencing membranes are made out of polymeric PFAS	?
- Analysing the phosphoamino content in proteins	Protein-sequencing membranes are made out of polymeric PFAS	?
Leather		
- Manufacturing of genuine leather	Improve the efficiency of hydrating, pickling, degreasing and tanning	?
- Repellent treatment (genuine leather)	Provide water and oil repellence, stain resistance and soil release	Hydrophobic and oleophobic, low surface tension
- Manufacturing of synthetic leather	Polymer melt additives that impart oil and water repellency to the finished fibres	Hydrophobic and oleophobic
- Shoe brighteners	Improve the levelling of shoe brighteners	Low surface tension
- Impregnation spray	Provide water and oil repellence, stain resistance and soil release	Low surface tension
Lubricants and greases	Form a thick oil layer and reduced wear	Non-reactive, non-flammable, operate also at high temperatures, do not form sludge or varnish
Medical utensils		
- Electronic devices that rely on high frequency signals (defibrillators, pacemakers, cardiac resynchronization therapy (CRT), positron-emission tomography (PET) and magnetic resonance imaging (MRI) devices)	High dielectric insulators	High dielectric breakdown strength
- Video endoscope	Use in charge-coupled device colour filters	?
- Microbubble-based ultrasound contrast agents	Fluorinated gas inner core, which provides osmotic stabilization and contributes to interfacial tension reduction	Low solubility in aqueous media (dissolve more slowly)
- X-ray imaging	Contrast enhancement agents	Radio-opaque
- Magnetic resonance imaging	Contrast agent	Lack of a 19F endogenous background signal *in vivo* and high magnetic resonance sensitivity of 19F atoms
- Proton and 19F NMR imaging	Contrast agents	Lack of fluorine in organs and tissue
- Computed tomography and sonography	Contrast agents	Lack of fluorine in organs and tissue
- Radio-opaque materials	Polymeric PFAS has been used	Radio-opaque
- Surgical drapes and gowns	Improve water-, oil- and dirt-resistance	Hydrophobic and oleophobic, low surface tension
- X-ray films	Wetting agents, emulsion additives, stabilizers and antistatic agent	Low surface tension, low dielectric constant
- Dispersant	Facilitate the dispersion of cell aggregates	Low surface tension
- Contact lenses	Raw material	
- Retinal detachment surgery and proliferative vitreoretinal	Endotamponade gases	High specific gravity, low surface tension, and low viscosity
- Retinal detachment surgery and proliferative vitreoretinal	Intraoperative tool during vitreoretinal surgery	High specific gravity, low surface tension, and low viscosity
- Eye drops	Delivery agent	Unique combination of apolarity and amphiphility
- Filters, tubing, O-rings, seals and gaskets in dialysis machines	Made out of polymeric PFAS	Low surface tension

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
- Dialysis membranes	Made out of polymeric PFAS	Low surface tension
- Catheter, stents, and needles	Provide low-friction and clot-resistant coatings	Low surface tension
- Surgical patches and vascular catheter	Use of polymeric PFAS	?
- Blood transfer and artificial blood	Oxygen carrier	Great capacity to dissolve gases
- Organ perfusion	Oxygen carrier	Great capacity to dissolve gases
- Percutaneous transluminal coronary angioplasty	Oxygen carrier	Great capacity to dissolve gases
- Toothpaste	Enhances fluorapatite formation and inhibits caries	Low surface tension
- Dental floss	Allows the narrow ribbon to slip easily between close-pressed teeth	Low surface tension
- UV-hardened dental restorative materials	Improve the wetting of the set materials	Low surface tension
- Ventilation of respiratory airway	?	?
- Anaesthesia	Polymeric PFAS is used to dry or humidify breath	Hydrophobic
- Artificial heart pump	Blood compatible and durable	Non-reactive, stable
- Wound care	Cleaning burn residues	Dissolve hydrocarbon
Metallic and ceramic surfaces	Generates easily removable sludge	Hydrophobic and oleophobic
Music instruments		
- Guitar strings	Prevent loss of vibration due to residue build up	?
- Piano keys	Contain polymeric PFAS	?
- Piano	Eliminate squeaks in piano key	?
Optical devices		
- Glass fibre optics	Able to include rare earth in glass fibre optics	?
- Optical lenses	Provide optical lenses with low refractive index and high transparency	Low refractive index
Paper and packaging		
- Paper and cardboard	Provide water- and oil repellency	Hydrophobic and oleophobic
- Manufacturing of paper	Release agent for paper-coating compositions	Low surface tension
Particle physics		
- Particle accelerators	Part of the detection assemblies	Non-reactive, stable, high ionization charge density
Personal care products		
- Cosmetics	Emulsifiers, lubricants, or oleophobic agents	Hydrophobic, low surface tension
- Cosmetics	Make creams *etc.* penetrate the skin more easily	
- Cosmetics	Make the skin brighter	
- Cosmetics	Make the skin absorb more oxygen	Great capacity to dissolve gases
- Cosmetics	Make the makeup more durable and weather resistant	Hydrophobic and oleophobic, stable, non-reactive
- Hair-conditioning formulations	Enhance wet combing and render hair oleophobic	
Pesticides		
- Insecticide against the common housefly and carmine mite	Suffocation of the insect by the adsorbed fluorinated surfactant	?
- Insecticide against ants and cockroaches	?	?

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
- Formulation additives	Anti-foaming agent	Low surface tension
- Formulation additives	Dispersant, facilitate the spreading of plant protection agents on insects and plant leaves	Low surface tension
- Formulation additives	Dispersant, increase uptake by insects and plants	Low surface tension
- Formulation additive	Wetting agent for leaves	Low surface tension
Pharmaceuticals		
- Active ingredient (fulvestrant)	Estrogen antagonists, inhibits the growth stimulus that the estrogen exert on cells	?
- Active ingredient	Pharmaceutical combination of dabigatran and proton pump inhibitors	?
- Formulation additives	Dispersant in self-propelling aerosol pharmaceuticals	Low surface tension
- Formulation additives	Solvent	Hydrophobic and oleophobic
Pipes, pumps, fittings and liners		
- Pipes, pipe plugs, seal glands, pump parts, fasteners, fittings and liners	Polymeric PFAS are used for these applications	Stable, non-reactive, low surface tension, hydrophobic and oleophobic
- Working fluid for pumps in the electronics industry	Stable to reactive gases and aluminium chloride	Extremely stable, non-reactive
Plastic and rubber		
- Plastic	Polymeric PFAS micropowder as additive ?	?
- Thermoplastic	Plasticizer	?
- Bonding of rubber to steel	Allow adhesiveness bonding	Low surface tension
- Rubber and plastic	Antistatic agent	Low dielectric constant
- Resin	Improve weatherability and elasticity	Non-reactive, stable
- Polycarbonate resins	Flame retardant for polycarbonate resins	Non-flammable
Printing (inks)		
- Toner and printer ink	Enhance ink flow and levelling, improve wetting, aid pigment dispersion	Low surface tension
- Toner and printer ink	Impart water resistance to water-based inks	Hydrophobic
- Ink-yet recording heads	Make them ink repellent	Low surface tension
- Recording and printing paper	?	?
- Lithographic printing plates	?	?
Refrigerant systems		
- Refrigerant fluid system	Heat transfer fluid	Good heat conductivity
- Refrigerant compressor	Lubricants	Non-flammable
Sealants and adhesives		
- Sealants	Can be made out of polymeric PFAS	Operate at a wide temperature range, non-reactive, stable
- Silicone rubber seals	Prevents soiling	Low surface tension, hydrophobic and oleophobic
- Adhesives	Improve levelling, spreading, and the penetration of the adhesive into the pore structure of the substrates	Low surface tension
- Adhesives	Antistatic agent	Low dielectric constant
Soldering		
- Vapour phase fluids in vapour phase soldering	Heat transfer medium	Good heat conductivity
- Fluxing agent in solder paste	Low-foaming noncorrosive wetting agent	Non-reactive, stable, low surface tension

Open Access Article. Published on 30 October 2020. Downloaded on 5/31/2021 4:22:48 PM.

Table 4 (*Contd.*)

Use category/subcategory	Function of PFAS	Properties of the PFAS employed
Soil remediation		
- Vapour barrier material on top of contaminated soil	Evaporation retarder	?
- Surfactants to mobilize pollutants	Surfactants to mobilize soil-bound contaminants in remediation	Stable, non-degradable (during photodegradation)
Sport article		
- Ski wax	Highly water repellent	Low surface tension, hydrophobic
- (Sailing) boat equipment	Weather protection of textiles; anti-fouling protection of ship hulls	Non-reactive, stable, hydrophobic and oleophobic
- Tennis rackets	Used in coatings for tennis rackets	?
- Bicycle	Lubricants	Hydrophobic
- Climbing ropes	Provide water repellence, stain resistance and soil release	Low surface tension, hydrophobic
- Fishing lines	No water absorption, invisible in water, high knot strength	Hydrophobic
- Golf gloves	Antifouling protection for the natural sheep leather of the glove	?
Stone, concrete and tile	Impart oil and water repellency to the surface; delay oxidation and ageing of surface	Low surface tension, hydrophobic and oleophobic
Textile and upholstery		
- Surface treatment	Provide water and oil repellence, stain resistance and soil release	Low surface tension, hydrophobic and oleophobic
- Waving yarn	Facilitate waving	?
Tracing and tagging		
- Tracking air–borne pollutants	Tracer in air	Non-radioactive, chemically and thermally stable, do not occur naturally, have very low atmospheric background concentrations
- Testing ventilation systems	Tracer in air	〃
- Mapping gas and petroleum reservoirs	Tracer in gas or petroleum	〃
- Leak detection in cables, pipelines, landfill waste and underground storage tanks	Tracer in leaking material	〃
- Tracking of marked items	Tracer in the marked item	〃
Water and effluent treatment		
- Filter membranes	Polymeric PFAS minimize the sorption of compounds to the filter itself	Low surface tension
Wire and cable	Provide high-temperature endurance, fire resistance, and high-stress crack resistance	Non-flammable, operate at a wide temperature range

Hunt, P., PFAS a toxic problem in “wild west” mining industry (2021)

AUSTRALIA'S MINING MONTHLY

https://www.miningmonthly.com/life-cycle-end-of-life-management/news/1413112/pfas-toxic-problem-in-%E2%80%98wild-west%E2%80%99-mining-industry

PFAS a toxic problem in 'wild west' mining industry

WESTERN Australia has no plan to phase out highly toxic chemicals found on mine sites and oil and gas projects and cannot quantify the level of contamination across the state.

PFAS foam being sprayed.

Asset Management > Life-cycle-end-of-life-management

Comments

Paul Hunt

Deputy Editor: Energy & Commodities

Per-and-poly-fluoroalkyl substances (PFAS) such as perfluorooctane sulfonate, perfluorooctanoic acid and perfluorohexane sulfonate have been used since the 1970s as firefighting foam across mining and oil and gas operations.

PFAS is used in both pre-engineered suppression systems such as haul trucks and mobile plants, as well as fixed suppression systems - installed tanks onsite filled with foam concentrate that is then mixed with water and sprayed on fires from a distance.

The toxic chemicals cause a range of health issues to people exposed, including cancers, liver and kidney failure, immunological problems, and pregnancy complications.

PFAS does not break down and accumulates over time in soils, surface and ground water.

Earlier this year mining giant BHP made headlines after PFAS contamination was **found in groundwater** at its Whaleback iron ore project in Newman, WA, close to public drinking water.

The WA Department of Water and Environment Regulation (DWER) declared the Mount Whaleback mine a dangerous "contaminated site" and ordered BHP to clean it up.

The incident sparked concern that PFAS could be an underestimated health and environmental disaster waiting to happen in WA.

After three months of inquiries, *Australia's Mining Monthly* can reveal the WA government has no inventory on the quantity of PFAS in the state.

AMM contacted the WA Department of Water and Environmental Regulation, Department of Mines, Industry Regulation and Safety, individual ministers, and peak body the Chamber of Minerals and Energy WA.

None of the organisations, departments, or ministers could provide any data on how abundant PFAS was on WA mine sites or resources operations.

CMEWA told *AMM* that the issue was a government one, and it was not responsible for gathering this data.

Speaking under anonymity, several sources also told *AMM* no formal meetings between industry and the government had taken place on how to manage PFAS contamination since the BHP incident. This is contrary to a report by the *Australian Financial Review* claiming meetings were taking place.

Furthermore, the government has no plan on how to phase out the harmful substance from resources operations and is instead waiting on the federal government to come up with a solution.

This is despite multiple other states moving quickly to ban PFAS.

Queensland banned PFAS in 2016 with a three-year phase-out period, while South Australia banned it in 2020. New South Wales more recently moved into its own staged process of banning it.

While WA has not moved to ban PFAS itself, the government has "strongly recommended" PFAS be replaced across mines and oil and gas operations with PFAS-free solutions.

DWER told *AMM* it was helping contribute to a national approach to PFAS and said laws had been introduced in recent years to "ensure contaminated sites are identified, investigated and, where necessary, cleaned up".

It could not say how many mine sites or oil and gas operations in the state were still using PFAS.

Fire and safety experts told *AMM* the government needed to join other states in banning PFAS in the short term.

Sicada Fire and Safety chief Robin Sellar said WA was known in the industry as the "wild west" and PFAS was most likely prominent across the "majority of resources operations" in the state.

In Queensland Sicada was a pioneer in removing PFAS from the mining industry. It watered down the toxic chemical and then disposed of it at a local high-temperature incineration facility.

There are only three incineration facilities in Australia with the capacity to destroy PFAS. All are located on the east coast.

Fellow leading fire protection company Wormald agreed with Sicada, that PFAS was "most likely prominent across WA and the Northern Territory".

Wormald technical director Justin Morris told *AMM* that PFAS would still be used in firefighting systems in WA.

"It definitely would be prevalent across mines, but how much is out there we just don't know," Morris said.

He noted contamination would also be highly likely due to testing requirements.

"There would definitely be residual legacy contamination on a lot of sites, because under WA law, all firefighting suppression systems need to be tested annually," Morris said.

"This means PFAS is being sprayed on the ground, so it makes sense there's ground contamination."

One of the key problems facing WA's mining industry is how to dispose of PFAS from fixed fire suppression systems.

Fixed suppression systems are generally large units on an oil platform, LNG plant, or mine site that can spray suppressants for long distances from a fixed location.

However, most of fixed systems in WA contain PFAS.

To extract the PFAS, clean the entire system, and replace equipment where necessary, could mean entire operations would have to be shut down.

Such a shutdown would cost large mining companies millions of dollars in lost time, never mind the cost of replacing PFAS chemicals and then incinerating them.

Morris said the cost of shutdowns and replacing the firefighting foam was a major inhibitor for industry to voluntarily remove PFAS from their sites.

"On a large fixed system at a mine site or oil and gas project, it is a significant cost," he said.

"It's cost of removal, downtime, and then disposal and incineration of PFAS.

"Maintenance and shutdowns can take anywhere from between a few days and weeks or longer, but it's different with every project."

Another problem facing WA is the fact that none of the operating incinerator facilities are located in the state.

While Queensland has two and NSW has one, WA has never built a purpose-built chemical incineration facility.

This would mean PFAS waste from mine sites and oil and gas operations would need to be transported across the country for disposal, and with states quickly banning the use and import of the chemicals, that could be problematic.

"There's the cost of transport, there's the risk of a spill, and then of course barriers in transporting the waste across state lines as well," Morris explained.

"This is a challenge. But building a new waste facility in Western Australia could be an option ... it would bring costs down for disposal for sure."

In the meantime, experts agree that without state government policy, miners and oil and gas companies would be unlikely to voluntarily undertake the extensive and expensive process of PFAS removal.

"Looking at other states that have successfully removed PFAS, it has taken state government leadership and policies before anything happened," Morris said.

Both Sicada and Wormald offer PFAS disposal services.

PFAS Adds Complexities to Environmental Drilling Jobs

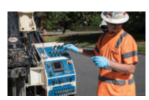
By Stephen Rasmussen

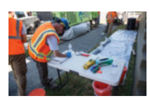
PFAS contamination is often high at sites that manufactured the substance or in areas like military bases where it was used in fire suppression foam.

Source: Holt Services Inc. photos

Before a company gets in the field, it should in

https://www.thedriller.com/articles/91558-pfas-adds-complexities-to-environmental-drilling-jobs





July 22, 2019

In January 2018, the documentary "The Devil We Know" debuted. The film is about toxic chemicals being dumped in a West Virginia town's water supply and the residents' fight with DuPont Corporation to try to hold it accountable for the contamination. But this story isn't new. It starts in 1938 with the invention of man-made chemicals designed for non-stick cookware. Companies found more ways to use these chemicals over the years to produce food packaging, stain and water repellents, and foam fire suppressants. PFOA — a toxic chemical in Teflon — is so widespread, the documentary claims it is in the blood of 99 percent of Americans.

PFAS contamination is often tied to sites that store or use flammable and combustible materials, and thus use fire suppression foams containing PFAS for firefighting missions. Foams are a better suppressant for these highly combustible fires because the foam can cool the fire, separate the flame and ignition source from the surface, suppress the vapors and prevent reignition.[1] The foams are great for putting out the fires. However, they're also permeating our groundwater supplies and finding other pathways to our most precious resource. This, in turn, adversely affects the food we eat. Thankfully, awareness of PFAS chemicals and their harmful effects is on the rise and new steps have been taken to reduce exposure and combat their presence in our natural environment.

Over the past few years, Holt Services Inc. has had the opportunity to work on several projects investigating and/or remediating the threat of per- and polyfluoroalkyl substances (PFAS) to the environment. Although PFAS is not necessarily a new chemical, its widespread presence and harmful effects on the environment have become alarming issues. Studies have shown that large doses of PFAS-related chemicals can cause reproductive, developmental, liver, kidney and immunological effects in laboratory animals.[2]

Environmental and engineering consulting firms continue to make headway in the identification, containment and treatment of PFAS contamination. I policies have also been introduced to help deal with and protect against human exposure, and with the ongoing threat to the environment.

Privacy - Terms

Under the direction of these consulting firms, Holt Services is working to combat the PFAS problem. Holt provides the most technologically advanced drill rigs in the environmental market, along with drill crews who have decades of experience working with and handling harmful contaminants. Having managers with PFAS experience is a vital piece in the success of a drilling project in which the contaminant you are trying to identify and remediate is found in many of the products, materials and equipment commonly used in the drilling industry.

Here are some things to think about before you get into the field.

Inspect the Manufacturer's Specification Sheet

A lot of commonly used groundwater pumps and tooling have grips, fittings, seals and other components made up of plastic materials that can contain or could have been manufactured and exposed to PFAS chemicals.[3]

Common Level D personal protective equipment (PPE) should also be inspected. This includes:

- Safety vests
- Steel-toed boots
- Hard hats
- Gloves
- Rain gear

PFAS is used in a lot of different manufacturing processes and is commonly found in stain and water repellants often used in PPE.[4]
Ensure there is no direct exposure with samples to prevent cross contamination.

Check the MSDS

Review the MSDSs to ensure the well materials used in the field do not contain PFAS substances. The most commonly found and best studied PFAS are perfluorooctanoic acid (PFOA) and perfluorooctanesulfonic acid (PFOS).

Some materials you'll want to look at include:

- PVC casing and sleeve
- Tubing
- Grout
- Bentonite
- Cement and concrete
- Fuels
- Oils
- Grease

Water Supply

PFAS chemicals do not readily breakdown in the environment and are water soluble. As a result, there are very low levels of PFAS in many areas of the environment. Contamination levels may be higher near facilities that manufactured, disposed of or used PFAS. Since water is often used to decontaminate equipment and assist with drilling activities, your water supply should be tested for PFAS.

Storage

Take care when storing materials and equipment that will be used in sample collection. Avoid storing materials and equipment in areas where there is a possibility of contact with materials containing PFAS.

Environmental contractors can do their part in the complex fight against PFAS and PFOA substances. A thorough check of equipment and supplies used on the jobsite can help contractors ensure the best samples and help reduce exposure to their crews and beyond.

Ms. Katrina Kessler
Commissioner
Minnesota Pollution Control Agency
520 Lafayette Road North
St. Paul, Minnesota 55155

RE: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing PFAS

Dear Commissioner Kessler,

Whirlpool Corporation appreciates the opportunity to comment on the Agency's approach to determining currently unavoidable uses of per- and polyfluoroalkyl substances (PFAS) in products. We support the **Minnesota Pollution Control Agency's (MPCA**) effort to narrowly regulate PFAS within appliances by excluding substances with no established persistent and bioaccumulation characteristics.

Additionally, we share key considerations supporting criteria for evaluating currently unavoidable uses essential for the health, safety, or functioning of society. Finally, we strongly support MPCA in establishing and releasing to the public initial currently unavoidable use determinations for hydrochlorofluoro-olefins (HCFO) substances such as SOLSTICE (LBA 290379) which have undergone federal authorizations and programs for specific uses[1].

Should criteria be defined for "essential for health, safety, or functioning of society"? If so, what should those criteria be?

Whirlpool Corporation supports MPCA in developing additional guidance on definitions for "essential for health, safety or functioning of society." A chief objective should include assessing alternatives to materials that are considered PFAS, and whether the alternatives

[1] Federal authorizations and programs includes the SNAP program, Section 5 of the Toxic Substance Control Act, and other federal programs deeming PFAS or products containing them acceptable for intended use by federal agencies

Whirlpool Corporation Global Headquarters
2000 N. M63
Benton Harbor, MI 49022
269-923-5000

would have negative impacts on products' energy efficiency, greenhouse gas emissions, safety[2], and end-of-life cycle management.

Many chemicals are approved for their respective end-use applications by federal agencies such as the United States Environmental Protection Agency (EPA) under Section 612 of the Clean Air Act (CAA), as well as specific Toxic Substances Control Act (TSCA) significant new use rules and various Section 5(e) Consent Orders. Further, these substances also are already subject to CAA and TSCA reporting requirements. Thus, we seek MPCA to clarify whether information submitted and reported at the federal level would suffice reporting requirements in Minnesota.

What criteria should be used to determine the safety of potential PFAS alternatives?

Whirlpool Corporation recommends that MPCA utilize established federal laws and regulations to make necessary determinations. For example, the Significant New Alternatives Policy (SNAP) program and Section 5 of the Toxic Substances Control Act have determined certain substances as acceptable uses.

Specifically, we support MPCA in considering the following factors when making safety determinations of potential PFAS alternatives:

- **Benefits**: Whether alternatives provide benefits to public health, protect the environment, and or are critical to the function of society.

- **Safety:** Whether alternatives present safety risks, including flammability, during production, use, or end-of-life management.

- **Economical feasibility of alternatives**: Whether PFAS alternatives can be technically and economically feasible for the same purpose, including whether their implementation is possible without significant changes in manufacturing processes.

Fluoropolymers such as SOLSTICE (LBA 290379) remain critical substances for home appliance manufacturers in the United States and ensure they can meet the needs of customers while protecting the environment.

[2] Considerations surrounding safety includes alternatives' flammability potential. This includes the use of alternatives being used during the product's manufacturing process and end-of-lifecycle management.

3

In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Whirlpool Corporation encourages MPCA to exempt products that are regulated at the federal level. We do intend to submit a currently unavoidable use request for hydroclorofluoro-olefins (HCFO), given the minimal risk to human health and low global warming potential.

Below, we briefly highlight the importance that HCFOs play in manufacturing appliances and maintaining safety and efficiency.

Hydrochlorofluoro-olefins (HCFOs)

HTS Code - SOLSTICE LBA 290379

Per existing law, HCFOs will be banned by the effective compliance date. HCFOs are utilized in refrigeration products as foam-blowing agents used for insulating walls and doors of household refrigerators and freezers.

HCFOs are one of a few climate-friendly alternatives that have ultra-low global warming potential. Not only do HCFOs have lower global warming potential compared to their predecessors but they also reduce the potential impact of ozone depletion which makes them less harmful to human health and the environment.

With the rise of state action banning hydrofluorocarbons (HFCs), EPA has encouraged the transition of low global warming potential alternatives such as HCFOs through the environmental review and approval via the SNAP program. As a direct result, federal action of phase-out of chlorofluorocarbons (CFCs), hydrochlorofluorocarbons (HCFCs), and HFCs have excluded foam blowing agents and refrigerants given the low risk and potential to harm human health and the environment[3].

[3] U.S. Environmental Protection Agency. *Overview of SNAP*. https://19january2017snapshot.epa.gov/snap/overview-snap_.html

Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

We highly encourage MPCA to determine initial currently unavoidable use determinations of HCFOs as part of the rulemaking using the proposed criteria. Failure to release initial currently unavoidable use determinations, based on the proposed criteria, will have a significant impact on consumers and households throughout the state of Minnesota.

Timely action on an unavoidable use determination for HCFOs is critical. Transitioning to an alternative, such as cyclopentane, presents unique challenges that would require significant manufacturing investments and product redesigns across four of our manufacturing facilities in North America.

Thank you for your consideration. Should you have any questions regarding our comments, please let us know.

Sincerely,

Anthony Price
Manager, Government Relations

Hazardous Waste Management Program

201 S. Jackson Street, Suite 5600, Seattle, WA 98104
www.kingcountyhazwastewa.gov

February 29, 2024

Minnesota Pollution Control Agency
Resource Management and Assistance Division
520 Lafayette Road North
St. Paul, MN 55155-4194

RE: Comments on Minnesota Pollution Control Agency's PFAS in Products Currently Unavoidable Use Rule (Revisor's ID Number R-4837)

To Whom It May Concern:

We want to express our gratitude for the opportunity to share our thoughts on the proposed PFAS in Products Currently Unavoidable Use Rule (Revisor's ID Number R-4837). The Hazardous Waste Management Program in Washington state is committed to ensuring public health and environmental quality in King County.

The Hazardous Waste Management Program in Washington state, authorized by the Washington State Department of Ecology, focuses on protecting public health and the environment in King County. With 2.3 million residents, King County is among the most populous in the United States. The program, which includes 42 local jurisdictions, aims to reduce threats from hazardous materials in consumer products, emphasizing the need to restrict PFAS (per- and polyfluoroalkyl substances) within commerce when not essential. The program provides the following comments on the Minnesota Pollution Control Agency's rulemaking, seeking workable policy solutions to achieve its goals and emphasizing the importance of both minimizing exposure to hazardous materials and reducing hazardous waste generation.

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

We recommend that MPCA determine that a use of PFAS in a product category is a currently unavoidable use (CUU) only if all the following criteria are met[1]:

(1) The function provided by PFAS in the product is necessary for the product to work.
(2) There are no safer alternatives to PFAS that are reasonably available.
(3) The use of PFAS in the product is critical for health, safety, or the functioning of society.

[1] For example, see California's proposed bill SB-903 bill (2023-2034): [Bill Text - SB-903 Environmental health: product safety: perfluoroalkyl and polyfluoroalkyl substances. (ca.gov)]

For many uses of PFAS, the criterion associated with whether a use is "essential for health, safety, or the functioning of society" will be more difficult to adjudicate compared to the other two criteria. In those cases, it is critical that MPCA be able to first determine whether PFAS are necessary for the product to work and whether there are safer and reasonably available alternatives, since, if either of these criteria are met, the use would not be consistent with any reasonable definition of an unavoidable use.

As Balan et al. (2023)[2] have recently written, it is possible to operationalize the above CUU criteria while avoiding unnecessary assessments—thereby maximizing efficiency—by asking the following three questions: (1) is the function of the PFAS necessary for the product?; (2) is use of the PFAS the safest feasible option?; and (3) is use of the PFAS justified because such use in the product is necessary for health, safety, or the functioning of society? If a response to any question is no, then the use of PFAS should not be considered a currently unavoidable use and the use can be substituted, discontinued, or denied approval. Therefore, MPCA could start with the question that is most easily answered no for any given use and possibly avoid the need for further assessment.

If an assessment of whether a use is "essential for health, safety, or the functioning of society" is required, we expect that decisions will necessarily be based on the specific context and information provided by the requestor. In any case, manufacturers petitioning for CUU status should be obligated to provide tangible and measurable public health, environmental, or societal benefits within their petitioning, and those benefits should be weighed against the long-term societal costs of continued use of PFAS.

Another important principle for CUU determinations is that individual PFAS chemicals or industries should not be deemed "essential," such that all uses of certain PFAS or within certain industries are designated as CUU; each specific use within a product should be assessed independently.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

We believe that it is reasonable to consider costs when determining safer, feasible, and available alternatives to PFAS. Cost considerations are well-recognized within the practice of alternatives assessment—for example, there is an entire module on cost and availability within the Interstate Chemical Clearinghouse (IC2) Alternatives Assessment Guide.[3] We further encourage MPCA to review criteria for feasible and available developed by the Washington Department of Ecology for implementing our state's Safer Products for Washington law.[4]

However, we believe that MPCA should not be explicitly required to show that costs are comparable when determining if alternatives are "reasonably available". It can be difficult for

[2] See Balan et al. (2023). Optimizing chemicals management in the United States and Canada through the essential-use approach. Environmental Science & Technology, 57(4), 1568-1575. https://doi.org/10.1021/acs.est.2c05932

[3] Alternatives Assessment Guide - Interstate Chemicals Clearinghouse (IC2) (theic2.org)

[4] See Appendix D in Regulatory Determinations Report to the Legislature: Safer Products for Washington Cycle 1 Implementation Phase 3.

agencies to obtain enough high-quality cost information to rigorously document that costs are comparable, so a requirement to do so would prevent the identification of safer alternatives. We further recommend that MPCA not define a specific cost threshold (e.g., a specific dollar amount or percentage cost difference) that would be a determinative factor in assessing whether an alternative is reasonably available. Such a threshold would not allow for consideration of potentially important context associated with individual use cases. For example, identical costs differences could have dramatically different impacts across different firms, industries, or customers. Additionally, markets can rapidly change due to factors such as technological advances or regulations. We note that the Washington Department of Ecology criteria mentioned above explicitly states that cost considerations will be evaluated on a "case-by-case basis—relying on existing alternatives assessments and frameworks and with stakeholder feedback."

Further, MPCA should work to develop these rules such that cost and economic considerations are not weaponized by manufacturers to avoid transitioning away from non-essential uses of PFAS. In particular, MPCA should balance consideration of manufacturers' costs with other society-level costs, such as remediation costs for removing PFAS from the environment, costs for disposing and handling PFAS-contaminated waste, or medical and healthcare costs associated with adverse human health impacts of PFAS exposure.[5]

3) Should unique considerations be made for small businesses with regards to economic feasibility?

No response.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

We urge MPCA to adopt criteria for determining safer alternatives that are consistent with state-of-the-art research, policy, and practice from the field of alternatives assessment. Most importantly, it is critical that MPCA recognize that ***safer alternatives to PFAS can be either alternative chemicals or alternative products, materials, or processes that eliminate the need for PFAS or alternative chemicals.*** For example, a safer alternative to a non-stick pan coating doesn't have to be a different nonstick coating; instead, it could be a process change to cook differently using oil or fat. We hope the MPCA will consider adopting the following definition, used in a recently proposed bill from CA[6]:

> *"Safer alternative" means an alternative that, in comparison with another product or product manufacturing process, has reduced potentially adverse impacts or potential exposures associated with PFAS. Alternatives include materials, processes, designs, products, or chemicals that achieve the desired result. For example, a safer alternative to stain resistant sprays for avoiding stains could be the use of detergents or the use of fibers that are inherently stain resistant.*

---

[5] The True Cost of PFAS and the Benefits of Acting Now (pubs.acs.org)

[6] See California's proposed bill SB-903 bill (2023-2034): Bill Text - SB-903 Environmental health: product safety: perfluoroalkyl and polyfluoroalkyl substances. (ca.gov)

In our own state, the Washington Department of Ecology has developed an adaptable, hazard-based criteria for identifying safer chemical alternatives, which is used to implement our state's Safer Products for Washington law.[7] Our state's law also considers alternative products and processes when determining safer alternatives to priority chemicals. We encourage MPCA to review these criteria to see if they are adaptable for the PFAS in Products Currently Unavoidable Use Rule.[8]

5) How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

For this law to have its intended impact of phasing out unnecessary uses of PFAS, it is imperative that currently unavoidable use (CUU) determinations be time limited. In principle, CUU determinations should not last so long that they reduce the incentive for users to identify safer alternative chemicals or processes. Any petition for renewal of CUU status by a manufacturer should require evidence of significant effort to develop alternatives, for example, peer reviewed studies or funding of third-party research with no financial conflict of interest.[9]

We also strongly believe that changes in information about available alternatives should allow for MPCA to re-evaluate a CUU determination. Additionally, MPCA should institute a public petitioning mechanism that allows external stakeholders to request a re-evaluation of CUU determinations. This could improve opportunities for timely decision making since other local, state, and federal government agencies; non-governmental organizations; and companies may have the deepest and most up-to-date knowledge of advances in research and development in PFAS alternatives.

6) How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

As mentioned in our response to question 5, we recommend MPCA develop a public petitioning mechanism to allow stakeholders the opportunity to bring forward timely information within a formal request to have MPCA re-evaluate CUU determinations on an ad hoc basis.

One type of information that MPCA should consider highly credible evidence that a use of PFAS is avoidable is if another government entity has already enacted a ban on the sale or use of a PFAS within a product or product category. If certain PFAS uses have already been banned in

[7] Safer Products for Washington - Washington State Department of Ecology

[8] See Appendix C in: Regulatory Determinations Report to the Legislature: Safer Products for Washington Cycle 1 Implementation Phase 3

[9] For example, see California's proposed bill SB-903 bill (2023-2034): Bill Text - SB-903 Environmental health: product safety: perfluoroalkyl and polyfluoroalkyl substances. (ca.gov)

another state, the United States, or other countries and if the ban is in effect, then that demonstrates that the use of PFAS is not a currently unavoidable use.[10]

7) In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

No response.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

We do not believe that MPCA should make any CUU determinations prior to rulemaking. It should be the responsibility of a manufacturer to petition for a CUU determination.

On the other hand, it is appropriate for MPCA to proactively identify product categories in which PFAS uses are avoidable. One straightforward approach for MPCA to accomplish this is by considering actions from other government entities (e.g., other U.S. states) to ban the sale or use of PFAS in a product or product category. If certain PFAS uses have already been banned in another state, the United States, or other countries and if the ban is in effect, then that demonstrates that the use of PFAS is not a CUU.

Here is a list of PFAS uses and product categories for which other states have already enacted bans, and should therefore not be considered a CUU:

- PFAS in textiles/apparel has been banned in California[11] and New York[12]; a ban in Washington is also forthcoming[13]
- PFAS in pesticides have been banned in Maine[14]
- PFAS in oil and gas products (e.g., hydraulic fracturing fluids) has been banned in Colorado[15]

Note that in some cases, restrictions for the use of PFAS in products or product categories in other states have been based on rigorous identification of safer alternatives—for example, see the recent report from the Washington Department of Ecology which identifies safer, feasible, and available alternatives to PFAS in apparel and cleaning products.[16] Further, we encourage MPCA

---

[10] For example, see California's proposed bill SB-903 bill (2023-2034): Bill Text - SB-903 Environmental health: product safety: perfluoroalkyl and polyfluoroalkyl substances. (ca.gov)
[11] California AB-1817 Product safety: textile articles: perfluoroalkyl and polyfluoroalkyl substances (PFAS). (ca.gov)

[16] Draft Regulatory Determinations Report to the Legislature: Safer Products for Washington Cycle 1.5 Implementation Phase 3

to review Tables 8 and 9 of the European Chemicals Agency (ECHA) Annex XV Restriction Report proposing restrictions for PFAS.[17] These tables summarize ECHA's findings on the existence of technically and economically feasible alternatives to PFAS and indicate several additional product categories for which PFAS is avoidable, including paints and other construction-related products.

9) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

We urge MPCA to use the broadest reasonable scope of a product category in making a CUU determination. We also want to make sure you're aware of the following sources of information on PFAS uses and potential alternatives.

- ZeroPM's database of PFAS alternatives[18]
- Consumer Product Safety Commission's PFAS source characterization database (and accompanying white paper and other relevant resources)[19]
- 3M's database of their PFAS containing products[20]

The Hazardous Waste Management Program thanks you for this opportunity to comment. If you have questions regarding the comments above, please contact Dr. Trevor Peckham, Environmental Scientist, at tpeckham@kingcounty.gov.

Respectfully,

Maythia Airhart, Director
King County Hazardous Waste Management Program

RE: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Submitted via https://minnesotaoah.granicusideas.com/

Dear Commissioner. Kessler,

The American Chemistry Council (ACC) represents over 190 companies engaged in the business of chemistry—an innovative, $639 billion enterprise that is helping solve the biggest challenges facing our nation and the world. The business of chemistry drives innovations that enable a more sustainable future, creates approximately 555,000 manufacturing and high-tech jobs—plus over four million related jobs—that support families and communities, and enhances safety through the products of chemistry and investment in research.

Per- and polyfluoroalkyl substances (PFAS), or Fluorotechnology, are a diverse universe of chemistries that helps make possible the products that power our lives – the cellphones, tablets and telecommunications we use every day to connect with our friends and family; the aircraft that power the U.S. military; alternative energy sources critical to sustainability goals; and medical devices that help keep us healthy. However, all PFAS are not the same. Individual chemistries have their own unique properties and uses, as well as environmental and health profiles.

As ACC communicated throughout the legislative process, we do not support the concept of unavoidable uses and believe this misguided policy will likely lead to significant unintended consequences for Minnesota.

The Minnesota Pollution Control Agency (MPCA) should be aware that as it initiates a regulation on the Currently Unavoidable Use (CUU) of PFAS, it could impact thousands of products and establish requirements for hundreds of companies to file for exemptions to continue to sell basic products across Minnesota. Without substantial modifications, under the CUU rulemaking, the following industries may need to file many exemptions to continue to operate and sell or distribute products in Minnesota:

- Electronics
- Medical
- Refrigeration
- HVAC
- Renewable Energy
- Optical and Data Transmission
- Automotive
- Aerospace
- Semiconductors
- Agriculture and Food
- Paint and Coatings
- Batteries and Battery Storage
- Industrial Equipment
- Specialty Films
- Others

ACC urges MPCA to recognize the full societal and economical weight of regulating a product or product component. ACC strongly recommends that MPCA consider the following additional factors where CUU determinations are concerned:

- **Overall Product Design, Safety, Performance, and Sustainability Factors** – Effective evaluation of uses should include the multiple factors that are important for overall product design and performance, including critical attributes related to efficacy and sustainability. Absent a robust and holistic assessment process, this new program will likely foster regrettable substitution and detract from some of the underlying objectives of the program. Moreover, there are a host of sustainability issues to consider in the context of overall electronic product design and performance, including energy efficiency, durability, light, weighting, and material selection, among other factors. Failure to consider these factors could ultimately impact product safety, performance, sustainability, and innovation. Active engagement with the actual end-users for the use will be important for this.

- **Consideration of Existing Product Codes and Standards** – Evaluation of uses should consider existing product codes and standards. There are numerous existing codes and standards that help inform and guide overall product design and performance. In addition, it is important to recognize that these are often viewed as minimum requirements for many Original Equipment Manufacturers (OEM) and that overall performance and safety can often go beyond these standards for specific applications. Changes in product design may affect the ability to meet certain standards and/or require product redesign, re-sourcing, re-testing and recertification.

- **Robust Assessment of Alternatives** – The assessment of alternatives is critical for this new program and is also needed to help avoid regrettable substitution. Key considerations for the assessment of alternatives include:

    - The safety and efficacy of alternatives.

    - The ability of the alternative to provide equivalent functional performance. This includes whether an alternative can meet relevant product and performance standards.

    - The regulatory environment for the identified alternatives as well as broader circularity and safety considerations relevant for product design related to the available alternative.

    - The technical and economic feasibility of deploying alternative technology. "Feasibility" under the National Academy of Sciences (NAS) Alternatives Assessment Framework[i] includes an analysis of both technical feasibility and economic feasibility. The process for evaluating potential alternatives should include both technical and economic feasibility. Technical feasibility requires a demonstration that a substitute chemistry or formulation provides equivalent or better performance for the relevant performance criteria for a particular product. In any given class of chemistry, different individual chemistries may be used or marketed for different applications with different levels of necessary performance. For example, marine paint, outdoor paint for a bridge, outdoor paint for a building, and interior paint for a kitchen, may have performance requirements that differ significantly.

    - The availability of the alternative including a.) what is the approximate cost and availability of other materials that may be required for use of the potential alternatives including required product design changes, b.) what will be the approximate costs and supply chain implications for redesigning the product, including product testing and recertification, and c.) how long would it take the relevant company/industry to transition.

  - **Alignment with Federal and International Regulations** – No state, federal, or international regulatory authority has yet to implement such a massive restriction on fluoro technology as the one considered in Minnesota. This would make the state an outlier, potentially decreasing products available for purchase in the state and potentially impacting broader product safety, innovation, and sustainability. If not implemented carefully, the current law may also run counter to federal and international health and safety standards.

  - **Consideration of Relevant, Existing Safety Assessments and Regulatory Determinations** – In many cases there are existing assessments and regulatory determinations that govern the use of specific chemistries. This includes instances where specific PFAS substances have been identified as a preferred alternative. Consideration of such information will be important as part of MPCA's assessment.

- **Consideration of Impact on Minnesota's Overall Priorities and Objectives** – MPCA should assess the product or uses for its relevance and contribution to overall Minnesota priorities and objectives including overall socio-economic considerations.

- **Global Supply-Chain Considerations** – Affirmative CUU determinations should extend to the entire supply chain necessary for the substance in use. A CUU cannot exist in the economy if the manufacturers and processors involved in bringing the CUU to market do not have adequate regulatory certainty. Product manufacturers operate in a global regulatory environment and must consider a broad range of product safety and design factors. This includes complex considerations related to product certification, performance, use and end of life, and even chemical registration and use. In addition, many manufacturers rely on a global supply chain for components and subcomponents. Any CUU evaluation should take these important global considerations into account. Products are designed for worldwide compliance and this needs to be considered.

- **Timelines for Any Potential Transitions** – The 2032 timeline may not allow sufficient time for manufacturers acting in good faith to adequately test and document the performance of PFAS versus potential substitutes at scale. While such information is being generated, certain uses could be banned, which could lead to shortages or disruptions of supplies critical to the health, safety, and functioning of society. Implementing regulations should have a mechanism for extensions for manufacturers acting in good faith to generate information to support a CUU determination. Therefore, MPCA should create a continuous process for CUU applications and determinations.

- **Product Innovation and New Technologies** – Similarly, advances in technology and/or the emergence of new societal threats and challenges may result in new CUUs being recognized after 2032. MPCA should ensure that the regulatory process under development will allow those "new" CUU applications to be designated as such and allowed in commerce in Minnesota after January 1, 2032. Failure to consider this will undermine product innovation and new technologies. The most recent examples of this include recent technological developments related to EV batteries, alternative energy sources, etc.

- **Utilization of Established, Science-Based Frameworks** – In order to support fact-based decision-making, MPCA should employ established methods and framework for risk assessment, life cycle assessment, alternatives analysis and socio-economic analysis and include transparent stakeholder engagement in their process. MPCA should obtain broad stakeholder and expert input and carefully consider the uses under consideration.

- **Protecting Confidential Business Information (CBI) and Intellectual Property** – CBI and proprietary technologies are important considerations. Absent appropriate CBI protection, many downstream users will be reluctant to file CUUs for consideration in a timely manner. Clear, tested process for handling CBI should be established. The MPCA should ensure that all confidential business information (CBI) submitted is afforded the protection this includes: 1) established process and procedures for protecting this information, 2) ensuring that any of contractors that review the information do so under a separate confidentiality agreement; 3) notifying the submitter if MPCA believes any information submitted as CBI does not meet required criteria for protection.

- **Ongoing Process for Engaging Downstream Users and Submission of CUUs** – There is imperfect information in the supply chain and that many downstream users are not aware of the Minnesota law or process to implement the law. MPCA should not assume that all downstream users are aware of this regulatory process or that that they realize their products rely on PFAS technology. To help address this MPCA should establish a regular ongoing process for the submission of uses. This is particularly true for complex supply chains where end-users will not be aware of where PFAS technology may be used, and which rely on subcomponents manufactured by others.

In addition to the critical points raised above, ACC provides comment on the following questions outlined by MPCA:

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

ACC recommends criteria should be defined for "essential for health, safety and functioning of society." An "essential" assessment should only be initiated when there is deemed to be a risk to human health or the environment from the use of an intentionally added PFAS in a product. Products that do not present an unacceptable risk to human health or the environment should be presumed to be "essential for health, safety and functioning of society." On this point, we reiterate that certain PFAS and certain PFAS subcategories do not present a risk. For example, fluoropolymers have been demonstrated to meet criteria for identifying polymers of low concern. If there is no concern about risk during the use of an intentionally added fluoropolymer, MPCA and stakeholder time and resources should not be wasted on an essentiality analysis. Neither should residents of Minnesota be denied access to a myriad of products important to their daily lives simply because those products contain polymers of low concern.

More generally, the concept of "essential" must be interpreted broadly to be workable. Under a narrow interpretation of "essential" it may be argued that products such as cell phones, laptop computers, or automobiles are not "essential to the functioning of society" since some would contend that society can continue to function without these conveniences. This narrow and inappropriate interpretation fails to properly account for the fact that these types of products are highly beneficial and are an essential feature of our society. Similarly, under a narrow interpretation of "essential" it could be argued that products such as refrigeration units are not "essential to health" since people can live healthy lives without refrigeration. However, this narrow interpretation ignores the critical role that refrigeration plays in supporting good health by preventing food spoilage and preserving pharmaceuticals. These are just a few examples of the types of products that, if they became unavailable, would cause massive social and economic dislocation. To avoid this type of disruption and unintended consequences, we strongly urge MPCA to adopt a broad interpretation of "essential".

The consideration of essential should also consider the critical end uses that PFAS technology enable including consideration on how uses enable product longevity, energy efficiency, sustainability and other important societal considerations.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Yes, MPCA should consider cost when identifying alternatives, and this should include a comprehensive assessment of costs.

In terms of cost, MPCA should not assume that the adoption of an alternative will be cost neutral in terms of the manufacturing process. Critical cost considerations, including retooling production facilities, changes in production yield, workforce training, and disposal costs should be factored in to alternatives. MPCA should also consider the substantial cost associated with replacing products more frequently due to relatively less durability. There will also be broader supply chain costs and impacts to consider.

As noted in our comments, the availability/economic feasibility analysis must consider costs other than price as part of the availability analysis. A substitute chemistry may require process or equipment changes; labor force changes; raw material sourcing changes; and so forth that impact the total cost of the substitution well beyond what an equivalent or similar price is for purchase of the chemical would be.

Evaluation of cost and availability should consider whether any potential substitution will be available at scale during the time for transition. If an entire industry were to switch on a short timescale from one chemical to another, this would create significant scale-up pressures on existing manufacturers and relevant supply chains. This is even more relevant for complex products which have multiple components and require product testing to confirm they meet designated safety and performance standards. In these cases, products must be carefully redesigned, reengineered, and recertified. Such product redesign and recertification processes for complex sectors may take several years so the lead time for these changes needs to be factored into the assessment. We note a recent supply chain challenge regarding the chemical PIP (3:1). Subject to a risk management action under the Toxic Substance Control Act (TSCA), the agency moved earlier this year to a restriction with a phase-out schedule that could not be met by global supply chains. PIP (3:1) was present in manufactured durable goods, like washing machines, and electronics that have multi-year sell inventory and sell-through schedules. The risk of global supply chain disruption from discontinuation of the availability of a commercially important chemical without adequate due diligence with respect to the availability of alternatives can have real, and significant consequences as this example illustrates.

Finally, as noted elsewhere in these comments, MPCA should utilize established frameworks and methodologies to evaluate cost-benefit considerations for a particular use.

ACC understands Minnesota has diverse citizenship with wide ranges of incomes. For some, even minor cost increases can be significant. MPCA should consider what effect the adoption of an alternative might have on the price and availability of the final good and whether such a price increase would affect disadvantaged communities access to important products, including technology like cell phones, computers, and automobiles.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

The Minnesota State Legislature did not to provide small business considerations in crafting this new law. Without provisions that cater to small business, they will be disproportionately burdened with costs associated with reporting requirements, testing products, and qualifying alternatives. MPCA should consider critical supply chains supported by small businesses and the impacts associated with this rulemaking. As noted elsewhere, some of these unique considerations should also apply to related suppliers and global supply chains.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

Any potential alternative should undergo a thorough safety assessment to help avoid regrettable substitution. Such analysis should be conducted on a life-cycle basis. Mere consideration of the hazard characteristics of a chemical is not sufficient and may result in regrettable substitution so a more comprehensive environmental health and safety analysis is required. ACC urges MPCA to compare the use of the alternative with the current product or product component. MPCA should also consider sustainability impacts in criteria, including water use, consumption of raw materials, emissions reduction, energy efficiency, reliability during use, and avoiding the use of landfill capacity. MPCA should include an evaluation for increased product or product component failure. Most importantly, criteria developed for testing alternative products should seek to have a reduced potential for risk to human health and the environment.

MPCA should take hazard, exposure, and risk into account in its alternatives assessment process. The Organisation for Economic Co-operation and Development (OECD) Alternatives Assessment framework[ii] defines "safer alternative" to mean "a chemical, product, or technology that is preferable, in terms of both hazard and potential for exposure to humans and the environment, than the existing option. Evaluating comparative hazard and exposure is an element of the process." In this framework, the OECD notes the "process of determining whether a chemical, product, or technology is "safer" consists of three key steps: comparative hazard assessment, comparative exposure assessment, and integration of hazard and exposure information." To avoid such regrettable outcomes, both the OECD and NAS alternative assessment frameworks recommend the use of comparative exposure assessment.

The alternatives assessment framework also considers broader sustainability factors and evaluates performance, technical feasibility, and economic feasibility before a conclusion may be reached regarding a preferred alternative. A hazard-only approach is not a best practice for alternative assessment.

As noted in our comments, there are established frameworks that can help inform MPCA's analysis of alternatives.

ACC urges MPCA to articulate the criteria that will be used for comparative evaluations of potential risk in the final rule and to seek additional public comment on these criteria.

5) **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

Unavoidable use determinations should last until demonstrably safer and more sustainable alternatives are discovered and can reasonably be implemented at scale in the economy. Significant changes in available information should trigger a re-evaluation. Re-evaluation should apply not only to the use of a substance with a CUU, as well as any alternative that was identified as the basis for denying at CUU.

In no case should re-evaluations take place more frequently than 10 years. ACC recommends MPCA consult with potentially affected industries to determine if a longer re-evaluation period may be necessary to evaluate alternatives or otherwise provide information for the re-evaluation process.

For any CUU that is declined (including CUUs that were granted and then subsequently declined on reevaluation), manufacturers must be provided adequate time to transition to the alternative. ACC urges MPCA to consider that the time needed to test and qualify an alternative may differ for various product or product component applications.

6) **How should stakeholders requests to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be**

determined to be currently unavoidable? What information should be submitted in support of such requests?

MPCA will need to establish a process that manufacturers and users (or their representatives) can request a CUU determination. The process should be flexible to accommodate multiple uses of a product or product component rather than applying use by use to synthesize the process and avoid an unnecessary time burden for MPCA and stakeholders. Requests for CUU determinations should be permitted to be submitted by individual product manufacturers or collectively by trade associations or similar organizations. When a CUU is approved by MPCA, it should apply to all manufacturers involved with that particular use, regardless of which entity submitted the request for a CUU determination.

A manufacturer that makes a timely submission of a request for a CUU determination should not be penalized if MPCA is unable to process the request by the statutory deadline of January 1, 2026, for identifying CUUs. In such cases, the manufacturer should be exempt from the ban until MPCA makes a final determination that the use is not a CUU.

ACC urges MPCA to consider the challenges in time and workload associated with accepting stakeholder requests that identify PFAS uses that are not currently unavoidable. This converse reporting option risks slowing down reviews for alternative uses and delays getting the safest products to consumers. Should MPCA move forward with the converse idea, ACC notes the information requirements for either request should be identical. No party in the process should have a relatively higher or lower bar for substantiating its request.

ACC also reiterates that any process surrounding granting or re-evaluation of a CUU must protect confidential business information.

7) **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

PFAS are a diverse form of chemistry that contribute to the functions of society – from transportation sources and medical devices to food packaging and basic construction materials, PFAS are woven throughout our daily lives. ACC urges MPCA to thoroughly and thoughtfully consider all product and product component applications submitted as part of this rulemaking process.

There will likely be thousands of submissions for evaluation. While many of these will likely be able to be grouped according to general industrial and commercial sectors, there will be multiple applications and uses within each sector. For an example of magnitude, the broad sector of electronic equipment which relies heavily on fluoro technology, accounts for more than a hundred pages of the U.S. International Trade Commission's Harmonized Tariff Schedule codes.

To help inform MPCA's inquiry, one information source is the recent comment period for the EU PFAS Regulations. In that process over 5000 stakeholders provided initial input including specific background on critical uses with examples of the many thousands of products that would be impacted available here.

Additional information on key uses of fluoro technology and its scope are available here, and the recently completed Department of Defense Report also outlines the numerous critical sues within this specific sector.

8) **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

ACC supports MPCA proposing initial CUU determinations as part of the rulemaking process. This will help create greater market certainty and ensure more of the products Minnesotans rely on for daily life can remain accessible.

9) **Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.**

Some CUU determinations will require MPCA to determine whether reasonably available alternatives exist. These comments outline important considerations that need to be part of such analysis. The basis for such determinations must be consistent, fair, transparent, and well-defined. MPCA should propose objective criteria for determining when alternatives are or are not "reasonably available," taking into consideration factors such as performance, safety, total cost of ownership, and reduced potential for risk to human health or the environment when compared to products or product components made with alternatives. See the above comments regarding other key considerations for evaluating uses.

ACC strongly supports the use of sound scientific principles during any rulemaking that impacts chemistry in commerce, and we stand ready to work with the MPCA during this process. Thank you for the opportunity to provide comments during this pre-rulemaking comment period. Should you have any questions or concerns, please reach out to Abbey Linsk by email at abbey_linsk@americanchemistry.com.

Sincerely,

____

AmericanCoatings ASSOCIATION℠

March 1, 2024

Katrina Kessler, Commissioner
Minnesota Pollution Control Agency
520 Lafayette Road North,
St. Paul, Minnesota 55155-4194

Re: MN PFAS in Products, Currently Unavoidable Use Rule
Submitted to the Office of Administrative Hearings online at:
https://minnesotaoah.granicusideas.com/
Submitted prior to 4:30 p.m. Eastern

Dear Commissioner Kessler:

The American Coatings Association ("ACA")[1] appreciates the opportunity to provide comment regarding currently unavoidable uses under Minnesota's PFAS in Products Currently Unavoidable Use Rule. The Association's membership represents 90% of the U.S. paint and coatings industry, including downstream users of chemicals who manufacture end-use formulated products such as paint, coatings, sealants and adhesives. ACA appreciates the significant challenges the agency faces in implementing Maine's PFAS in Products Law, and we appreciate DEP's willingness to engage with stakeholders during this process. ACA is commenting in response to DEP's request for information towards developing criteria for "currently unavoidable use."

Minnesota's Products Containing PFAS Statute (Ch. 60, Art. 3, Sec. 21 [Minnesota Statutes Ch. 116.943]) defines, "currently unavoidable use" as:

> "Currently unavoidable use" means a use of PFAS that the commissioner has determined by rule under this section to be *essential for health, safety, or the functioning of society* and for which *alternatives are not reasonably available.*

---

[1] ACA is a voluntary, non-profit trade association working to advance the needs of the paint and coatings industry and the professionals who work in it. The organization represents paint and coatings manufacturers, raw materials suppliers, distributors, and technical professionals. ACA serves as an advocate and ally for members on legislative, regulatory and judicial issues, and provides forums for the advancement and promotion of the industry through educational and professional development services. ACA's membership represents over 90 percent of the total domestic production of paints and coatings in the country.

MPCA seeks comment regarding the two elements of "currently unavoidable use," as it effects: 1) essentiality of PFAS; and 2) reasonably available alternatives.

ACA welcomes the opportunity to provide comment on this matter. As a general observation, use or manufacture of paint, coatings, sealants or adhesives is not the cause of PFAS contamination in the State of Minnesota. As described below, these products provide essential benefits by facilitating functionality of critical infrastructure, water delivery systems, specialized industrial uses, buildings, equipment, medical devices, etc. PFAS contamination in the state is caused by mishandling of PFAS, including improper disposal at manufacturing sites and discharges of PFAS-containing firefighting foam, often occurring decades ago. PFAS, however, can be used safely in our products without the effects associated with mishandling of PFAS.

ACA and its members respectfully submit the following comment addressing "currently unavoidable use" criteria:

I. Criteria for essentiality of PFAS

ACA suggests that Minnesota harmonize approach to currently unavoidable use of PFAS with Maine, where currently unavoidable uses are products determined to *be essential for health, safety or the functioning of society*. Maine DEP further describes "essential for health, safety and functioning of society" as:

> Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction.[2]

Federal agencies have also recognized products used in construction as essential to the functioning of society. During the COVID-19 pandemic, the U.S. Department of Homeland Security, Cybersecurity & Infrastructure Security Agency, worked with other agencies to issue a definitive federal list of essential workers by industry sector. The federal government deemed manufacture of building materials as an essential industry, recognizing "painting and coating" as an essential function within this industry sector. Agencies recognized manufacture and commercial operations related to all building materials as essential, with "paintings and coatings" as one example. Building sector products also typically include sealants and adhesives.[3]

---

[2] See Maine Department of Environmental Protection request for proposals on currently unavoidable uses in products, available online at: https://www.maine.gov/dep/spills/topics/pfas/PFAS-products/cuu.html

[3] DOH, CISA, with other federal agencies, *Ensuring Essential Critical Infrastructure Workers Have the Ability to Work Safely*, p. 21-22, v. 4.1 (Aug. 5, 2021), designating all building materials and workers facilitating manufacture and commercial operations of building materials, including but not limited to "painting and coatings" as essential. Available online at: https://www.cisa.gov/sites/default/files/publications/essential_critical_infrastructure_workforce-guidance_v4.1_508.pdf

When considering essentiality, MPCA should also consider the benefits of specialized industrial uses of PFAS. Specialty industrial coatings containing fluoropolymers are critical to manufacturing and machinery, national defense, energy infrastructure, mass transport and transportation infrastructure. Specialized industrial coatings applications typically do not cause contamination under normal use. Additional information is included in Section III below, in response to MPCA's Question No. 7 from its Request for Comment, requesting information about products.

II. Criteria for Reasonably Available Alternatives

MPCA has requested comment about criteria for reasonably available alternatives and whether criteria should include consideration of costs. ACA suggests that reasonably available alternatives must meet criteria for 1) environmental and health effects associated with substitution; 2) reasonable costs of substitution; and 3) technical feasibility of alternatives, including performance characteristics and availability of supply.

MPCA must consider environmental and health effects of each potential substitute with characteristics of the individual PFAS chemistry being phased out. Since PFAS encompasses thousands of fluorinated chemistries with varying toxicological profiles, substitution comes with a high risk of replacing a benign fluorinated chemical with a substitute of potentially unknown or greater hazard. Product manufacturers should be allowed to submit relevant information to MPCA regarding factors. MPCA must make a case-by-case determination.

MPCA must also consider cost of substitution. ACA and its members anticipate significant costs associated with developing viable substitutes in coatings used across a variety of demanding conditions, such as pipelines, defense equipment and infrastructure, bridges, buildings, etc. In many instances, "drop-in" substitutes are not available for high-performance coatings that rely on fluorinated chemistries for performance characteristics. As such, costs will be associated with R&D and product development. Efficacy of substitution must also be factored into a cost analysis. A less effective coating results in greater costs over time from more frequent coating. An OECD market study considering non-PFAS coatings for construction and critical infrastructure concludes that coatings without PFAS are not as durable, requiring more frequent repainting, increasing costs.[4]

ACA does not recommend establishing a single threshold cut-off for unreasonable cost increases vs. reasonable cost increases. ACA recommends MPCA make a case-by-case determination based on overall potential costs considered with changes to performance and any health and environmental effects of substitution.

---

[4] See *Alternatives in Coatings, Paints and Varnishes (CPVs) (Report on the Commercial Availability and Current Uses,* available online at: https://www.oecd.org/chemicalsafety/portal-perfluorinated-chemicals/per-and-polyfluoroalkyl-substances-alternatives-in-coatings-paints-varnishes.pdf).

MPCA's consideration of technical feasibility of alternatives, including performance and availability of supply, is critical to implementation of the law. When dealing with other (non-PFAS) chemical ingredients, ACA members have faced situations where state regulators identify an alternative raw material that is not readily available on the market and/or does not perform in the same manner. In effect, where a regulation intended to phase out a potentially hazardous chemical, state implementation would have functioned as a broad product ban affecting critical industry sectors.

III. ACA responses to questions posed by MPCA

In developing the currently unavoidable use rule, the MPCA would appreciate comments on the following questions. ACA's responses are included below:

1) Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

   ACA Response: ACA encourages recognizing the essentiality of certain product categories by referencing critical industries recognized by federal agencies and the definition of essentiality in the State of Maine, while also considering specialized industrial coatings. See Section I above.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

   ACA Response: Consideration of costs, technical feasibility and environmental and health effects of substitution are critical considerations when determining if a substitute is "reasonably available." Cost thresholds must be determined on a case-by-case basis. Please see Section II above for additional discussion.

3) Should unique considerations be made for small businesses with regards to economic feasibility?

   ACA Response: Yes, small businesses often do not have the compliance resources, including resources to identify alternatives, reformulate products and to manufacture using a more expensive raw material, assuming one is available. ACA recommends incorporating small business considerations into assessment of availability of substitutes.

4) What criteria should be used to determine the safety of potential PFAS alternatives?

   MPCA must consider both hazard characteristics and risk profile of alternatives as compared to the PFAS chemistry currently in use. When considering PFAS, EPA has typically referenced its PBT (persistent, bioaccumulative and toxic) criteria. MPCA can also consider hazards as identified in OSHA's Hazard Communication System at 29 CFR 1910.1200. A substitute can also affect risk associated with coating application. In cases where a substitute renders a coating less effective, a substitute can cause additional risk due to increased usage from more frequent application, possibly in greater quantities. This can result in greater exposure to paint applicators and disposal of waste materials.

Another consideration is the impact on safety caused by substitution in a coating or other construction product that has a proven track record of high performance, enhancing durability and preventing corrosion of critical infrastructure, buildings, industrial parts, machinery, pipelines, water delivery systems, medical devices, etc. Substitution can detract from safety of a product or infrastructure due to increased corrosion or other changes to product functionality. In challenging outdoor environments like those encountered in Minnesota, this consideration is particularly critical. Another example is the critical function of intumescent coatings applied to buildings and other infrastructure designed to delay or stop fires from spreading. These coatings perform a critical safety function by allowing additional time for emergency personnel to respond. When considering the safety function of paints, coatings, sealants and adhesives, MPCA should further note that these products are not associated with PFAS contamination in the State.

5. How long should PFAS currently unavoidable use designations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

   ACA Response: This will vary depending on the essentiality of the type of PFAS being substituted. In the coatings industry, certain high-performance, specialty coatings have no available substitute, and substitution would cause environmental effects. In other uses, coatings manufacturers may be able to reformulate within 10 years.

   Reformulation may include identification of substitutes and/or developing replacement technologies requiring overall product reformulation. Industry is currently working towards this end, but this is a time-consuming process requiring research and development, efficacy testing that includes evaluation of government and other client specifications, evaluation of environmental and health effects and risk mitigation strategies and time for EPA's approval process. EPA's TSCA (*Toxic Substances Control Act*) review process alone can take several years, often resulting in indefinite delays. ACA would welcome the opportunity to discuss identification of new technologies and the process for phasing out PFAS in more detail with MPCA.

6. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

   ACA Response: Currently unavoidable use determinations should be made in consultation with product manufacturers. ACA recommends an application process where a product manufacturer would address criteria for essentiality and reasonably available alternatives. ACA further recommends MPCA allow meetings with MPCA staff and the product manufacturer to discuss and clarify application and considerations. ACA further recommends providing a written determination explaining MPCA's decision and application of currently unavoidable use criteria. The stakeholder process should be limited to the product manufacturer, since the product manufacturer is best leveraged to describe technical specifications related to the product, potential environmental and/or health impacts, current risk mitigation strategies during product use, etc.

Opening the process to general stakeholders is likely to flood MPCA with generic information related to uses and hazards of PFAS already known to the agency or readily accessible in the public domain and/or information that is not narrowly tailored to the chemical or specific use at issue. This could include information based on inappropriate surrogate substances, speculative data and/or data incorporating modeling methods based on inappropriate assumptions.

Considering the potential for error, any open stakeholder process should be accompanied by a subsequent opportunity for a chemical supplier, manufacturer and end-use product manufacturer to address concerns and provide additional data. This would also provide a more complete record for later review by MPCA or other judicial bodies. To that end, MPCA's decision process should include both an administrative and judicial appeals process.

7. In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

ACA Response: ACA encourages a general exemption for paint, coatings, sealants and adhesives manufactured with fluoropolymers. Fluoropolymer resins perform an important role in specialty industrial coatings that are critical to manufacturing and machinery, national defense, energy infrastructure, mass transport and transportation infrastructure.

Adhesives and sealants that incorporate trace amounts of PFAS are used in specialized applications including construction adhesives for residential waterproofing, high performance industrial gaskets sealants, mold release agents in manufacturing and specialized high performance silicone sealants. Use of these products is not associated with contamination in the State of Minnesota. They are also critical to preventing deterioration on a variety of substrates in a challenging environments such as Minnesota.

Fluoropolymer binders are essential for providing the kind of durability, safety, and sustainability that permit long lifespan protective coatings for critical infrastructure such as bridges, buildings, and other structures, required to meet performance standards and specifications. Fluoropolymers are recognized by several regulators as being chemically stable, non-toxic, non-bioavailable, non-water soluble and non-mobile. While noting that MPCA is not seeking complete information at this time, ACA will provide additional references and information when MPCA has defined criteria and is prepared to consider products for a currently unavoidable use designation.

Briefly, we note one reference from the Department of Defense, *Report of Per and Polyfluoroalkyl Substance Uses* (Aug. 2023)[5], providing additional information at p. 13:

> Fluoropolymers are used in resins for specialty high-temperature or weather-/UV-resistant composites due to their temperature-, pressure-, wear-, and chemical-resistance properties. Fluoropolymers are also used in high cleanable, high weathering and chemical resistant coatings for military assets. Many aircraft topcoats contain fluoropolymer resins due to their UV and chemical resistance properties. PFAS are not actually in the coatings themselves but are used in fluoropolymer resin manufacturing. Moving to alternatives in under 10 years may require a return to previous methods of parts construction which produced shorter life and higher weight composites with lower performance characteristics.

ACA would also seek a general exemption for paint, coatings, sealants and adhesives incorporating solvents with a single fluorinated carbon atom. Such solvents are used to manufacture low-VOC emitting paints, and they are not associated with contamination.

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

   ACA Response: ACA supports early decision-making for unavoidable use. However, ACA does not support a determination prior to finalizing criteria. At the proposal stage, criteria is subject to changes that could result in an unfair advantage to companies, if MPCA makes a determination based on proposed, rather than final criteria. ACA encourages MPCA to consider unavoidable use determinations while finalizing criteria to ensure consistent application and a rapid determination of unavoidable use shortly after final publication of criteria.

9) Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination

   ACA Response: See Sections I & II above.

IV. Conclusion

ACA encourages developing a clear and consistent understanding of risk posed by PFAS in products. To that end, ACA encourages MPCA to harmonize its approach to construction products with existing designations developed by Maine and federal agencies, while further developing detailed criteria to evaluate availability of alternatives and the effects of

---

[5] *Report of Per and Polyfluoroalkyl Substance Uses*, p. 13 (Aug. 2023), available online at: [Report on Critical Per- and Polyfluoroalkyl Substance Uses (osd.mil)]

substitution. MPCA should also further consider essentiality of specialized industrial applications used in critical machinery, pipelines, water delivery systems, etc. ACA has submitted similar comment to the State of Maine.

ACA also encourages MPCA to develop a process so companies can apply for a “currently avoidable use” designation on a rolling basis, past the reporting deadline. This flexibility will allow companies to complete analysis of its products, use of PFAS substances and potential for substitution.

ACA appreciates the opportunity to submit this comment. Please let me know if I can provide any additional information.

Sincerely,

Riaz Zaman

Consumer Technology Association™ ITI

March 1, 2024

Katrina Kessler
Commissioner
Minnesota Pollution Control Agency
520 Lafayette Road North
St. Paul, Minnesota 55155

Re: Consumer Technology Association and Information Technology Industry Council Comments on Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing PFAS

Dear Commissioner Kessler:

On behalf of the Consumer Technology Association (CTA)[1] and the Information Technology Industry Council (ITI),[2] we respectfully submit these comments on the Minnesota Pollution Control Agency's (MPCA) planned new rules governing currently unavoidable use (CUU) determinations about products containing per-and polyfluoroalkyl substances (PFAS).

Minnesota Statutes Section 116.943[3] restricts the sale of products containing intentionally added PFAS beginning January 1, 2032, unless MPCA determines by rule that that use of PFAS is a currently unavoidable use. Certain uses of PFAS in electrical and electronic devices are essential to the health, safety, and functioning of society and do not have available alternatives. We respectfully ask that MPCA through its rulemaking ensure that the essential commercial uses of PFAS in electric and electronic products are maintained.

CTA previously submitted comments[4] on a separate MPCA rulemaking (the Reporting Rule) to implement Section 116.943, subdivision 2, which requires reporting on intentionally added PFAS in products by January 1, 2026. We reiterate our request in those comments that the MPCA grant a reporting deadline extension for the electronics sector and provide clarity on the substance of reporting.

Our comments below are organized around the questions MPCA solicited feedback on regarding CUU determinations rulemaking:

[1] CTA is North America's largest technology trade association. Our members are the world's leading innovators – from startups to global brands – helping support more than 18 million American jobs.
[2] The Information Technology Industry Council (ITI) is the premier advocacy and policy organization for the world's leading innovation companies. ITI navigates the constantly changing relationships between policymakers, companies, and non-governmental organizations to promote creative policy solutions that advance the development and deployment of technology and the spread of digitization around the world.
[3] https://www.revisor.mn.gov/statutes/cite/116.943
[4] https://www.pca.state.mn.us/sites/default/files/c-pfas-rule1-02.pdf

1. Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?

Criteria should be clearly defined for "essential for health, safety, or the functioning of society." This criteria should not rely on narrow, ambiguous, or subjective definitions that could lead to arbitrary or potentially harmful outcomes. The MPCA CUU rule should establish criteria for each of the three terms within "health, safety, and the functioning of society." Industry will rely heavily on these definitions, so it is essential to have regulatory certainty on the meaning of these terms.

We encourage MPCA to engage with the Maine Department of Environmental Protection in their development of definitions and criteria. We hope to avoid different standards in different states resulting in a costly patchwork. In their rulemaking last year, Maine DEP proposed the following definition[5]:

> "Essential for Health, Safety or the Functioning of Society" means products or product components that if unavailable would result in a significant increase in negative healthcare outcomes, an inability to mitigate significant risks to human health or the environment, or significantly interrupt the daily functions on which society relies. Products or product components that are Essential for Health, Safety or the Functioning of Society include those that are required by federal or state laws and regulations. Essential for the Functioning of Society includes but is not limited to climate mitigation, critical infrastructure, delivery of medicine, lifesaving equipment, public transport, and construction."

While we support harmonization across states, CTA did have some concerns with this definition. In CTA's comments to DEP, we said[6]:

> The last sentence of this definition lists out a series of examples for what is considered essential for the health, safety, or the functioning of society. We are concerned that this list unnecessarily limits the definition, reducing DEP's future flexibility in granting exemptions for necessary products. We note that there are numerous other vital categories such as communication, food production, social interaction, recreation, education, law enforcement, research and development, energy production, and countless others that are not included within this list of examples. We ask that DEP not limit its future determinations on this issue and make clear that this term can be interpreted to encompass a wider range of potential needs.

Additionally, CUU determinations should not be only determined on a finished-products level but should be established based on the specific use of PFAS instead. Limiting CUU determinations to finished products would likely result in Minnesota prematurely deciding that some products have currently unavoidable uses while missing others. Any CUU determination should not only apply to the end product itself, but to each of the products and processes in the supply chain that are necessary to produce that product. Without this, a determination could be worthless or at least undermined given that it is not possible to produce the end product without these upstream products and processes.

6 https://www.maine.gov/dep/ftp/temp/PFAS-in-Products/comments%20on%20public%20notice%2002-14-2023/CTA_Comment%20on%20Chapter%2090_%20Products%20Containing%20PFAS.pdf

The European Union has invested significant technical resources in defining the essential use concept and associated criteria to help phase out PFAS chemicals. We recommend MPCA also consider the results of this effort in defining criteria for determining "essential for health, safety, and the functioning of society."

2. Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

Costs must be considered in the definition of whether an alternative is "reasonably available." Cost is a reflection of an alternative's actual commercial availability. The cost threshold cannot be set with an arbitrary threshold but instead should be defined with flexibility.

MPCA should conduct economic analyses to determine whether alternatives are reasonably available. A significant increase in cost and waste is anticipated due to the R&D involved in manufacturing products using alternatives, accompanied by a lower production in products in general. This would significantly impact certain businesses, and at this time there is no guarantee that alternatives are available for all PFAS uses in the tech sector. Products with PFAS alternatives should also be able to obtain the same quality certifications, satisfy customer standards, and evaluations.

For an alternative to be "reasonably available," it should not result in a decrease in availability, performance, life expectancy, or durability of the product or the supply chain production activities associated with that product. A reasonably available alternative should not result in a significant increase in manufacturing, design, testing, capital investment, or other costs for the product or for the supply chain production activities associated with that product. The definition for "reasonably available" alternative should also factor in that an alternative should not result in increased risks to human health or the environment compared to intentionally added PFAS.

Products such as complex electric and electronic products do not exist in a vacuum; instead, these products sit in various stages of supply chains and the evaluation of an alternative must include how the alternative may affect other parts of the chain. The evaluation of costs should consider not only the cost of the particular alternative, but the cost of the whole project of designing and implementing that alternative. This includes an evaluation of redesign and replacement costs, how the costs of identified alternatives would vary by product category, and the changes that may be required to processes, equipment, labor forces, and raw material sourcing.

The risks of alternatives must be assessed from a life-cycle approach and avoid regrettable substitutions. Regrettable substitution occurs not only from "an alternative that may actually pose similar or higher chemical risks, but also the substitution by alternatives that may be unsustainable from a lifecycle (or footprint) perspective, taking into account energy consumption, sourcing resource efficiency or may lead to loss of performance and/or decreased life expectancy of the product." This is in line with Organisation for Economic Co-Operation and Development (OECD) guidance: Substitution planning involves an evaluation of safer alternatives from a comparative hazard and exposure perspective, as well as "a broader set of environmental, social, and economic factors . . . includ[ing] 'upstream' and 'downstream' chemical or product impacts, resource depletion, circularity, energy use, climate change potential, environmental justice considerations, and worker and community health and well-being." [7] The MPCA should heed OECD's direction in crafting the CUU Rule.

4. What criteria should be used to determine the safety of potential PFAS alternatives?
Determining the safety of potential PFAS alternatives is not part of the statutory requirements of a CUU determination. However, we believe that safety determinations may come into play in the evaluation of whether a PFAS use has a reasonably available alternative. In Question 2 above, we suggest that MPCA should not consider a PFAS alternative as "reasonably available" if it would lead to an increased risk to health or safety. Safety must be assessed under a risk-based framework and lifecycle approach. MPCA would also have to conduct thorough assessments of the risk associated with the PFAS an alternative would be replacing in order to properly compare the relative safety of an alternative.

5. How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided? Should significant changes in available information about alternatives trigger a re-evaluation?
MPCA should clearly state how long CUU determinations are effective when it creates its CUU rule. Given that the estimates for finding and implementing PFAS alternatives for many uses in the electronics sector may range from 5-12 years,[8] we recommend that MPCA grant CUU determinations for the electronics sector for 12 years. At minimum, all products given a CUU determination should be for at least 5 years with a possibility of renewals. MPCA will likely receive requests for CUU determinations for thousands of products and it would be a large and ongoing expense for MPCA to continually run, and for manufacturers to navigate, such a technical and time-consuming exercise.

6. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?
Since Maine has a similar law and its Department of Environmental Protection is already undergoing a similar CUU determination process, we encourage MPCA to coordinate with the Maine DEP to align definitions of CUU and to create an approach that allows manufacturers to submit CUU requests that can apply to multiple jurisdictions. We also ask that MPCA grant CUU determinations for products which have been granted CUU determinations in other states.

[7] OECD, Guidance on Key Considerations for the Identification and Selection of Safer Chemical Alternatives (2021), https://www.oecd.org/chemicalsafety/risk-management/guidance-on-key-considerations-for-the-identification-and-selection-of-safer-chemical-alternatives.pdf

[8] Attachment titled "DIGITALEUROPE - uPFAS use-specific derogation requests electronics_September 2023"

The MPCA should encourage the option for CUU determination requests to be submitted by groups of manufacturers or trade groups with comparable use cases of specific PFAS or categories of PFAS. This will allow manufacturers to pool resources in requesting determinations, and it will ease the reviewing burden on the MPCA by preventing the submittal of duplicative requests. Requesting determinations as a group is also consistent with a recent request for proposals on CUU determinations announced by Maine DEP.

As part of the determination process, the MPCA must adopt a well-defined CBI framework for any information that manufacturers must include in their requests in order to protect valuable intellectual property that may otherwise be jeopardized. The electronics sector treats the chemical composition of materials, as well as production and sales volume data, as proprietary information that is carefully protected and of significant commercial value. Any CUU Rule must therefore contain explicit language explaining how manufacturers may provide CBI as part of their requests in a generic/sanitized manner, how MPCA will evaluate CBI claims, and how such CBI will be stored and ultimately protected from unlawful disclosure to third parties.

MPCA should be cognizant of the fact that upstream suppliers may be reluctant to provide manufacturers with specific information about PFAS used in products and components. Upstream suppliers may claim that the use of PFAS are essential but not provide additional details due to confidentiality concerns. Therefore, supplier statements should be allowed to be submitted to substantiate a manufacturer's request. If MPCA insists on obtaining data from upstream suppliers, it should set up a system that would allow suppliers to provide information directly to MPCA, though we recognize this could create procedural hurdles as well.

Stakeholders should not be able to request that a PFAS use not be determined to be currently unavoidable. Especially given CBI considerations, such requests are unlikely to have a direct understanding of the product at issue. Requests that a PFAS use not be determined to be currently unavoidable would be unnecessary anyway, since non-manufacturer stakeholders would have an opportunity to submit public comments on any proposed MPCA rulemaking designating a use as currently unavoidable.

The MPCA should be required to timely respond to requests before the compliance deadline of January 1, 2032. If the agency fails to timely respond to a request, that should function as an automatic determination for as long as the MPCA is late. This is critical to prevent a situation where a manufacturer is forced make a product unavailable to Minnesotans because the MPCA was delayed in making a determination. It is also consistent with exemption protocols under other chemical regulatory regimes, such as RoHS Article 5 where an existing exemption to the directive's restrictions remains valid until a decision on a renewed exemption application is made by the European Commission. The CUU Rule should employ a similar logic to account for potential delays in determination decisions.

7. In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present

your full argument and supporting information for a possible currently unavoidable uses determination.
To streamline requests from manufacturers in the electronics industry, MPCA should grant a CUU determination for all PFAS uses in components of electric and electronic products. MPCA should expect a very large number of requests, many of which will be from manufacturers of products which contain electric and electronic components. As an example, the European Chemicals Agency (ECHA) received over 5,600 comments on its PFAS restriction proposal under REACH, many of which were from stakeholders in our industry.[9]

Electric and electronic products are essential for health, safety, and the functioning of society for countless reasons. These products make modern life possible, and they include but are not limited to computers, phones, tablets, printers, and the equipment used to support such devices such as cables, cords, batteries, and data enter equipment. Alternatives for intentionally added PFAS are not reasonably available for many internal components of electric and electronic products. It is anticipated to take many years just to identify PFAS in these components, let alone implement alternatives. This identification process will involve significant costs since a single electric or electronic product can have thousands of internal components which are sourced from numerous suppliers around the world.

While a CUU determination for components of electric and electronic products is justified as explained above, the determination should at the very least cover the PFAS uses with requested derogations in DigitalEurope's comments[10] to ECHA concerning the PFAS restriction proposal under REACH. These uses include:

- Printer related uses (e.g., printheads, sealing materials, valves and pumps in inkjet printers, uses of PFAS in factories where inks are manufactured, electrophotographic printers, paper guiding parts);
- Lithium-ion batteries (e.g., cathode and separator binder material for lithium-ion battery cells);
- Coating materials (e.g., coating and paint for enhanced abrasion resistance in electrical and electronic equipment, coating in connectors, optical isolation layers for display applications);
- Anti-dripping agents (to help prevent propagation of flames in case of fire);
- Cables and connectors (e.g., DC cable insulation, coaxial cables and discrete cable insulations and jackets, connector jackets);
- Capacitors;
- Grease and lubricants (e.g., grease/lubricants on mechanical parts in electrical and electronic equipment, lubricants in connectors);
- Cooling in data centers;
- Mechanical applications for electric and electronic equipment (e.g., to meet tribology requirements such as for friction, wear, and lubrication);
- Ingress protection vents for communication devices; and

[10] Attachment titled "DIGITALEUROPE - uPFAS use-specific derogation requests electronics_September 2023"

- Mobile telecommunication network infrastructure equipment.

To describe how PFAS are used for the functioning of electronics and what alternatives are reasonably available, we are attaching and has listed below notable resources and submissions created by other electronics trade associations from the past year.[11][12][13][14] These documents outline critical uses for PFAS in the electronics sector – essential functions in semiconductors, batteries, capacitors, coatings, and many other electronic components. These documents also outline where there is a lack of proven, available alternatives for many of these uses. While viable alternatives may someday become available for the electronics industry, it may take several years for them to be found, tested, and implemented.

[15] https://echa.europa.eu/restrictions-under-consideration/-/substance-rev/72301/term

In addition to the materials referenced above, CTA would also like to specifically direct MPCA's attention to the JP4EE Input to Submission Requirements on CUUs which are submitted to Maine DEP this week. They have a thorough examination of this issue regarding the electronics sector.

Additionally, PFAS are currently undergoing regulatory review by several agencies at the federal government. The U.S. Department of Defense recently released a report that identifies several ongoing critical PFAS uses and also states that due to the difficulty of identifying PFAS in supply chains "the information presented represents a fraction of the mission critical PFAS uses due to a lack of knowledge of the complete chemical composition" in equipment.[16]

CTA and ITI have also engaged with the U.S. Environmental Protection Agency (EPA) during the TSCA Section 8(a)(7) Reporting and Recordkeeping Requirements for Perfluoroalkyl and Polyfluoroalkyl Substances (PFAS Reporting Rule) by submitting several rounds of comments.[17][18] Additionally, we submitted comments to the U.S. Consumer Product Safety Commission (CPSC) for their "Notice of availability and request for information on Per- and Polyfluoroalkyl Substances (PFAS) in Consumer Products."[19]

8. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

We strongly recommend MPCA make some initial determinations as to what uses of PFAS constitute "currently unavoidable use." In our response to Question 7 above, we outline how electric and electronic products have uses for PFAS which do not currently have available alternatives. The electronics sector should be granted a broad CUU determination.

The investigation into the use of PFAS and preparation needed to submit for the reporting portion of the law is anticipated to take a significant amount of time and resources. If initial determinations can be made, that would alleviate some of the burden on the industry to find alternatives that may not exist and allow the industry to focus on complying with the reporting and prohibition requirements where there are feasible alternatives.

9. Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.

When MPCA is considering whether an alternative to PFAS is available, we encourage them to examine the work conducted by the Washington State Department of Ecology under their

DIGITALEUROPE

European Chemicals Agency consultation:

Per- and polyfluoroalkyl substances (PFAS) restriction proposal

– DIGITALEUROPE use-specific derogation requests –

Submitted: 22 September 2023

DIGITALEUROPE
Rue de la Science, 14A, B-1040 Brussels
T.+32 (0) 2 609 53 10 / www.digitaleurope.org / @DIGITALEUROPE
EU Transparency Register: 64270747023-20

Table of Contents

Introduction

Shared goal of a safe transition toward PFAS-free electronics

The digital industry has been, and continues to be, committed to improving the environmental performance and safety of all products placed on the market.

DIGITALEUROPE members support moving towards PFAS-free electronics and are actively investigating the uses of PFAS and the availability of alternatives in an effort to substitute PFAS wherever possible in a timely fashion.

It will however take time for the digital and electronics industries to replace PFAS in their products and processes in a safe, responsible manner. There are considerable challenges related to full implementation of PFAS substitution plans in this sector, such as accurately cataloguing PFAS uses across thousands of component articles, identifying and developing non-PFAS alternatives that can meet the safety and performance needs for each application, and the time needed for material qualification, component and full product re-design, testing and certification. In many cases, there are currently no technically viable alternatives known, and they will need to be developed, qualified and made commercially available.

DIGITALEUROPE contributions to the public consultation

In our first contribution[1] to this public consultation, DIGITALEUROPE has highlighted the need for derogations for:

- **Spare parts for repair of finished consumer electronic equipment already placed on the market,**
- **Spare parts for repair of finished professional business-to-business electronic equipment already placed on the market,**
- **Re-supply of articles already placed on the market (pre-owned products)**

In our second contribution[2] DIGITALEUROPE has explained the need for a **general five-year derogation for electronics (in addition to the generally applicable 18-month transition period called for in the proposal)** for electronics suppliers and manufacturers to gather complete, accurate data and to complete the redesign, testing, certification, and production.

For a number of uses of PFAS in electronics, very specific information is already available on why PFAS is used, which substances are used and the feasibility of several alternatives. In the current document an overview is presented of those specific uses for which, in our view, time-limited derogations are required.

Depending on the availability of alternatives and their maturity, a longer (13.5-year) or shorter (6.5-year) derogation is requested. For several uses we request a 6.5-year derogation (5 years on top of the 18-month transition period), these derogations will not be needed if a general 6.5-year derogation is granted for all electronic equipment (as requested in our second contribution).

[1] RCOM 5927, submitted on 28 June 2023
[2] Submitted concurrently with this document

Detailed information is provided to allow the ECHA scientific committees to evaluate these derogation requests. If for any reason more information is needed, we invite the committees to contact us.

Contributions from other sector associations

As also highlighted in our previous contribution to the public consultation, although the total amount (annual tonnage) of PFAS in electronics is very small, the number of different uses is very large. The current document does not intend to provide a complete overview of all derogations that are required in order to secure the availability of electronic devices. Electronic devices contain many components that can have long supply chains. PFAS can be required by other actors in the supply chain. If these uses are critical for their applications, they are also critical for the entire electronics industry. For example, the entire electronics sector depends fundamentally on the availability of cutting-edge semiconductor technology. The semiconductor manufacturing sector generally sits upstream in DIGITALEUROPE members' supply chains. Our understanding is that PFAS uses are irreplaceable for a number of semiconductor manufacturing-related applications, and that PFAS may be used in (or residues found on) semiconductors as well. We therefore strongly support the detailed assessments and derogation substantiations that we understand will be submitted to ECHA by our partners in the semiconductor value chain[3]. Other sector associations have also submitted derogation requests for other uses. We want to emphasize the need to also provide these derogations.

Impact of the restriction proposal and proportionality

Economic study

If the universal PFAS restriction as proposed by the dossier submitters in the Annex XV report would enter into force unchanged, the impact on the electronics industry would be devastating. There are many uses of PFAS in electronics and as REACH requires each individual article in a complex product to comply, the entire product cannot be sold if only one single element of PFAS cannot be replaced in the product.

A recent study by Ricardo Energy & Environment, commissioned by the European Chemical Industry Council (Cefic), estimated the final economic impact of the PFAS restriction on various sectors.[4] A significant number of DIGITALEUROPE members contributed data to the study. The results clearly demonstrate that the PFAS restriction, should it enter into force in its currently proposed form, would have a devastating impact on the economic performance of the electronics industry in Europe. The annual overall turnover losses for computers, small and large printers, electronic and optical products are estimated at 78% against a 2021 baseline. For electronic components, an 84% turnover loss is estimated.[5] This strongly underlines the need for the derogations requested by DIGITALEUROPE in our contributions.

[5] ibid p. 57-58

Emissions

According to the Annex XV report the emissions to the environment from electronics are less than 1% of all PFAS emissions. Most uses in electronics concern fluoropolymers. Since fluoropolymers do not evaporate, are not water-soluble and are solid, the emission during the use-phase is negligible. Most fluoropolymers are not classified as hazardous according to the EU CLP regulation.

Not granting the derogations that are required to manufacture and sell electronic products would be disproportionate to the low risk of emissions for the environment.

Overview of DIGITALEUROPE use-specific derogation requests

Table 1 presents an overview of all use-specific derogation requests covered in this submission.

Table 1 Overview of DIGITALEUROPE derogation requests

Requested derogation	Requested derogation duration (in addition to the 18-month transition period)
Printer-related uses	
Printheads	12 years
Sealing materials, valves and pumps in inkjet printers	12 years
Factories for ink and printer components	12 years
Electrophotographic printers	12 years
Paper guiding parts	Until 2035
PFAS material in Lithium-ion batteries	
Cathode binder material for Lithium-ion battery cells	12 years
Separator binder materials in Lithium-ion battery cells	5 years
Coating materials	
Anti-fingerprint coating	5 years
Coating and paint for enhanced abrasion resistance in EEE	5 years
Coating in connectors	5 years
Optical isolation layers for display applications	5 years
Anti-dripping agents	12 years
Cables/Connectors	12 years
Capacitors	12 years
Grease & Lubricants	
Grease/lubricants on mechanical parts in EEE	12 years
Lubricant in connectors	12 years
Cooling in data centres	Unlimited
Mechanical Applications	5 years
Ingress Protection Vents for Communication Devices	12 years
Mobile Telecommunication network infrastructure equipment	12 years

1. Printer related uses

In printing equipment and in the manufacturing of inks and toners, PFAS can currently not be replaced in the following applications:

- Print heads
- Sealing materials, valves and pumps in inkjet printers
- Factories for ink and printer components
- Electrophotographic printers
- Paper guiding parts

1.1 Printheads

General summary of the application category

The parts of the nozzle plate of the printhead used in inkjet printers and printing presses produce printed materials at high speed and quality, providing users with printed materials that can be used for documents, photographs, and commercial applications. Taking advantage of the features of digital printing, it contributes to shortening the delivery time and reducing waste such as trial printing, and it continues to develop while mutually complementing conventional analogue printing.

Inkjet printers use PFAS in the parts of the printhead's nozzle plate for ejecting ink for the purpose of developing functions described below.

With the current technology, there is no substitute that can maintain the same quality as PFAS. If PFAS materials cannot be used, a complete redesign of the printing process in the printer is required since the functionality of the printhead is at the heart of the printer. But even after a redesign, the quality of the product will be much worse than current. As a result, there is a risk that the product life will shorten and the environmental impact will increase due to the increase of waste.

There is no substitute at present, so new material development will be necessary, and if the quality equivalent to PFAS cannot be achieved, not only the print head material may need to be changed, but also the unit configuration of the printer body and the control mechanism may need to be redesigned. Because of the required development of new materials and printers including a long-term evaluation, a sufficient exemption period (approximately 12 years) must be set.

The key functionalities provided by PFAS for the relevant use

To provide such an objective at a low cost and with a simple mechanism, PFAS is used in the parts of the print head nozzle plate.

In particular, technological advances in the latest print heads include a decrease in the volume of ink droplets. This serves two purposes. One is to reduce the graininess of the image, which stands out when the droplet size is large. In order to produce high-quality images as required for photography and commercial applications, low graininess is required.

The second purpose is to minimize user costs and the environmental impact of operating inkjet printers. The use of ink can be significantly reduced by efficiently coating the recording media with small ink droplets in high density. This can help reduce the cost of using ink and the CO_2 emissions associated with transportation. And while commercial high-speed printing machines require drying of the ink by evaporation of moisture, the energy required for drying can be significantly reduced to minimize environmental impacts by lowering the droplet volume.

In order to form a print with a minimum amount of ink and with good image quality, the ink needs to land precisely on the medium at a defined location. To make such small droplets of ink to fly stably, it is important that the surface of the nozzle plate is clean and that the nozzle plate does not deform (swell) over a long period of use.

If the surface of the nozzle plate is contaminated, for example, by ink sticking to it, there is a risk that the flight will be bent when ink is ejected from the nozzle plate or that no ink will be jetted at all from that nozzle. Also, even if the nozzle plate swells, the flight angle may change. This results in a bad image quality.

Especially in recent years, the volume of droplets has become smaller. Very small ink droplets are susceptible to contamination of the nozzle plate surface, and the surface must be kept extremely stable.

For this reason, water repellent PFAS materials are used as nozzle plate surface coating to prevent contamination of the nozzle plate surface. PFAS material in the nozzle plate is applied to prevent deformation (swelling) of the nozzles that form the ink channel. Without the use of PFAS materials it is not possible to make the small droplets fly stably in the right direction.

Critical requirements of the nozzle plate coating are- (1) low surface energy & low ink adhesion enables ink to not wet, easy to clean off, no residue left by jetted drop, maintain drool pressure, (2) chemical inertness towards ink, (3) high temp & pressure stability to enable adhesive bonding steps (~ 24 bar, 270 oC) during PH fabrication, (4) ability to be drilled cleanly by lasers yielding crisp & well defined nozzle edges, & (5) Manufacturable (coating on nozzle plate substrate) with tight tolerances.

Information on (lack of) alternatives and supporting arguments

Detailed information on the lack of alternatives can be found in the confidential appendix. It can be concluded that there are no viable alternatives to the use of PFAS for water repellence of the printhead nozzle plate.

Information on required timing on replacement

As mentioned above, there are currently no candidates for alternative materials, and it is necessary to advance the development of materials that achieve PFAS equivalent performance without increasing user cost or environmental impact during operation.

Building on previous research findings, we will continue the investigation for alternative materials. Because it is very difficult to reach the target simply by substituting materials alone, we believe that it is necessary to review the structure and mechanism of inkjet printers/printers, such as the maintenance mechanism of the print head, as well as to simultaneously develop inks to accommodate these changes.

Thus, adding to the scope not only the development of alternative non-PFAS materials but also a redesign of the printing system, we believe that a minimum of 12 years is necessary, approximately 7 years for the development of materials and systems and 5 years for the confirmation of mass production of materials and the evaluation of their deployment in various products.

In case the development of such alternative materials does not go well, we believe that other methods need to be studied in parallel. These studies need to be initiated from scratch, and similarly, a period of about 12 years may be required.

Information on cost of substitution

The costs of substitution are more than 100,000 euro per kg substituted PFAS.

See confidential appendix for more details.

Substance name and tonnage

Perfluoropolyether and combinations of perfluoropolyether with other polymers are used. See confidential appendix for more specific details.

Information on emissions to the environment

Printheads can either be manufactured in the EU or manufactured outside the EU and imported with the printer itself or supplied as spare parts for replacement.

During coating of the nozzle plate, the solution evaporates into a chamber that is exhausted by the building's air handling system. The oven is also vented to the building air handling system. Small amounts of evaporated fluorinated solvent are currently not captured. Unused coating solution is disposed off as hazmat chemical waste.

The print heads are loaded into the printer and consumed. PFAS is a component hat is integrated in/coated on the printhead's nozzle plate, so there is little risk of it being released outside the printer.

Cartridges that have reached the end of their life or run out of ink are collected or disposed of as waste.

Measures to minimise release into the environment

The Electrical and Electronic Waste (WEEE) Directive requires the collection and safe recycling of end-of-life electronic products. When considering recycling, it is important to ensure long-term durability. Alternative materials will not be as durable as PFAS, and it is expected to be difficult to reuse usable parts of recovered print heads.

With the collection of cartridges/printheads and the very low concentration of PFAS in the printhead the emissions to the environment are considered to be very low.

As described above, the use of PFAS in printers is unlikely to significantly increase environmental pollution. The ban on PFAS used in print heads risks generating more waste due to the shorter life time of printers and printer parts.

Proposed derogation

No alternative is available or known. New substances have to be developed. An exemption for a period of 12 years is needed.

The following text is proposed for the exemption:

Paragraph 1 and 2 shall not apply to fluorinated compounds, fluorinated resins and perfluoropolyethers which are PFAS for use in inkjet printer print heads until 13.5 years after EIF

1.2 Sealing materials, valves and pumps in inkjet printers

General summary of the application category

In all inkjet printers the parts that are in direct contact with ink must be resistant to that ink. In small home office printers, the ink system is small and only a few parts in the ink reservoir and in the print head are in direct contact with ink. In larger printers there are more parts with ink contact, for example tubes, pumps, valves etc. PFAS is typically used for parts that must be flexible as well as ink-resistant. Examples of these parts are:

- O-rings: a non-leaking connection between different components of the ink system is of high importance. No ink may leak out of the printer during its lifetime. Proper sealing is provided by flexible rubbers
- Tubing: in small printers, the ink supply is mounted on the printhead. In large printers the ink supply is in a fixed location separated from the moving printhead. Because of the printhead movement, flexible tubing is required
- Pumps and valves: interior parts of pumps and valves are intended to move and must also provide a good sealing to prevent leaking.

These flexible parts are made of plastics or rubbers. Many plastics and rubbers show an interaction with ink. Over time they can become brittle, beak up or dissolve, ultimately leading to breakdown of the printer or even leaking of ink from the printer. Rubbers may swell due to interaction with ink. Swelling leads to deformation of the rubber and can ultimately result in leaking of ink from the printer. Leaking will damage the property of customers with stains that cannot be cleaned again. It can also lead to safety issues because of exposure of customers to hazardous materials. This must be avoided at all times.

Often PFAS plastics and rubbers have to be chosen because of their resistance to ink and other liquids. These other liquids that are handled in a printer include primers, coolants and varnishes.

Alternatives

In general there are two groups of materials that are flexible and resistant to ink during printer life time: polyethylenes and PFAS. Very often a fluorinated substance is the material of choice.

For tubing an inner layer of polyethylene can be used as an alternative. It is expected that it is possible to change the printer design and replace PFAS tubing with a PFAS-free alternative in new printers before the end of the transition period.

For O-rings a rubber material is required. Non-PFAS rubbers include for example EPDM, silicones and NBR. Non-PFAS rubbers have insufficient resistance against important ink ingredients.

One category of inks is the UV-curable ink. It contains acrylates and photo-initiators. After initiation with UV light, a polymerization reaction starts. The acrylates are the monomers and join together in the polymer network resulting in a dry and very robust in layer on the paper or other substrate.

Most rubbers are not resistant to acrylates (acrylic acid esters). Information on the chemical compatibility of different types of rubbers and plastics is widely available on the internet. See footnote[6] for examples. It can be seen that there is some resistance with polyethylene and

[6] https://dutchwatertech.net/en/kenniscentrum/chemical-resistance-epdm/

polyamide and good resistance against acrylates for fluoroplastics. Non-fluorinated rubbers are not compatible with acrylates. Although a single rubber might be resistant to a single acrylate, they are not compatible with the acrylate mixture in UV curable inkjet inks. FKM rubber (a fluorinated rubber) is not even resistant to all acrylates.

Our actual experience in practice confirms the information that non-fluorinated rubbers cannot be used in combination with UV curable inks: either the rubber is deteriorated by the ink or components of the rubber dissolve in the ink and make it unusable. Even standard FKM rubbers are affected by the ink. The more fluorinated FFKM or special grades of (F)FKM like peroxide cured (F)FKM or PTFE coated FKM are the only suitable rubber materials for UV curable inks.

The other main category of inkjet inks, besides UV curable ink, is the aqueous ink. On the paper, this ink is not cured by polymerization but dried by evaporation of water and other solvents. Sometimes the printer jets a primer liquid in combination with these inks. In general the ingredients in these ink are “milder” than those in UV curable inks and more rubber materials are compatible with these inks. However there still are some ink and primer formulations for which only fluorinated rubbers can be used safely. An example can be seen in the confidential appendix.

The test results in the appendix are in line with other tests that have been performed. The non-PFAS EPDM rubbers are suitable for use in combination with several aqueous inkjet systems, but not with all. For some applications in aqueous inkjet only special grades FKM rubbers and FFKM rubbers can be used safely.

Pumps and valves also contain some polymer material. Two metal parts cannot move along each other and at the same time provide a sealing that does not allow the liquid to pass. A polymeric gasket, seal or seat is always used. In diaphragm pumps the diaphragm is made of a flexible material, a polymer. As for O-rings, for UV curable inks and for some aqueous systems only fluorinated rubbers are inert to the ink and can be used in pumps and valves. If a plastic material is used, polyethylene has insufficient mechanical strength to withstand the frequent movement. This makes fluoropolymers like PTFE the only suitable material.

Similar to the situation of O-rings, not all inkjet printers will require PFAS materials for all pumps and valves. In some cases EPDM rubbers can be used or a gear pump can be used instead of a diaphragm pump. Although it leads to a significant increase in cost price, it leaves out the diaphragm. Nevertheless, gear pumps are not compatible with UV curable ink. They break down quickly.

Stop using UV curable inks and move to aqueous inks is also not an option. Both ink systems have their own application range. UV inks provide a better robustness, water resistance and adhesion to non-paper media. For printing books and paper document aqueous ink can be used. For outdoor applications and several non-paper application UV ink cannot be replaced by aqueous ink.

Currently there are no other materials known that can serve as replacement for the PFAS materials in O-rings, valves and pumps. New materials will have to be developed and no quick solution is foreseen. A derogation for 12 years is required with the possibility to extend if no suitable materials have been developed after 12 years.

https://www.fernco.com.au/wp-content/uploads/2022/07/Fernco-Rubber-Chemical-Resistance-Chart-V002JUL22-LR.pdf

Substances and amounts

The substances involved are PTFE, PVDF, FKM and FFKM.

For annual volumes, see appendix.

Emissions

Emissions to the environment are not expected during the lifetime of the article. The are no volatile PFAS components, there is no emission. Only in the waste phase the materials will be discarded. The printers are treated as electronic waste and will be handled and disposed of according to all locally applicable regulations.

Proposed derogation

No alternative is available or known. New substances have to be developed. An exemption for a period of 12 years is needed.

The following text is proposed for the exemption:

By way of derogation, paragraphs 1 and 2 shall not apply to fluoropolymers for use in sealing materials, valves and pumps in inkjet printers until 13.5 years after EIF.

1.3 Factories for ink and printer components

General summary of the application category

Just like in any other chemical factory, there are several uses of PFAS in the factories where inks are manufactured. Those parts of the equipment that come into contact with ink, its ingredients or other chemicals must be resistant to these chemicals. If there is an interaction between the material and the chemical, the material will start swelling, deforming, degrading or dissolving. The result is that the product gets contaminated with the equipment material and even worse, the equipment will start leaking.

For rigid materials, stainless steel is a suitable material. For flexible and moving parts plastics or rubbers must be used. As already described in the section about the use of PFAS in inkjet printers there are only a few materials that are resistant to all inks. For an ink factory the situation is more critical because ingredients are processed in their pure form (instead of only diluted in the ink) and sometimes at elevated temperatures. Only fluorinated materials are resistant against all ink ingredients.

PFAS therefore have to be used for example in:

- Valves (PTFE ball valve seats allow opening and closing of the valve while ensuring non-leaking when it is closed)
- O-rings (used for closure and sealing of lids, connectors etc)
- Diaphragm pumps (the diaphragm is moving and must be flexible)
- Gaskets (rotating parts like the axis of pumps and stirrers)

- Flexible tubing (rigid piping is not possible when equipment parts are moving)

Printers contain several components that require special manufacturing processes. These components include printheads, photoconductor drums or belts, fixation rollers etc. The manufacturing process includes chemical processing using solvents and other liquids. When certain solvents are used and especially at elevated temperatures the only flexible materials resistant to these chemicals are fluoropolymers.

Alternatives

Because of the required flexibility and sealing properties, only plastics and rubbers can be used. These plastics and rubbers must be able to resist the chemicals they are in contact with.

The type of plastic and rubber that can be used depends on the chemical and on the temperature of use. When the medium is water, non-PFAS rubbers can be used for sealing. Examples of non-PFAS materials are: EPDM rubber and silicone rubbers.

As explained in the section about ink handling components in printers, for several applications only fluorinated materials are not affected by ink and ink components. Currently no alternative is known. PFAS materials that are used for this application include

- PTFE (9002-84-0)
- PVDF (24937-79-9)
- FKM
- FFKM

Currently there are no alternatives known. The suppliers of the process equipment and parts do not have suitable PFAS-free parts available. If an alternative has to be developed, first the material has to be developed, then the manufacturer of the equipment has to design equipment using the new materials. When new equipment parts are to be used in existing equipment it usually does not fit in the same way as the old part. To some extend the piping and the connections have to be changed. Considering that there are several thousands of parts with PFAS in a factory (a first count in our ink factory resulted in over 2000 parts; probably still incomplete), it is a significant effort to replace a PFAS-containing part by a future PFAS-free part once the old part fails. So even after PFAS-free equipment parts would become available it will take time to make the factory suitable for using them. Therefore a 12 years exemption is requested, with the possibility to extend the exemption if no alternatives are available yet after 12 years.

Amount

The articles can either be fully made of PFAS or have a PFAS coating. The total PFAS usage in a typical manufacturing site is not exactly known but is estimated to be around 100 kg or a few hundred kg per year. The number of toner and ink manufacturing sites in the EU is limited. The total usage in toner an ink manufacturing is not expected to exceed one or a few tons per year.

Emissions

Since the materials involved are all polymers with high molecular weights, there is no evaporation or emission to the air. When the equipment parts are end of life, they are discarded as waste metal.

Consequences when no exemption is granted

When no exemption is granted there is no more manufacturing of ink and printer components possible in the EU. It will have to move to non-EU countries. This will have a huge impact on the EU economy and will lead to extremely high costs for printer companies to build new factories outside the EU.

Proposed derogation

No alternative is available or known. New substances have to be developed. An exemption for a period of 12 years is needed, with the possibility to extend this exemption if no alternative materials have been found after 12 years.

The following text is proposed for the exemption:

By way of derogation, paragraphs 1 and 2 shall not apply to fluoropolymers for use in factories for ink and printer components until 13.5 years after EIF.

1.4 Electrophotographic printers

General summary of the application category

In electrophotographic printers and copiers, PFAS materials are used in parts that come into contact with toner or are at the core of the printing process and are subjected to high stress such as high temperature or high voltage. These are for example the charge roller, photoconductor (or photoreceptor) drum, intermediate transfer belt (ITB), fuser parts. See the figures below for the location of these parts in the printer. More explanation about the function of a printer can be found in several open sources on the internet.

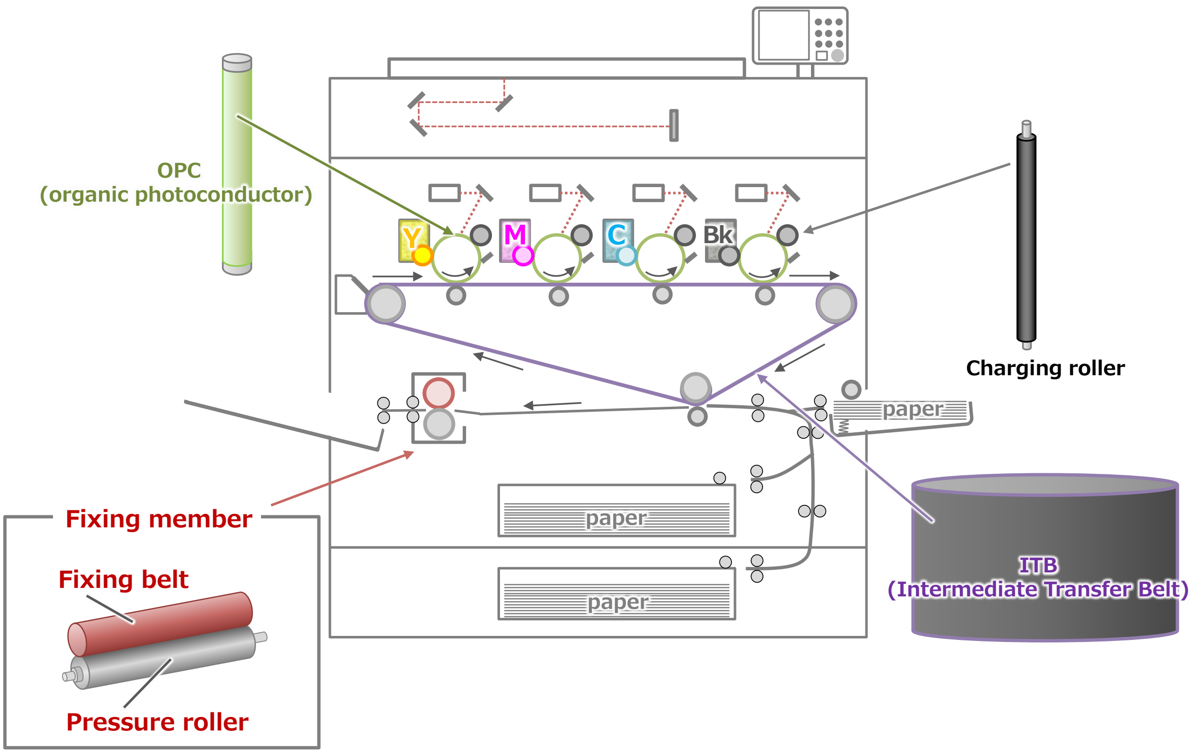

Figure 2 Electrophotographic printer (1)

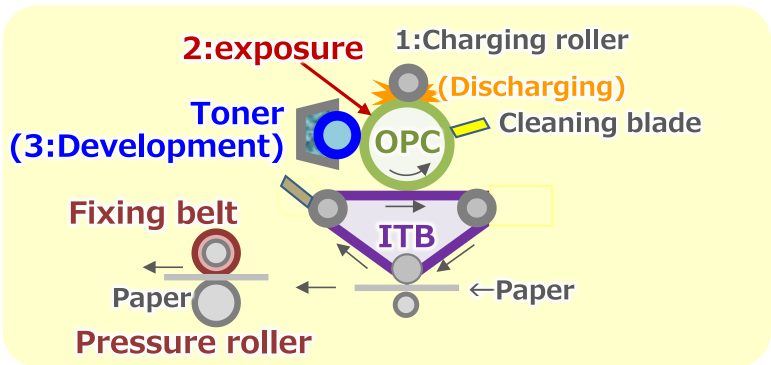

Figure 1 Electrophotographic printer (2)

With the current technology, there is no substitute alternative that can maintain the same quality as PFAS materials, and if PFAS materials become unavailable, the image output becomes impossible in the electrophotographic device. As a result, there is a risk that the product is no longer usable as a printer.

For the charge roller, the photoconductor drum and the ITB the available non-PFAS alternatives have not yet achieved sufficient performance. However, with technological progress the challenges could be overcome in the future. For the fuser parts the alternative components have no prospect of becoming functioning alternatives.

Technical function

The charge roller, photoreceptor drum, intermediate transfer belt (ITB), and fuser parts used in electrophotographic products need to have a good releasability with toner. Toner consists of small particles and in order to avoid contamination of the printing system, it must be possible to release these particles again from the roller, drum, ITB and fuser parts. To improve the releasability with the toner, a PFAS compound is contained as an additive/filler in the surface layer. This PFAS compound also reduces the required torque and reduces the physical wear of the component. It is inert to the solvents used in component manufacturing.

Charge roller, drum and ITB

In the charge roller, photoreceptor drum and ITB, the surface in contact with the toner uses electrostatic force to move the toner. In other words, the toner and parts slide against each other while constantly being exposed to high voltage electrical energy and friction energy. These components must continue to exhibit releasability under severe conditions. Fluoropolymers, which are PFAS, are chemically stable and durable, and can exhibit release properties for long periods even under these harsh conditions. In addition, the latest electrophotographic products tend to use smaller toner for better image quality. This is to reduce the graininess of the image and to reduce the amount of toner used. On the other hand, the smaller the particle size of the toner, the less the release property of the toner, and therefore, the more waste toner remains. Fluoropolymers can reduce the amount of waste toner in the first place, so that they can meet the ever-increasing demand for reducing toner waste. In addition, PFAS compounds in the charge roller, photoconductor drum and ITB also have a friction-reducing effect, which can reduce the amount of wear on these components and reduce the frequency of replacement, thereby contributing to waste reduction. Depending on the customer's usage, it is quite possible that a component that can last from six months to the life of the machine using fluoropolymers, etc. will only last for a few days or months without PFAS.

Fuser parts

The fusing process is a process in which the toner is instantly melted and the melted toner is soaked into the paper fibres to fix the toner on the paper. At this time, the fuser contacts the toner and applies heat (up to approx. 240 °C) and pressure (up to approx. 0.6GPa) to bring the toner into contact with the paper. The toner containing resin or wax melts and penetrates into the paper fibres. At this time, the toner should remain on the surface of the paper but not on the surface of the fixing member. For this reason, it is necessary to have a material that maintains the releasability to the resin under high temperature and high pressure, and whose performance can be obtained stably over a long period of time. In addition, materials are limited in the sliding part with the heater, which is another key part in the fixing process. In the sliding portion between the heater and the fuser belt, the material and grease must be a material that remains highly slidable even at high temperatures up to approx. 270 °C. The fluoropolymers and fluoropolyethers currently in use are chemically stable and have excellent heat resistance, as well as excellent releasability and slidability, and their performance is stable over a long period of time.

Fuser parts: Rollers in high-speed printers

In high-speed printers that have monthly print volumes of several hundreds of thousands up to millions of prints per months, contamination of the fuser system can be a significant problem. Small amounts of additives from the paper can be transferred to the fuser belt during the fusing of the toner. Because of the large printing volume, these small amounts can build up to significant quantities over time. The presence of substances that originate from the paper cannot be influenced by the printer manufacturer. However, in these high-volume printers cleaners are included that clean the fuser belt. Unfortunately, not all substances can be cleaned for 100%. Some substances can migrate to the rollers in the fuser unit (e.g. the pressure roller or one of the rollers inside the fuser belt). When these substances accumulate, they can cause swelling of the outer layer of the rollers, which is made of rubber. This swelling is not evenly distributed along the roller. One part of the roller will get a larger diameter then another part of the roller. This will result in serious printing problems. Examples of these problems are: a cleaner that does not function on the complete width of the belt anymore, speed differences across the fuser belt or temperature differences across the fuser belt. This results in print quality problems or severe pollution of the printer to the extent that the printer will fail.

To prevent the build-up of contamination in the rollers, the outer layer of the rollers is covered with fluoropolymers. Fluoropolymers are resistant to most other chemicals. In this application they are inert to swelling due to contaminants. Fluoropolymers are also resistant to the temperatures of up to 175 °C in these systems. And fluoropolymers are strong enough to withstand the mechanical forces in the system.

Alternatives

No alternative drop-in raw material is known. Requirements for alternatives are constrained by current product portfolio and subsystems. Any change may require customized changes in other materials/subsystems to enable.

For the charge roller, photoconductor drum and intermediate transfer belt (ITB) alternative materials have been investigated. The performance is not sufficient yet, but with further progress in research the challenges could be overcome.

Alternate fillers explored in the past include particle fillers (SiO_2, TiO_2, TiO_2 core with Si shell, hydrophobic silica), which required customized surface treatments to reduce electronic effects. Silica could be a potential option for both photosensitive and non-photosensitive layer applications. The addition of plasticizers or high molecular weight monomers to reduce surface energy and improve cleaning were explored and may enable removal of PFAS, however, reduced part life is likely, and the effect on the electronic performance is unknown. If the same quality as PFAS materials cannot be achieved, it may be necessary not only to change the materials of the above components but also to redesign the unit configuration and control mechanism of the whole electrophotographic machine.

For the fuser parts, there is no expectation that the technical problems with the available alternatives will be overcome. The development of alternatives will have to start from scratch again, as there are currently no alternatives that can play the full role of PFAS. In addition, even when the properties required by the material quality are not achieved, the fundamental principle of fusing cannot be changed, so that the lack of properties cannot be compensated by redesigning the machine. So far, no replacement is in sight.

See the confidential appendix for more details.

Information on required timing on replacement

There are currently no candidates for alternative materials, and the development of materials that can achieve comparable performance needs to start from scratch.

In the past, the implementation of an alternate PFOA-Free PTFE filler in a photoconductor to comply with regulations took 3 years to source material, qualify in manufacturing process, and validate performance across the product portfolio. In this case it was only a relatively small change while the main material (PTFE) remained the same. The development of a totally new material will require longer time.

In addition to the search for alternative PFAS materials to achieve equivalent release and lubricity, it will take approximately seven years to develop the required electrical, optical, and durability fittings for each component. It would also take five years to evaluate the production process to produce each component with alternative materials for PFAS, the start-up of the production equipment and its deployment to various products, including current products. As a result, we believe a total of 12 years is at least necessary.

Also, if the development of alternative materials does not go well, it may be necessary to develop materials that have tried an entirely different approach, such as inorganic surface materials, or other means that do not rely on material properties. In that case, it will be necessary to develop manufacturing equipment, and there is a possibility that even 12 will not be enough.

References regarding industry approach and complexity of replacement:

The extract below from The History and Development of Organic Photoconductors for Electrophotography by David S. Weiss[7] shows the complexity of replacing the filler, with competitors employing their own proprietary methods.
"Ricoh has described an approach where the OCL is filled with semiconductor oxide particles, Al2O3 for example, to increase its hardness. The filler content had to be optimized to permit some wear of the layer, and additives such as antioxidants had to be used to prevent increased conductivity leading to image spread. Silsesquioxane sol–gel OCLs have been commercialized by Eastman Kodak. The sol–gel is a solution coated onto the OPC where drying and partial curing occurs. The overcoated OPC was subsequently thermally cured to optimize the crosslinked structure for hardness, brittleness, and conductivity. The latter was accomplished by the addition of LiI but this caused image spreading at high humidity due to increased conductivity. This was minimized with formulation optimization. More recently hole transport functionalities have been incorporated into the sol–gel such that the OCL will function as a second CTL. Witt and co-workers (Sensient Imaging Technologies and AEG Elektrophotografie) have described a sol–gel OPC overcoat. The overcoat (1–2 µm) has little effect on the dark and photodischarge characteristics of the OPC and significantly improved the OPC wear characteristics. One technical obstacle is that the sol–gel formulation crosslinks with time, so in dip-coating applications the pot life is limited."

Costs

Information on the costs can be found in the confidential appendix

[7] Weiss, David. (2016). The History and Development of Organic Photoconductors for Electrophotography. Journal of Imaging Science and Technology. 60. 10.2352/J.ImagingSci.Technol.2016.60.3.030505

Substances and amounts

The substances are all fluoropolymers. See attached confidential appendix for details on substances and volumes.

Emissions

These components are manufactured both in the EU and outside the EU and are included in the electrophotographic printer. They are also replaced by service personnel as consumables and service parts.

Despite the fact that copiers and printers use about 0.0001% to 0.1% PFAS by weight (depending on the type of printer), they play an almost crucial role, especially when it comes to fuser parts. Therefore, if the use of PFAS is effectively prohibited, the entire copier must be discarded despite the use of PFAS of at most 0.1%.

According to International Data Corporation (IDC) estimates, about 17 million copiers and printers that use electrophotography and inkjet are shipped to Europe annually. These are estimated to be approximately 500,000 tons by weight. If the number of copiers and printers already on the market is estimated to be about 5 times the annual sales, the number in operation would be 85 million. It is estimated that if all of these were discarded, 2.5 million tons of waste would be generated when the regulations were implemented. The impact on the environment is enormous.

In copiers and printers, parts including PFAS do not come into contact with people. The aforementioned fuser parts, photoreceptor drums, ITBs, and charge rollers are not touched by people during the service life of the copier, except by the service technician who replaces them. There are no volatile PFAS components, there is no emission.

In addition, because the fluoropolymers are chemically stable, it is almost impossible for them to react chemically with the human body when touched. Contact with human bodies and the environment is limited after disposal, but as mentioned above, the WEEE directive is followed and the risk of contamination is minimized. It is unlikely that PFAS caused by copiers and printers will spread into the environment and become a source of pollution that threatens the human body.

Proposed derogation

No alternative is available or known. An exemption for a period of 12 years is needed.

The following text is proposed for the exemption:

paragraphs 1 and 2 shall not apply to fluoropolymers and perfluoropolyethers for the use in drums, rollers and belts in electrophotographic printers until 13.5 years after entry into force

1.5 Paper guiding parts

General summary of the application category

In high speed printers the paper is transported through the printer by many different parts. Because of the high speeds there can be high friction forces between the paper and the printer parts. In some cases this can lead to contamination of these parts with toner and ink. When the contamination builds up during use of the printer, it will damage the prints and eventually lead to paper jams. This is often solved by using low friction and non-stick PTFE parts or PTFE coatings on parts.

Technical function

Paper guiding rollers

"Continuous feed printers" do not print on cut sheet papers, but on large rolls of paper that are cut into sheets after printing. These are high speed production printers. Monthly production print volumes reach several millions of pages per month. The inkjet printing process on a continuous paper feed includes a paper transport system with a series of rollers to pass the paper through the first print station (with sub functions inkjet print heads, drying, cooling), a turning unit and the second print station for two sided printing. These printers are well-balanced systems and are the result of over a decade of research, development and step-wise product improvements. In this printer some paper transport rollers are coated with PTFE.

The printing process includes following main functions:

- jet ink droplets on paper side 1 by drop on demand printheads
- dry ink on paper to achieve sufficient robustness of the printout
- cool down paper to allow further processing
- turn over paper side
- jet ink droplets on paper side 2
- dry ink to achieve sufficient robustness of the printout
- cool down paper to allow further processing

See confidential appendix for a more details.

Technological innovations to improve colour gamut and resolution have been driving factors for successful marketing of new inkjet production printing systems. In order to achieve these targets new ink recipes have been developed.

Ink composition is constrained by many factors like environmental requirements (water based inks), print quality, incl. e.g. colour gamut and good ink adsorption on a wide range of papers, stable jetting properties of the picolitre-size droplets, long storage stability. Also drying properties are taken into account but need to be balanced with all other key aspects. Due to these limitations ink has not yet reached full robustness after the fixation unit. Robustness of the print will come with time, but when the paper is still in the printer, immediately after drying, the ink tends to stick to contact surfaces. This results in problems with ink pollution on the transport rollers. To prevent ink pollution and deterioration of print quality an anti-adhesive coating based on PTFE is used for the rollers after the drying unit.

Paper heating and guiding plates

In high speed cutsheet printers, metal plates are used to guide the paper and/or to heat the paper. The warm paper will move along these plates. Pollution of these plates with toner must be avoided. Also pollution from pre-printed logos and images on the paper must be prevented. Since these printers print high monthly volumes, small amounts of toner pollution on the plates can quickly build up to larger amounts. This larger toner pollution on the plates will damage (scratch) the prints or can lead to paper jams. The pollution can be avoided by using a PTFE coating on the plates.

Other paper guiding parts

There are other small components involved in the transport of the paper through the printer. For those parts that come into contact with the printed paper and have high friction with the paper, toner or ink contamination will build-up leading to damaged prints and paper jams. Also in these cases including PTFE in these parts lowers the friction, provides non-stick properties and solves the contamination problem

Alternatives

No alternatives are known at this moments. If the PTFE is left out and standard materials are used, there is a build-up of contamination that will eventually lead to damaged prints and paper jams. Cleaning these parts is time consuming and not always possible. The build-up of contamination can be even within a few hours of printing. Leaving out the PTFE is not an option. Alternative low-friction and non-stick materials have been investigated but have not been successful so far.

See confidential appendix for more details on materials that have been tested.

Costs and timing of replacement

The feasibility of alternative coating materials without PFAS is unclear at this moment. The known candidates have been tested and failed. There are no other candidate materials known.

Technological innovation could allow other solutions in future. However, the risk of not finding a suitable solution without PFAS is estimated high, besides the fact that industrialization of a technological innovation requires high additional efforts and long lead times.

The costs of alternatives materials cannot be estimated because an alternative material is not known. However, an estimation can be given of the resources required to implement a new material in printers. As an example, the costs for a change in the coating of the paper guiding rollers in continuous feed printers is given.

Developing an alternative coating will require more than 5 years due to the required improvement iterations and lifetime testing. In a first step material candidates need to be identified, samples have to be prepared by the supplier and evaluated with respect to anti-adhesive properties and potential side effects on paper transport stability. Each iteration would take at least 6 months. Lifetime testing would start under laboratory conditions within R&D. After successful completion a customer staging is needed with min. 1 year duration. Including preparation of serial production and manufacturing ramp up 3-5 years lead time are estimated for market introduction. However, since all known candidate materials have been tested and were not suitable, there is a high risk that no solution compliant to the PFAS restrictions can be found. In that case we have to wait for new materials to enter the market. In that case it can easily take more than 10 years before an alternative is implemented in our printers.

An alternative approach could be based on a complete redesign of the printing process including a change of the ink or toner recipe together with modification of printing, drying and cooling process. A modification of these process means that the fundamental design of the printer has to be changed. This will take at least five years and will require at least 50 man years. Given the uncertainty of the feasibility it is also possible that the investment of man years will be twice as much. The total development costs are between 12 and 25 million euro for the coating of the paper guiding rollers in a single printer type only. For the paper guiding plates and other parts similar numbers apply. A redesign of would also have costs in the same order of magnitude for a single printer type/model series.

Substances and amounts

See confidential appendix.

Emissions

Since the materials involved are all polymers with high molecular weights, there is no evaporation or emission to the air. When the equipment parts are end of life, they are discarded as waste metal. Due to abrasion there will be some wear of PFAS containing components. It is estimated that less than 50% of the PFAS material will be released into the environment in this way.

Required exemptions

Changing the PFAS material has an uncertain lead time because there are no PFAS-free candidates yet. New materials have to be invented. An exemption for 12 years would be required.

A fundamental redesign of the printing processes, eliminating the need for PFAS would cost millions of euros. When taking into account the current annual emission of PFAS use for ten years, a full redesign of the printing system only for this purpose would cost more than 50,000 euro per kg avoided PFAS emission. This is not proportionate if this redesign is done only for avoiding PFAS. However, it is expected that a new generation of printers will be developed and ready to place on the market ultimately in 2035. The substitution of PFAS can be included in the development of this next generation.

An exemption for the use of PTFE as coating on paper guiding parts in printers is required until 2035.

Proposed derogation

paragraphs 1 and 2 shall not apply to fluoropolymers for the use paper guiding parts in printers until 1-1-2035.

2. PFAS material in Lithium-ion batteries

2.1. Cathode and separator binder material for Lithium-ion battery cells

Name of PFAS substance(s) Polyvinylidene fluoride (PVDF), Polytetrafluoroethylene (PTFE), Ethylene tetrafluoroethylene (ETFE) and Fluorinated ethylene propylene (FEP)

CAS Number(s) 24937-79-9, 9002-84-0, 25038-71-5, 25067-11-2.

General summary on the application category

All Lithium-ion battery cells use PVDF or PTFE as the binder material for all types of positive electrodes (cathode). They are also widely used in separators. These PFAS binder materials help to improve energy density, durability, reliability, and usable lifetime of the battery. It also prevents them from self-discharging when idle.

Product durability/useful life is a key focus of policy efforts as part of the Circular Electronics Initiative and has been a key feature in the review of Ecodesign Regulation 617/2013 (Lot 3) - Computers and Computer Services. The durability of batteries potentially limits the lifetime of the device it is powering, if battery replacement is economically not feasible, or technically not possible. This may lead to early disposal of devices. Prolonging life is particularly important for lithium-ion batteries (LIB), not only do LIB contain a high amount of critical materials such as cobalt, they also involve substantial environmental impacts during their manufacturing (Source, JRC, 2018, https://publications.jrc.ec.europa.eu/repository/handle/JRC105156).

For the cathode, many other binder materials have been evaluated as replacements for PVDF and PTFE, however all other materials have been found to oxidize at the high voltage at the positive electrode (RCOM Ref. 3925, Supplier Survey 2023). In practice, this would mean that batteries in electronics would need to be replaced very frequently, leading to a corresponding growth in e-waste, battery waste, and demand in critical raw materials. Restricted high-voltage operation also means low run time for any portable devices, which would not meet consumers' daily use requirement.

Although the PFAS binder comprises only a small portion of the composite electrode (typically 2–5% of the mass of the electrode), the binder plays an important role in battery performance. The PFAS binder:

- Helps to disperse the active material and the conductive additive in the solvent during the fabrication process, enabling a homogeneous distribution of the slurry.
- Holds the active material and the conductive additive together and connects them to the current collector, ensuring the mechanical integrity of the solid electrode without significantly impacting electronic or ionic conductivity.
- Acts as an interface between the composite electrode and the electrolyte. In this role, the PFAS binder protects the composite electrode from corrosion and the electrolyte from depletion while facilitating ion transport across this interface.
- Tailors the viscosity of the slurry to allow a smooth coating onto the current collector during electrode manufacturing.

PVDF and PTFE have several unique properties that enable them to fulfil these critical roles[8]:

- Mechanical properties, including stiffness, toughness and hardness as well as good adhesion to the active material, the conductive additive, and the current collector. The positive electrode binder must be able to withstand the forces that result from the expansion and contraction of active materials during charge/discharge cycles.
- Thermal properties, particularly thermal stability, are also important, both for the high temperatures commonly used for curing and drying during electrode fabrication and also for operation of the battery at various temperatures.
- Good dispersive capabilities are important to help distribute the slurry evenly over the current collector during fabrication,
- Chemical and electrochemical stability are essential properties to enable the binder to function for long periods and over numerous cycles without degradation of the battery. The positive electrode binder must not react with any other components or intermediates formed during operation. In particular, the positive electrode binder must remain stable at the high and low voltage potentials experienced by the cathode. This stability guarantees its safe use in the electrochemical environment of the lithium cell.

Many academic-level and lab-scale investigations are currently looking at replacing PVDF as the cathode binder material but remain at this stage small scale research - there is still a significant gap before these can be tested, proven, produced, deployed, and sourced at the large mass production scale needed to replace PVDF.

For the separator (which is an indispensable part of batteries which separates the negative electrode from the positive electrode to prevent internal short circuits, whilst not participating in electrochemical reactions), PVDF is used because it offers excellent adhesion in liquid electrolyte which in turn ensures interface stability resulting in better performance (lower impedance and degradation) and durability. Further, the polarity of the C-F bond in the PVDF is high. While PMMA has been trialed to replace PFAS as the separator binder coating, there are issues with accelerated decay in the later stage of cycling and degradation of the negative electrode interface under high-rate charging.

A PFAS restriction without derogations for batteries will seriously limit the Green Deal and prevent Europe from achieving a net zero economy by 2050. The European Green Deal is one of the world’s most ambitious climate policies to usher the European Union and its Member States into a net zero economy by 2050 by decoupling economic growth from fossil fuel dependency. The Green Deal relies on batteries to achieve objectives for low-emission mobility, decarbonized energy generation and digitalization.

Batteries have been identified by the European Commission as a strategic value chain. The Commission states: ""Batteries are thus an important source of energy and one of the key enablers for sustainable development, green mobility, clean energy, and climate neutrality".[9]

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Refer to RCOM Ref. 3925 (RECHARGE submission) - Section 4 PFAS consumption in tonnes and emissions during battery life cycle.

[8] RCOM Ref. 3925
[9] https://eur-lex.europa.eu/legal-content/EN/TXT/PDF/?uri=CONSIL:ST_5469_2023_INIT&from=EN

The key functionalities provided by PFAS for the relevant use[10]

1. Mechanical properties, including stiffness, toughness and hardness as well as good adhesion to the active material, the conductive additive, and the current collector.
2. Thermal properties, particularly thermal stability.
3. Good dispersive capabilities are important to help distribute the slurry evenly over the current collector during fabrication
4. Chemical and electrochemical stability enable the binder to function for long periods and over numerous cycles without degradation of the battery at the high and low voltage potentials experienced by the cathode.

For which uses of PFAS is there no alternative?

Outlook: No alternative has yet been identified.

R&D activity: refer to details in RCOM Ref. 3925 (RECHARGE submission):

For Lithium-ion rechargeable batteries, PVDF was previously also used as the binder material for the negative electrode as well as for the positive electrode. For graphite negative electrodes (anodes), companies have successfully substituted PVDF with water-based CMC/SBR binder materials. CMC/SBR is now the most common commercially used binder material for the graphite negative electrodes due to its good cell performance, lower cost and reduced environmental impact[11].

For cathodes, no alternatives are available. The European Commission has recently funded the GIGAGREEN research project on dry alternatives and water-based binder systems for the positive electrode which propose to utilise a range of polymers including CMC/SBR, poly(acrylic acid), sodium alginate, polyurethanes and catechol-bearing polymers[12]. Whilst these initial research studies have indicated that these aqueous binder systems may have good adhesion properties, further research and development is required to investigate whether these alternatives have adequate chemical, mechanical, and electrical properties[13]. There are significant concerns about whether water-based CMC/SBR technology will have the necessary rheology and stability to match with today's positive electrode active materials such as LCO, NMC, NCA, LNMO, LFP. There are also specific concerns about the use of water in the slurry production and the electrode coating, drying and calendaring processes, particularly if the water is not completely removed before the battery is assembled.

The German Government has funded the DigiBatt Pro 4.0[14] research project which also includes development of water-based binder systems for positive electrodes. As part of this research project, positive electrodes of around 100 metres in a lab scale with roughly 1/100 to 1/50 the scale of mass production have been produced using a nickel rich NCM cathode active material, $LiNi_{0.83}Co_{0.12}Mn_{0.05}O_2$. The cells could be successfully charged and discharged

1,000 times at 25°C before they fall below 80% of initial capacity[15]. Whilst this research project appears to show promising results for very high nickel content batteries, correspondence with the project partners highlights that:

- Positive electrodes manufactured using water-based binder materials show increasing impedance/resistance with increasing numbers of charging and discharging cycles,
- The stability of the charging and discharging cycles is substantially lower than state-of-the-art positive electrodes using PVDF binder materials,
- The rapid increase in pH alkalinity of the water-based binder materials results in a very short shelf life for the mixed slurries, this would be very challenging for an industrial process as the mixture would go out of specification very quickly.

Further investigation of this research project confirms it focused on a very specific high nickel NCM cathode active material at a moderate cell voltage of 4.2V. There is no evidence that this water-based binder material could be developed to meet the performance targets for positive electrodes with LCO chemistries operated at higher voltages, which is what many electronic devices use today.

It is also important to note that this research project focused on a very specific cylindrical 21700 cell form factor used in certain automotive and power tool applications[16]. Performance in this specific form factor is not directly transferrable to other cell form factors used in other applications. There are many unknowns which would need to be investigated before this technology could be adopted in other chemistries and other form factors, including:

- cycle life and calendar life and impedance growth under wide range of temperatures
- swelling, fast charge cycling is unknown,
- electrode processibility for multilayer pouch cells and uniformity of coating is unknown,
- correspondence with the project partners highlighted that the positive electrodes manufactured using water-based binder materials show higher cell resistance and faster growth in resistance with increasing numbers of charging and discharging cycles with the high nickel NCM cathode active material. This trend is anticipated to become worse when industry moves to cathode active material operating at higher voltage, higher energy and higher power.

Several other research laboratories have reported developments in water-based binder systems for positive electrodes using other polymer materials in limited applications on the lab scale with simple coin cell batteries, but none of these efforts have successfully been scaled up to perform for industry relevant chemistries, cell configurations and production volumes. For example, Lawrence Berkeley National Laboratory reports they have tested polyacrylic acid (PAA) with the cross-linking agent polyethylenimine (PEI) as the binder for sulfur cathodes for LiS coin cells operating between 1.5v and 2.8v for 100-200 cycles[17]. No information is provided on performance in larger cells or industry-scale applications. Furthermore, industry

relevant chemistries such as LCO and NMC have high pH when dispersing in water and this may not be compatible with the binding function of this PAA/PEI binder.

New research papers and grant applications are regularly being proposed to develop alternatives to PVDF as the cathode binder and/or NMP as the solvent. We investigate all these research papers in detail and include comments on all research papers published up to August 2023 in this dossier. However, some research papers may be published after the public consultation closes in September 2023 and where we are not able to comment on them in this dossier.

Furthermore, replacing the PVDF cathode binder likely requires the development of new cathode active material and Aluminium current collectors that are compatible with a new binder and solvent system. Water is known to cause poor cycle life and increased impedance growth in Lithium-ion cells. A new grade of active cathode powder may need to be developed to increase particle surface protection against water.

Replacing the PVDF cathode binder with new binder and solvent also requires development of a compatible electrode and cell manufacturing process and equipment. The necessary process and equipment change at mass production scale is unknown at this point and will be different for different companies depending on which alternative technology they pursue. The performance of mass production line produced PVDF free battery may have significant performance gaps compared with current batteries. Addressing these performance gaps may require a significant number of iterations of materials improvement, production process change and cell performance testing.

Replacing the PVDF cathode binder with new binder and solvent also requires development of a compatible electrode and cell manufacturing process and equipment. The necessary process and equipment change at mass production scale is unknown at this point and will be different for different companies depending on which alternative technology they pursue. The performance of mass production line produced PVDF free battery may have significant performance gaps compared with current batteries. Addressing these performance gaps may require a significant number of iterations of materials improvement, production process change and cell performance testing.

Given the above, we estimate that efforts to develop and commercialise high performance non-PFAS cathode binder, Al foil, active materials and corresponding cell manufacturing processes would take at least 10 years, followed by 5 years to commercialise the new technologies.

PFAS is also used as a binder material on the separator of Lithium-ion battery cells. The separator is an indispensable part of batteries which separates the negative electrode from the positive electrode to prevent internal short circuits, whilst not participating in electrochemical reactions. At present, the most commonly used commercial separators are polyolefin separators, such as polypropylene (PP), polyethylene (PE) and multi-layer composite separators (PP-PE-PP). The layer materials are processed to make them porous by including tiny pores or voids at 35-45% porosity. The typical pore size is 200 nm - 1µm which is large enough for the lithium ions to move smoothly through the separator.

Commercial tri-layer PP/PE/PP separators take advantage of the difference in the melting point of PP (165°C) and PE (135°C), using PE as the shutdown layer and PP to protect structural integrity. When the cell temperature rises near the melting point of the PE layer, the PE layer will melt at a temperature of 135°C and close the pores in the separator to stop the current flow while the PP layer, which has higher melting temperature than PE, remains solid. However, such protection is only effective below the melting point of PP.

To provide better thermal and mechanical stability, commercially available ceramic coated separators have been developed. Ceramic particles, such as alumina, silica, or zirconia can be mixed with polymeric binders and slurry-coated onto the polyolefin separators. In comparison to PP layers, ceramic coatings offer a better electrolyte wettability, which translates into better Li-ion transport through the separator and therefore a better performance of the battery. Although ceramic coatings have proven effective in improving the thermal stability of separators, the effectiveness of the protection is still limited by the thermal stability of the polymeric binder used.

Some companies use PVDF as the binder material for the ceramic coating to provide good adhesion to the electrolyte/composite electrode, as well as providing good adhesion of the ceramic coating to the separator. Other companies have developed non-PFAS binders which also provide good levels of adhesion to the separator and the electrolyte/composite electrode. PMMA is considered as a potential alternative material for PVDF separator binder, but there are issues with accelerated decay in the later stage of cycling and degradation at the negative electrode interface under high rate charging. Some organizations are researching the use of binder-free, thin-film ceramic-coated separators which may be able to provide improved safety for Lithium-ion batteries. Additional time is required for battery manufacturers to study and qualify non-PFAS alternative solutions to ensure performance and safety and to commercialize the technology broadly.

In addition, contrary to what is stated in Annex E (page 416) of the PFAS Annex XV dossier, solid state batteries are not potential non-PFAS alternatives to Lithium-ion batteries. This is because solid state batteries do use PFAS, specifically PVDF and PTFE in the binder within the active material, in solid electrolytes and in gel polymer electrolytes.[18]

Substitution:

Substitution is estimated to take at least 15 years, and possibly longer. This will first depend on the battery industry to develop a suitable potential alternative material. As detailed in RCOM Ref. 3925 (RECHARGE submission), the estimated time to develop and commercialize high performance non-PFAS cathode binder, Al foil, active materials and corresponding cell manufacturing processes would take at least 10 years, followed by 5 years to commercialize the new technologies.

Proposed derogations

Paragraph 2(c) shall apply from (**13.5 years** after entry into force) to PFAS used in **cathode binder materials in Lithium-ion battery cells**. **The European Commission shall review this derogation by 3 years before its expiry to assess whether alternatives are now available or whether further renewal is needed and to publish amendments to the Regulation.**

Paragraph 2(c) shall apply from (**6.5 years** after entry into force) to PFAS used in **separator binder materials in Lithium-ion battery cells.**

[18] Source: RCOM Ref. 3925 (RECHARGE submission)

2.2. Lithium-ion batteries: Socio-economic impacts

The European Green Deal is one of the world's most ambitious climate policies to usher the European Union into the net zero economy by 2050. The Green Deal relies on batteries to achieve objectives for low-emission mobility, decarbonised energy generation and digitalisation. **A PFAS restriction without a derogation for batteries, and without a review clause, will limit the Green Deal and prevent Europe from achieving a net zero economy by 2050.**

Batteries have been identified by the European Commission as a strategic value chain. The Commission states:

'*Batteries are thus an important source of energy and one of the key enablers for sustainable development, green mobility, clean energy, and climate neutrality*'[19].

More than EUR 20 billion has been devoted to the EU battery value chain via the European Commission framework on Important Projects of Common European Interest (IPCEI), the European Investment Bank and research funding in the last few years. Dozens of billions more are available via the European Union InvestEU fund and the European Commission Recovery and Resilience Facility. Over half of all lithium batteries on the EU market in 2022 were produced in Europe, with the continent projected to become the world's second biggest battery cell manufacturer by the end of the decade[20]. As a direct effect, this will require 800 000 workers by 2025[21]. The installation and maintenance of batteries as well as end of life recycling could potentially create between 3-4 million jobs by 2025[22].

- Europe is on track to produce 6.7 million battery electric cars (BEV) by 2032, or just over half of all the cars produced, which is in line with the recently agreed -55% CO2 target for carmakers for 2030 that is expected to result in a 50-60% share of BEV sales[23].
- Half of the lithium battery cells used in electric vehicles and energy storage systems in the EU were already made in the bloc in 2022, notably in Poland, Hungary, and to a lesser extent in Germany and Sweden. Transport & Environment analysis of the battery cell capacity announcements to date shows that Europe can be self-sufficient in battery cells, i.e. produce 100% of our lithium battery cell demand from 2027[24].

- Europe has secured much investment: the continent is projected to produce up to a third of lithium-ion batteries globally by 2030 (from just a few % today)[25].

However, this investment will likely not proceed if the derogations are limited to 13.5 years only. A company is not likely to invest in building a battery cell production factory with the knowledge that they will have to close the factory in 13.5 years.

Even if this derogation is granted with a review clause, this may still not provide sufficient certainty for companies to invest in Europe because there is risk that the derogation may not be renewed and therefore prevent any further competition. This uncertainty is already diverting some investment from Europe and putting a high risk on the current investment in Europe, which could jeopardise the current set up of the European value chain. For this reason, the European Battery Association RECHARGE will propose an alternative approach to manage the PFAS emissions risk in a different way.

Figure 1 summarises the battery cell production sites in Europe that are in planning, under construction or partly already in operation[26]. These 45 sites represent over 56 billion Euros of investment and more than 43,000 jobs and provide the potential for Europe to become self-sufficient in battery cells as early as 2028 as an integrated value chain.

Figure 3 Battery cell production site in Europe

A PFAS restriction without a derogation for batteries, and a review clause, will stop these battery cell production sites operating in Europe.

[25] A European Response to the US Inflation Reduction Act, T&E report January 2023, https://www.transportenvironment.org/discover/a-european-response-to-us-inflation-reduction-act/

[26] Figures include EU Member States and European Economic Area countries – therefore Russia, UK & Serbia have not been included in our calculations. Figures obtained from IPCEI Market Analysis Q4 2022, https://www.ipcei-batteries.eu/fileadmin/Images/accompanying-research/publications/2023-02-BZF_Kurzinfo_Marktanalyse_Q4_22-ENG.pdf.

EV batteries

Batteries are critical to the functioning of society to enable electric vehicles to replace sales of new combustion engine vehicles by 2035. On 29 June 2022, all climate ministers of the 27 EU member states agreed to the European Commission's proposal (part of the 'Fit for 55' package) to effectively ban the sale of new internal combustion vehicles by 2035 (through '[introducing] a 100% CO_2 emissions reduction target by 2035 for new cars and vans')[27]. Requiring new cars sold in the EU to emit zero CO_2 from 2035 would make it impossible to sell new internal-combustion engine cars. In 2026, the Commission will assess whether hybrid vehicles or CO_2-neutral fuels could comply with the goal with future technological developments. The Commission commented that it would keep an “open mind” but that at present, hybrids did not deliver sufficient emissions cuts and alternative fuels were prohibitively expensive.

Most EU Member States have also signed up to the COP26 declaration on accelerating the transition to 100% zero emission cars and vans[28]. All signatories support an accelerated transition to zero emission vehicles in line with achieving 100% of new car and van sales being zero emission in leading markets by 2035, and by making them accessible, affordable and sustainable in all regions by 2030.

These climate proposals aim to ensure the EU – the world’s third-biggest greenhouse gas emitter – reaches its 2030 target of reducing net emissions by 55% from 1990 levels. Doing so will require governments and industries to invest heavily in electric vehicles.

A PFAS restriction without a derogation for batteries, and a review clause, will stop sales of new and second-hand electric vehicles in Europe.

Industrial batteries

In electricity generation, batteries enable grids to install more renewable energy capacity using solar and wind sources. One of the well-known shortcomings of solar and wind energy sources is their large variability in power generation - the sun does not always shine, and the wind does not always blow. Battery storage helps renewable generators reliably integrate with existing grids by storing the excess generation and by smoothing the energy distribution.

Batteries also help traditional suppliers manage the stability of energy distribution thanks to their unique ability to quickly absorb, store, and deliver electricity as needed. Among its many uses, batteries help operators regulate the frequency of the electrical current - an important aspect of electricity transmission – to help store electricity until transmission capacity is available and help maintain capacity reserves. Batteries also make isolated and off-grid installations viable and less dependent on diesel generators.

While there are many technologies used for utility-scale energy storage, rechargeable lithium batteries have become favoured in new installations due to their flexibility and scalability, and their declining costs. At the beginning of the 1990s, the storage capacity that is required to power a regular-sized house for a day would have cost about 75,000 Euro and the battery package would have weighed 111kg[29]. The same level of capacity can now be obtained at a cost of around 2,000 Euro from a 40kg, small backpack-sized cell.

[27] https://www.consilium.europa.eu/en/press/press-releases/2022/06/29/fit-for-55-council-reaches-general-approaches-relating-to-emissions-reductions-and-removals-and-their-social-impacts/
[28] https://www.gov.uk/government/publications/cop26-declaration-zero-emission-cars-and-vans/cop26-declaration-on-accelerating-the-transition-to-100-zero-emission-cars-and-vans
[29] https://www.economist.com/graphic-detail/2021/03/31/lithium-battery-costs-have-fallen-by-98-in-three-decades

Industrial batteries also include small primary lithium batteries, which are essential for applications that require long battery lifetimes (up to 25 years) or instant readiness after long standby periods (for applications such as pacemakers, defibrillators, emergency alarm systems, and remote IoT applications).

A PFAS restriction without a derogation for batteries, and a review clause, will inhibit the growth of renewable energy and stop the sales of life-saving equipment.

Portable batteries

The public in Europe rely on their electronic devices to continue to function in an emergency when a main power source is not available. For example, a long battery life is needed in communication devices such as smartphones, tablets and laptops so that in case of a health or safety incident, the device can continue to function to enable people at risk to continue to communicate effectively with the emergency response authorities. Batteries provide indispensable back-up power to these communication devices in case of a power cut.

Today's society is an information-rich world which is becoming more and more portable. Portable electronic devices including laptops, tablets, mobile phones, and wearable electronic devices are critical to support the rapid growth of information processing and sharing in society. Without batteries, these devices would not be portable and instead would require permanent connection to a fixed power source.

From VOIP to global telecom carriers, portable electronic devices enable people to travel the world and stay connected. To respond effectively to global pandemics such as COVID 19, remote workers and international businesses need to be able to utilize video calls and conference calls via the Internet to keep their businesses going without interruption. Portable electronic devices support increased productivity by enabling working from home opportunities that simply were not available previously. At the same time, more flexible working arrangements have enabled a larger cross-section of society to contribute their knowledge and skills into the workplace.

Portable electronic devices have enabled more people to access education opportunities. Online seminars allow people to learn in a faster, more convenient, and efficient fashion.

Portable electronic device help people to carry out complex tasks in a simpler, quicker manner. Smart bracelets and health apps enable people to monitor, analyse and alter personal health habits. Many hospital systems have online gateways that allow patients to obtain their medical records, or communicate with their physician online, nearly instantly. Batteries are indispensable to make these devices portable so that they can deliver these critical functions to society.

Significant financial costs can be expected to arise due to the lack of substitutes for PFAS in lithium-ion batteries:

1. Annual value of EU sales: In 2022, the computer hardware market in Europe generated a total revenue of over 60 billion euros, selling around 630 million units. Storage units made up the majority of volume at approximately 462 million units, followed by laptops and keyboards, both with approximately 42 and 40 million units sold, respectively.[30]
2. Indirect cost - European employment in the ICT sector: In 2022, more than 9 million persons worked as ICT specialists across the European Union (EU). The highest number (2.1 million) worked in Germany, which provided work to more than one-fifth

[30] Statista, 2023 see https://www.statista.com/forecasts/1256748/volume-segments-computer-hardware-europe

(22.6 %) of the EU's ICT workforce. France (1.2 million) had the second largest ICT workforce (13.0 % of the EU total), followed by Italy and Spain (both 0.9 million; 9.6 % and 9.4 % respectively).[31]

3. Cost to companies in the EU: In a survey conducted by the IDC (2010), 68 % of respondents confirmed that the battery lifetime on their notebook computers was not sufficient for their business needs, and over half stated that battery failures caused problems for their business. The most common problem was lost productivity, cited by 45 % of respondents, followed by lost/delayed sales (22 %) and loss of critical company data (17 %).
4. Material efficiency via optimized design: The yearly rate of estimated material saving if dedicated functionality for the optimization of the lifetime of batteries (a.1) were used ranges from around 2 360 to 5 400 tonnes (t) of different materials per year. About 450 t of cobalt, 100 t of lithium, 210 t of nickel and 730 t of copper could be saved every year.[32]
5. R&D, retooling, retesting, recertifying supply chain costs: not able to be estimated.
6. Cost to consumers & companies in the EU to repair/replace electronic devices on more frequent cycles: A Eurobarometer survey observed that, when a main failure occurs, 77 % of EU citizens would rather repair their goods than buy new ones, but ultimately have to replace or discard them because they are discouraged by the cost of repairs and the level of service provided (European Commission, 2014b). Viegand Maagøe and VITO (2017) reported a typical lifetime of 5 years for notebooks, 6 years for desktop computers. (Sources: Viegand Maagøe and VITO, 2017. Preparatory study on the Review of Regulation 617/2013 (Lot 3) — Computers and Computer Servers & Flash Eurobarometer 388 report of June 2014 entitled 'Attitudes of Europeans towards waste management and resource efficiency'.)
7. Impact of downtime to EU businesses when electronic devices fail: Data in the public domain tends to focus on the cost to businesses resulting from network outages rather than devices, but costs will vary according to the sector and size of the business but will include productivity losses, replacement costs, and lost sales.
8. Impact to employment: Approximately 45 battery cell production sites in Europe that are in planning, under construction or partly already in operation represent 56 billion Euros of investment and 43,000 jobs (PCEI Market Analysis Q4 2022, https://www.ipcei-batteries.eu/fileadmin/Images/accompanying-research/publications/2023-02- BZF_Kurzinfo_Marktanalyse_Q4_22-ENG.pdf). This will aid Europe to become self-sufficient in battery cells as early as 2028 as an integrated value chain. Without PFAS derogations for batteries, these battery production sites will stop operating in Europe.

A PFAS restriction without a derogation for batteries, and a review clause, will stop Europe from achieving Green Deal digitalisation objectives.

3. Coating materials

3.1. Anti-fingerprint coating

Name of PFAS substance(s): Fluoropolymers (e.g. PTFE), Perfluoropolyether (PFPE), Perfluoroalkoxy alkanes (PFA)

General summary on the application category

PFAS substances are widely used in anti-fingerprint coatings in various electronic products such as laptops, smartphones, keyboards and visual devices.

These coatings are used because they are chemically inert, easy to clean, and have excellent aging performance, abrasion resistance (due to the self-lubricating property of PFAS) and adhesion durability.

The anti-fingerprint coating creates a layer of water- and oil-resistant material with a water contact angle greater than 110º and oil contact angle greater than 80º, effectively preventing grease and various chemicals from sticking to the surface. The coating also allows easy removal of dust and dirt (from hand creams and tomato ketchup to alcohol and sunscreen) from the surface.

ChemSec has highlighted silicone alternatives, however during testing they have demonstrated more severe fouling as compared to PFAS coatings when tested with multiple substances, including artificial sweat, vegetable oil, coke and coffee etc., and poorer abrasion resistance and durability. They also exhibit a water contact angle of less than 100º meaning they are much harder to clean as compared to PFAS coatings.

The finger is often coated with sebum, an oily substance. The oil-phobic characteristics of PFAS coated on substrate can remove the sebum, and the touch feeling is smooth without sluggishness. However, if there is no PFAS coating, an oil-phobic coating, the sebum is adhered on the substrate. The sebum adhered on the substrate makes the sliding motion un-smooth. Silicone based coating has hydrophobic but not oil-phobic characteristics. The sebum is therefore kept on the silicone-based coating surface, making the sliding motion unsmooth.

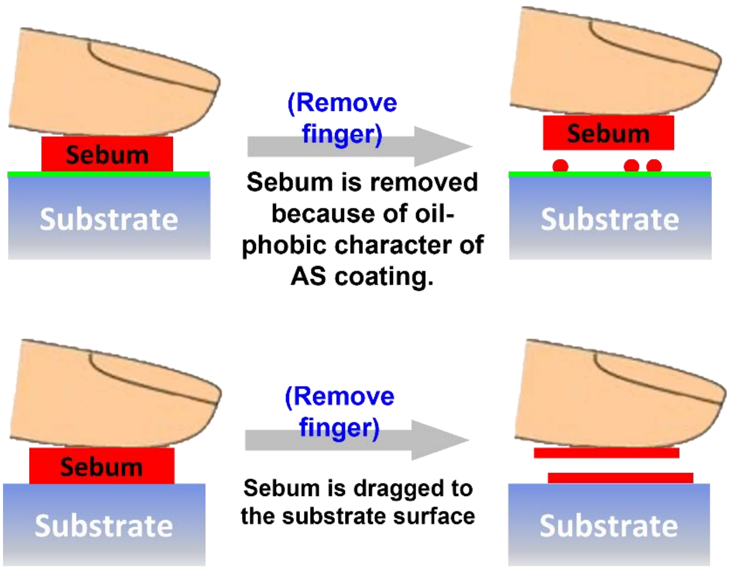

Figure 4 Oil-phobic characteristics of PFAS anti-fingerprint coating

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Insufficient information to quantify/See confidential annex for details.

The key functionalities provided by PFAS for the relevant use[33]

1. Very low surface energy on the substrate surface to promote water and oil repellency (>=110° water contact angle; >=80° oil contact angle)
2. High chemical resistance, against water and oil-based materials
3. High abrasion resistance and low friction coefficient (< 0.3)
4. High adhesion durability
5. 100% visible light transmittance possible in <100 nm coating thicknesses

For which uses of PFAS is there no alternative?

Outlook: No alternative has yet been identified.

R&D activity: Some potential non-PFAS alternatives have been assessed - mainly Si-based materials, but also PU and chlorinated chemistries.[34]

Alternatives cannot match the performance of PFAS:

- Surface tension / energy of alternatives is not as low as PFAS. Alternatives are unable to achieve water contact angle >=110°, and oil contact angle >=80° which causes wetting of surface.
- The anti-fouling performance of alternatives is not as good as PFAS. Coatings based on PFAS exhibit much better easy-cleaning ability than Si-based coatings.
- Chemical stability and resistance of alternatives is not as good.
- Abrasion resistance of alternatives is not good, resulting in poor long-term durability [Supplier Survey 2023, OECD]
- Temperature stability/resistance of PFAS is superior, which can operate at >200 °C[35]
- Thicker coating may need to be applied for alternative [OECD]. Silica-based coatings such as silicone polymers can be used as alternatives to radiation curable coatings in electronics as they have similar properties and therefore can carry out similar function as PFASs used in this application. In electronics, however, PFAS can be applied in a thinner layer compared to non-PFAS alternatives - fluoropolymers are typically applied in a coating thickness of 1-2 µm (nano coating), whereas alternatives such as acrylic, PU and silicone are applied at >25 µm.[36]

Si-based alternatives may meet lower specifications for abrasion resistance, contact angle and anti-fouling tests, but these are not acceptable per industry and customer experience

[33] Source: Supplier Survey 2023
[34] Source: Supplier Survey 2023, Chemsec, OECD
[35] ChemSec (2023), Check Your Tech: A guide to PFAS in Electronics, https://view.officeapps.live.com/op/view.aspx?src=https%3A%2F%2Fchemsec.org%2Fapp%2Fuploads%2F2023%2F04%2FExcel_ChemSec-Electronics-Guide.xlsx&wdOrigin=BROWSELINK
[36] Chemsec (2023)

requirements and will result in shorter product service life. In addition, silicone coating absorbs oil, is sticky, causes cross contamination and leads to adhesion loss of other components.[37]

Substitution:

- The time required to develop a new material that meets all the performance requirements is unknown. It is estimated to take at least 2 years for suppliers to study, screen and identify a potential substitute.
- Once a potential substitute is identified, it will take 1.5 years for material qualification, manufacturing process development and part level qualification (environmental aging simulation, adhesion duration, storage stability, easy cleaning performance).

Proposed derogation

Paragraph 2(c) shall apply from (**6.5 years** after entry into force) to **anti-fingerprint coatings** in electrical and electronic equipment. By [18 months before the derogations are due to expire] the Commission will review derogations in light of new scientific available information and information on alternative materials or processes and if appropriate modify this derogation accordingly.

3.2. Coating and paint for enhanced abrasion resistance in EEE

Name of PFAS substance(s) PTFE

General summary on the application category

Components inside devices can corrode or degrade when exposed to contaminants, moisture or wear. The degradation can reduce the electrical and mechanical performance of the device and cause device failure in some cases. Manufacturers use specialized paints/coatings to protect these sensitive components.

Fluoropolymers are used as additives/binders in paints because they confer protective properties on the paints such as durability, weatherability and resistance to corrosion and dirt pick up as well as acting as a barrier to UV deterioration and providing a soft feel 'texturizer' for some applications. Fluoropolymers commonly used in paints are primarily based on PVDF, PTFE, FEP, ETFE and FEVE. They impart excellent self-lubricating property, wear resistance, water, heat and chemical resistance and high-performance electrical insulation. These characteristics help extend the lifespan of components and improve their fire safety.

Product durability is a key focus of policy efforts as part of the Circular Electronics Initiative and has been a key feature in the review of Ecodesign Regulation 617/2013 (Lot 3) - Computers and Computer Services.

Si-based alternatives have been tested but have so far failed to meet performance and durability requirements.

[37] Chemsec (2023)

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Insufficient information to quantify -

The key functionalities provided by PFAS for the relevant use[38]

1. Very low surface energy on the substrate surface to promote water and oil repellency (>=110° water contact angle; >=80° oil contact angle)
2. Excellent durability and abrasion resistance (also due to very low friction coefficient)
3. Wide temperature range and thermal stability (-30℃ -150℃)
4. High resistance to chemicals and compatibility with oxygen
5. Excellent adhesion durability

For which uses of PFAS is there no alternative?[39]

Outlook: No alternative has yet been identified.

R&D activity: Alternatives examined included PE waxes and Si-based solutions.

Alternatives cannot meet performance and durability requirements:

- Worse abrasion durability
- Worse chemical resistance
- Worse anti-fouling performance

Si-based alternatives may meet lower specifications for abrasion resistance, contact angle and anti-fouling tests, but these are not acceptable per industry and customer experience requirements and will result in shorter product service life. In addition, silicone absorbs oil, is sticky, causes cross contamination and leads to adhesion loss of other components.

Substitution:

- The time required to develop a new material that meets all the performance requirements is unknown. It is estimated to take at least 2 years for suppliers to study, screen and identify a potential substitute.
- Once a potential substitute is identified, it will take 1.5 years for material qualification, manufacturing process development and part level qualification (environmental aging simulation, adhesion duration, storage stability, easy cleaning performance).

Proposed derogation

Paragraph 2(c) shall apply from (**6.5 years** after entry into force) to **fluoropolymer coatings and paints for enhanced abrasion resistance** in electrical and electronic equipment. By [18 months before the derogations are due to expire] the Commission will review derogations in light of new scientific available information and information on alternative materials or processes and if appropriate modify this derogation accordingly.

[38] Source: Supplier Survey (2023)
[39] Source: Supplier Survey (2023)

3.3. Coating in connectors

Name of PFAS substance(s) Fluoropolymers

General summary on the application category

Plug-in connections are used wherever components or assemblies need to be connected temporarily. Electrical contacts have basically two main tasks: the possibility to mechanically separate an electrical connection and the transmission of electrical energy without losses in closed position. As they are used in a wide range of different environments, like heat or damp heat, the contact surface of the electrical contact has to meet various requirements.

The main function of this PFAS coating on the gold plated elements is to seal micro pores on the surface and prevent corrosion. Thin gold plating can be microscopically porous and corrosion would lead to increased contact resistance. For plastic parts, the PFAS anti-flux coating helps to ensure efficient soldering when performing surface mounting - limiting the flow of solder when being applied.

To date, no alternatives have been found.[40]

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Insufficient information to quantify/See confidential annex.

The key functionalities provided by PFAS for the relevant use

1. Low wettability (through low surface tension / energy)
2. Sealing micro-sized holes offering effective corrosion protection

For which uses of PFAS is there no alternative?

Outlook: Potential alternatives all contain PFAS according to the supply chain. It is important to find a material that does not stick during the manufacturing process.

Substitution[41]*:*

- The time required to develop a new material that meets all the performance requirements is unknown. It is estimated to take at least 2 years for suppliers to study, screen and identify a potential substitute.
- Once a potential substitute is identified, typical duration of manufacturing process update and testing takes at least 20 months, depending on application and the required tooling investment.

[40] Supplier Survey (2023)
[41] Supplier Survey (2023)

Proposed derogation

Paragraph 2(c) shall apply from (**6.5 years** after entry into force) to **fluoropolymer coatings in connectors** in electrical and electronic equipment. By [18 months before the derogations are due to expire] the Commission will review derogations in light of new scientific available information and information on alternative materials or processes and if appropriate modify this derogation accordingly.

3.4. Optical isolation layers for display applications

Name of PFAS substance(s) Fluoropolymers (e.g. PTFE), Perfluoropolyether (PFPE)

General summary on the application category

PFAS-containing low optical loss and refractive index coatings and adhesives are used to preserve total internal reflection (TIR) of the light in advanced display applications like waveguides. Waveguides leverage specific optical properties of the material to guide wavelengths if sound, light or other radiational energy across the material. Basic examples would be optical fibers and magnetrons within microwaves. If the optical properties are not maintained then the light will not be effectively transferred across the material by either absorption or misdirection losses. Key requirements for effective transmissions are low optical loss (<0.5%), low RI (<1.35), ability to cure at ambient or low (<80C) temperatures, low moisture absorption, non-yellowing, PFAS-containing materials and high elongation at break. Currently, the PFAS-containing materials are the only HVM-compatible option available that can satisfy the required optical and mechanical properties of the coatings.

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Insufficient information to fully quantify, but we can elaborate on the expected emission points, mitigations in place, potential volumes.

Expected Volumes – The end use of this material will be used in EEE. Market acceptance will be a significant variable in determining the total number of products on the EU market. Each product would contain approximately 1 g of PFAS.
Manufacturing - Substance will be applied in a closed loop system that is under strictly controlled conditions.
Recovery - This material will be contained in EE and subject to WEEE. Expected 90% recovery/refurb/reuse of the product.

The key functionalities provided by PFAS for the relevant use

1. Low Refractive index (<1.35)
2. Low optical loss in visible region (<0.5% over 2 um)
3. Low moisture absorption
4. Good adhesion between various interfaces
5. Low modulus and high elongation at break to accommodate for CTE mismatch between layers

For which uses of PFAS is there no alternative?

Outlook:
Alternative commercially available materials like silicones are limited to RI of ~1.40 making them unsuitable for these applications. The high refractive index causes the light to deflect at a much greater angle thus distorting the projections to an indistinguishable state. There is active academic research in porous low RI materials, but these materials are brittle and suffer from high moisture absorption making them unsuitable for these applications as well. In recent years, the coatings industry has initiated the research and development of hollow nanoparticles matrix composite materials to achieve low RI (~1.36) and low temperature curable materials. These materials are in early stage R&D with long cycle times for development and currently suffer from high moisture absorption and delamination.

Substitution:

- The time required to develop a new material that meets all the performance requirements is unknown. It is estimated to take at least 4 years for suppliers to study, screen and identify a potential substitute.

- Once a potential substitute is identified, it will take 1.5 years for material qualification, manufacturing process development and part level qualification (environmental aging simulation, adhesion duration, storage stability, TIR performance).

Proposed derogation

Paragraph 2(c) shall apply from (**6.5 years** after entry into force) to **Optical Isolations Layers For Coatings**. By [18 months before the derogations are due to expire] the Commission will review derogations in light of new scientific available information and information on alternative materials or processes and if appropriate modify this derogation accordingly.

3.5. Coatings: Socio-economic impacts

The consequential economic (in euros) and social (e.g. jobs) impacts arising from any restriction of PFAS in respect to its use in coatings is difficult to quantify. However, significant financial costs can be expected to arise because of the inability to substitute.

While industry will face increased costs associated with conducting repairs in warranties and searching for alternatives, perhaps the greatest cost impact will be felt by businesses and consumers to replace electronic devices on more frequent cycles due to device failure and/or loss of consumer expected performance, and the impact to EU businesses as a result of downtime when products fail.

1. Annual value of EU sales: In 2022, the computer hardware market in Europe generated a total revenue of over 60 billion euros, selling around 630 million units. Storage units

made up the majority of volume at approximately 462 million units, followed by laptops and keyboards, both with approximately 42 and 40 million units sold, respectively.[42]

2. Cost to companies/consumers in the EU to repair/replace electronic devices on more frequent cycles: A Eurobarometer survey observed that, when a main failure occurs, 77 % of EU citizens would rather repair their goods than buy new ones, but ultimately have to replace or discard them because they are discouraged by the cost of repairs and the level of service provided (European Commission, 2014b). Viegand Maagøe and VITO (2017) reported a typical lifetime of 5 years for notebooks, 6 years for desktop computers.[43]
3. Impact of downtime to EU businesses when electronic devices fail: Data in the public domain tends to focus on the cost to businesses resulting from network outages rather than devices, but costs will vary according to the sector and size of the business but will include productivity losses, replacement costs, and lost sales.
4. Total sector agnostic annual savings through extended component lifetime: Fluoropolymer coatings, linings and components prevent corrosion in demanding environments. Each percent reduction in corrosion is estimated to deliver savings of some €150m per year across Europe. Amongst other benefits, they support savings in maintenance through increased component lifetime. Consultation suggested their use effectively doubled the lifetime of equipment, potentially yielding savings in the order of €100m annually. (Source, FPG, Plastic Europe, 2017 https://fluoropolymers.plasticseurope.org/application/files/7816/1167/4026/Final_SEA_Fluoropolymers_summary2017_3.pdf)
5. R&D, retooling, retesting, recertifying supply chain costs: not able to be estimated.

4. Anti-dripping agents

Name of PFAS substance(s) PTFE

General summary on the application category

Flame retardant polycarbonate (PC) resins and alloys, such as PC/ABS used in thin-wall (thickness <1.0 mm) electronics applications play a critical role in consumer safety and require the use of PTFE as an anti-drip additive. These flame-retardant polycarbonate resin formulations are used where product safety (mitigated risk of flame/fire and/or electrical shock) is of utmost importance.

Thin-walled parts reduce the amount of plastic used and therefore the amount of plastic waste produced during the manufacturing process as well as at the electronic devices' end of life. Before these tough thin-wall flame retardant polycarbonates were available, typical wall thicknesses in consumer electronics were 2-3 mm, which in comparison can lead to a 100% to 200% increase in resource consumption and solid waste generation, depending upon the electronic application design requirements. As the devices are subsequently lighter, have resulted in reduced scope 3 emissions (category 4- upstream transportation and distribution, and category 9 downstream transportation and distribution)[44]

Our justification for requesting derogation of PTFE as anti-drip agent in flame retardant polycarbonate compounds comprises two elements:

- there are no alternatives to polycarbonate that provide adequate impact resistance and ductility for thin wall (<1.0 mm) applications in electronic products
- in order to ensure that the polycarbonate thin wall has adequate flame retardancy, it is essential to use PTFE as the anti-drip agent.

Alongside many unique properties, polycarbonate is an inherently tough material which provides device integrity during and after an impact event, so that the electronic device can continue to function, and does not produce an electrical hazard (short circuit, shock hazard) or a fire hazard. There are no alternative engineering plastics available today that provide the necessary combination of impact resistance, ductility, and flammability properties for thin-walled (<1 mm) electronic device parts. These properties are crucial to:

- provide a durable product that does not break during normal use, including drops and other foreseeable events,
- ensure safety by avoiding exposure of life circuitry, and
- meet EU regulatory requirements on the safety of electrical device.

The next best material is polyphenylsulfone (PPSU) which has almost half the ductility. By extension, we can expect that electronic products with thin walls (<1.0 mm) made from PPSU would be twice as fragile compared to the same products made with polycarbonate. Increased fragility means increased risk that the device may break after an impact event, which may result in electrical hazard (short circuit, shock hazard) or fire hazard.

[44] RCOM Ref 4009, RCOM Ref 4407

To ensure that thin-walled polycarbonate resins and alloys have adequate flame retardancy, it is essential to use PTFE as the anti-drip agent. PTFE, in combination with flame retardant additives, increases the ignition resistance of the polycarbonate thereby lowering the probability of a fire event. If a flame event does occur, the unique properties of PTFE help prevent flames from spreading and allow individuals more time to escape a fire.

Extensive research in the plastic industry has not found any alternatives that provide adequate flammability performance for thin-walled polycarbonate while also maintaining adequate impact resistance and ductility. Plastics manufacturers have carried out in-house experiments to investigate whether they could develop alternative additives that could be used instead of PTFE. None of the alternatives that were tested were able to provide adequate flame-retardant properties without significantly degrading impact resistance or other mechanical properties.[45]

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

No PTFE is released from parts manufactured from thin-walled polycarbonates during their use phase.[46] At end-of-life, when these articles containing 0.1-0.5 weight% of PTFE in the polycarbonate matrix will eventually enter the waste stage, the amount of PFAS emissions depends on the waste (pre-) treatment method, e.g., recycling/re-use, landfilling and incineration. However, PTFE is a fluoropolymer that is not water soluble and therefore does not present the specific hazards which are found with non-polymeric PFAS. PTFE is chemically, thermally, and biologically stable and therefore is not expected to transform to dispersive nonpolymeric PFAS when disposed of in a landfill. A recent study[47] presented results from OECD guideline biodegradation studies demonstrating that PTFE is stable and does not degrade to non-polymeric PFAS under environmentally relevant conditions. Further, PTFE meets the criteria to be considered a Polymer of Low Concern, PLC, which has negligible leachables, unreacted monomers, and oligomers most likely destroyed in use processing and would therefore not be expected to significantly contribute to landfill leachate.

The key functionalities provided by PFAS for the relevant use[48]

Nearly all electronic devices have an inherent risk of fire and a risk of shock. Product safety standards use material fire resistance and electrical insulation requirements as two critical safety elements to help mitigate these risks. For fire resistance, there are several common industry test standards that require materials to resist ignition, burning, and the dripping of flaming particles. One common standard is "*UL 94, the Standard for Tests for Flammability of Plastic Materials for Parts in Devices and Appliances*" which is now harmonized with the IEC 60707, 60695-11-10 and 60695-11-20 standards and the ISO 9772 and 9773 standards that are used to demonstrate compliance to flame retardant requirements in the EU. There are 6 flame classifications of materials that are used in enclosures, structural parts and electrical insulators in electrical devices: HB, V-2, V-1, V-0, 5VA and 5VB. The higher ratings – V-1, V-0, 5VA and 5VB - all require that samples do not drip flaming particles.

Since polycarbonate is designed to be shaped/flowed by heat, direct flame application can lead to melting and dripping of the polycarbonate before or during ignition. Any flaming melting/dripping has the chance of spreading flaming material beyond the initial ignition event and is almost always more pronounced in thinner rather than thicker walls. PTFE is the only viable additive for polycarbonate resins used in thin walls that can inhibit dripping **and** retain

(2022), A critical review of the application of polymer of low concern regulatory criteria to fluoropolymers II: Fluoroplastics and fluoroelastomers, Integrated Environmental Assessment and Management Vol. 19 Issue 2, https://setac.onlinelibrary.wiley.com/doi/10.1002/ieam.4646#pane-pcw-references
[48] RCOM Ref 4009, RCOM Ref 4407

all the impact resistance and ductility properties which are essential for product safety and compliance with regulatory requirements.

During melting and shaping of the polycarbonate into injection molded parts, the PTFE does not melt and instead undergoes a physical form change from being semi-spherical particles to highly elongated fibrils. These long fibrils form an entangled network inside the polycarbonate resin matrix. During a flame event, this network of PTFE fibrils does not burn/ignite and instead helps promote char formation and provides much higher melt strength to the thin polycarbonate wall. PTFE as an anti-drip agent is typically used in the range of 0.1-0.5% by weight of the total polycarbonate resin formulation.

For which uses of PFAS is there no alternative?

Outlook: No alternative has yet been identified.

R&D activity: Various flame-retardant materials have been examined as potential alternatives to polycarbonate resins, including PP, Nylon, PPE/PS, Polyetherimide, PPSU, and PEEK.

Why there are no alternatives to polycarbonate resins: Toughness

In addition to flame resistance, it is essential for product safety that thin plastic walls have adequate toughness to

- provide a durable product that does not break during normal use, including drops and other foreseeable events
- ensure safety by avoiding exposure of live circuitry, and
- meet EU regulatory requirements of the electrical device.

Toughness is comprised of a combination of two physical properties: impact resistance and ductility. Impact resistance is the material's *ability to absorb shock or impact energy without breaking*. Ductility is the material's ability to stretch without breaking.

A material's impact resistance and ductility can be measured using Notched Izod Impact (NII) and Tensile Elongation (TE). These techniques measure the amount of energy a material can absorb during impact and the percentage amount the material will stretch before breaking in controlled laboratory settings, following standardized test methods (e.g., ASTM D256[49]/ ISO 180[50] for NII and ASTM D639[51]/ISO 527[52] for TE). The higher the impact resistance and the ductility, the tougher the material is and the more resistant it is to cracking or breaking.

As highlighted in Table 1 polycarbonate resin formulations provide unmatched impact resistance and ductility in the afore-mentioned tests compared to other engineering plastics, while also providing the required flame resistance, as measured by the ability to pass UL94 V0 flame testing at less than 1.0 mm thickness. The other engineering plastics in the below table were selected, based on our technical expertise, as most likely to represent viable alternatives to polycarbonate blends. However, as described below, none of these other thermoplastics represent viable alternatives to polycarbonate based on our research.

	PPE/PS	☑	12% (88% decrease)	14% (86% decrease)
	Polyetherimide	☑	4% (96% decrease)	55% (45% decrease)
	PPSU	☑	83% (17% decrease)	55% (45% decrease)
	PEEK	☒	11% (89% decrease)	46% (54% decrease)
	Polypropylene	☒	4% (96% decrease)	120% (20% increase)

Table 2 Flame resistance, impact resistance and ductility of engineering plastics compared to polycarbonate

As can be seen in Table 1, several materials can achieve similar flame resistance to the polycarbonate, however none of these materials have a comparable combination of both impact resistance and ductility (hence, overall toughness).

Why there are no alternatives to PTFE for thin wall polycarbonate

There are several strategies that can be employed to increase resistance to flame dripping by increasing the melt strength or the stiffness of the material with either viscosity enhancers or mechanical fillers. However, Table 2 highlights that none of these strategies can provide the necessary flammability performance for thin-walled polycarbonate while also maintaining adequate impact resistance and ductility.

Highly branched/high viscosity polycarbonate can increase the melt strength and reduce flame dripping. However, this results in a significant reduction in impact resistance and ductility by 86% and 56% respectively and does not provide adequate overall flammability performance at less than 1.0 mm wall thicknesses.

Glass fiber or other inorganic fillers (Clay, Talc, Carbon Fiber) can be added to increase the stiffness of the material and reduce flame dripping. However, these additives must be used at relatively high loadings (20-50% or more by weight) to have a significant effect on flame dripping properties, and these high loadings cause a dramatic decrease in the ductility and impact resistance of the material. Glass, Talc and Clay fillers, at 20 weight % loading significantly reduce the impact resistance and ductility by 84% and 96% respectively (and these properties will continue to deteriorate as filler loading increases), and do not provide adequate overall flammability performance at less than 1.0 mm wall thicknesses. Carbon fiber does provide adequate overall flammability performance at less than 1.0 mm wall thicknesses but significantly reduces the impact resistance and ductility by 90% and 99% respectively.

Property Comparison in PC

	Property	Flame Resistance	Impact/Crack Resistance	Ductility
PTFE Replacement		Passes UL94 V-0 @<1.0 mm?	Notched Izod Impact, % of Reference	Elongation @Break, % of Reference
	PTFE	☑	100% (Ref)	100% (Ref)
	Branched/High Viscosity Resin	☒	14% (86% decrease)	44% (56% decrease)
	Mineral (Glass, Talc, Clay)	☒	16% (84% decrease)	4% (96% decrease)
	Carbon Fiber	☑	10% (90% decrease)	1% (99% decrease)

Table 3 Flame resistance, impact resistance and ductility of alternative anti-drip agents compared to PTFE in polycarbonate

As can be seen in the table, only one alternative approach to PTFE (carbon fiber) can achieve adequate overall flammability performance, however the significant reduction in impact resistance and ductility does not allow it to meet product safety requirements and so this approach cannot be used in design and manufacture of consumer electronics.

Substitution:

There are no alternatives to PTFE available today for thin-wall flame retardant polycarbonate resins. A wide range of potential alternatives have already been tested and found to fail to provide the necessary properties. A new round of extensive, fundamental laboratory research will be needed to attempt to identify a completely new material, unknown today, that may potentially be developed into an alternative to PTFE. It is estimated to take up to 8 years for this basic research.

If a new alternative material is identified it would take several more years to test, qualify, certify, and start manufacturing parts from this replacement material. Companies may need to make changes to their manufacturing equipment and processes to use the new material in their injection molding lines. These changes to manufacturing equipment and processes may be significant and require extensive time and capital investment.

Product requalification is a very time-consuming exercise which will require extensive resources over many years. The completion of this task will require sufficient test house capacity and transition time to requalify all existing thin-wall flame retardant polycarbonate resin parts in products which are used in Europe for safety and performance. For a company with a wide range of existing product designs, we estimate it could take up to 5 years to carry out the necessary manufacturing equipment changes and product re-qualifications.

Proposed derogation

Paragraph 2(c) shall apply from (**13.5** years after entry into force) to PTFE used as **anti-dripping for polycarbonate resins and alloys (includes thermoplastics, such as Polycarbonates (PC), Polyvinyl Chloride (PVC), Polyamides, Acrylonitrile Butadiene Styrene (ABS), Polycarbonates (PC) and Acrylonitrile Butadiene Styrene (ABS) blend, Polypropylenes (PP), Thermoplastic Polyurethane (TPU), Polyethylenes (PE), Polyesters**.) **used for thin-walled parts** in electrical and electronic equipment.

4.1. Anti-dripping agents - socio-economic impacts

Statistics from several European countries reveal that electrical equipment account for 25 - 30% of all domestic fires, estimated in 273,000 fires per year. Fires can be generated by devices connected to the mains power, or battery powered devices. Lithium-ion batteries, in a fault condition, are also capable of overheating leading to ignition and subsequent explosion.

Flame retardancy has been proven to work and continues to be a powerful tool in the overall efforts to prevent fire related injuries and save lives. One of the most important benefits of flame retardancy in product design is they can stop small ignition events from turning into larger fires. Even if ignited material with flame retardancy also delay the spread of fire to give people sufficient time to escape. For example in the EU, due to the introduction of increased fire safety standards — the number of fire victims fell by more than 48% in France from 1982 to 2012, and by 56% in the UK from 1982 to 2013. Overall Europe has achieved substantial improvements in fire safety, with fire fatalities dropping by 65% over the last 30 years[53]. Since 2017, nearly different 500 types of electronic products have been recalled, withdrawn, or banned from sale in the EU due to fire hazards[54].

Other materials and components used in electronics are insufficient to prevent or delay the spread of fire from electronics. For example, protective components within electronics can reduce but not eliminate the risk of fire from electrical malfunction/failures. For example, a thermal fuse in a motor operated appliance will offer protection against an abnormal overload condition but it will not protect against other component failures like overheated power switches, connectors, wiring etc.

Another example is current-limiting components such as circuit breakers that are triggered by current rather than voltage. Once they are triggered, current limiting devices restrict power from reaching the equipment being protected without having to dissipate that power as heat. Therefore, there is virtually no limit to the amount of energy that they can handle. However, current-limiting devices do not generally respond fast enough to protect equipment from fast

[53] Modern building alliance Europe: Fire Death Rate Trends: An International perspective
[54] Safety Gate: the EU rapid alert system for dangerous non-food products

transient overvoltage's generated by lightning or electrostatic discharge which can lead to a flashover/arcing.

It is therefore essential to continue to guarantee the availability of PTFE and flame-retardant polycarbonate for the safety of electrical equipment on the European market until an effective and safe alternative can be found.

The consequential economic (in euros) and social (e.g. jobs) impacts arising from any restriction of PFAS in respect to its use as anti-drip additive in polycarbonate plastics is difficult to quantify. However, significant financial costs can be expected to arise.

1. **Annual value of EU sales**: In 2022, the computer hardware market in Europe generated a total revenue of over 60 billion euros, selling around 630 million units. Storage units made up the majority of volume at approximately 462 million units, followed by laptops and keyboards, both with approximately 42 and 40 million units sold, respectively.[55]
2. **Indirect cost - European employment in the ICT sector**: In 2022, more than 9 million persons worked as ICT specialists across the European Union (EU). The highest number (2.1 million) worked in Germany, which provided work to more than one-fifth (22.6 %) of the EU's ICT workforce. France (1.2 million) had the second largest ICT workforce (13.0 % of the EU total), followed by Italy and Spain (both 0.9 million; 9.6 % and 9.4 % respectively).[56]
3. **R&D, retooling, retesting, recertifying supply chain costs:** not able to be estimated.
4. **Cost to companies/consumers in the EU to repair/replace electronic devices on more frequent cycles**: A Eurobarometer survey observed that, when a main failure occurs, 77 % of EU citizens would rather repair their goods than buy new ones, but ultimately have to replace or discard them because they are discouraged by the cost of repairs and the level of service provided (European Commission, 2014b). Viegand Maagøe and VITO (2017) reported a typical lifetime of 5 years for notebooks, 6 years for desktop computers.[57]
5. **Impact of downtime to EU businesses when electronic devices fail**: Data in the public domain tends to focus on the cost to businesses resulting from network outages rather than devices, but costs will vary according to the sector and size of the business but will include productivity losses, replacement costs, and lost sales.

5. Cables/Connectors

General summary on the application category

A wide variety of materials is available as insulation and jacket for cables and connectors. Many types of plastics, rubbers and fluoropolymers are used in different applications. Fluoropolymers (PTFE, FEP, PVDF and PFA) are only chosen when other materials cannot meet the specific requirements on dielectric properties, flame and heat resistance, chemical inertness and/or durability. They are predominantly used in Direct Current (DC) cables and coaxial cables, but fluoropolymers can also be required for other cable types in demanding applications.

A DC cable is an electrical connector for supplying direct current power to electronic devices like computers and laptops.

Coaxial cables are used to carry high-frequency electrical signals. They are used in the electronics sector for the transmission of data - coaxial cables allow for high bandwidth and to transfer data over shorter distances in typically commercial and consumer settings. They differ from other shielded cables because the dimensions of the cable and connectors are controlled to give precise, constant conductor spacing, which is needed for it to function efficiently as a transmission line. Coaxial cables work by carrying data in the center conductor, while the surrounding layers of shielding perform to prevent harmful radiation while minimizing signal loss (also called signal attenuation). The first layer, called the dielectric, provides distance between the core conductor and the outer layers, as well as some insulation.

A discrete wire is a wire with a single conductor that terminates on one connector contact. When discrete wires are used to make cable assemblies, it is known as a discrete cable assembly. Discrete cables are commonly used for power transfer in the cable circuit design when the transmission current is higher within the same usable space in the device.

The uses of fluoropolymers (PTFE, FEP and PFA) are essential to the functioning of several types and/or uses of cables. PTFE, FEP and PFA are robust fluoropolymer materials that are used to insulate cables to improve performance for demanding applications. They have superb flame-retardant properties: no additional flame retardants are needed (reduces the use of halogenated flame retardants), they have high melting points and low rates of heat release and low smoke generation.

For coaxial cables with a diameter exceeding a quarter inch / 6.3mm alternative materials such as polyethylene foam can be used for certain applications. The minimum diameter relates to a minimum thickness of the dielectric material (reducing radio frequency signal losses to an acceptable level). This material has a much lower flammability rating which is acceptable only in specific applications.

Fluoropolymers also have excellent electrical properties (which means very low losses when transmitting high signals) and the widest temperature range of any plastic material – being able to withstand everything from -200ºC up to +260ºC and even up to +400ºC for a short length of time, which means they can transmit high power and withstand the high soldering temperature. Furthermore, they are highly resistant to sunlight, and therefore unlikely to degrade even in outdoor conditions. They provide excellent resistance to oils and other chemicals and UV light. They have superior mechanical flexibility – no plasticizers are needed (reduces the use of ortho-phthalates) and have the lowest coefficient of friction of any solid materials. Fluoropolymers are hydrophobic and resistant to hydrolysis; the typical properties and dimensional stability remain unchanged even after long immersion in water which is good for cables/connectors for outdoor use.

There are no other chemicals that can provide all of these critical properties in combination in a standalone substance for cables/connectors. The uses of fluoropolymers in cables and connectors also enhance the product durability which is a key focus of policy efforts as part of the Circular Electronics Initiative and has been a key feature in the review of Ecodesign Regulation 617/2013 (Lot 3) - Computers and Computer Services.

Alternatives highlighted by ChemSec and by the Dossier Submitter

Analysis by ChemSec highlighted a high degree of uncertainty on whether alternatives were available.[58] This has been corroborated through extensive supplier engagement. No alternatives have yet been found that meet all the properties offered by these PFAS substances in cables and connectors.

The Dossier Submitters proposed alternatives for wire insulation. These non-PFAS alternatives are PEEK, PC and EDPM. A review was conducted to ascertain their feasibility as viable non-PFAS alternatives, focusing upon several prominent properties.

Dielectric Constant

Most fluoropolymers have a dielectric constant of ~ 2.0.[59] This is extremely critical as the size of electronic devices continues to shrink, which introduces new obstacles such as signal crosstalk, power consumption and time delays, as a result, fluoropolymers with low dielectric constants are needed to achieve faster and stable signal transmission.[60] Such dielectric characteristics are the result of the fluoropolymers' symmetrical molecular structure $(C_2F_4)n$ and the short distance between the carbon and fluorine[61].

The three proposed non-PFAS alternatives have much higher dielectric constants ranging from 2.7 – 4.5[62], which will result in much slower and unstable signal transmission. This will greatly affect the functioning, safety and quality of the electronic product for which these cables/connectors are utilised. Thicker insulation might solve this problem, but not in all applications there is sufficient space. Consequently, on this critical property alone, none of the proposed non-PFAS alternatives are suitable to replace PFAS for all cable applications.

Dissipation Factor

The dissipation factor can also be used to assess the characteristics or quality of an insulating material in applications such as cables, connectors, terminations, joints etc. The lower the value, the better the dissipation factor. Fluoropolymers have a low value of 2.0[63] which provides a highly efficient insulator. EPDM also performs well with this quality with a dissipation factor of 2.5[64], however, the other proposed non-PFAS alternatives PC and PEEK

have dissipation factors of 9 and 30[65] respectively which are not best suited for cables/connectors.

Coefficient of Friction

Fluoropolymers have a Coefficient of Friction (COF) in the range of 0.02 - 0.08[66] which are effectively the lowest of any known solid material. Such properties have proven to be invaluable to the electronics industry in providing sustained durability. PC has the closest COF with a range of 0.05-0.18[67] to that of the fluoropolymers. PEEK has higher values of 0.15-0.40[68] while EPDM has very high values of 1.36 - 2.76[69] which are not suitable for cables/connectors.

Flame Retardancy

In terms of flame retardancy, a primary safety function, fluoropolymers are unique with their extremely high Limiting Oxygen Index (LOI) of ~95%[70] which inherently means they are non-flammable. The proposed alternatives have LOI values ranging from 19.5 - 24[71]. Taking EPDM with the lowest LOI value of 19.5, implies that it is a highly flammable substance that restricts its further application and development particularly within the electronics industry[72]. PC and PEEK also have low LOI values which would require flame retardant additives to be employed. However, the "Regulatory Strategy for Flame Retardants" published by the European Chemicals Agency in March 2023, which stated that "the substances in scope of this strategy are in principle all flame retardants.", places a very high degree of uncertainty on the future availability of flame retardants that would be required for the non-PFAS alternatives proposed by the Dossier Submitters.

In essence, the proposed non-PFAS alternatives have some of the necessary properties required for use in cables/connectors. However, they all have inappropriate characteristics that would require in some cases, the addition of supplemental chemical substances to render them functional which are also on a roadmap to be regulated under the REACH regulation. Others such as EPDM with its flammability properties precludes them on safety grounds from undertaking a meaningful function with cables/connectors.

Non-PFAS Alternatives Identified Through Research

Focusing upon research into non-PFAS alternatives has required an extensive literature review to determine what if any non-PFAS alternatives are being considered for cables and. The on-line library search engine utilised for this review was Summon™.

Error! Reference source not found.4 illustrates the keywords/phrases utilised in an effort to comprehend what research into non-PFAS alternatives for cables and connectors taken place or indeed is still on-going.

Keyword or Phrase	# of Results	Results of Relevance to PFAS in Cables/Connectors/Capacitors
PFAS	68,857	Reviewed the first 1,000 results. None of them were relevant.
PFAS in electronics	1,791	None
Non PFAS alternatives in electronics	19	None
PFAS alternatives in electronics	78	None
Fluoropolymer alternatives in electronics	84	Most of the results focused upon fuel cells, membrane materials for alternative energy and sustainability applications. None were relevant for cables, connectors and capacitors.
PFAS in electrical cables	188	There were some relevant results, but the papers emphasised the benefits of fluoropolymers in cable products.
Fluoropolymer alternatives in electrical cables	10	None
PFAS in electrical connectors	8	None
Fluoropolymer alternatives in electrical connectors	0	None

Table 4 PFAS literature review for non-PFAS alternatives in cables, connectors and capacitors

Based upon the findings in Table 4, it is apparent that if there is on-going research into non-PFAS alternatives for cables and connectors, none of it is finding its way into the public domain. This scenario is more than likely a result of the lack of research into these electronic components/products.

Waste

Latest data from Eurostat showed that the recycling rate for separated WEEE stood at 84.5% in 2020.[73] Due to the likely presence of POPs, antimony trioxide and plasticizers in cables, they attract a hazardous waste code. Indeed, since the introduction of more stringent requirements in respect to POPs, any WEEE plastic waste suspected of containing POPs are either burnt in high temperature incineration (i.e. cement kilns) or disposed of in hazardous waste landfills.

In the next three sections 5.1 – 5.3 examples are given of cables and connectors for which there is no PFAS-free alternative for all uses. These examples are not exhaustive. Other types of cables may also require the use of PFAS in demanding applications/environments.

[73] https://ec.europa.eu/eurostat/web/circular-economy/monitoring-framework

5.1. DC cable insulation

Name of PFAS substance(s) PTFE, FEP and other fluoropolymers

CAS Number(s) 9002-84-0, 25067-11-2, 25190-89-0 and more

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Insufficient information to quantify/See confidential annex for details.

The key functionalities provided by PFAS for the use in DC cable insulation

1. High temperature stability

   Melting point of FEP is 285°C and PTFE is 327°C. These are significantly higher than potential alternative materials[74]

2. High flame retardant ratings

   The UL flammability ratings of FEP and PTFE are both V-0. This is essential to ensuring the fire safety of the product. Alternative materials typically have lower flammability ratings and therefore could compromise the safety of the product.[75]

3. High chemical resistance[76]: Fluoropolymers (e.g. FEP or PTFE) are inert to acid and base. This is a key characteristic of fluoropolymers to ensure safety and well protection on the conductor inside.

4. High mechanical flexibility (see details below)[77]

For which uses of PFAS is there no alternative?

Outlook: Analysis by ChemSec highlighted a high degree of uncertainty whether alternatives were available. This has been corroborated through extensive supplier engagement. No alternatives have yet been found that meet all properties offered by these two substances in this use.

R&D activity: To date, materials that have been examined include TPE, PVC as well as polyolefins, such as PE and PP.

- **PE, PP and TPE have relatively low melting points compared to PFAS and cannot meet the high temperature stability requirement for certain applications.**
  The melting point for the insulation material is key to DC cables. This is particularly crucial due to the soldering/welding process involved in the manufacturing process. When soldering, temperatures around 300°C are transmitted to the insulation through the conductor. If the material's melting point is significantly below 300 °C, it can lead to insulation burns and ultimately result in malfunction. For instance, the melting point of PE typically ranges from 130 to 135 °C. PP has a melting point that typically ranges from 130 to 171 °C. TPE has a melting point around 60-200 °C. PFAS materials, on the other hand, have high melting points up to 327 °C. The melting point of the material is crucial in ensuring the insulation's integrity and preventing malfunctions.

[74] Supplier Survey 2023; RCOM Ref. 4011, 3909, 3961
[75] Supplier Survey 2023
[76] RCOM Ref. 4011
[77] Supplier Survey 2023, RCOM Ref. 4011

In addition, the operating temperature must be taken into account. The operating temperature for DC cables can go up to 80°C. TPE has a low melting point below 80°C, while other materials have melting points above 80°C.
PFAS is the only type of material that remains structurally stable and does not deform or melt under both two conditions, which results from its exceptional heat resistance and thermal stability. This characteristic is crucial in ensuring the safety of the cable.

- **PE, PP and TPE have relatively low flame-retardant ratings as compared to PFAS**
  High flame resistance is essential for the DC cables used in consumer electronics as it plays a significant role in ensuring user safety and protecting property. Manufacturers need to prioritize incorporating flame-resistant materials in DC cables to meet stringent safety requirements.
  PFAS materials exhibit excellent flame retardant performance and have a UL flammability rating of V-0. PP, PE and TPE materials cannot achieve the same flame retardant rating as PFAS materials.

- **PE and PP have lower mechanical flexibility as compared to PFAS**
  The flexibility and durability for DC cable application is essential to ensuring that the cables can withstand mechanical stress, bending, and dynamic movement without failure. The elongation at break value for FEP typically ranges from 300% to 400%, PP is less than 100%, PE is above 100% and TPE can exhibit a range from 300% to 500% depending on the specific type, grade, and formulation. TPE is a good alternative in terms of flexibility and durability, but it is important to note that flexibility and durability along not guarantee to meet the relevant safety requirements.

- **PVC has poor high temperature stability**
  PVC is often used as wire insulation for moderate temperatures. It can however not be used for temperatures above 70~100 °C. Another disadvantage is the halogen content of PVC.

Substitution:
- The supply chain has reported potential alternative materials to replace PFAS in DC cable applications. However, it will require significant product resign and requalification, and may reduce the safety performance of the cables. The time required to verify the alternative materials is at a minimum:

- 12 months for cable level development and testing: develop specification of raw cable, update manufacturing process, and cable reliability testing and certification.
- 12 months for device level integration testing and certification.
  - If the alternative material does not work, the time required to develop a new material that meets all the safety and performance requirements is unknown. It is estimated to take at least 1-2 years for suppliers to study, screen and identify a potential substitute.
- After successful implementation in a single product, a similar cycle of development and testing is required for the entire product portfolio.

5.2. Coaxial cable and discrete cable insulation and jacket

Name of PFAS substance(s) PFA, FEP, PTFE

CAS Number(s) 26655-00-5, 25067-11-2, 9002-84-0

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Insufficient information to quantify.

The key functionalities provided by PFAS for the relevant use[78]

1. Compliance with safety standard UL1354
2. High temperature stability
3. Melting point of FEP is 285°C , PTFE is 327°C and PFA is 305°C. These are significantly higher than potential alternative materials
4. Good electrical performance which ensures reliable signal transmission over a wide range of frequencies. PFAS has low dielectric constant which minimizes signal loss when it's being transferred through the cable hence maintaining excellent signal integrity. Application may malfunction without excellent signal integrity.
5. Low dielectric constant which enables smaller cable diameter (compared to using alternative materials) while maintaining the required electrical performance
6. High insulation resistance and dielectric strength which improves cable reliability and safety, preventing breakdown of equipment, insulation issue or short circuit accidents
7. High flame retardant ratings
8. The UL flammability ratings of FEP, PFA and PTFE are V-0. This is essential to ensuring the safety of the product. Alternative materials typically have lower flammability ratings and therefore could compromise the safety of the product.
9. High mechanical flexibility

   Fluorinated polymers, like FEP and PTFE possess superior Shore D hardness compared with PE and PP:

Material	Shore D
PTFE	D55
PFA	D60
FEP	D55
PVDF	D80
PEEK	D85
PE	D60-D70
PP	D77-D83

   The material with lower Shore D hardness provides better flexibility and better durability. Some cables, like antenna cables, in electronic device often need to pass through the hinge and then must be abraded and rotated following hinge operation. The high shore D hardness insulator cannot be an adequate buffer for the conductor inside, and therefore the conductor cannot bear the frequent twist and abrasion. The

[78] Supplier Survey 2023, ChemSec 2023; RCOM Ref. 4011, 3909, 3691

low hardness of PTFE, FEP and PFA can provide an adequate buffer to protect the conductor and also bear the frequent twist and abrasion. This feature also ensures a longer life cycle for cables used in electronic devices.

10. High chemical resistance: Fluorinated polymers, no matter whether FEP or PTFE, are inert to acid and base. This is a key character of FEP and PTFE for safety to ensure the well protection on the conductor inside.

For which uses of PFAS is there no alternative?

Outlook: Analysis by ChemSec highlighted a high degree of uncertainty whether alternatives were available. This has been corroborated through extensive supplier engagement. No alternatives have yet been found that meet the properties offered by these two substances in this use.

R&D activity: PE and PP, TPE, PVC and silicone resins have been evaluated as alternatives.

- **Non-PFAS materials cannot meet high frequency electrical performance requirements**
  PFAS materials (PTFE, FEP, PFA) are effective in handling high-frequency signals - they can meet the attenuation requirement and support signal transmission over a wide range of frequencies from a few megahertz (MHz) to several gigahertz (GHz) or higher. On the other hand, TPE, PP, PVC, and PE have a frequency range that only extends from a few kilohertz (KHz) to several hundred megahertz (MHz), rendering them unable to meet the gigahertz-range application requirements. A thicker cable insulation might solve this problem, but this does not fit in all applications.
- **Using non-PFAS materials will result in larger cable diameter which does not meet the required specification of a coaxial cable**
  A coaxial cable must have its characteristic impedance controlled, most commonly at 50Ω, to transmit a signal. The value of characteristic impedance changes depending on the dielectric constant of the insulated core and the outer diameter of the insulated core. If a material with a high dielectric constant is used to insulate the coaxial cable, the cable diameter will be increased. Therefore, it is necessary to use materials with a dielectric constant as low as possible for the insulation of coaxial cables. PFAS materials have a dielectric constant that is lower than that of non-PFAS materials. FEP, PFA and PTFE have a relative dielectric constant of 2.1, and is characterized by being able to form an insulating coating as thin as 0.02mm by extrusion molding. On the other hand, PVC has a dielectric constant of 3.1 to 7.0, and the minimum thickness that can be extruded is 0.15mm. Therefore, if the coaxial cable using PFA has an outer diameter of 1 mm, the coaxial cable using PVC will have an outer diameter of 1.4 mm. Similarly, in the case of TPE, it has a dielectric constant is 3 to 8, and the minimum thickness that can be extruded is 0.2 mm, so the outer diameter of the coaxial cable will be 1.8 mm. The dielectric constant of silicone resin is 2.6~3.7, and the minimum thickness that can be extruded is 0.05mm. Therefore, the outer diameter of the coaxial cable will be 1.06mm.
  In summary, resins other than PFAS have a larger dielectric constant and a larger minimum wall thickness that can be extruded, so the outer diameter of the cables will be larger and cannot meet the product specification.
- **PE, PP and TPE have relatively low melting points compared to PFAS and cannot meet the high temperature stability requirements**
  The melting point for the insulation material is key to coaxial cables and discrete cables. This is particularly crucial due to the soldering/welding process involved in the manufacturing process. When soldering, temperatures around 300°C are transmitted

to the insulation through the conductor. If the material's melting point is significantly below 300 °C, it can lead to insulation burns and ultimately result in malfunction. For instance, the melting point of PE typically ranges from 130 to 135 °C. PP has a melting point that typically ranges from 130 to 171 °C. TPE has a melting point around 60-200 °C. PFAS materials, on the other hand, have high melting points of up to 327 °C. The melting point of the material is crucial in ensuring the insulation's integrity and preventing malfunctions..

During use phase of electronic products, PP and PE cable jackets are not suitable for high temperature applications.

- **PE, PP and TPE have relatively low flame retardant ratings as compared to PFAS** High flame retardancy is essential for coaxial cables and discrete cables used in consumer electronics as it plays a significant role in ensuring user safety and protecting property. Manufacturers need to prioritize incorporating flame retardant materials in cables to meet stringent safety requirements. PFAS materials (PTFE, FEP, PFA) exhibit excellent flame retardant performance and have a UL flammability rating of V-0. PP, PE and TPE materials cannot achieve the same flame retardant rating as PFAS materials.

- **PE and PP have lower mechanical flexibility as compared to PFAS** The flexibility and durability for coaxial cable and discrete cable application is essential to ensuring that the cables can withstand mechanical stress, bending, and dynamic movement without failure. The elongation at break value for FEP typically ranges from 300% to 400%, PP is less than 100%, PE is above 100% and TPE can exhibit a range from 300% to 500% depending on the specific type, grade, and formulation.

  TPE is a good alternative in terms of flexibility and durability, but it is important to note that flexibility and durability along not guarantee to meet the relevant safety and electrical performance requirements.

- **PVC was also disregarded due to its halogen content and poor high-temperature stability**[79]

- **Silicones have lower mechanical strength**

  Silicone wire insulation can withstand temperatures up to 180 °C. However, its tensile strength and mechanical properties are not good enough. ChemSec also confirmed that rubber substitutes have less mechanical strength and less abrasion resistance and that silicone insulation would lead to chemical deposition on the sensors, leading to malfunctions. [Source: ChemSec 2023]

- **Non-PFAS materials are not as resistant to chemicals as PFAS materials**

  When there is a risk of cables being exposed to chemicals, the jacket must be resistant to these chemicals. The material of choice depends on the chemicals it has to be resistant to. To some chemicals only PFAS materials are resistant.

Conclusion

It can be concluded that alternative materials do have some of the required properties and are suitable for use in less-demanding applications. However, for more demanding applications only PFAS materials have all the required properties.

[79] Supplier Survey 2023

Substitution:

- The time required to develop a new material that meets all the safety and performance requirements is unknown because for some properties no material is currently known. It is estimated to take at least 2 years for suppliers to study, screen and identify a potential substitute.
- If a substitute is eventually available, the time for substitution is at a very minimum:
    - 12 months for cable level testing: develop specification of raw cable, update manufacturing process, cable reliability testing and certification
    - 15 months for device level integration testing and certification.

5.3. Connector jacket

Name of PFAS substance(s) PTFE, FEP

CAS Number(s) 9002-84-0, 25067-11-2

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Insufficient information to quantify.

The key functionalities provided by PFAS for the relevant use[80]

1. Good dielectric properties
2. High/low temperature stability
3. Good chemical resistance
4. Mechanical properties of resin

Limited data from supply chain

For which uses of PFAS is there no alternative?

Outlook: ChemSec's research has been unable to find an alternative that delivers all of the critical properties in cables and connectors (ChemSec, 2023) which has been corroborated through extensive engagement with suppliers.

R&D activity: Alternatives examined by the industry for connector applications include PA and LCP, but there is no positive result yet.[81]

In general, products using alternatives cannot meet at least one of the safety or performance requirements (mechanical properties, dielectric strength, flame retardancy, temperature and chemical stability).[82]

[80] Supplier Survey 2023
[81] Supplier Survey 2023
[82] RCOM Ref 4011

Substitution:

- The time required to develop a new material that meets all the safety and performance requirements is unknown. It is estimated to take at least 2 years for suppliers to study, screen and identify a potential substitute.
- If and when a substitute is available, it is estimated to take at least 12 months to produce and qualify the new part.

Proposed derogations – Cables/Connectors

Paragraph 2(c) shall apply from (**13.5 years** after entry into force) to **fluoropolymers in cable insulation and jacket and connectors**.

5.4. Socio-economic impacts

The consequential economic (in euros) and social (e.g. jobs) impacts arising from any restriction of PFAS in respect to its use in cables and connectors are difficult to quantify. However, significant financial costs can be expected to arise because of the inability to substitute and because of the strategic importance the EU has placed in developing an advanced digital and data economy as part of its European Data Strategy & communication "Shaping Europe's digital future"".

1. Annual value of EU sales: In 2022, the computer hardware market in Europe generated a total revenue of over 60 billion euros, selling around 630 million units. Storage units made up the majority of volume at approximately 462 million units, followed by laptops and keyboards, both with approximately 42 and 40 million units sold, respectively[83]
2. Indirect costs - European employment in the ICT sector: In 2022, more than 9 million persons worked as ICT specialists across the European Union (EU). The highest number (2.1 million) worked in Germany, which provided work to more than one-fifth (22.6 %) of the EU's ICT workforce. France (1.2 million) had the second largest ICT workforce (13.0 % of the EU total), followed by Italy and Spain (both 0.9 million; 9.6 % and 9.4 % respectively).[84]
3. Indirect European employment - data professionals: Professionals working in the new and growing data economy rely on the efficient transfer of data. When publishing the EU's data strategy for the EU, the number of data professionals was expected to grow from 5.7m in 2018 to 10.9m in 2025, touching nearly every sector across the economy.
4. Indirect financial consequences of less efficient data transmission: The European Commission estimates that the EU's data economy will be worth €829 billion in 2025, from 2% to 6% of regional GDP[85]
5. Wider economic impacts - expected growth: Christensen et al (2018) estimated, using the RHOMOLO model, that implementing the third pillar of the Investment Plan for

[83] Statista, 2023, https://www.statista.com/forecasts/1256748/volume-segments-computer-hardware-europe
[84] Eurostat, 2023, ICT Specialists in Employment, https://ec.europa.eu/eurostat/statistics-explained/index.php?title=ICT_specialists_in_employment#Number_of_ICT_specialists
[85] EU factsheet, https://ec.europa.eu/commission/presscorner/detail/en/fs_20_283

Europe, including efficiency gains from the Digital Single Market, would contribute to a 1.5% increase in GDP per year until 2030 and create between 1 and 1.4 million jobs.[86]

6. R&D, retooling, retesting, recertifying supply chain costs: not able to be estimated.
7. Fluoropolymer related impact[87]

   Employment:

   - Indirect and induced employment resulting from the production of fluoropolymers: The average GVA per employee in relevant industries is €100,000.
   - Overall, in the EU around 4,500 employees are directly employed in manufacture of fluoropolymers, and in the wider sector an estimated 4,400 people. This suggests some 8,900 people in total are sustained directly and through indirect and induced effects by the production of fluoropolymers. This does not include employment in sectors using fluoropolymers, which is many multiples higher. (P23)
   - Volumes of fluoropolymers placed on the market in the EEA in 2020: Around 40,000 tonnes of fluoropolymers estimated to be sold in EEA (P10)
   - Growth projections: The EU Chips Act is anticipated to allow the EU to reach its ambition of doubling its current market share of semiconductor technology to 20% in 2030. This indicates that fluoropolymers will likely follow a similar trend over this period. (P11)
   - Sales value of products sold in the EEA in 2020: €750million (P14)
   - Two estimates of Downstream applications market of fluoropolymers in EU: sales to electronic sector in 2020:
     - 3,500 tonnes of fluoropolymers, value: €70 million (source: 2017 FPG SEA study)
     - 4,000 tonnes and €80 million (source: studies supporting PFAS restriction proposal)

   Note: this means the EU electronics sector is around 10% of fluoropolymer volumes in the EU. Sales value estimates are consistent at approx. 10%.

[86] M. Christensen, A. Conte, F. Di Pietro, P. Lecca, G. Mandras, & S. Salotti (2018), The third pillar of the Investment Plan for Europe: An impact assessment using the RHOMOLO model (No. 02/2018). JRC Working Papers on Territorial Modelling and Analysis
[87] FPG 2022 report https://fluoropolymers.plasticseurope.org/application/files/1216/5485/3500/Fluoropolymers_Market_Data_Update_-_Final_report_-_May_2022.pdf

6. Capacitors

Name of PFAS substance(s) PTFE, PTFE co-polymer, Poly(difluoromethylene),. alpha.-(cyclohexylmethyl)-.omega.-hydro-, etc.

CAS Number(s) 65530-85-0

General summary of the application category

PFAS is used in several materials such as electrodes (anode), masking, seals, coatings, insulators, and paste materials. The properties they provide include:

- highly reliable seal against electrolyte diffusion along the tantalum anode wire.
- resist distortion during the oxidation and impregnation process.
- binder for electrodes – similar application as PFAS in batteries

Non-PFAS Alternatives Identified Through the Supply Chain or Research

The electronics industry has a very deep and complicated supply chain which operates on a global basis. Ascertaining data on feasible non-PFAS alternatives for capacitors has yielded no drop-in replacements to date. Nonetheless, the investigation will continue indefinitely.

Moving beyond the supply chain and focusing upon research into non-PFAS alternatives has required an extensive literature review to determine what if any non-PFAS alternatives are being considered for capacitors. The on-line library search engine utilised for this review was Summon™.

Error! Reference source not found. illustrates the keywords/phrases utilised in an effort to comprehend what research into non-PFAS alternatives for capacitors has taken place or indeed is still on-going.

Keyword or Phrase	# of Results	Results of Relevance to PFAS in Cables/Connectors/Capacitors
PFAS	68,857	Reviewed the first 1,000 results. None of them were relevant.
PFAS in electronics	1,791	None
Non PFAS alternatives in electronics	19	None
PFAS alternatives in electronics	78	None
Fluoropolymer alternatives in electronics	84	Most of the results focused upon fuel cells, membrane materials for alternative energy and sustainability applications. None were relevant for cables, connectors and capacitors.
PFAS in capacitors	62	There were some relevant results, but the papers emphasised the benefits of fluoropolymers in capacitors.
Fluoropolymer alternatives in capacitors	5	None

Table 5 PFAS literature review for non-PFAS alternatives in cables, connectors and capacitors

Based upon the findings in **Error! Reference source not found.**, it is apparent that if there is on-going research into non-PFAS alternatives for capacitors, none of it is finding its way into the public domain. This scenario is more than likely a result of the lack of research into these electronic components/products.

The combined lack of data on non-PFAS alternatives from the supply chain in conjunction with the lack of research into these electronic components/products, surmises that there are no drop in alternatives currently available and the likelihood of such alternatives being available at the entry into force timeframe is questionable.

Proposed derogation

Consequently, it is requested that a derogation covering the uses of various capacitor types is granted from the proposed REACH Restriction on PFAS for **13.5 years** after entry into force.

7. Grease & Lubricants

7.1. Grease/lubricants on mechanical parts in EEE

Name of PFAS substance(s) PTFE; Perfluoropolyether (PFPE) oil; Ethene, 1,1,2,2-tetrafluoro-, oxidized, polymd.

CAS Number(s) 9002-84-0; 60164-51-4; 69991-61-3

General summary on the application category

PFAS-containing greases are used on mechanical parts (e.g. hinge of laptops) in electronic products. These greases are used because they offer a low friction coefficient, have a wide service temperature range, are chemically inert, oxidation resistant, and have excellent material compatibility.

The use of PFAS greases are essential to ensuring long service life and durability of the products. Product durability is a key focus of policy efforts as part of the Circular Electronics Initiative and has been a key feature in the review of Ecodesign Regulation 617/2013 (Lot 3) - Computers and Computer Services.

As an example, laptop hinge lifecycle test is one of the many tests that are conducted to ensure the durability of the devices. As of yet, no alternatives can meet the industry standard durability requirements. For alternatives tested so far to replace PFAS, the projected part service life is (at a maximum) approximately half of the service life achievable by using PFAS.

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Insufficient information to quantify.

The key functionalities provided by PFAS for the relevant use[88]

1. Lowest known coefficient of friction (≤ 0.1)
2. Stable coefficient of friction and wear resistance over extended period of time
3. Chemically inert, oxidation resistant and excellent material compatibility
4. High temperature stability and wide service temperature range (-35℃-250℃)

For which uses of PFAS is there no alternative?[89]

Outlook: Despite extensive exploration, suitable alternatives have yet to be identified.

R&D activity: Among the substitutes trialed are PE, graphite, molybdenum(IV) disulfide, PVD surface treatment and even no grease entirely.

1. Not using grease at all on computer hinge frames and supports, resulted in the hinge breaking after a limited number of lifecycle tests which corresponds to less than 5% of the target service life time of the part.

[88] Supplier Survey (2023)
[89] Supplier Survey (2023)

2. Alternative surface treatment, such as Physical Vapor Deposition (PVD), was trialed. The intention of PVD is to achieve lower roughness of the surface, which is helpful to lower the friction between different surfaces. This has failed due to poor bonding between the surface and the PVD layer, as the PVD layer peeled off after a limited number of lifecycle tests which corresponds to less than 5% of the target service lifetime of the part. The peeled-off PVD layer also increases the friction of the hinge, therefore further reducing the hinge life.
3. Use of high precision turning process to achieve low roughness of the surface. This has failed to meet lifecycle and torque degradation requirements.
4. Use silicone or polyol ester to replace PFAS. However, both failed due to inadequate lubricant ability and inadequate thermal stability. These features of PFAS make it irreplaceable so far, especially with regards to extending the lifecycle of electronic devices.[90]

	Thermal Stability	Oxidation Stability	Hydrolytic Stability	Fire Resistance	Lubricating Ability
PFPE	E	E	E	E	E
Polyol Ester	G	G	G	G	G
Silicone	G	G	G	G	P

E: excellent; G: good; P: poor.

5. The use of other solid lubricant such as graphite and Molybdenum(IV) disulfide cannot pass the lifecycle test. Estimated service life for parts using these lubricants is approximately half of the service life achievable by using PFAS grease/lubricants.

Substitution: Time for substitution

- The time required to develop a new material that meets all the performance requirements is unknown. It is estimated to take at least 1-2 years for suppliers to study, screen and identify a potential substitute.
- Once a potential substitute is identified, it will take 1.5-1.8 years for material qualification (grease stability after aging, tribology test) and Hinge qualification (assembly + reliability test, part level assembly + reliability test, device level assembly + reliability test).
    - If the alternative material does not work, the time required to develop a new material that meets all reliability and performance requirements is unknown. It is estimated to take at least 1-2 years for each study and screening cycle to identify potential candidates.

Proposed derogation

Paragraph 2(c) shall apply from **(13.5 years** after entry into force) to **grease and lubricants** used in electrical and electronic equipment.

[90] Driving Auto Performance Through Lubricant Selection (https://pages.chemours.com/rs/509-VCL-038/images/Whitepaper_Auto_101_2017edits.pdf)

7.2. Lubricant in connectors

General summary on the application category

Plug-in connections are used wherever components or assemblies need to be connected temporarily. Electrical contacts have basically two main tasks: the possibility to mechanically separate an electrical connection and the transmission of electrical energy without losses in closed position.

As they are used in a wide range of different environments, like heat or damp heat, the contact surface of the electrical contact has to meet various requirements. Further, fretting corrosion continually exposes fresh layers of the metal surface to oxidation.

PFAS containing lubricants are used in gold-plated connectors to protect the part against oxidation and fretting corrosion, while also minimizing degradation through contact wear, thus helping to extend the connector life (Supplier Survey, 2023).

Product durability is a key focus of policy efforts as part of the Circular Electronics Initiative and has been a key feature in the review of Ecodesign Regulation 617/2013 (Lot 3) - Computers and Computer Services.

A thin film of lubricant can also reduce mating force by as much as 80 percent, an important factor in connector assembly. For electronic connectors with dozens or even hundreds of pins, a low insertion force helps to ensure solid connections.

No alternatives have been successful to replace PFAS to date.[91]

The annual tonnage and emissions (at sub-sector level) and type of PFAS associated with the relevant use

Insufficient information to quantify - may reference Cefic socio-economic study once it becomes available.

The key functionalities provided by PFAS for the relevant use

1. Low coefficient of friction (≤ 0.1) which protects the connector from mating and unmating forces and improves durability
2. High corrosion resistance
3. Stable coefficient of friction and wear resistance over extended period of time
4. High temperature stability and wide service temperature range (-35℃-250℃)

For which uses of PFAS is there no alternative?

Outlook: No alternatives have been identified to date. ChemSec suggested alternatives have proved to be unsuccessful substitutes.

R&D activity: Supply chain reported that all the potential alternatives evaluated so far contain PFAS. Other non-PFAS wax or grease are not suitable for industrial use. Suppliers are actively looking for alternative coating liquid that is not sticky in the manufacturing process, which has been the case when testing silicone alternatives.[92]

[91] Supplier Survey (2023)
[92] Supplier Survey (2023)

Alternative dry coatings have been tested and failed for either corrosion or cosmetics. Alternative lubricants have been tested and do not meet performance requirements.[93] After some usage, the coating is also peeled off easily and then peeled-off particles further increase the surface friction. The higher surface friction reduces the lifecycle of parts.

Substitution:

- The time required to develop a new material that meets all the performance requirements is unknown. It is estimated to take at least 1-2 years for suppliers to study, screen and identify a potential substitute.
- Once a potential alternative is identified, it will take 1.8-2 years for testing lifecycle, assembly line optimization, and evaluation of mass production.
  - If the alternative material does not work, the time required to develop a new material that meets all reliability and performance requirements is unknown. It is estimated to take at least 1-2 years for each study and screening cycle to identify potential candidates.

Proposed derogation

Paragraph 2(c) shall apply from **(13.5 years** after entry into force) to **grease and lubricants** used in electrical connectors.

8. Cooling in data centres

Introduction

The growth rate of data volume globally is nothing but astonishing. Information produced by the EU Commission as part of its EU Data Strategy illustrates a phenomenal 530% increase predicted from 2018 to 2025. Indeed, it is estimated that during the same timeframe, the value of the data economy to the EU will grow from €301 in 2018 to €828 billion by 2025 (Figure 5.0).

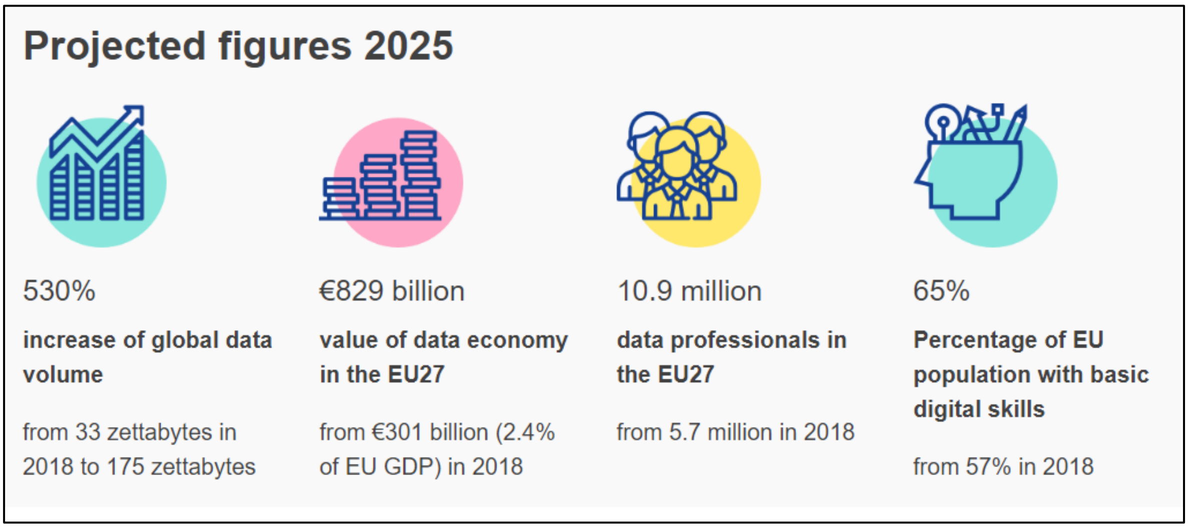

Figure 5 EU Data Strategy projected figures for 2025

In an effort to sustain or meet such data demands, there needs to be an equivalent increase in computational power. It's not just a case of doing more of the same as what's been done in the past to augment the necessary computational power. The growth rate of Artificial Intelligence (AI) and high-performance computers has driven the need for more powerful processors and hardware accelerators. This has resulted in generating significant increases in silicon or processor thermal design power (TDP) beyond 1kW/each processor and semiconductor package thermal density.

These semiconductor devices are housed in servers which in turn are accommodated in data centres. Simultaneously, there is regulatory focus on reduced energy consumption, increased energy efficiency at data centre level, reuse of waste heat from data centres as well as meeting sustainability goals. Together these trends are creating significant strain on today's data centres which require alternatives to today's state-of-the-art cooling technologies to handle the coming data demands.

Issues with Current Cooling Technologies

Cooling of data centres is frequently the largest energy loss in the facility and as such represents a significant opportunity to improve efficiency. The primary cooling methods employed in data centres are air and water based.

The objective of airflow management is to circulate only the necessary amount of air through the data centre at any time that is required to remove the heat actually created by the IT equipment. This means no air returns to the cooling system without absorbing heat and no air circulates more than one time through the IT equipment.[94] When considering water-based cooling methods, the water utilised needs to be sufficiently chilled which can have a significant impact on the data centre's energy efficiency. Due to the changing climate, water is becoming a precious commodity in several geographies across the globe including the EU and several regulations are being imposed on data centre operators to limit the use of water for data centre cooling applications such as towers or evaporative air cooling. Also, to cool high wattage processors, water needs to be chilled using chillers therefore reducing the overall efficiency of cooling solutions.

These air- and water-cooled methodologies are becoming increasingly inefficient with the cooling load required for the greater demands of server products. Consequently, alternative cooling methodologies have been investigated to cater for today's requirements but more importantly future needs as well.

Alternative Cooling Technologies

Unfortunately, there are no commercially available alternatives that address the future needs for high TDP, high heat flux silicon, and global energy efficiency demands that have no PFAS chemistry. Traditional forced air cooling has already been optimised within the practical limits of data centre airflow delivery. Traditional propylene glycol-water based fluids support high TDP but fall short on supporting high package thermal density as compared to pumped refrigerant 2-phase cooling. Also, due to the lower effective heat transfer of legacy liquid cooling methods, more power is required for primary loop water chillers and secondary loop fluid pumps (Figure 2.0) when compared with the pumped refrigerant 2-phase cooling method (Figure 3). It's important to note that water or air chillers used for current data centre cooling is already or will be shortly using one of these hydrofluoroolefins (HFO) refrigerants.

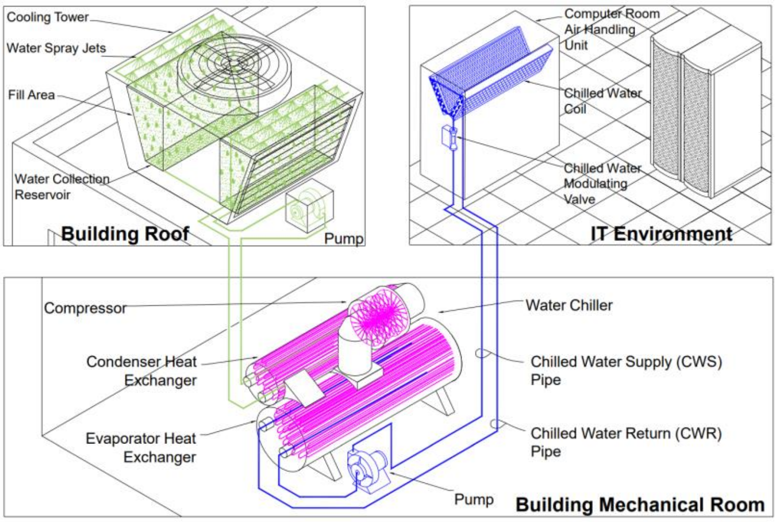

Figure 6 Traditional air-cooled data centre using water-cooled chiller system[95]

Put another way, refrigerant-based server level cooling allows deployment of AI silicon into markets where warm facility water usage is required to meet its energy efficiency and sustainability targets.

[94] Joint Research Centre (2023) Best Practice Guidelines for the EU Code of Conduct on Data Centre Energy Efficiency. European Commission.
[95]Image courtesy of Schneider Electric

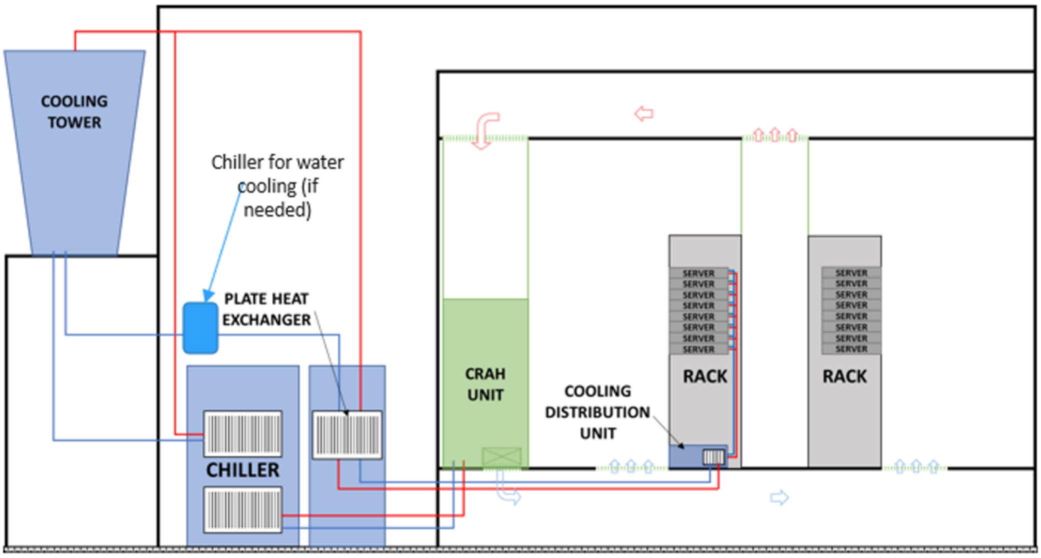

Figure 7 Hybrid air cooled data centre using propylene glycol fluid in server racks with water cooled chiller system or pumped refrigerant fluid in server racks eliminating high power water-based chiller systems

The use of F-gases particularly HFOs have shown to be extremely efficient in performing the required cooling of server products in data centres through this application known as two phase liquid-vapour cooling. This involves the circulation of low-to-medium pressure refrigerants (HFOs) through cold plates attached directly to high-powered AI silicon.

In this approach, the refrigerant is circulated through cold plates as a saturated liquid, absorbing heat from processors before it vaporizes. Due to higher latent heat of vaporization (compared to just sensible heat for single phase water-based cooling), the process requires relatively small pumping power and is vastly more capable and efficient than traditional air and water-based cooling methods. Please note this is a different technology to what is known as immersion cooling. The HFOs of interest that fulfil this cooling distribution function are captured in Table 6.0.

Refrigerant	Pressure	Chemistry	GWP	ODP	Toxicity	Flammability
R513A	medium	HFC/HFO	573	0	low	zero
R515B	medium	HFO	299	0	low	zero
R1234ze	medium	HFO	6	0	low	mild
R1234yf	medium	HFO	<1	0	low	mild
R1233zd	low	HFO	1	0	low	zero

Table 6 Suitable HFOs for Date Centre Cooling

The characteristics of the HFOs outlined in Table 6.0 illustrate excellent global warming potential which significantly supports the EU's climate ambition's goals as the more typically utilised F-gases in data centres such as R134a and R410a have global warming potentials of 1,430 and 2,088 respectively. One major advantage of these medium pressure refrigerants is with their low boiling point (well below traditional atmospheric temperature) if emitted or leaked,, it would immediately vaporize and not contaminate soil or ground water. Also, the half-life of these refrigerants is very short compared to traditional PFAS coatings and other compounds.

The cooling system itself is known as a cooling distribution unit (CDU) and is a closed system. This hardware utilises fluoropolymers such as gaskets and seals given their unique characteristics in addition to prolonging the service life of the CDU. There are no intentional releases of the HFOs with this technology. Currently there is less than one tonne of HFOs utilised globally for this application. These refrigerants are handled only by trained technicians as per HVAC industry protocols who have passed extensive certifications such as those outlined in the EU F-gases regulation, US EPA 608 etc. Hence, the safe use and handling of these refrigerants is already being monitored and is not handled by any non-certified technicians.

Suitability of Dossier Submitter Proposed Non-PFAS Alternatives

The Dossier Submitter in its Annex XV report proposed several non-PFAS alternatives for electronics cooling in data centres. Two of these proposed alternatives - Hydrocarbon Systems and Ammonia - had been questioned by the Dossier Submitters themselves on grounds of flammability and toxicity issues which would reside inside the data centre hall. The other non-PFAS alternatives such as basic ventilation, small-scale air-conditioning systems and water are simply not feasible given the pending demands of cooling technologies with the anticipated growth in data volume.

Critique of Dossier Submitter Conclusions Concerning HFO Emissions

The HFOs outlined in Table 6.0 which are needed to run this cooling distribution technology are known to degrade in the atmosphere to trifluoroacetic acid (TFA). Although, the cooling technology is not designed to release HFOs, it is important to stress the degradation profile of these F-gases to illustrate the low risk they pose to the environment and consequently should be seen as a viable and pragmatic solution to the current and pending cooling demands within data centres.

The Dossier Submitter noted in the PFAS Annex XV report in the section dealing with PFAAs (arrowheads and precursors), "as most of these substances are expected to ultimately degrade in the environment to TFA (details in Annex B.4.1.), they will contribute to the overall exposure to and risks of PFAAs". Such a statement or indeed conclusion by the Dossier Submitter is not accurate when examined against the number of peer reviewed studies conducted and even ECHA itself on TFA. According to the trifluoroacetic acid (TFA)[96] REACH registration dossier and Chemical Safety Report (CSR), this substance does not fulfil the criteria for a PBT or vPvB substance under Annex XIII REACH. Neither does it raise equivalent levels of concern under Article 57(f) REACH.9In this respect, ECHA already reviewed/evaluated the TFA dossier without concluding that further regulatory actions were needed. The United Nations Environment Programme (UNEP) in its Environmental Effects Assessment Panel in 2020 noted that "Historical and current measurements of TFA in soil and surface-water indicate de minimis risks when compared to no-effect-concentrations (NOECs) in laboratory and field-based testing". UNEP also called out what they identified as erroneous claims that TFA was toxic to plants, and to set the record straight stated that "There is no scientific basis for this conclusion and risks from current and future releases of TFA from the use of fluorinated precursors regulated under the Montreal Protocol to aquatic and terrestrial plants are de minimis".

In their 2022 report, UNEP highlighted that "There has been considerable discussion as to the inclusion of TFA in the class PFAS for regulatory purposes…We are of the opinion that the

[96] Trifluoroacetic acid, EC no: 200-929-3, CAS no: 76-05-1, Molecular formula: C2HF3O2

properties of TFA indicate that it should not be included in this class for the purposes of generic regulatory risk assessment".

It would appear that the Dossier Submitter and the United Nations Environment Programme have diametric opinions about TFA and consequently HFOs in terms of their risk and suitability for inclusion into a PFAS grouping effort for regulatory purposes.

EU Initiatives

The proposed cooling technology will fully support many of the EU Commission's priority policies. These include Energy and Climate policy, the vast number of initiatives captured under the Green Deal, EU Chips Act and indeed the Digital Decade.

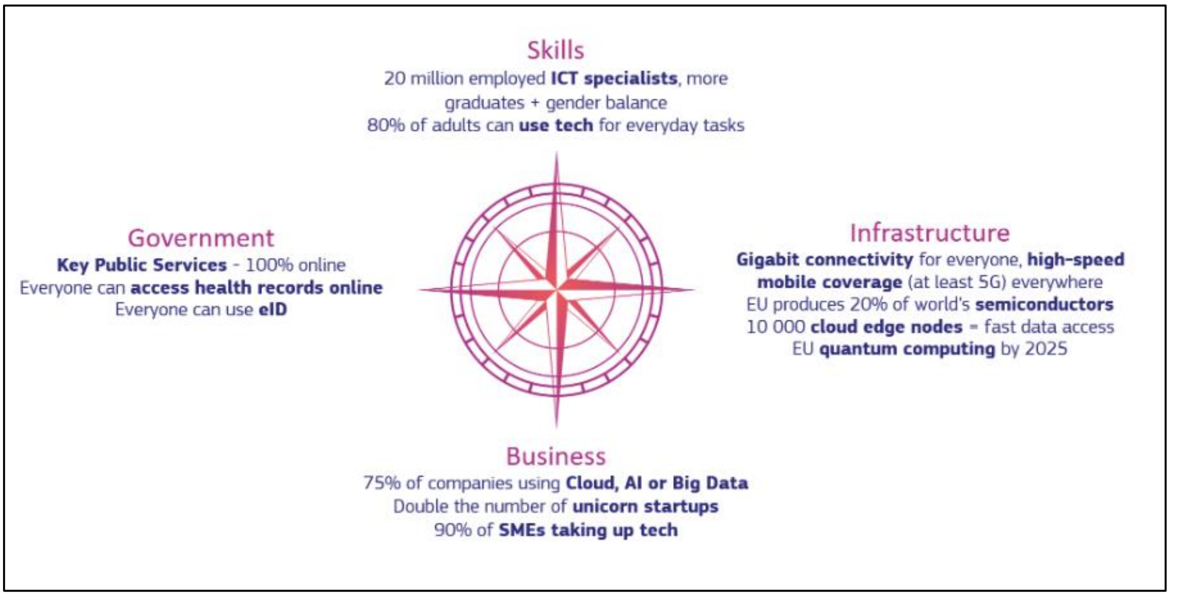

Figure 8 Europe's Digital Decade Targets for 2030

Upon examining the primary strands of the Digital Decade, Figure 8.0 depicts the associated policy programme with targets and objectives for 2030. All of these - Skills, Infrastructure, Business and Government necessitate the use of data centres. It is imperative that these data centres utilise a superior and sustainable cooling technology such as that provided through the cooling distribution systems outlined.

Proposed derogation

Consequently, it is critically important that this technology, including its refrigerant chemistries (HFOs) and hardware (fluoropolymers), are appropriately granted a time-unlimited derogation.

9. Mechanical Applications

General summary of application category

PTFE is used as an additive in plastic parts to meet tribiology requirements (e.g., friction, wear, lubrication). It is widely used in printers for gears, rollers and other plastic parts that require low friction, wear, and noise.

There is no drop-in replacement for PTFE, but there are potential alternatives materials, such as silicone, wax, polyethylene, aramid, and graphite. **It is unlikely that one material will be able to substitute all of applications of PTFE.**

Another important use of PTFE is Teflon tape. There are a lot of components and parts in one electronic device. Especially in mobile devices, the parts or components may abrade each other during operation. For example, local abrasion causes the conductors to break. Copper is most used as conductor in electronic device because of its good extensibility, good conductivity and abundance in the world. However, even if there is jacket outside to protect the copper wire, the stress or heat of abrasion still can break the copper wire. Teflon tape is often used to increase the durability and robustness in specific locations.

Another example are the coaxial cables in charge of transmitting the signal of antenna module to the circuit board. The coaxial cables pass through the hinge, and the part in the hinge is often abraded when laptops are opened and closed. The stress of the hinge operation may cause the coaxial conductor to break. The best solution to improve cable durability under hinge operation is to apply Teflon tape. The coefficient of friction (0.05-0.20) is low and therefore the coaxial cable can be protected.

Purpose	Location	Photos
Protect cable close to hinge cap to reduce the friction between cable and hinge cap.	hinge cap inside	 Protect cable close to the base close to the C cover horn protrusion. Reduce the friction between C cover inside and cable.	C COVER inside horn protrusion	 
Reduce the abrasion between cable outside and enclosure inside during hinge operation.	1. antenna cable in/out location 2. Hub Cable in/out location 3. EDP Cable in/out location	  
Table 7 Teflon tape application examples

The annual tonnage and emissions and type of PFAS associated with the relevant use

Insufficient information to quantify.

For which uses of PFAS is there no alternative

For the wear-resistance improvement application, HDPE is often the alternative candidate to replace Teflon, because of the similar chemical structure. However, Teflon still has a smaller coefficient of friction (COF) for better durability. Based on COF, PET and PI are also often mentioned to replace Teflon and both these two materials posess good heat resistance. However, the brittleness of PET and PI make the tape less durable than Teflon.

	COF (coefficient of friction)
Teflon	0.05-0.2
PE (HDPE)	0.29
PET	0.19
PI (polyimide)	0.22

It must be noted that PTFE has a much higher heat deflection temperature and corrosion resistance whereas HDPE has an excellent strength-to-weight ratio. Currently there is no alternative for durability-enhancement application in electronic devices. For desktop platforms, like DTO tower, AiO or monitors, the slighter space limitation can use HDPE tapes, PI tapes or PET tapes to enhance the durability by thicker usage. For mobile devices, like laptops or tablets, the components are all compressed in a small space. To get good durability in limited space and achieve the desired lifecycle, Teflon is the only one option so far.

Physical Property	HDPE	PTFE
Melting Point (°C)	120-140	327
Density (g/cm3)	0.96	2.15
Ultimate Tensile Strength (MPa)	31.7	10.3 - 20.6
Water Absorption (ASTM D570) (% by weight)	0.1	< 0.01
Heat Deflection Temperature (°C) @ 0.45 MPa	90	120
Tensile Elongation (%)	600	100 - 200
Dielectric Strength (kV/mm)	17 - 24	20 - 48

Proposed derogation

Paragraph 2(c) Shall apply from (**6.5 years** after entry into force) to **PTFE and Teflon tape used in mechanical applications for electronic equipment**. By (18 months before the derogations are due to expire) the Commission will review derogations in light of new scientific available information and information on alternative materials or processes and if appropriate, modify this derogation accordingly.

10. Ingress Protection Vents for Communication Devices

General summary on the application category

Devices used for communications, which includes smartphones and wearable electronic devices like smart watches and wireless headphones, have become a part of everyday life for citizens in Europe and critical for use in emergencies. In 2022, approximately 200 million smartphones and 80 million wearable devices were sold in the EU[97]. These devices must have openings to the environment to allow for pressure equalization, the transmission of acoustic signals to and from microphones and speakers, and to enable sensors to collect environmental data like air and water pressure. Users expect that their device will not be damaged or destroyed if it falls into water, is exposed to rain, or is cleaned.

Due to the sensitive nature of the electronics (microphones, speakers, sensors, circuits) in these devices, they can be easily damaged by particulates, water, oils, cleaners and other contamination.

To overcome this issue, device manufacturers provide ingress protection by using a PFAS-based microporous vent. The protection helps eliminate component failures, extends the life of the device, and reduces the environmental waste from prematurely replaced devices. These vents contain an extremely low mass of PFAS, are often only 4 mm in diameter and weigh approximately 40 µg. Without effective protection against external contaminants such as liquids and dusts, devices fail and must be replaced. Figure 9 illustrates how a vent for air and/or sound transmission is assembled into a typical smartphone.

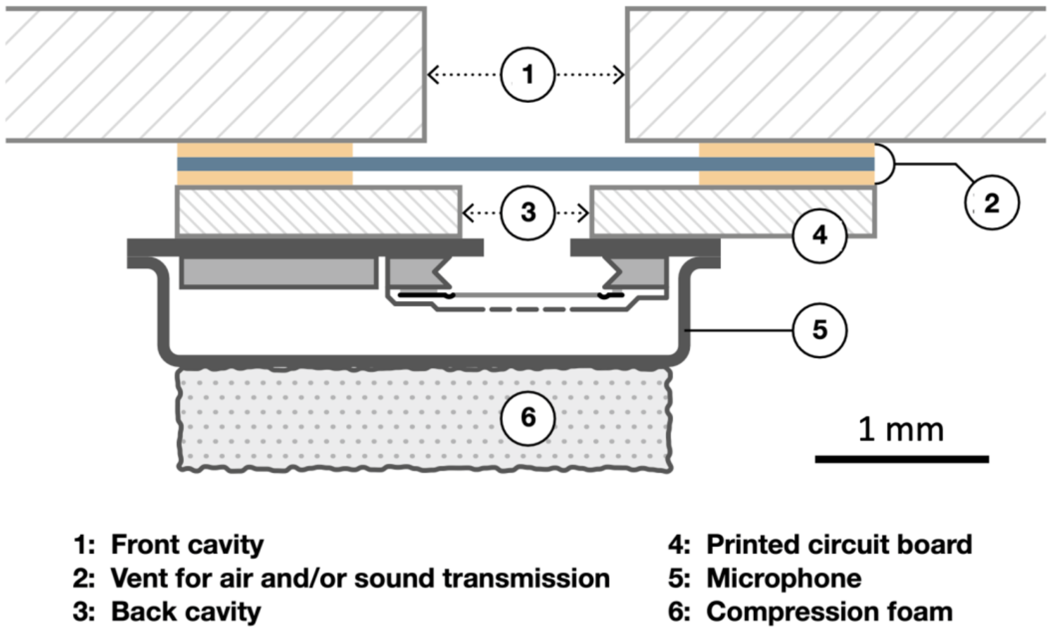

Figure 9 Ingress protection vent for air and/or sound transmission in a typical smartphone

A derogation for the use of PFAS in Ingress Protection Vents for Communication Devices is needed because:

[97] International Data Corporation (IDC), https://www.idc.com/prodserv/insights/manufacturing/latest-research

- **Protecting communications devices from failure due to liquid or dust ingress is a critical function** for hundreds of millions of EU citizens in personal, professional, and sometimes emergency settings. Increasing the longevity of such devices is also an important factor in reducing electronic waste and the consumption of critical raw materials.
- Currently, **no alternative is available** that would prevent device failure and that would not require PFAS chemistry.
- An **exceptionally low volume of PFAS is required** for this end use in the EU (< 35 kg annually).
- Decades of research has not provided a suitable alternative. If suitable alternative materials are identified in the future as a result of ongoing research, which is currently ongoing, it would take several additional years to develop, test and produce devices that can incorporate the alternative materials.
- Without a derogation, there would be a significant increase in the failure rate of these devices which both the general population and professionals (emergency services, transport operators, etc.) rely on for their daily and urgent communications. This would result in an increase in waste and resource consumption. Furthermore, consumers could face a cost increase of more than €600 per device to replace damaged devices, which at an EU level amounts to a cost of more than €20 billion per year. These costs are not justified given the exceptionally low volume of PFAS required for this end use.

In the following sections we provide detailed evidence for this derogation based:

- The **performance requirements** for ingress protection in devices used for communications
- The **lack of availability of alternatives** that would provide the required level of performance
- The **time required** for research and development to investigate and evaluate potential alternative materials, and if a feasible alternative is identified, the time required to identify develop, test and commercialize a new vent in a device
- The **extremely low volume of PFAS** needed for this application in comparison to the **large socio-economic cost** of restricting the use.

Performance Requirements for Ingress Protection Vents

Ingress protection vents for communication devices have a wide range of unique and technically demanding requirements. The primary challenge is providing ingress protection whilst enabling adequate airflow.

At the device level, a common standard used for communications devices is the Ingress Protection rating (or IP rating), which is an international standard (IEC 60529) used to rate the degree of protection or sealing effectiveness in electrical enclosures against intrusion of objects, water, dust or accidental contact. It corresponds to the European standard EN 60529. A summary of the rating system is shown in table 4 below.

Protection Against Foreign Solid Object (X)		**Protection Against Liquid (Y)**	
0	No protection	0	No protection

1	Protection against solid objects > 50 mm, such as a hand	1	Protection against vertically dripping water, some ingress permitted
2	Protection against solid objects > 12.5 mm, such as a finger	2	Protection against dripping water with enclosure tilted up to a 15° angle
3	Protection against solid objects > 2.5 mm, such as tools	3	Protection against spraying water
4	Protection against solid objects > 1.0 mm, such as wire or small screws	4	Protection against splashing water
5	Dust resistant, limited protection from the ingress of dust, ingress of dust not sufficient to cause harm	5	Protection against jets of water directed at the enclosure
6	Dust-tight, total protection from the ingress of dust	6	Protection against powerful jets of water directed at the enclosure
		7	Protection against submission or exposure to water up to 1 m for a period of 30 minutes
		8	Continuous immersion in more than 1 meter of water for 30 minutes in test conditions subject to agreement between manufacturer and user.
		9k	Protection against high pressure and temperature water jet

Table 8 Ingress Protection (IP) standards : Ingress Protection Rating Format: IP X Y

IP 68 means a total protection from the ingress of dust and continuous immersion in more than 1 meter of water for 30 minutes in test conditions agreed on between a manufacturer and user, meaning that a device with an IP68 rating may be designed to withstand 3 meters immersion or 6 meters immersion. Meeting this rating is critical for everyday and emergency performance.

In addition to IP rating, there are more challenging requirements placed on communications devices that protect from challenges that arise in common use cases. For example, devices must often retain their immersion protection after coming in contact with soapy water, as might happen when a smart phone is cleaned or dropped in a sink, or when a smartwatch is worn during hand washing. This requirement puts more stringent contamination resistance requirements on vents to prevent premature device failure. Soapy water is just one of many potential low surface tension fluids that may challenge vents in this application, all of which are more likely to cause ingress and potential device failure than a pure water challenge.

Microporous Structure - Good Sound Transmission and Ability to Equalize Pressure

The immersion protection capability of a membrane against ingress of liquids or solid particles is determined by multiple factors of which porosity has a large impact. Large pores allow more ingress than small ones. At its extreme, the ultimate material for immersion protection is a full density, non-porous material (e.g. having no opening, for example a sheet of metal) which allows no liquid ingress. However, this approach does not provide the needed breathability or acoustic properties to function as a vent on a communications device.

The membranes which are used in these vents for air and/or sound transmission need to be a thin and low-mass membrane with mechanical properties and porous microstructure that enable optimal transmission of air and/or sound. In some cases, the membrane vibrates easily and quickly in response to sound waves, converting their airborne energy to mechanical vibrations. These vibrations are reproduced on the other side of the membrane to create high-quality acoustics. In other cases, the vent microstructure is permeable enough to allow direct transmission of the sound waves through the membrane's porosity.

The optimized permeation properties enable the vent structure to rapidly equalize pressure changes due to temperature increases or decreases or air pressure differences as they may occur, e. g., during air transports. The vent structure also protects sensitive electronics against condensation from water vapour entering the device, and minimize stress on device seals originating from high air pressures.

Hydrophobicity and Oleophobicity - Barrier to water and oily liquids

For ingress protection, the material needs to be hydrophobic enabling the membrane to repel water and, at the same time, oleophobic enabling it to repel oily fluids. The ability to repel substances is dependent on surface energy. Surface energy is a typical material property used to characterize hydrophobicity and oleophobicity.

Thermal Stability

Some ingress protection vents must also survive the extremely high temperatures (250 °C) associated with the soldering processes used for device assembly. While the device shown in Figure 2 shows an ingress protection vent that is attached to the outer casing of a device, some applications for ingress protection for communication devices require the vent to be integrated into an individual electrical component (e.g. integrated into the microphone or a sensor). This approach allows for more robust device designs, removes potential leak points in adhesive seals to the outer casing, and can thereby further reduce the risk of device failure due to water ingress. But integrating the ingress protection vent into the electrical component requires that the ingress protection material can survive temperatures associate with solder reflow, a process used to attach the electrical component to a circuit board. This solder reflow process often uses temperature in excess of 250°C.

Uses of the PFAS and Assessment of Alternatives

Why Fluoropolymers and other PFAS can uniquely deliver the needed performance

Today, only PFAS based vents can meet the combination of the above-described highly demanding requirements. Polytetrafluoroethlene (PTFE) is the primary material used for vents in communications devices. Additional fluoropolymers and other PFAS listed below in Table 2 are used to construct the finished vent article and provide an enhanced oleophobic surface on the PTFE membrane so that it more effectively repels oils, sweat, cleaning solutions, and other common fluids that can threaten device reliability.

Microporous structure

PTFE is the only known material that has the inherent physical properties listed above and can also be expanded into a thin, strong microporous membrane. All of these in combination deliver the key characteristics necessary for this end use.

Its microstructure facilitates the transmission of air and sound, while effectively repelling water, other fluids and particulates. **It is the unique combination of the properties listed below which have not been identified in any other alternative materials, or combination of materials, that have been investigated by leading vent manufacturers to date.**[98]

The PTFE membrane is engineered with a porous microstructure that enables optimal transmission of air and/or sound. The thinness and specific pore size allows sufficient acoustic transmission.

The transmission properties of the expanded PTFE membrane also enable the vent structure to be air permeable to rapidly equalize pressure changes, protecting sensitive electronics against condensation and minimizing stress on device seals. The combination of small pore size and hydrophobicity enable resistance to wetting with water. The image of an expanded PTFE membrane in Figure 3 shows the complex microscopic pores providing this combination of properties. For a sense of scale, a very fine human hair (30 microns in diameter) would cover the entire field of view in this image.

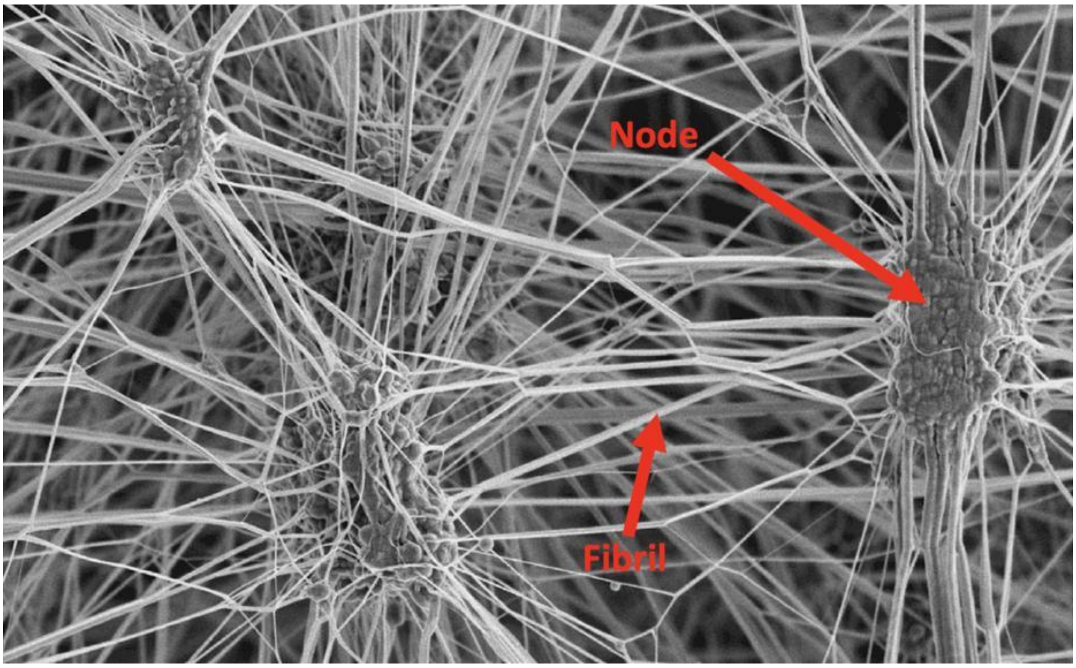

Figure 10 Example of ePTFE Microstructure Showing the Node and Fibril Microstructure

The image above shows a “node and fibril” microstructure which is characteristic of an expanded PTFE membrane. “Fibrils” are the thin fibers, and “nodes” are the solid regions to which the fibrils are connected.

Very few polymers can be processed into microporous structures, and the process used for producing PTFE membranes[99], known as “paste processing and expansion”, is particularly well-suited to creating a wide range of microstructures and thicknesses of membranes not typical of other membrane fabrication processes.

---

[98] RCOM Ref 4520

[99] This process, known as paste-processing, was first described in US Patent 3,953,566, assigned to W. L. Gore and Associates. The process is also outlined with some detail in “Expanded PTFE Applications Handbook: Technology, Manufacturing and Applications” by Sina Ebnesajjad.

The membrane properties that result from such a process depend on many factors, including the starting polymer properties, the temperature at which the membrane is expanded, and the amount of stretching that is applied during the expansion process. The wide range of process space allows for a wide array of ePTFE membranes to be manufactured through this process. One key attribute of PTFE is that it has a very wide range of temperatures over which it can be stretched (from around room temperature up to in excess of 300°C). The expansion process converts starting polymer particles (called “fine powder”) into “fibrils”, and polymer that is not converted into fibrils remains in “nodes”, resulting in expanded PTFE’s characteristic node and fibril structure in a high porosity form. The node and fibril microstructure of PTFE membranes is well-known[100] to offer a unique combination of air permeability, water resistance, mechanical strength, and acoustic transmission.

The membrane can optionally be laminated with other support materials, coated, or otherwise treated to impart additional properties. For example, the membrane can be treated with additional PFAS in the form of a coating or surface treatment to increase its oleophobicity and contamination resistance, further adding to the unique combination of material properties of the PTFE membrane.

PTFE is the only polymer that has been found to be capable of being commercially produced using the above-described process. Extensive research and development by leading vent manufacturers[101] has not identified any other polymer material which:

- is compatible with paste processing
- can be expanded to produce a microporous membrane
- is available in the fine powder form required for paste processing
- has a wide processing temperature range
- can currently be developed into commercial processes.

Therefore, there are no known alternative membranes with this characteristic microstructure.

Hydrophobicity

Hydrophobicity is the ability a solid material to resist the spreading of water on its surface. Hydrophobicity is a key property for a material which is used to manufacture a membrane to provide ingress protection of communication devices. Membranes made from polymers with hydrophobic polymers resist wetting with water and thereby prevent water entry into devices which can cause failure. The greater the hydrophobicity, the better a mmbrane can resist wetting. The less hydrophobic a material is, the more likely it is that it will fail to resist wetting with water and lead to device failure.

Surface energy is a fundamental measure of hydrophobicity. The lower the surface energy, the more hydrophobic a material is.

Expanded PTFE is naturally hydrophobic and has a surface energy of 19 dynes/cm. This allows it to easily repel fluids with surface tensions above 40 dyne/cm, such as water (72 dynes/cm) and coffee (40 dyne/cm). When treated with an additional fluoropolymer, the surface energy can be further decreased.

[100] US Patent 6512834B1 “Acoustic protective cover assembly”, W. L. Gore and Associates
[101] RCOM Ref 4520

Not all polymers are hydrophobic, and no other polymer as inherently hydrophobic as PTFE can be processed into as broad an array of microstructures as PTFE.

An extension of hydrophobicity is oleophobicity, which requires even lower surface energy, and enables non-wetting properties with lower surface tension fluids and will be discussed later.

Oleophobicity/Contamination Resistance

Oleophobic treated PTFE has a reduced surface energy and can effectively repel fluids with very low surface tensions.

For example, the surface tension of household cleaners range from 27–32 dynes/cm, and the surface tension of isopropanol (a key component of rubbing alchohol) is 22 dynes/cm. If these fluids were to penetrate through a vent during cleaning, they could cause catastrophic damage to electronic components. In the later section detailing alternatives assessment, we will provide specific data that shows that the presence of an oleophobic treatment on a PTFE membrane enables durable water resistance after a vent is exposed to soapy water. Without this treatment, exposure of a communication device to soapy water (e.g. cleaning a device, dropping a cell phone in a sink, vigorously washing one’s hands while wearing a smartwatch) could significantly degrade its immersion protection, leading to device failure.

In addition to reducing the ingress of liquids, the oleophobic properties of treated PTFE reduce the wettability of the acoustic vent membrane, so that liquids do not remain on the membrane and degrade acoustic performance or risk clogging the microstructure.

Achieve IP68 Standards

Although the expanded PTFE membrane is extremely thin, its unique structure is engineered to effectively repel debris, water, and other fluids. It also provides ingress protection up to IP68 standards, which represents complete protection from particles and at least 1 meter immersion protection (at a level that is specified by the manufacturer). The membrane has a complex, three-dimensional microstructure which provides a tortuous path through the material. This complex, tortuous path traps very small particles with high efficiency creating an effective barrier to particles of varied sizes. The image below is a scanning electron micrograph of a membrane used for ingress protection for communication devices. The pores in this microstructure are considerably smaller than one micron in diameter, and their complex geometry ensure capture of small particles.

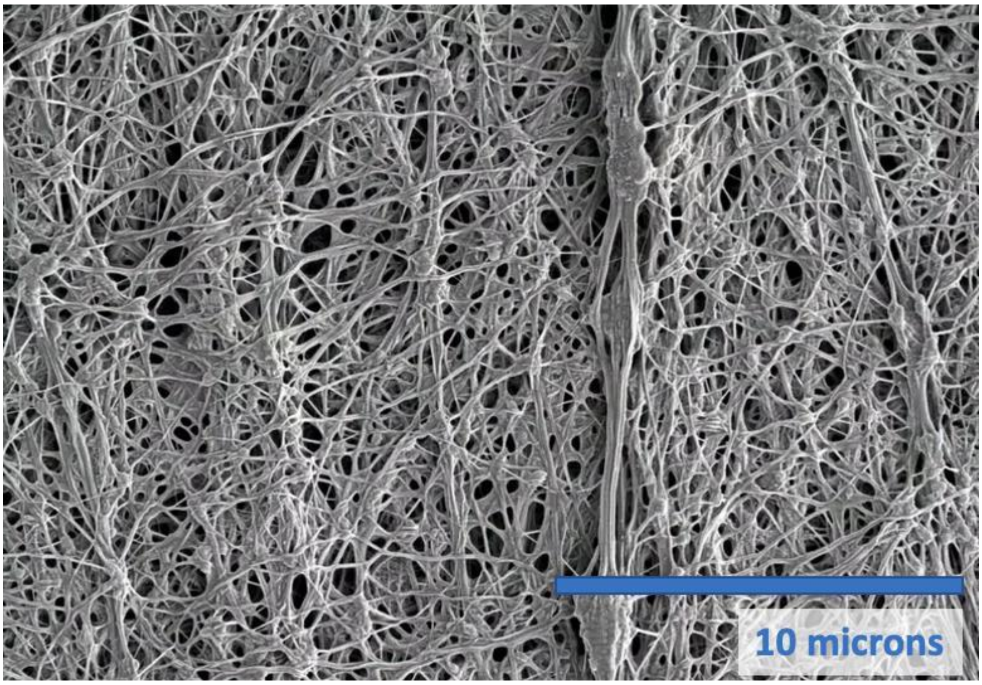

Figure 11 Typical Membrane used in Ingress Protection Vents

In addition to having the appropriate microstructure, the membranes must have sufficient strength to survive the mechanical challenge associated with pressurization. For example, if a membrane is used to protect a device from immersion in 6 meters of water, the water will apply a pressure of 60 kilopascals to the surface of the membrane when under challenge. Under this applied pressure, the membrane must not break or significantly deform in a way that would allow water to enter and damage components, thus causing device failure.

Thermal stability

Many ingress vents must also survive the soldering processes used for device assembly and cope with high temperatures (≥250°C).

PTFE is a very thermally stable polymer, only melting at temperatures well above 300°C, allowing its use in such conditions. Most other polymers that can be made into porous materials cannot survive such temperatures. For example, porous membranes can be made from polyethylene, polyurethane, PVDF, nylon, and polysulfone but all of these polymers start degrading well below 250°C. Two thermally stable polymers that can be made into porous membranes are PEEK (polyether ether ketone) and PI (polyimide). However, they have considerably higher surface energy than PTFE (42 dynes/cm[102] and 44 dynes/cm[103]), and therefore do not have the required hydrophobicity and oleophobicity properties. They are also not compatible with the process used to make PTFE membranes, so they do not offer the characteristic node and fibril microstructure known to be associated with strong performance in this application.

There are no polymers available today that can survive the high temperatures experienced during the component soldering process and can also be engineered to provide

[102] http://www.surface-tension.de/solid-surface-energy.htm, accessed 5/22/2023
[103] https://ntrs.nasa.gov/api/citations/20090026494/downloads/20090026494.pdf, accessed 5/22/2023

microstructure, hydrophobicity, and oleophobicity of a PTFE membrane with an oleophobic treatment. PFAS-based treatments that can be applied to PTFE also can survive such temperatures.

Alternative Materials Referenced in the Restriction Proposal

The Dossier Submitters (DSs) researched the electronics applications of PFAS in detail (as presented in Annex A Table A.1, page 5) and the use of polytetrafluoroethylene (PTFE) is listed in the context of sound-permeable membrane (Restriction Proposal Annex A, Table A.48, page 107). The properties required and provided by PTFE are acknowledged (air permeability, water pressure resistance, liquid repellence and acoustics characteristics).

However, in Annex E of the Restriction Proposal where the derogation and availability of alternatives are discussed, the Dossier Submitters did not assess the need for PFAS in these applications.

Alternatives mentioned by the dossier submitters (DS) in the restriction proposal for the broad category of electronics are not suitable for protection of devices used for communications.

No non-PFAS alternatives are available that would prevent device failure. Alternative non-PFAS materials, and combinations of alternative non-PFAS materials, may be able to replace a singular property, but as discussed in this document, multiple properties are required simultaneously in communication devices. Thus, the only currently viable material is a composite article made from fluoropolymers and other PFAS.

In the analysis of alternatives, the applications described in this document fall within the succinct statement by the DSs that considering *"the inconclusive evidence pointing to the non-existence of technically and economically feasible alternatives at EiF in all other uses, no derogation is proposed"* (Annex E, Table E.131, page 404). The applications described in this document do not appear to have been included in the DS analysis of alternatives for electronics. Considering the broad variety of applications of PFAS in electronics and that the DSs chose to discuss together alternatives covering electronics, semiconductors and even energy sectors (Annex E, section E.2.11.2. from page 389), it remains unclear which alternatives have been considered for PFAS in acoustics vents in communications devices.

In this document, we provide evidence that there are no currently available technically and economically feasible alternatives for ingress protection, and therefore a derogation is warranted.

Assessment of Alternatives

The Dossier submitters identified several materials as potential alternatives for PFAS applications in electronics and semiconductors (Annex E, table E.128, page 396). Not all these materials are relevant to ingress protection for communication devices. We will only discuss technologies which are relevant to the application referenced in this submission.

Non-porous covers (urethane, silicone, PEEK)

Non-porous covers such as urethane, silicone or PEEK can be used to cover apertures when immersion protection is needed with satisfactory sound transmission. However, these materials do not breathe and do not allow for pressure equalization, which is required to alleviate pressure changes that may arise due to typical use (e.g. going up in an elevator or airplane or due to temperature changes), and may in turn also degrade sound transmission. If pressure is not equalized, it will build, applying undue forces to the membrane, device seals, and every other internal component. Such forces will destroy the membrane, break seals, and damage components that are critical to the function and continued survival of the device. **Therefore, non-porous covers are not a viable alternative to ingress protection vents.**

Woven mesh covers

Woven mesh covers can protect an aperture from liquid splash, light spray or rain. However, any dust particles smaller than the defined hole size will pass through these mesh covers because they consist of a single-layer grid and spacing pattern with a defined hole size. Moreover, this alternative will not protect against immersion or aggressive spray. A device which is not robustly protected can allow ingress of dust, which can degrade or induce failure in sensitive components like microphones. A device without protection from immersion is subject to water ingress, which can lead to total device failure. **Therefore, woven mesh covers are not a viable alternative to ingress protection vents.**

Alternate porous membrane

A variety of non-PFAS polymers can be used to fabricate porous membranes, but these cannot be processed to yield the characteristic node and fibril microstructure of expanded PTFE associated with suitable applicability in ingress protection vents for communication devices. These non-PFAS polymers are also not water repellent (do not have low enough surface energy) and so are not viable alternatives for ingress protection vents.

There are several processes that can be used to produce porous membranes from non-PFAS materials. Phase inversion processing is a type of process for making porous membranes by transforming a polymer solution into a solid state in a controlled manner. Electrospinning is a process that uses high voltage to spin fibers from polymer solutions. Track etching is a process that uses nuclear tracks to create pores in polymer films. Sintering is a process which fuses particles of polymer into membranes. The diagrams below show representative examples of membranes made through each of these processes. In each case, it is readily apparent that the membranes have different microstructures than what is shown in Figure 4.

Phase Inverted Membranes

Phase inverted membranes have no presence of node and fibril microstructure. An example of such a membrane is a Polysufone (PES) membrane[104], shown below. **Polysufone is not water repellent because it has surface energy of 47 dynes/cm, which is much too high for use as an ingress protection vent.**

[104] https://www.sigmaaldrich.com/US/en/product/mm/gpwp04700, accessed 5/23/2023

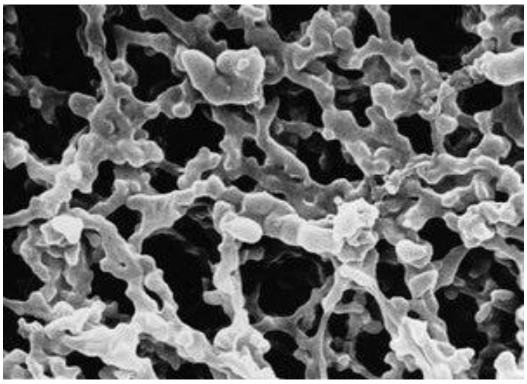

Figure 12 Porous PES

Track Etched Membranes

Track etched membranes do not have a node and fibril structure. An example of this technology, a track etched PET membrane[105], is shown below. **PET is not water repellent because it has a surface energy of 39 dynes/cm, which is too high for use as an ingress protection vent. In addition, these membranes are of low porosity, and offer poor permeability.**

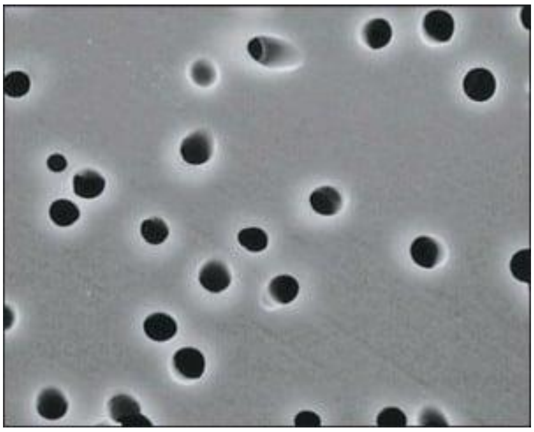

Figure 13 Porous PET

Sintered Polymer Membranes

Sintered polymer membranes do not have a node and fibril microstructure. An example of this type of membrane, a sintered polymer membrane, is shown in the diagram below. **These membranes have a low porosity and are relatively thick. Furthermore, the sintered polymer membranes are not water repellent and are not a viable alternative to ingress protection vents.**

[105]https://www.sterlitech.com/blog/post/etching-the-tracks-in-a-polycarbonate-track-etched-membrane-filter, accessed 5/22/2023.

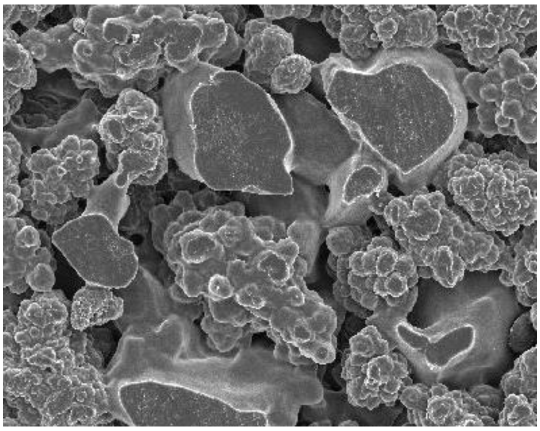

Figure 14 Sintered porous membrane[106]

Electrospun Membranes

Electrospun membranes are comprised of extremely long fibers, which do not have connection points at nodes like in a node and fibril microstructure, as can be seen in the diagram below[107]. Such membranes are also typically characterized by having low cohesive strength. **Electrospun membranes offer some features that may be useful for venting applications for communication devices, but are either comprised of polymers which are not water repellent because they have high surface energy (polyurethane, nylon, e.g.) or they are fluoropolymers (PVDF, e.g.).** One electrospun membrane has been characterized more completely as will be described in the following section.

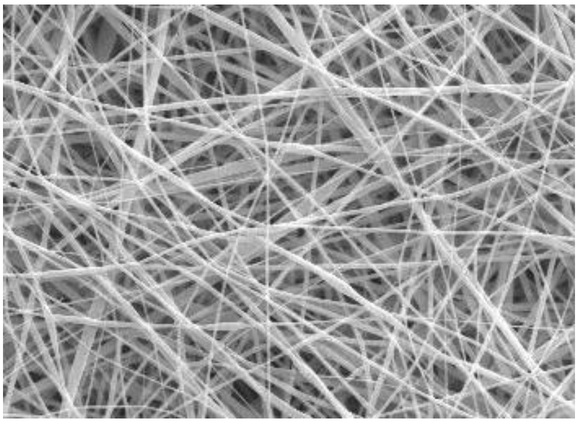

Figure 15 Electrospun Membrane

Polyethylene (PE) and polyurethane (PU)

Two potential membrane technologies which appeared to have some level of hydrophobicity and well-established manufacturability are expanded polyethylene (PE) and electrospun polyurethane (PU). These were selected by a leading vent manufacturer for more thorough evaluation as their property profiles indicated they may possibly be potential candidate

[106] https://www.porex.com/porous-polymers-technology/, accessed 5/22/2023.

alternative materials ().[108] As shown in Table 5, samples having average pore sizes similar to current PFAS vent solutions were selected.

Sample Type	**Average Pore Size [microns]** [109]
Commercial ePTFE + PFAS Coating (GAW342)	0.50
Commercial ePTFE (GAW337)	0.61
ePE Reference #1	0.69
ePE Reference #2	0.43
Electrospun Polyurethane Reference	0.43

Table 9 Membranes Selected for Contamination Resistance Study

These membranes were evaluated for their immersion protection properties when subjected to industry qualification methods which model typical mobile device consumer behavior. As highlighted above, an ingress protection level of IP68 means a total protection from the ingress of dust and continuous immersion in more than 1 meter of water (in agreement with the manufacturer and user) for 30 minutes. In this case, the immersion depth that is relevant for these materials is 6 meters, so that was the depth at which testing was performed.

Table 6 shows survival probability in a water submersion test after exposure[110] to soapy[111] water for each membrane material, which is a typical qualification method for electronic devices. After exposure to 0.01 % soap in water (ten times less concentrated than a standard solution), all candidate alternative materials (ePE and electrospun polyurethane) as well as uncoated ePTFE exhibit a failure rate of 50 % or greater.

All alternative materials and **uncoated ePTFE** exhibit a survival probability near 0 % after exposure to a standard soapy water solution of 0.1 % soap in water. In contrast, more than 80 % of samples made of ePTFE with an additional PFAS coating pass the submersion test after exposure to 0.1 % soapy water.

[108] RCOM Ref 4520
[109] Pore sizes of these membranes were determined via a bubble point measurement on a Quantachrome 3GzH capillary flow porometer, in accordance with ASTM F316-03.
[110] Samples of these flat sheet membranes with a diameter of 1.5mm were prepared, and small droplets of soapy water (20 microliters in volume) were placed on the surface of the parts. Soap solutions were prepared in a range of concentrations (e.g. 0.01% v/v, 0.1% v/v, 1% v/v). The samples were dried in an oven at 60°C for three hours until completely dry. Once dry, samples were pressurized with clean water on the soapy membrane surface at a pressure equivalent to submersion in 6 meters of water (0.6 bar)[110]. If water was passed through the membrane, the time was noted, and the test was marked as a failure.
[111] The soap is a mixture of sodium lauryl sulfate (SDS or SLS), lauramine oxide (LO), sodium chloride (NaCl), and water. The ratio of SLS:LO:Salt is 5:2:3, and the mixture is 80% water by mass.

Sample Type	0.01 % Soap/Water	0.1 % Soap/Water
Commercial ePTFE + PFAS Coating (GAW342)	> 80 %	> 80 %
Commercial ePTFE (GAW337)	< 30 %	~ 0 %
ePE Reference #1	< 20 %	~ 0 %
ePE Reference #2	< 40 %	~ 0 %
Electrospun Polyurethane Reference	~ 50 %	~ 0 %

Table 10 6 meters water submersion survival probability

Despite having comparable average pore size to fluoropolymer based membranes, PE and PU did not show sufficient resistance to wetting after exposure to soapy water.

Only the expanded PTFE membrane with PFAS coating showed acceptable survival in the water immersion challenge after a typical soapy water exposure. This is attributable to its low surface energy, which is a unique property of PFAS materials.

One of the reasons why expanded PE membranes and electrospun PU membranes fail the soapy water test is that these polymer membranes are not as inherently low surface energy as expanded PTFDE, and therefore not as inherently hydrophobic. Polyethylene has a surface energy of 30 dynes/cm, polyurethane has a surface energy of 38 dynes/cm, while PTFE has a surface energy of 19 dynes/cm.

They also do not offer thermal stability comparable to PTFE, which does not melt until temperatures in excess of 300°C. Ultra-high molecular weight PE, the most thermally stable grade of PE, melts at approximately 150 °C, at which point structure and other properties will degrade considerably. Thermal degradation of PU can also begin at temperatures as low as 150 °C[112].

So, while membranes made with these potential alternative materials have some properties similar to PTFE membranes, their level of performance in testing shows that they are not suitable alternatives in their current forms due to fundamental material properties inherent to their chemistry. **Therefore, Polyethylene (PE) and polyurethane (PU) membranes are not viable alternatives to ingress protection vents.**

Other Design Approaches

Alternative design approaches which have been considered are shown below, however **they do not provide ingress protection, and are therefore not viable alternatives.**

[112] https://www.americanchemistry.com/industry-groups/center-for-the-polyurethanes-industry-cpi/resources/library/polyurethanes-and-thermal-degradation-guidance

Alternative Technologies/Design: As the DSs focus essentially on alternative materials, we would like to complement the alternative discussion and present option that requires an alternative technology/design.	**<u>Open apertures</u>** Open apertures provide unimpeded sound, but provide no protection from dust, liquids or immersion. Designs with open apertures are highly susceptible to component failures and decreased device life, so this approach is not a feasible alternative. **<u>Sealed housings</u>** Sealed housings protect electronic devices by providing a barrier against water or dust but prevent pressure and temperature equalization. As the device generates heat or experiences changes in pressure (due to going up in an elevator or an airplane, e.g.), pressure will build inside the housing. These internal pressure changes put significant stress on the housing seals which over time will fail, allowing water and contaminants to enter. This approach has similar downsides to non-porous covers, and neither represents a reasonable alternative.

Table 11 Alternative Design Approaches

<u>Conclusion</u>

For more than 20 years leading material suppliers and device producers have looked for alternative materials and methods for protecting communications devices, but nothing has proven capable of meeting sufficient performance as compared to the PFAS based vents. There has been significant incentive based on the high value and large number of users for this application.

Why a 13.5 year Derogation is Required

The DSs have not specifically assessed the need for fluoropolymers and other PFAS in membranes for ingress protection, as the draft PFAS restriction is currently written, these products would fall under the default transition period of 18 months after EiF. We have demonstrated that no alternative is currently available which meets the performance requirements, and in the following we will illustrate the timeframe needed in the unpredictable case that a new material would be discovered or invented for this application.

Despite the high cost of raw materials[113] and the inherent incentive to find cheaper alternatives, no viable alternative materials have been identified and developed to date for use in communications devices. We, and other key actors in the supply chain, estimate it could take at least another five years to identify and develop possible alternative polymer materials. This first step involves discovery, to which a specific timeline cannot be planned.

[113] The Restriction Dossier refers multiple times to higher costs of fluoropolymers (Annex E, page 285, 390, 444, 458, 504, ...)

Any possible alternative materials will then need further development to optimise them for specific application requirements (e.g., ingress protection and acoustic performance). We estimate that steps within this stage could take more than a year. The ingress protection and acoustic properties of these alternative materials will need to be evaluated to ensure that they provide adequate performance.

The final optimised material will then need to be manufactured into vent components so that reliability testing can be carried out, ultimately leading to creation of a new supply chain for assembly in devices that users may come to rely on.

Steps for substitution	What activities does this step entail?	Time required for step
Discovery	Identify and develop suitable alternative materials. Material and process development from lab discovery to prototype scale. This will involve independent development of membrane and treatment technologies, as well as confirmation of their compatibility.	**Unknown** Estimate 3-5 years for this use
Development	Optimise material for specific application requirements (e.g. ingress protection and acoustic performance). This may involve transitioning processes to pilot scale or small-scale manufacturing.	1-2 years
Certification	Reliability testing of manufactured components, and initial validation of reliability in prototype device and/or representative testing.	1-2 years
Production	Investment, installation, and qualification of new mass production capability. Establishing robust material supply chain.	1-2 years
End Device	Development cycle of new communications device products, including establishing specific performance criteria (ingress protection, acoustic transmission, pressure equalization, etc.) in collaboration with end device manufacturer, developing tooling specific to individual devices, in-house and third party testing, and validation of processes for conversion into parts for installation in devices.	1-2 year
Total		**7-13 years**

Table 12 Estimated Timeline for Substitution

Material use and emissions

The amount of PFAS required for this end use is extremely low - less than 35 kg of PFAS are placed on the market in the EU each year.

We estimate that the total annual number of new smartphones and wearable communication devices sold in the EU with IP68 ingress protection ratings is approximately 172,000,000.

A typical vent for air and/or sound transmission for a smartphone has an estimated diameter of 4 mm (with an inner diameter of 1.6 mm) and the thickness of the fluoropolymer membrane is about 0.007 mm. The typical density of the membrane in smartphone vents is about 0.4 g/cm^3 and a typical smartphone generally has four microphones (two at the bottom of the phone, one at the top of the phone and one on the back of the phone to assist with video recording) and two speakers (one at the bottom of the phone and one at the top of the phone). Therefore, the total amount of PFAS in a typical smartphone due to vents is estimated at about 0.2 mg which results in an estimated total annual weight placed on the market in the EU of about 35 kg per year.

Ingress protection vents are not a significant source of PFAS emissions across their lifecycle

Without a derogation, devices which both the general population and a wide range of professionals (police, emergency medical and fire services, military, transport operators, etc.) rely on for their daily and urgent communications would have an increased failure rate. This will lead to disruption to routine and critical communications and have a significant environmental and financial impacts on EU citizens.

- **Productivity and Safety Impact –** PFAS based vents are critical to the performance and reliability of communications devices which are essential to daily life and work for hundreds of millions of EU citizens. In addition to being important for daily communication and coordination, these devices are also used for critical communication with emergency services (medical, police and fire) and more recently have begun to track and report critical health care data including glucose levels, heart health data, along with automatic car crash and fall detection. A failed device isn't just an inconvenience, it can delay or prevent critical lifesaving services.
- **Environmental Impact** – Management of electronic waste is an important priority. PFAS based mobile device vents prevent device damage, increase product longevity which in turn keeps millions of devices from being disposed each year. When a device prematurely fails, more waste is generated and critical raw materials, energy, and associated greenhouse gas emissions are required to replace these devices creating a greater burden on the environment.
- **Financial Impact –** Without PFAS based vents, the rate of failed devices will increase significantly, creating a significant productivity and financial burden for EU citizens who must invest hundreds of millions of Euros each year on replacement devices. In 2016, it was estimated that 100,000 phones were damaged per day before high levels of Immersion Protection ratings were widespread. Consumers could face a cost increase of greater than 600 euro/device due to replacement of prematurely failed devices, which at an EU level amounts to a cost of more than €20 billion per year.

  There would be an impact to industry as well. Communications devices represent a large and growing industry that generates significant income and supports a large number of jobs in the EU. Value chain disruptions from restricting a key component for communications devices may therefore significantly impact the EU economy.

Proposed derogation

Paragraph 2(c) shall apply from (**13.5 years** after entry into force) to **PFAS used in ingress protection vents for communication devices**. By (3 years before the derogation is due to expire) the Commission shall review this derogation to assess whether alternatives are now available or whether further renewal of this derogation is needed and publish amendments to the Regulation.

11. Mobile Telecommunication network infrastructure equipment

General summary of the application category

Mobile telecommunication network infrastructure equipment uses high power Radio Frequency (RF) signals to communicate with various mobile devices. For several applications within the RF-signal path the combination of dielectric- and mechanical-properties of materials are essential. This is the case in applications where the wavelength of the signal is of similar length as the physical dimensions of the design.

PFAS in the form of fluoropolymers are today used in radio frequency (RF) related parts of the (B2B) mobile telecom network infrastructure equipment (NIE). For example, Radio Units (which amplify the electrical digital signals to high power RF signals), RF cables and connectors (which connect the Radio Unit with the Antenna) and Antenna parts (that send the signal from the base station to the mobile devices connected with it).

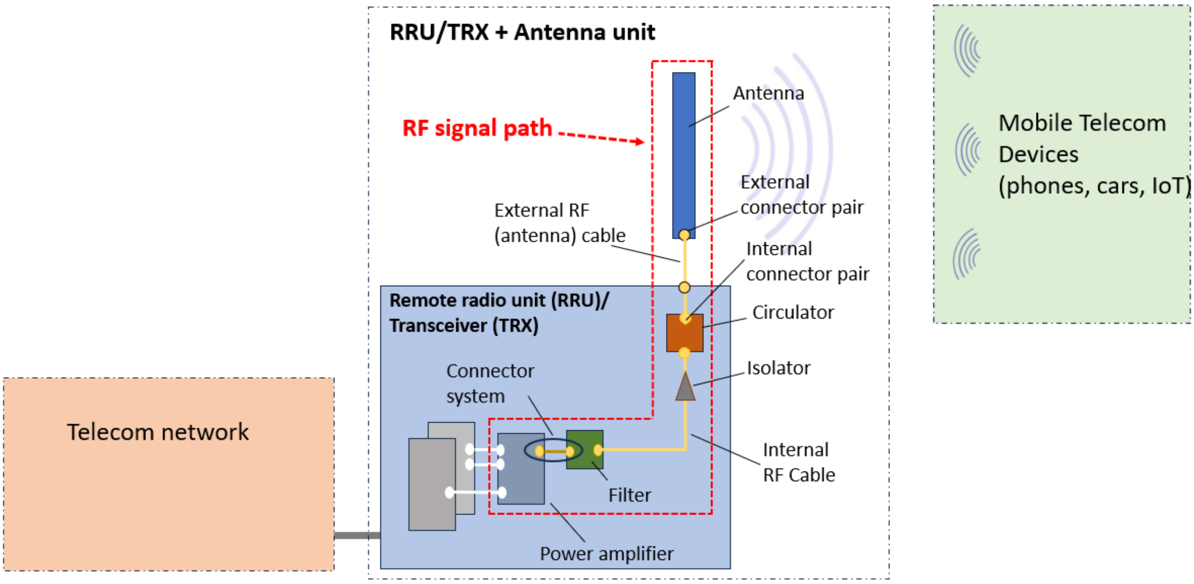

Figure 16 Schematic representation of the wider telecommunication network (left), the mobile telecommunication network infrastructure equipment containing the RF-signal path which via the antenna communicates with mobile devices through electro-magnetic waves.

Reasons for use

The fluoropolymer (e.g. PTFE, PFA) key material properties related to electro-magnetic radio frequency waves are Dissipation factor (or RF loss factor) (Df), Passive Intermodulation (PIM) and Relative permittivity (Dk) which are essential for the performance and energy efficiency of the high power RF signal carrying part of mobile telecom NIE. Fluoropolymers, and primarily PTFE, because of the above properties as well as intrinsic fire retardancy and mechanical properties, have been widely used in the industry as the material of choice for the RF-signal path.

For certain applications within the RF-signal path the combination of low Dk, low Df and low PIM levels are necessary and currently only achievable with fluoropolymer materials. The RF-signal carrying parts are what are called "transmission lines" where the mechanical dimensions of the design are as important as the electrical design. This implies that whenever alternatives will be provided by polymer producers, all the designs of RF-signal path will need to be reviewed. The RF-signal path is dimensionally designed for the fluoropolymer chosen with its dielectric characteristics. Changing the polymer means changing dielectric properties of the insulator, including the dimensions of the interfaces of coaxial connectors as well as the printed circuit boards in both the radio and antenna part of the system. The performance reduction by switching to materials with higher levels of Dk and/or Df cannot be fully compensated by dimension adaptations. For example, the currently most prevalently used Printed Circuit Boards (PCB) material (FR-4: a glass reinforced epoxy material) cannot come close to meeting these requirements.

The use of fluoropolymers in applications associated with high power radio communication technology (i.e. professional infrastructure equipment with output power and frequencies beyond Bluetooth and Wifi) including radio and television broadcasting is ubiquitous due to the fact that it combines excellent dielectric properties with mechanical properties.

Alternative materials parameter comparison

Features	PTFE	LCP	TPX	PEEK	PEI	PE
Dielectric Constant (Dk)	~2.1	~3.0	~2.2	~3.0	~3.1	~2.3
Dissipation factor (Df)@ 10GHz	<0.001	<0.002	<0.001	<0.003	<0.004	<0.001
PIM (dBc)	-164	-149	-149	-149	-149	-149
Abrasion resistance	++	+	+	++	+	+
Operation temperature	++	+	+	++	+	--
Machinability	++	+	+	+	+	+
Corrosion/Weathering resistance	++	+	+	++	+	+
Price	+	+	--	---	--	--
Manufacturability	- (CNC, Compression Molding)	++ (Injection molding)	++ (Injection molding)	++ (Injection molding)	++ (Injection molding)	++ (Injection molding)

The impact of differences in these properties is significant. Especially when used at frequencies in the 1 to 10 Giga Herz range used for telecommunications. For example, PCBs are used for several different components and applications in passive and active antennas for mobile telecommunication NIE. The electrical requirements and especially the radio frequency parameters and their tolerances are tightly defined and demanding for the materials. Only very special material set-ups for dual- and multilayer PCB realizations can fulfil these requirements.

Standard requirements of antennas for mobile telecommunication

Three main electrical requirements define and determine the material choice for PCBs for mobile telecommunication antennas. One additional aspect is essential for production robustness and acceptable yield:

- high power level (e. g. >= 400 W input power for a single low-band system at 600-900 MHz)
- high efficiency = low losses necessary
- very low level of PIM
- resilience to production processes, e.g. several soldering processes (including subsequent repair if needed)

Requirements for PCB materials

With the requirements for the antennas, it is possible to derive the requirements for the base materials (or substrates) and the general set-up of PCBs:

- losses should be as low as possible (losses generate heat and require higher amplifier power to produce the required output power)
- very low level of PIM
- high level of peel strength of copper foil

A comparison of mean values of losses of typical materials with and without fluoropolymers used in the antenna industry can be seen in fig. 17. With this comparison it can be shown, that fluoropolymer materials have a clear advantage compared to non-PFAS materials due to lower losses which will also reduce heating in components for high power applications.

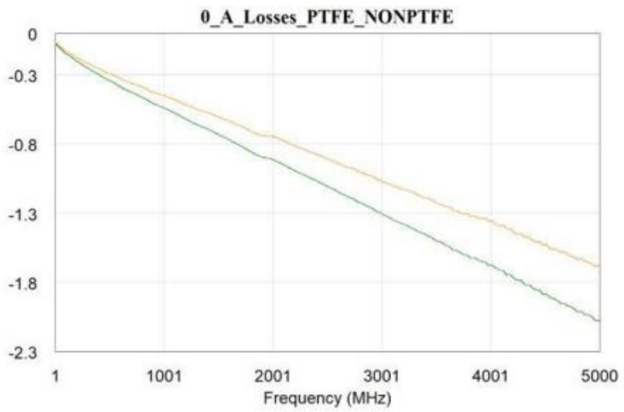

Figure 17 Mean values of losses of typical PTFE- (orange/upper line) and non-PTFE (green/lower line) materials over frequency. Measured with 50 Ohm lines, length of 560 mm. Three typical materials for PTFE and non-PTFE, 20 samples each candidate. Y-scale in dB indicating clearly lower losses of PTFE candidates

In fig. 18 a comparison of mean values of PIM of several typical PTFE- and non PTFE-candidates is made. The PIM performance is far better with PTFE materials and gives sufficient buffer for antenna applications.

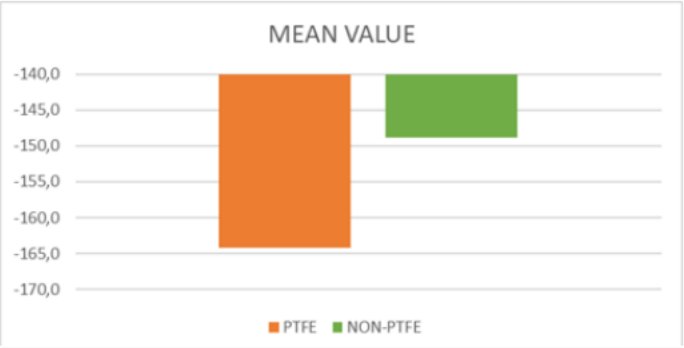

Figure 18 ***Mean values of Passive Intermodulation of typical PTFE- (orange/left) and non-PTFE (green/right) material. Measured with test coupons at 2x20 W at 900 MHz, 1800 MHz and 2600 MHz. Three typical materials for PTFE and non-PTFE, 20 samples each candidate. Y-scale in dBc. As this is a logarithmic scale, the difference of 15 dB in value means that the PIM power is ca 30 times higher for the alternative material, indicating better performance of PTFE materials.***

Process and product robustness and reliability of PCBs is a matter of copper foil peel strength. Higher levels of initial peel strength will better survive several production steps (e.g. sequence of soldering processes) than a low starting level.

Typical peel strength levels for PTFE and non-PTFE materials are between 0,72-0,88 N/mm for non-PTFE and 1,75-2,4 N/mm for PTFE materials. That means, the peel strength for PTFE materials is at least twice of the level of non-PTFE materials. This results in significant higher robustness, yields and life time for components and products using PTFE based PCBs.

These properties play a similar role in all other parts in the RF-signal path such as connectors, cables and filters. Generally the stability of parameters over larger volumes (e.g. lengthy cables) and subsequent batches is critical to the repeatability of the production processes involved.

Exception to the need for fluoropolymers in cables is in certain outdoor antenna cables where in larger diameter cable (from a quarter inch / 6.3mm or larger) where polyethylene foam can be used. This material has a much lower flammability rating which is less of an issue in outdoor cables and is possible due to the larger dimensions both in conductors and dielectric (reducing signal losses to an acceptable level) which in turn reduces the minimum bend radius but allows for lower weight per length of cable.

Explanation of key parameters

- **Relative permittivity (Dk)** (or dielectric constant) is single most important parameter to describe electrical behavior of a certain material. Repeatability of Dk and tight tolerances are necessary for high requirements and quality. Combination of low Dk and Df are necessary for certain high power and low-PIM applications. Currently only PTFE meets these requirements. Non-PTFE materials with low Dk values have higher Df values = higher level of heating of systems and lower efficiency. Relative permittivity - Wikipedia
- **Dissipation factor (Df)** (or Radio Frequency loss factor) **=** Parameter for electrical losses in the material, defines the efficiency of the system. High efficiency means lower waste of energy during operation and less internal heating of system. Internal heating causes problems with electronical and mechanical components and reduces lifetime/robustness/reliability of system in general. Dissipation factor - Wikipedia
- **Passive Intermodulation (PIM) =** Passive Intermodulation (PIM) is a nonlinearity inherent in electrical components that distorts the transmitted signal, causing lower signal quality as well as additional out-of-band emissions. These types of non-linearity are very difficult to compensate and can degrade the sensitivity of the receiver causing loss of coverage. Passive Intermodulation (PIM) -Wikipedia

Interdependencies

Since connectors are used as interface between the components of the RF-signal path (see Fig. 16): **Radio** (board mounted connector) / (cable mounted connector) **cable** (cable mounted connector) / (board mounted connector) **antenna** any dimensional change in either connector or cable will affect the whole design of the RF-signal path.

Connector dimensions are highly standardized and a change in dimensions will require time to develop new standards to ensure various brands can be used without introducing reliability issues. Any change of materials (if at all possible) will require qualification of all materials involved, redesign of the whole product and reliability testing as well as conformity testing to ensure all essential requirements are met both at material level and at system level. Since viable PFAS-free drop-in alternatives for the uses described above are not available today, many years are needed to identify, qualify and design-in substitute materials.

Additionally, there is significant raw material and supply chain infrastructure dedicated to testing and acquiring PFAS materials that will have to be reorganized and run-in to use alternative materials, either with current vendors or new vendors that will have to be vetted and on-boarded.

Substitution timeline

(Example for implementing a substitute in one model radio printed circuit board (PCB)):

1. **Identify potential substitutes** (2-3 years minimum as no alternatives are on the horizon according to material suppliers)
2. **Qualify substitutes** at material level, assembly level & initial reliability testing (1-2 years)
3. **Develop PCB**, produce & qualify samples of the PCB- assembly (2 year)
4. **Develop system enclosure**, test & qualify at system level (1-2 years)
5. **Conformity testing**: Initiate and pass 3rd party conformity testing (1 year)
6. **Production ramp up:** Start-up of volume production from material vendors through to final product assembly (1 year)

Assuming that each step is successful, the **best-case scenario** for substituting the PCB material in one radio will take 8 to 10 years to complete. The engineers that need to do this work are currently the ones working on the development of the next generation (more circular, more energy efficient) 5G equipment as well as 6G equipment. In order to build a PFAS free Mobile Communications site at least the radio, connectors, cable and antenna would need to pass system level conformity testing – and this would be for just one model.

Multiple models are needed to build an efficient communications network. Once the substitute material initial application is a success, the substitution in other models can build on that and will take less time. However, 12 years at minimum will be required to complete the substitution in the portfolio if no barriers are encountered.

For spare parts none of the above is viable since the product dimensions are set – and cannot change unless a 100% compatible material is found.

Emissions

Emissions to the environment are not expected during the lifetime of the article. Under normal conditions of use the materials are not exposed to mechanical wear and tear and as there are no volatile PFAS components, no emission are to be expected during the lifetime of a product.

The main potential emissions will be generated during manufacturing (production waste) and during the waste phase. Both production and end of life ewaste are managed and treated in a controlled fashion. as electronic waste (not from private households) and will be handled and disposed of according to, at minimum, the requirements of the EU WEEE Directive.

Proposed derogations:

Paragraph 2(c) shall apply from (**13.5 years** after entry into force) to PFAS used **for fluoropolymers meeting the PFAS definition in radio frequency related parts of mobile telecommunication network infrastructure equipment**. **The European Commission shall review this derogation by 3 years before its expiry to assess whether alternatives are now available or whether further renewal is needed and to publish amendments to the Regulation.**

An exemption for fluoropolymers used in spare parts for radio frequency related parts of mobile telecommunication Radio Access equipment.

Environmental impacts and emissions

The quantity of fluoropolymers that are introduced in the EEA in Mobile Telecom Radio Access Equipment (Remote Radio Unit (RRU) or Transceiver (TRX) + Antenna system including all parts in the RF signal path) based on averages over the various types of products (such as single/multiple frequency band, passive or active antenna) and the anticipated market in the EEA for such equipment is estimated at 277.5 ton per year (industry total). (Low estimate: 225.8t /y; High estimate 340.9t)[114]. As the uses described above may not be included in table 1 of the ANNEX XV RESTRICTION REPORT – Per- and polyfluoroalkyl substances (PFASs).

This volume is likely to decrease over time as future equipment designs continue to result in next generation products that are more efficient as regards to the amount of materials used and any substitutes that are identified will be implemented.

With respect to spare parts the quantities are negligible 1) due to the very high reliability nature of telecommunication network equipment failure rates are very low over the normal lifetime of products and 2) failures that do occur in most cases are caused by failing electronic components on the PCB assembly. The PCB assembly is usually repaired by replacing the defect component and subsequently utilized in future repairs. While failure of the PCB itself or associated connectors and cables is rare it cannot be ruled out and replacement parts must be available during the agreed lifetime of the product.

Socio-economic impact

It is difficult for the telecom network equipment manufacturers to estimate the socio-economic impact of replacing fluoropolymers as far as equipment pricing because there are no clear replacement solutions identified and while extensive research and development efforts are required the costs to citizens are unlikely to be prohibitive.

An uncontrolled phase out of fluoropolymers, without any alternatives with similar performance, would increase signal loss and RF output power (increased Df and Dk values), leading to higher energy use, while at the same time the signal quality would deteriorate (worse PIM levels). Further, fire resistance would need to be achieved with intentionally added flame retardants; material properties could not be guaranteed during the entire life cycle (10-20 years) resulting in reduced product lifetime; and high operational temperatures would be challenging for non-fluoropolymer materials. Further, fluoropolymers show good performance

[114] Based on product analysis data and EEA market share assumptions for the industry; details in the confidential annex

in the production processes (high soldering temperatures), where alternatives would lead to higher scrap levels during production. Lastly, since the material characteristics are important for the overall design of the equipment, an immediate change to non-fluoropolymer materials cannot be performed. Hence, sub-optimal substitution may affect both industry and consumers.

Consequently, the whole product needs to be redesigned, tested and qualified, which takes a long time. Hence, there would be a risk that telecommunication infrastructure equipment could not be placed on the market for a period after the entry into force and transition period of the restriction.

The additional time requested will, however, minimize unnecessary market and supply chain disruptions in the sector, prevent a delay of roll-out and upgrading of current mobile communication networks. Socioeconomic impacts linked to a delay in mobile network evolution will include reduced economic growth and reduced access to mobile digital services for all end-users.

As substitutes for fluoropolymers when implemented in new product designs will change the form factors of the products the provision of spare parts for the repair of current network elements is impossible without a specific derogation for repair. Without that derogation, mobile network operators will struggle to consistently provide consistent mobile telecom services even if substitution for new products would be achieved.

Dependable mobile network services are critical to the functioning of modern society.

Notes:

1. The details of the specific PFAS (fluoropolymer) applications as well as issues identified with substitution may vary between companies and therefore cannot be disclosed publicly. More details can be provided by each individual company.
2. Relevant manufacturers of the above-mentioned coaxial connectors plan to submit an industry wide request for derogation that would outline their efforts to identify and suggest alternative materials.
3. Similarly, relevant manufacturers of the above-mentioned Printed Circuit Board materials plan to submit a request for derogation that would outline their efforts to identify and suggest alternative materials.

Re: Comments of Valmet Inc.
New Rules Governing Currently Unavoidable Use Determinations
Revisor's ID Number R-4837; OAH Docket No. 71-9003-39667

Dear Commissioner Kessler:

On behalf of Valmet, Inc. and Valmet Flow Control Inc. (Valmet or the Company), we appreciate the opportunity to comment on considerations for developing proposed rules for determining when products should be exempt from the January 1, 2032, ban on distribution and sale of products containing intentionally added PFAS.

Enclosed are Valmet's comments on the particular issues raised by the Agency in its Request for Comments document, together with detailed information on a number of Valmet's products that contain PFAS (fluoropolymers and fluoroelastomers) for which Currently Unavoidable Use (CUU) determinations would be warranted. Minnesota Statutes 116.943, subdivision 5(c). The comments include additional background on the Company's products, the important role played by fluoropolymers and fluoroelastomers in the listed CUU products, the particular challenges and costs of attempting substitutions in complex equipment, and the societal impacts of the bans going into effect without appropriate CUU exemptions.

Valmet's comments also urge the Agency to interpret the scope of the products rule to be limited to consumer products and to exclude industrial products. Its comments demonstrate the impracticability and high cost of applying these rules to industrial products and the limited benefit.

Thank you for your consideration of these materials. We look forward to further engagement on this important topic. Please contact me for any additional information or clarification of any matter presented.

Very truly yours,

James G. Votaw
Partner

Comments of Valmet Inc. and Valmet Flow Control Inc.
New Rules Governing Currently Unavoidable Use Determinations
Revisor's ID Number R-4837; OAH Docket No. 71-9003-39667

Valmet, Inc. and Valmet Flow Control Inc. (Valmet or the Company), appreciates the opportunity to comment on considerations for developing proposed rules for determining when, Minnesota Statutes 116.943, subdivision 5(c), products should be exempt from the January 1, 2032, ban on distribution and sale of products containing intentionally added PFAS (Currently Unavoidable Use Determinations).

At the outset, we urge the Agency to adopt a common sense understanding of the appropriate scope of the statute. A plain reading of the words of the statute indicates that the PFAS in products prohibition should apply only to *consumer* goods (including their individual components), and we encourage the Agency to take that approach.[1] Applying the prohibition to most industrial goods will not significantly reduce human exposure or environmental release and, as Valmet's submission illustrates, it will be enormously complicated and costly to implement.

In addition to the following comments, the Company also supports the comments to be submitted by the Flow Control Coalition. For Valmet, the Coalition's proposal represents a thoughtful, balanced and pragmatic approach to managing PFAS while ensuring that critical functions of industry and society continue while at the same time, mitigating adverse impacts on businesses, communities, and public health.

A. Products Containing PFAS for Which Currently Unavoidable Use Determinations are Warranted

As requested by the Agency, Valmet is submitting information on a number of its products that contain PFAS (fluoropolymers and fluoroelastomers) for which Currently Unavoidable Use determinations are warranted, as provided by Minnesota Statutes 116.943, subdivision 5(c). We understand that the Company will have further opportunities to (1) identify additional products warranting CUU determinations and (2) to provide additional supportive information and argument if needed. This product information and brief CUU determination

[1] "Product" is defined as "*an item … prepared for sale to consumers, including but not limited to its product components*…". M.S. 116.943, subd. 1(q). While the definition certainly includes consumer products and their components wherever they are distributed (whether sold or used for consumer or industrial use) ("*product components, sold or distributed for personal, residential, commercial, or industrial use, including for use in making other products*"), the definition is still bounded the foundational characteristic that the covered products are limited to those that are "*prepared for sale to consumers*." This definition does not cover products (and their components) that are only distributed for industrial (non-consumer) uses, such as industrial paper manufacturing equipment, industrial boilers or emission control devices. We understand that Maine has taken a different approach, but if the statute were intended to cover non-consumer industrial products, the definition would only need to refer to "*all products.*" The Agency needs to give meaning to that additional language, but not in a way that is internally inconsistent.

justification is provided in the accompanying CUU Product Group spreadsheet. Those listings and brief justifications should be read together with these narrative comments for full context.

B. Valmet Inc. and Valmet Flow Control

Valmet is a leading global developer and supplier of process technologies, automation and services for the pulp, paper, energy and other process industries.

A number of Valmet's products contain fluoropolymer and fluoroelastomer components. As detailed in the accompanying CUU Product Group Proposals Spreadsheet, these are highly engineered products and include paper, tissue and board production machines and related technologies; pulp mills; and material handling technologies for each of these. The Company also produces energy for power and heating production, gasifiers, and related automation solutions and air emission control technologies for all of the above and other sectors of process industry. These in turn contain a wide range of fluoropolymer and fluoroelastomer components, including power cable insulation, seals, gaskets, metal and glass protective coatings, mechanical parts, hoses, connectors, windows, spray nozzles, heat exchanger coatings, o-rings, valve and valve components, gasket sealings; flange sealing, bearings, filling rings, valves, swinging prevention plates, chemical dosing pump membranes and seals, flue gas filters, pulp and paper manufacturing components (special rills, headbox flow ducts, drying cylinders and pressure vessels, stretchers and guides, tail threading equipment, high pressure cleaning and cutting components, and steam and condensate joints).

These end products are used and critical to the operation of a wide range of industrial applications. Valmet's technologies are used in the production of pulp, paper, tissue, board, bioenergy, biofuels, biochemicals and different bio-based materials. In addition to these, Valmet's technologies cover a range of processes used in the circular economy, such as fiber-to-fiber textile recycling, chemical plastics recycling, high-efficient energy recovery from waste, and emission control equipment and automation. The Company's automation technologies and industrial internet solutions are used even more widely, from the automation of food production lines and LNG terminals to balancing city wide electricity and heat production as well as municipal water and wastewater systems. The Company's intelligent valves are used in a wide variety of different process industries to transfer, for example, hydrocarbons and hydrogen in pipelines. The Company's emission control systems are used in industry and the marine sector. The Company's measurement systems are used in industry to ensure steady performance and quality.

C. Essential Function of Fluoropolymers and Fluoroelastomers

These highly engineered systems may contain thousands of components designed, tested and built to work together in particular environments. Fluoropolymer and fluoroelastomer components are often used in these manufacturing and processing systems because of their many exceptional properties, including, as needed, low coefficients of friction, inertness to most chemicals, tolerance of high temperatures, and overall durability. There are no practicable substitutes for the fluoropolymer components. Indeed, it would be necessary to develop hundreds of substitutes to match the properties of the full variety of tuned fluoropolymer and fluoroelastomer products developed over years to meet specific needs. Even if these were available, it would take years to test performance and compatibility of the new materials, and perhaps additional years to develop supply chains and customer acceptance. Furthermore, many of our products, such as pressure vessels, need to comply with various standards, such as the

ASME pressure vessel code. Materials we use in such products must comply with certain material standards and the standardization process for new materials takes typically many years.

Without them, any system built during the last 40 years will not operate as designed. Without spare parts that are tested and certified, and which from a technical perspective also fit the existing design, the Company could not serve its customers, and capital investments by the Company's customers would soon become stranded assets as existing systems will shut down when replacement parts become unavailable. As discussed herein, that could be expected to shut down significant industries, such as pulp and paper manufacturing and in the energy sector.

D. Practical Impacts of a PFAS Product Ban

1. Example: Pulp and Power Industry

Pulp and paper industry (HTS group 8439) provides a remarkable variety of products to current society, from newspapers and books to packaging, tissue solutions for hygiene products, as well as production of pulp for textile applications. Machines to produce these use numerous components (pneumatic and hydraulic cylinders, valves, sliding bearings, self-lubricating bearings, sealings, hydraulic and pneumatic fittings, rotating joints) verified for special process requirements and many of these include fluoropolymer and fluoroelastomers components. These components in general, provide high thermal, abrasion and chemical resistance properties for the machinery. PFAS containing components are used as surface treatments on rolls, which improve the runnability of the machine, for example lowering friction and hence lowering the energy consumption of the process. Shortened equipment lifetimes or reconditioning intervals would mean extra use of resources and increased energy consumption. The Company estimates that equipment lifetimes could drop by half or more from existing levels if enhanced functionality from fluoropolymer and fluoroelastomers were lost due to a ban. This could result in the permanent shutdown of production lines.

As an example, PVDF fluoropolymer is used in the headbox components in paper machines (HTS product category 8439). Producing PFAS plastic components for this application is much more energy efficient than producing them from steel. Possible alternative non-PFAS plastic components would have shorter lifespan and therefore unexpected failures would be more common. This would result in higher spare part costs and loss of production. In addition, part breakages would lead to increased maintenance work which typically is hands on work in a high-risk environment. In principle, these fluoropolymer components could be replaced with substitute stainless steel components, but production of stainless steel is more energy intensive than producing plastics. In addition, related to stainless steel, there is a heavy competition for some raw materials, such as nickel, with battery and car industry.

Other examples from the pulp and paper industry include PTFE fluoropolymer coated steel bands, sealings and rotating couplings that are critical for severe operating environments such as high temperature, contact with harsh chemicals, acids and hydrocarbons, and friction. To avoid the use of PTFE in this context, when a viable substitute is not available, would require a massive redesign and rebuilding of the paper machines with a subsequent loss of production. If the hydraulic sealings fail, there will be releases and potential exposure to contained chemicals and oil.

However, some substitutes have been identified. For hydraulic static sealing applications there might be alternatives for FKM in some applications, such as nitrile butadiene rubber (NBR) or Hydrogenated NBR (HNBR), but product lifetimes for these substitutes are much shorter with much greater operation and maintenance costs over lifecycle. And U.S. EPA currently is completing a TSCA risk evaluation for all conditions of use for 1,3-butadiene and may soon impose severe restrictions on the use of that chemical going forward.

In energy production, chemical resistance especially is required. PFAS are used, for example, in heat exchanger coatings at temperatures that range from 32º to 392ºF. There are many environments where metallic heat exchangers suffer from extremely rapid corrosion.

The current pulp, energy and paper mill plants are the result of decades of design, redesign and development work. There are many PFAS-containing components in the processes, such as valves, pumps, filters, chemical dosing units, coatings and related automation solutions electronics etc. These pulp and energy production solutions are tightly linked to each other and have multiple interdependencies in their operations. In addition, there are other supporting processes such as flue gas cleaning, essential for the plant to operate according to permits. Rapidly redesigned plant sites without any PFAS-components would be much less efficient and manufacturing of some high-end types of paper (such as lightweight packaging grades and graphic paper) would not be possible at all. For example, without any resistant fluoropolymer components, operating temperature would be required to be decreased from by 300ºC to 120ºC (e.g., by replacing hot thermal oil heating by hot water) which would have a significant impact on the production rate and the quality of paper (estimated 10-30% lower machine speed combined with unexpected breakdowns and more frequent shutdowns for maintenance). In addition, it would not be possible to use dryers (due to high temperature conditions) and this leads to a lower quality of paper (insufficiently dried paper cannot be used in converting or printing processes). The ban also would lead to traditional types of fabric change methods, maintenance and shutdown times would increase and overall, the time efficiency of the production machinery would decrease.

To conclude, reliability of paper making lines would drop dramatically, down time for the machines would increase, resulting in losses in production and decrease of the competitiveness of the industry.

2. Example: Flow Control Products

Flow control refers to management of movements of liquids and gases in a variety of processes. A variety of the Company's valves, pumps and related supplies can be used in pulp, paper and board industry, mining and metals, chemicals, refining, energy and in many other process industries as well as municipal water and gas infrastructure. Most of valves are equipped with components (seals, bearings, o-rings, liners, actuator bodies, lubricants and coatings) made from a wide range of fluoropolymers and fluoroelastomers, formulated to meet the specific needs of each type of application. These fluoropolymer and fluoroelastomer materials are chosen for flow control components because their superior performance in demanding harsh conditions, such as high temperature, harsh chemicals, high friction, and their combinations. The critical uses include spare parts for existing installations as well as supply of new technology.

Fluoropolymers and fluoroelastomers are used in valves for sealing purposes, *i.e.*, to prevent leakages through the valve, when it is closed and to prevent fluid media from escaping into the atmosphere through shaft sealing. If these are substituted with less performing material, the risk for fugitive emission is high and these emissions may be harmful for both the employees and the environment. In most application areas in the process industry, there are currently no viable alternatives for fluoropolymers. Proposed substitutes, such as graphite packing rings without PTFE lubrication, resulted in more fugitive emissions which is not acceptable trade-off in industrial processes.

Banning valves (and replacement parts) containing PFAS would have far reaching effects. One process plant, for example, may have thousands of industrial valves installed. Banning PFAS-containing components (99% of current valves in use) would have a huge impact in industrial operations. It also may prevent the completion of new industrial infrastructure.

3. Example: Future Solutions

In addition, as industry is trying to tackle the future challenges, such as building for the hydrogen economy, banning fluoropolymers would be a significant setback. For example, there are no alternatives for sealing applications related to storage and transport of hydrogen as the hydrogen molecule is so small that there is always a leak if alternative polymers are used.

Banning PFAS components would have a major impact also to automation of industries as PFAS-components are widely used in electronics, for example, circuit boards, semiconductors, capacitors, wire insulation and cables, mechanical parts, windows etc., which are parts included in the Company's technology deliveries. PFAS-free components are not readily available on the market and PFAS are needed for high performance in demanding industrial environments so these systems may become unavailable in this state.

Banning fluoropolymers also would have serious implications for national and international trade flows. The fluoropolymer containing technologies banned in Maine or Minnesota will continue to be used elsewhere, giving companies in the same industries in other states or countries a competitive advantage. Policymakers should expect industries hobbled by industrial product policies to shift production, if they can, to site processing facilities located elsewhere in the U.S. or abroad.

E. Considerations for Alternative Technologies

1. The question of alternatives: no "drop-in" solutions

Potential alternatives to fluoropolymers and fluoroelastomers evaluated to date have been inadequate, even for non-critical applications. They have not performed as well as fluoropolymers and fluoroelastomers. Their use results in higher energy consumption, more frequent maintenance, and lower service life, leading to increased consumption of raw materials and generating more waste. For example, so far, the best identified alternative material for PTFE for seals in valves is Polyether ether ketone (PEEK). However, the properties of PEEK are less favorable than those of PTFE. First, the coefficient of friction is 3.5 - 4.5 times higher in PEEK (0.35-0.45) compared to PTFE (0.1). This means much higher energy consumption of valves and a higher wear rate of the seals. A higher wear rate leads to a faster increase in leakages and increased waste in the related industrial process. Second, PEEK is much more rigid and brittle than PTFE, and its compressive modulus is much higher than that of PTFE. These properties can cause the valve seat to be less flexible to deformation against the mating surface, therefore, the internal tightness of the valve is reduced. Third, the corrosion resistance of PEEK is not as good as that of PTFE. For instance, PEEK is not chemically compatible with strong acids (HCl, H2SO4, etc.), and these chemicals are often used in chemical processing industry. There is no margin for deficient performance of the equipment, when the risk for environmental, health and safety hazards is obvious. More maintenance work and required repairs will lead to unexpected shutdowns and hence further increase these risks.

There are alternative materials that can be used in less demanding applications, but no alternative has all the properties of most fluoropolymers. For example, in paper production, in some parts stainless steel component could be used, but it has poor friction resistance, leading to wearing of counterparts and consequently to higher risk of unexpected breaks and health and safety incidents, and also to significantly higher energy consumption.

Alternatives to some parts in the Company's technologies may be available, and we are actively looking for them. But even in these cases, lengthy testing program including redesign and re-certification of products would be necessary before they could be used (for example, testing, redesign and recertification of automation electrical systems may be very lengthy).

3. Long transition times required

A lot of luck was involved when fluoropolymers were discovered, and it is far from certain that alternative materials meeting the needs in the process industry will be found within the current transition period. In the Company's sector for example, it is not uncommon that it takes 15-30 years from innovation to market uptake. In the case of the PFAS ban, creating well-functioning substitute materials is not all that is needed to substitute fluoropolymers.

In process industry, new components and chemicals are seldom "drop-in solutions." All the components and parts in the machinery need to be matched together and redesigned, validated, standardised, tested, and certified. This may need to be performed for thousands and thousands of components and parts. Industries that have developed complex systems with thousands of components and parts over decades cannot be expected to develop alternatives, and then iteratively redesign and test processes using the new materials in a few numbers of years. Furthermore, the fluoropolymers are used so widely, that it is doubtful that a limited number of trained personnel, laboratories and certification bodies can meet the testing needs in such a few short years even if solutions were already available.

For example, valves, depending on their application, need to pass the following extensive certification testing: The most time-consuming certification testing is done for fugitive emission testing, according to API 641 or ISO 15848-1. Furthermore, the valves need to comply with internal tightness tests according to API 598, ISO 5208 and others, such as fire-safe tests according to API 607. Due to the duration of a certification test (average 7 weeks for one valve) and a high number of fugitive emission certificate tests (over 150 pieces) the testing to re-certify valves with new material replacing PFAS will take approximately 20 years just to cover the Company's current valve offerings. This testing can take place only after finding suitable substitute materials for PFAS components and when redesigning of the whole product offering is complete.

Without exemptions, some sectors such as pulp and paper manufacturing, would have to be completely redesigned and they would inevitably lose their production capacities and competitiveness because of the performance of the alternatives (it would basically be a return to 30 years old technologies). Taken into consideration, that redesigned applications are unlikely to pass the certification criteria shortly and the plants will not necessarily pass environmental and safety standards and permits conditions directly, this would lead to closure of plants and consequent unavailability of the corresponding pulp, paper, board, tissue, bioenergy, biofuels, biochemicals, and biomaterials.

F. Response to the Agency's Specific Request for Comment

1. *Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?*

Criteria should be established for recognizing "currently unavoidable uses" (CUU) that warrant exemption from bans on products containing PFAS. Criteria are necessary as a guide for consistent and reasoned decision-making.

The CUU criteria should include aspects related to the functioning of society. For example, if PFAS are banned in 2032, the ban could reasonably be expected to (1) directly impact the availability of replacement parts for existing capital equipment of all kinds designed to operate with components containing PFAS, (2) causes businesses or public institutions to close or suspend operations (in whole or in part); and (3) significantly decrease reliability of the processes and the competitiveness of the operations that current use PFAS-containing components (*e.g.*, by switching to less durable components).

Fluoropolymers and fluoroelastomers (PFAS) are critical components in a wide variety of products and assemblies used in process industries due to the physical demands of those applications and the exceptional properties of the materials. They are used because they are extremely useful and enable a wide range of technologies in large and small ways. They are used, for example in industrial equipment valves, and for sealings, lubricating, insulating, coatings, and other critical functions. Over the course of the past decades, innovators have sought to take advantage of these properties by incorporating them where needed to improve the functioning, efficiency and durability of a wide range of equipment and processes.

For example, a wide variety of products such as machines for producing paper, board and tissue, energy infrastructures and renewable fuels production and many circular economy processes include PFAS materials as integrated, critical parts of their functioning. Adequate substitutes are generally unavailable, but even if they were, the process of reengineering nature, complex systems such as those described is very costly and cannot be done at all except over time. New equipment may be able to take advantage of that kind of incremental innovation, but existing capital equipment and infrastructure designed and perhaps certified to incorporate fluoropolymer and fluoroelastomer technologies will continue to need fluoropolymer enabled replacement parts to operate.

Premature or improvident product bans have the potential to be disruptive in wide swaths of the economy in this state by forcing some operations to curtail operations or close. This may have significant consequences to the green transition, as well as the competitiveness, growth and jobs due to risks in the operational capacity of the several industrial sectors.

When assessing the currently unavoidable uses from the perspective of functioning of society, all these commodities and products mentioned above are critical in modern life.

2. *Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?*

Costs should be considered in defining "reasonably available." Costs of substitution should be measured in a practical way as they will be experienced by those incurring the costs. For example, this would include (a) simple costs of purchase, (b) full costs of successful substitution (e.g., redesign compatible and performance and durability testing); (c) increased operating costs over equipment lifetimes; (d) costs of lower performance (e.g., emissions, spills, increased maintenance ,more frequent replacement); (e) costs of lost jobs and economic output; (e) increased costs to replace incompatible equipment and all other transition casts. An important factor in determining the cost of transitions is the time period over which the transition will occur. Reasonable time frames for forced transitions will dramatically increase societal costs.

Inherent in the concept of a "reasonable" cost is the concept of *proportionality* – a cost that is appropriate or fair; sensible and moderate. Is the cost to make the (forced) substitution proportionate to the expected quantifiable benefit from the substitution? Proportionally more cost might be tolerated for forms and applications of PFAS that, without substitution, are more likely to represent a release to the environment and to the general population. Conversely, if the substitution is unlikely to result in little if any significant reduction in human exposure or environmental release, it would be disproportionate and unreasonable to incur any significant cost to achieve that marginal reduction. We submit that fluoropolymers and fluoroelastomers included in articles are unlikely to be sources of human exposure or environmental release due to their physical form and chemical composition. This potential is even lower when the fluoropolymers and fluoroelastomers are used within heavy industrial processing equipment and electronics.

Purported alternatives for fluoropolymers and fluoroelastomers available to date, even for non-critical applications, have so far always had lower level of performance, higher energy consumption, required more maintenance and lower service life, leading to increased consumption of raw materials and generating more waste. There is no margin for deficient performance of the equipment, as the risk for environmental, health and safety hazards is obvious.

Therefore, it is very difficult to define 'reasonable' costs threshold in process industry, as viable, well performance alternatives do not exist. In addition, in process industry, it is seldom possible to change one article without any effects on the others. Therefore, the total costs are not limited to the article to be replaced, but instead, when changing one article, the whole process may need to be redesigned to avoid unwanted effects. In addition, substitution of separate items may lead to decreased efficiency, temporary shutdowns, increased resource use and in general, to increased costs of stranded assets. Thus, the costs are multiple compared to the costs of a separate item and as substitution of items may lead to lower performance of the process, which inevitably increases daily running costs and has an effect on the competitiveness of the company. Therefore, taking into account all possible costs, both direct and indirect costs, calculating the total costs is impossible.

The definition of "reasonable available" should be limited to cases in which substitution is indisputably technically and economically feasible and available in conventional supply chains and substitution does not increase the health and safety risks of individuals or environment. If the component gets "reasonably available" status, the transition period should be minimum of 25 years to avoid the loss of competitiveness of the industrial sector. In addition, a permanent derogation for spare parts in existing machinery and plants is necessary.

4. *What criteria should be used to determine the safety of potential PFAS alternatives?*

PFAS-containing components currently in use must be able to be used in industrial processes until the safety and overall effects of the alternatives on the environment and users have been thoroughly evaluated to avoid unwanted trade-offs. To be deemed "reasonably available," candidate substitute materials should be safer from a life cycle perspective than the PFAS materials they would replace. It would be unreasonable to expect substitutions to be made with materials that would not be perform at the same level as the existing materials.

Thorough testing is needed for alternatives to ensure their use is positive in all perspectives. The testing should include testing in its operational environment, whatever it is, to ensure it meets the quality required in the process as well as the operational safety aspects. The process industry is full of complex interdependencies and changing one component in the process may have effects on various others. The use of alternative materials may significantly increase the risk leaks of hazardous (elevated temperature, corrosive, reactive, toxic, hot, pressure) process gases and liquids and pressurized media to the workplace or the environment.

From a safety perspective, reasonable acute and chronic human health toxicity and ecotoxicity assessment is necessary. A holistic analysis of the results should also consider the volumes/amounts of alternative components, so that the net effect from various perspectives is positive compared to the currently used PFAS containing components.

5. *How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?*

PFAS-containing components currently in use must be able to be used in industrial processes until safe and effective alternatives have been identified, and adequate and appropriate transition periods have elapsed. These should be set on an individual product basis to take into account, for example, necessary performance validation and verification procedures applicable to the equipment. In addition, trade in spare and replacement parts for existing equipment designed to function with fluoropolymer and fluoroelastomer components must be permitted indefinitely where substitution would be impracticable. Large capital equipment may be in service for decades. And for complex equipment, CUU status must continue to apply until all PFAS-containing components in the affected equipment can be replaced.

In process industry, new components and chemicals are seldom "drop-in solutions." Components are designed to operate as integral and connected parts of complex systems. Before changing the composition of one component of the system, the parts need first to be innovated, matched together and redesigned, validated, standardized, and certified. All this takes years.

When taking the investment decisions, companies rely also to the stability and predictability of the regulatory environment of the society. When investing to a new process industry plant, a service life up to 30 to 60 years is expected. To support successful industrial activity, regulatory processes should be iterative only and avoid sudden bans without a particularly significant reason. One example of iterative approach may be that using spare parts in running plants are exempted from the ban.

Currently unavoidable uses components may be reviewed in regular intervals, for example in every 8th year. And after the review, the same 25 years transition period is needed for any industrial use, as demanding any short-term changes in processes *i.e.*, regressive legislation would be fatal for industries.

6. *How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?*

Products should be defined for exemption at the whole product level and should automatically be considered to include (1) all component parts, (2) spare and replacement parts for such products sold separately and (3) all products and materials needed to produce the CUU exempt equipment. Agency information submission systems should be designed to accept upload of template worksheets (*e.g.*, CSV files) and automatically populate the Agency's data management systems. This permits submitters efficiently to prepare information offline using standard commercial software, and allows effect error free transfer of submitted data into Agency systems.

8. *Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?*

MPCA should not make CUU determinations based on the submitted examples. But the Agency should use the submitted examples to design and vet its information management and decisional making systems, and then present its tentative analysis of some or all of the submitted examples to demonstrate how it would anticipate making decisions in the future, including information needed and decisional criteria. Those proposed approaches to different decisional criteria should be made available for public comment.

9. *Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination*

During a consultation process in 2023, our company identified over 170 uses for PFAS containing materials only in our technologies, and the list is unlikely to be exhaustive. In addition to the large number of uses, one process technology plant may have thousands of parts with PFAS. For example, just the number of valves in one process plant can be in thousands. When considering any potential bans of PFAS-components, we support broad exemptions for industrial actors. There are currently no viable alternatives for most fluoropolymers in technology applications in process industry. The critical applications are technology components such as seals, O-rings and coatings that are used in industrial processes exposed to harsh conditions (temperature, chemicals, high friction and their combinations) and include spare parts to existing installations as well as supply of new technology. Given these uses, replacement would be a high cost, low practical benefit exercise.

Our view is, that in process industry, the use of PFAS-containing products and components ensures greater safety overall as they are often the best tools to assure the mechanical integrity of closed systems handling hazardous materials of all kinds. They also enable many other protective technologies, such as air emission control equipment and electronic control systems. They will also enable low carbon technologies, such as hydrogen fuels and advanced recycling technologies. For industrial uses, any risk from air emissions or water discharges, if any, should be managed by traditional pollution prevention regulation rather than simple bans of PFAS-containing components.

G. Conclusion and Contact

Valmet appreciates the opportunity to comment on the Agency's emerging approach to developing and implementing the PFAS in products rules. For clarifications or additional information from Valmet in connection with these requests, please contact:

Taco Comfort Solutions
A Taco Family Company

March 1, 2024

To: Minnesota Pollution Control Agency
Via Electronic Submission - public eComments website

RE: Request for Comments: Planned new Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID number R-4837.

Taco, Inc. is an industry leading manufacturer of pumps, valves and controls based in Cranston, Rhode Island. Taco stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality in critical applications in order to meet stringent safety standards. Our products are used extensively in critical applications to move water for heating, cooling, and domestic hot water distribution in commercial and residential applications.

In line with our commitment to finding balanced solutions, we have worked through our industry associations: Hydraulic Institute, Fluid Sealing Association, Valve Manufacturers Association, the Water and Wastewater Manufacturers Association (a.k.a. the Flow Control Coalition) which have developed a comprehensive Currently Unavoidable Uses (CUU) proposal, that is being submitted to the states of Maine and Minnesota. This proposal is founded upon expert knowledge of the design of critical processes, and incorporates valuable insights gathered from diverse stakeholders including design engineers, end-users and manufacturers of critical system components.

By engaging engineers and experts from the various segments of the fluid handling industry, the Associations have applied a collaborative, systems level approach to this complex issue. Highly corrosive materials, high temperatures, harsh environments, public health and comfort, accessibility and life-cycle considerations all are part of the design criteria of the industrial and other process systems which currently require PFAS as there are no viable alternatives to handle toxic substances, prevent hazardous leaks and fugitive emissions, ensure clean air and water, etc.

Taco actively participated in the consultation process and supports the Flow Control Coalition's submission. We believe that their proposal represents a thoughtful and pragmatic approach to managing PFAS and ensuring that critical functions of industry and society continue while at the same time, mitigating adverse impacts on businesses, communities, and public health.

Sincerely,

Mark Chaffee
VP Governmental Affairs and Commercial & Industrial Product Management

XPSA Comments in Response to Minnesota Pollution Control Agency (MPCA) Request for Comment on PFAS in Products Currently Unavoidable Use Rule

XPSA is the trade association representing manufacturers of extruded polystyrene (XPS) foam insulation products. XPSA members collectively manufacture more than 95 percent of all XPS destined for use in the United States market. XPSA promotes the safe use of XPS foam insulation in commercial and residential construction. XPSA formally submits this request to the MPCA for a Continuing Unavoidable Use designation for XPS foam insulation, and any product where the only "PFAS", per the current definition, added are hydrofluoroolefins and hydrochlorofluoroolefins (HFOs/HCFOs).

XPS foam insulation is a high-efficiency foam plastic insulation product which offers unique performance characteristics that make it a valuable insulation product. XPS foam insulation has excellent compressive strength and moisture resistance characteristics, as well as a high R-value, which makes it ideally suited for certain kinds of insulation applications where there is no alternative capable of providing the same performance. XPS foam is used to insulate commercial and residential buildings, generating significant energy efficiency benefits. Its properties also make it uniquely suited for certain desirable engineering applications.

Some of the applications for which XPS foam insulation is uniquely suited include insulating below grade foundations, which allows for the use of frost-protected shallow foundations - a practical and more sustainable alternative to deeper, more-costly foundations in cold regions with seasonal ground freezing.[1] XPS foam insulation is also the preferred insulation specification choice for protected membrane insulation installations, which facilitate "blue" or "green" roof construction, allowing the efficient use of rooftop space for urban greening and to aid in stormwater collection.

In addition, state codes for energy efficiency often have prescriptions for continuous insulation in combination with cavity insulation – this is a baseline prescriptive path in the energy codes for northern climate zones. XPS foam insulation is an important product for continuous insulation applications and for reducing energy consumption, which is a recognized priority of most state building codes. Minnesota's own state energy codes specify a combination of R13 cavity insulation with R5 continuous insulation for climate zone 6 (Southern Minnesota) as one of two prescriptive options.[2]

In recent years, XPSA members have moved away from high-GWP blowing agent formulations to low-GWP blowing agents. This transition took many years and presented a challenging engineering problem. All XPSA members now use blowing agent blends with a 100-yr GWP below 150. This transition to low-GWP blowing agents puts XPSA members in compliance with the recent EPA AIM Act Technology Transition rule, which has established a 100-yr GWP limit of 150 as of 1/1/2025 for 'Polystyrene – extruded boardstock and billet' products.[3]

[2] Minnesota 2020 State Energy Code Residential Provisions – Table R402.1.1 Insulation and Fenestration Requirements by Component

[3] https://www.federalregister.gov/d/2023-22529/p-973

In order to comply with these GWP limits, XPSA members transitioned from the use of hydrofluorocarbons into the use of hydrofluoroolefins and hydrochlorofluoroolefins (HFOs/HCFOs), which are the only replacement technology to work in manufacturing XPS foam insulation and ensure XPS foam insulation product performance. The use of HFO/HCFOs will be an ongoing need for the XPSA members. Unfortunately, because the definition of PFAS in Minnesota Statute 116.943 is overbroad, HFOs and HCFOs would fall under the statutory definition of PFAS, which would eventually remove XPS products from the marketplace in Minnesota.

In response to question 6 of the Request for Comment, XPSA suggests that MPCA should certainly *not* allow stakeholders to request a PFAS use not be determined to be currently unavoidable. Under the statute, the burden of proof is already on industry and manufacturers to prove that their existing products are net beneficial to society. In other words – the law already bans all PFAS that cannot be demonstrated to have unavoidable uses. Opening the record to suggestions from stakeholders that certain uses should not be considered unavoidable (which is already the presumption of the existing legal language) will only increase the workload for MPCA.

In response to questions 7 and 8 of the Request for Comment, XPSA suggests that the MPCA immediately exempt from the requirements of the statute any product where the only "PFAS" added are HFOs/HCFOs. These chemicals are not classified as biopersistent, bio-accumulative or toxic.[4] Any product which uses these chemicals is likely to generate a request for a CUU in future. MPCA could reduce the volume of eventual filings for products manufactured with HFOs and HFCOs by making an initial currently unavoidable use determination for any product made with these chemicals.

XPSA takes issue with the definition of PFAS in the statue – it is an overly broad definition which will impose a blanket ban on thousands of chemicals which are industrially useful and not substantially harmful to human health or society. An example of a responsible definition of "PFAS" is found in the US EPA reporting rule published October 11, 2023, which does not include HFOs or HCFOs. In fact, there are approximately 23,000 additional substances besides HFOs whose only fluorine atom is in a terminal -CF_3 and that do not share a fluorinated substructure that is likely to result in their persistence in the environment, nor degrade to a substance that shares toxicological or physiochemical properties with the PFAS of real concern, like PFOA, PFOS, or GenX.[5] In addition, the US EPA has also deemed HFO/HCFO blowing agents "acceptable" as a replacement for HFC blowing agents under the Significant New Alternatives Policy (SNAP) program. EPA determined that HFO foam blowing agents "reduce overall risk to human health and the environment compared to other substitutes for the particular end-use."[6] The MPCA therefore should take the very broad definitions of the statute into account when issuing CUUs, to alleviate the substantial burden that this law will impose on the citizens of Minnesota. CUUs should be readily issued to products (like XPS foam insulation) which rarely come into contact with human beings in situ, are made with chemicals of little toxicological concern, and cannot easily be replaced by alternative products available in the market today.

XPS foam insulation manufacturers - and the vendors who supply raw materials to the industry - spent more than a decade researching and developing HFO and HCFO blowing agent blends to replace HFC

[6] Final Rule, Protection of Stratospheric Ozone: Listing of Substitutes Under the Significant New Alternatives Policy Program in Refrigeration, Air Conditioning, and Fire Suppression, 88 Fed. Reg. 26382, 26414 (Apr. 28, 2023).

blowing agents. There are no alternatives available, at present, to the HFO/HCFO blends now in use in XPS foam insulation. It is also unlikely that any blend could be found which would provide the needed insulation properties and not also fall under the overly broad definition of "PFAS" in Minnesota Statute 116.943.

XPS foam insulation is a unique building product with valuable properties, which has contributed significantly to the push for energy efficiency and sustainable construction across the United States. XPS foam insulation should be evaluated in light of the overall effects it has on energy use, the environment, and the long-term public health and environmental implications of reduced CO_2 emissions, which are a net positive.[7] For the reasons contained in this letter, we respectfully urge the Minnesota Pollution Control Agency to provide a Currently Unavoidable Use designation for the blowing agents used in XPS foam insulation, allowing it to remain in the marketplace to keep Minnesotans warm and safe.

Best,

Michael Fischer

Re: MPCA Request for Comments regarding *Currently Unavoidable Use Determinations in Products Containing Per-and polyfluoroalkyl (PFAS),* Revisor ID No. R-4837

Dear Ms. Kessler,

Polar Semiconductor (Polar) offers the following comments on the PFAS regulations being developed by the Minnesota Pollution Control Agency (MPCA) as authorized in Chapter 60 of H.F. 2310. The MPCA has requested comments on planned new rules for the *Currently Unavoidable Use Determinations in Products Containing PFAS* (Revisor ID No. R-4837).

Polar wholeheartedly supports the goal of limiting the release of harmful PFAS substances into the environment. Polar is concerned, however, about the incompatibility of PFAS regulations with the State's goal to expand its semiconductor industry. In these comments, Polar offers recommendations on how the rules should be drafted to protect the environment while simultaneously allowing semiconductor manufacturing to thrive in the State. Polar also reiterates its support for the comments submitted by the semiconductor industry association SEMI in response to the MPCA's request for comments.

POLAR AS AN ECONOMIC DRIVER AND ENVIRONMENTAL STEWARD

Polar is a Minnesota-based company that produces integrated circuits and discrete semiconductor devices on 8-inch wafers at its fabrication facility in Bloomington. Polar's processes start with a bare silicon substrate and end with a finished wafer containing functional devices. Polar is the largest semiconductor chip manufacturing facility in Minnesota. Semiconductors are a necessary part of all electronic devices, controlling and managing the flow of electric current and enabling advances in communications, computers, transportation, military systems, and clean energy. Polar supplies products to a diverse group of end market users, with approximately 60% of its manufactured wafers dedicated to the automotive sector. The remaining share of Polar's wafers cater to industrial, commercial, and defense customers. Demand for semiconductors is projected to increase with the electrification of nearly every part of the economy and society.

Polar is in the midst of an exciting transformation. With help from the Minnesota Investment Fund, Job Creation Fund, Minnesota Forward Fund and potentially, federal CHIPS Act funding, Polar plans to expand within its current footprint and increase manufacturing capacity by 85%. This expansion will create 74 construction jobs and 98 new full time Minnesota-based jobs at Polar's Bloomington facility.

Polar prioritizes sustainability at its facility and is committed to reducing or mitigating its environmental impact. It maintains an ISO 14001 certified Environmental Management System (EMS) and has established environmental improvements goals related to hazardous waste reductions, water conservation, and greenhouse gas emission reductions. For example, Polar recently transitioned operations to be powered 100% by renewable energy through purchased Renewable Energy Certificates.[1]

CRITICAL ROLE OF PFAS IN SEMICONDUCTOR MANUFACTURING

PFAS-containing materials are essential components of semiconductor manufacturing. While completed semiconductor devices do not contain intentionally added PFAS, liquid chemicals and fluorinated gases, which either are PFAS themselves or contain intentionally added PFAS, are necessary inputs in the manufacturing process. For example, fluorocarbon gases, the molecular structure of which meets the statutory definition of PFAS, are used in plasma etch processes, fluorinated chemicals are used in photolithography, and fluorinated chemicals are used as refrigerants and heat transfer fluids. The carbon-fluorine chemistry of these PFAS-containing materials alters surface tension, thermal stability, and chemical compatibility in ways essential to the semiconductor manufacturing process. Despite years of extensive research, there have been no viable PFAS-free alternatives identified. In short, the semiconductor manufacturing process is enormously dependent on PFAS, for which there are currently no viable alternatives.[2] Because PFAS-containing products are critical for semiconductor manufacturing, the 2032 ban on all products containing intentionally added PFAS would hamstring the ability of all semiconductor manufacturers in Minnesota, including Polar, to manufacture their products.

Polar recognizes that PFAS can have impacts to human health and the environment, and is committed to finding alternatives to PFAS-containing materials. In the meantime, Polar is actively investigating various technologies including ion exchange to mitigate potential PFAS in discharged treated wastewater. However, during the period of transition, Polar believes the State should balance its dual commitments to environmental protection and creating a thriving semiconductor manufacturing ecosystem in Minnesota by making an exemption for semiconductor manufacturing inputs with intentionally added PFAS as a currently unavoidable use.

COMMENTS ON *CURRENTLY UNAVOIDABLE USE DETERMINATIONS*

1) **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**

    Polar supports SEMI's proposed language regarding criteria that places responsibility on manufacturers or trade groups to assess and provide documentation that its products are essential for health, safety or functioning of society **and** that PFAS substitutes are not available.

---

[1] Xcel Energy Renewable*Connect

[2] Semiconductor Industry Association (SIA) Background on Semiconductor Manufacturing and PFAS (May 17, 2023).

The commissioner shall grant a currently unavoidable use determination for PFAS applications or end products, and for the supply chain production activities required to produce such PFAS applications or end products, when the commissioner has evidence, or when a manufacturer, organization, or other entity has submitted evidence, that an application, product or category of products provides benefits relating to health, safety, or the functioning of society and that there are no reasonably available alternative substances or technologies for that use. A product shall be deemed to provide benefits to the functioning of society where the manufacturer has submitted evidence that the product fulfills identified consumer, commercial, or industrial demands for the product in Minnesota.

2) Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?

In evaluating "reasonably available" potential PFAS alternatives, the MPCA should consider both commercial availability and performance equivalence.

An August 2023 U.S. Department of Defense report discussed the current unavailability of PFAS alternatives - with the necessary functional performance properties - for the semiconductor industry, and the time required to bring alternatives to market. (*Report on Critical Per- and Polyfluoroalkyl Substance Uses*[3]):

Currently, no alternatives to PFAS have been identified that can provide the functional properties required for photolithography or some applications in semiconductor manufacturing equipment. Even if alternative chemicals and technologies were discovered today, due to the extremely complex qualification process throughout the value chain, it would take another 15 years to deploy them in high-volume manufacturing. Therefore, continued access to PFAS is a prerequisite for high-volume and advanced semiconductors. Lack of continued access to PFAS could lead to an inability to produce and supply semiconductor manufacturing technology.[3]

While Polar is committed to finding alternatives, it is unlikely that any will be reasonably available in the next decade. Even if alternatives are found, it is unlikely that they will be commercially available to manufacturers for an additional period, or they may be available only at a high cost. Polar, like all manufacturers, must also spend time confirming that the alternative is an acceptable replacement.

In developing regulations, MPCA should allow semiconductor manufacturers to continue use of PFAS-containing inputs to produce semiconductor chips until there is a commercially available alternative that allows the same standards of production and is widely available on the market at a competitive price point. These standards for "reasonable availability" will allow a transition to non-PFAS containing products while growing a domestic semiconductor manufacturing industry competitive with international foundries.

[3] https://www.acq.osd.mil/eie/eer/ecc/pfas/docs/reports/Report-on-Critical-PFAS-Substance-Uses.pdf

3) **Should unique considerations be made for small businesses with regards to economic feasibility?**

Polar does not have comments on this issue at this time.

4) **What criteria should be used to determine the safety of potential PFAS alternatives?**

Polar does not have comments on this issue at this time.

5) **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

Polar supports SEMI's proposed language regarding length of currently unavoidable use determinations:

CUU determinations should be indefinite, because this is needed to give manufacturers the necessary repose to rely on the originally issued determination, and Section 116.943 does not authorize a time-limited scheme. Indefinite determinations reflect how, especially for the semiconductor industry, the identification of PFAS, search for potential alternatives, testing of potential alternatives, and implementation of appropriate alternatives takes many years. Therefore, members of our industry need to be able to rely on a CUU determination for long enough for these steps to occur, and this time cannot be reliably estimated at the onset of the determination.

6) **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

The MPCA should encourage groups of manufacturers or trade groups to submit currently unavoidable use determination requests to prevent duplication and reduce the MPCA's reviewing burden, but also allow individual manufacturers to submit requests as needed. MPCA should provide an electronic format for requests and solicit detailed information such as PFAS type and use applications.

7) **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

If companies are required to seek individualized currently unavoidable use determinations, Polar would submit a currently unavoidable use determination request for products used in its manufacturing and support processes including, but not limited to, fluorocarbon gases and fluorinated liquid chemicals used in photolithography and etch processes, fluorinated chemicals used as refrigerants and heat transfer fluids, and fluoropolymers and other PFAS used in production of high-purity water. If required, Polar would submit detailed documentation showing the necessity of each product for its semiconductor manufacturing.

8) Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Polar requests that the MPCA begin the 'currently unavoidable use' designations now as a part of this rulemaking. One of these initial designations should be for inputs and materials used in semiconductor manufacturing and associated support processes as currently unavoidable uses.

CONCLUSION

Polar is proud to be the largest semiconductor chip manufacturing facility in Minnesota. Without carefully crafted regulations or a currently unavoidable use exemption for semiconductor manufacturing products, the PFAS prohibition will have a profound impact on Polar's short-term expansion, Polar's long-term viability, and the semiconductor manufacturing industry in the State.

Thank you for the opportunity to provide comments to the MPCA on currently unavoidable use determinations. Polar welcomes further discussion with the MPCA on the role of PFAS in semiconductor manufacturing and mitigation measures underway.

Sincerely,

Surya Iyer

RE: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS) and Lead in keys

Dear Commissioner. Kessler:

The powersports industry which includes several hundred companies represented by the Motorcycle Industry Council (MIC)[1], the Specialty Vehicle Institute of America (SVIA)[2], and the Recreational Off-Highway Vehicle Association (ROHVA)[3] write to request "essential for health, safety, or the functioning of society" and currently unavoidable use (CUU) determination for motorcycles, all-terrain vehicles (ATVs) and recreational off-highway vehicles (ROVs which are also commonly referred to as side-by-sides or UTVs). We also ask for relief from the ban on lead and cadmium in keys and keychains.

Existing law would prohibit any product containing per- and polyfluoroalkyl substances (PFAS) being sold in Minnesota after January 1, 2032, unless the Minnesota Pollution Control Agency (MPCA) determines that it is essential for health, safety, or the functioning of society, or is a currently unavoidable use.

The state is asking:

1) **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**
2) **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

[1] The Motorcycle Industry Council (MIC) is a not-for-profit, national trade association representing several hundred manufacturers, distributors, dealers and retailers of motorcycles, scooters, motorcycle parts, accessories and related goods, and allied trades.

[2] The Specialty Vehicle Institute of America (SVIA) is the national not-for-profit trade association representing manufacturers, dealers, and distributors of all-terrain vehicles (ATVs) in the United States. SVIA's primary goal is to promote safe and responsible use of ATVs.

[3] The Recreational Off-Highway Vehicle Association (ROHVA) is a national, not-for-profit trade association formed to promote the safe and responsible use of recreational off-highway vehicles (ROVs – sometimes referred to as side-by-sides or UTVs) manufactured or distributed in North America. ROHVA is also accredited by the American National Standards Institute (ANSI) to serve as the Standards Developing Organization for ROVs. More information on the standard can be found at https://rohva.org/ansi-standard/.

The MPCA should absolutely consider criteria be defined for "essential for health, safety, or the functioning of society" and those criteria should include essential vehicle needs used for transportation, law enforcement, first responders, search and rescue, and recreation. Many of these vehicles have parts and components that require PFAS that are currently unavoidable uses (CUU).

The powersports industry is a nearly $48 billion economic driver in the United States with $1.4 billion of that being in Minnesota where our vehicles are designed, researched, and built. Motorcycles, ATVs and ROVs are complex vehicles which are required to comply with many state and federal regulations from the Federal Motor Vehicle Safety Standards (FMVSS) at the National Highway Traffic Safety Administration (NHTSA), the Consumer Product Safety Commission (CPSC), the Environmental Protection Agency (EPA) and more. Numerous parts and components in our powersports vehicles contain PFAS to withstand extreme heat and chemical blends in fuel and other fluids, and for water resistance, corrosion resistance, and friction properties. Likewise, PFAS are used in electrical insulation to provide flexibility and durability which maintains safe operating conditions. For example, fuel hoses must withstand a myriad of fuel blends while maintaining flexibility and structural integrity to prevent cracking or catastrophic leaks. Gaskets used throughout the vehicles must stand up to high heat and various fluids to keep vehicles functioning properly while simultaneously ensuring fluids and fuel vapors do not exit the vehicle causing clean air violations, environmental contamination, and risk of vehicle fires. Proper gaskets must be used to ensure compliance with clean air mandates by EPA and states.

Without an essential for health, safety, or the functioning of society designation and a CUU exclusion for these vehicles and parts, the state risks an exit from the market of motorcycles, ATVs, and ROV which are used by Minnesotans for commuting, recreation, agriculture, law enforcement, parks and forest officials, fire, rescue, and the military. The state would also lose access to replacement parts for thousands of powersports vehicles leaving law enforcement, first responders, and state agencies that utilize the vehicles without critical tools to accomplish their jobs that are vital to security and functioning of society.

We have also attached a considerable list of Global Product and Harmonized Tariff Codes for vehicles, parts and components which we request CUU designation.

During the global COVID-19 pandemic the U.S. Department of Homeland Security recognized a critical need for powersports to continue functioning and granted our manufacturers suppliers and dealers Essential Service destination under their national CISA Guidance. Below are examples of powersports vehicles used by first responders and government entities:

When it comes to the questions of "Should costs of PFAS alternatives be considered in the definition of "reasonably available," we absolutely believe that cost of alternatives should be considered not only on an economic basis, but also on a risk to life and the environment. As noted earlier, there are currently not alternatives available for many of our products, but if/when alternatives are discovered they need to be economically feasible. As was also noted, PFAS is necessary to protect human life and the environment by preventing the leaking of chemicals and fuels that could ignite or contaminate surroundings.

Request for Safe Harbor Provisions for Products Currently in the Market

In addition to granting our vehicles and parts "essential for health, safety, or the functioning of society" and CUU designations, there needs to be recognition and allowance for vehicles and replacement parts that are already in inventory across Minnesota awaiting sale. Manufacturers, dealers, service stations, and parts distributors likely have multiple years of replacement parts and other products already in distribution channels and in inventory at retailers. A failure to allow safe harbor language for these products would mean that every dealership, repair shop, aftermarket distributor, and retailer would need to return or dispose of all inventories that arrived prior to implementation of this new law. That is simply not feasible and could cause scores of small businesses to shutter their doors and walk away from their livelihood.

A provision banning lead and cadmium in keys and keychains was also tucked into the large PFAS bill (HF 2310 became [Minn. Stat. § 325E.3892](https://www.revisor.mn.gov/statutes/cite/325E.3892)) and there was no grace period for transitioning away from the chemicals. Our manufacturers and dealers have significant concerns about this provision and we've reached out to MPCA to voice the concerns. Staff there suggested we include our concerns in these comments and indicated that they will be releasing a "Q&A" document soon.

We are specifically concerned with Sec. 24, which states that keys, key chains, and key rings are products that a "person must not import, manufacture, sell, hold for sale, or distribute or offer for use in this state any covered product containing: (1) lead at more than 0.009 percent by total weight (90 parts per million); or (2) cadmium at more than 0.0075 percent by total weight (75 parts per million)."[4] There was no rule making, safe harbor provision, or phase-in period for these products and our we are seeking relief from the new law.

Lead is present in keys of all types and fashion, including typical blade-style keys as well as key fobs that may contain a blade or just solder for circuitry. Because nearly every key and key fob required to operate cars, motorcycles, snowmobiles, OHVs, boats, outdoor power equipment and other craft contain lead or cadmium, this provision affects thousands of products and countless businesses across MN. Due to this provision of HF 2310 passing with an immediate effective date, it has given manufacturers no time to adequately research and explore alternatives to comply with requirements. Minnesota must allow manufacturers sufficient time to find possible replacements.

We request that Minnesota provide temporary relief from the new law while exploring a more workable standard for the chemicals in keys. For example, the proposed end-of-life vehicles directive (ELV Directive) being considered by the European Union (EU) would allow for products containing lead to be no more than 0.1% by weight, and cadmium to be no more than 0.01% by weight[5]. This is a more feasible solution that allows for manufacturers to be certain they can comply with state law requirements.

We take compliance very seriously and the current law which has an extremely low threshold and allowed no time to transition away from existing keys, keychains, and key fobs, is one that put virtually everyone selling products with keys in Minnesota immediately out of compliance. That was not likely the intent of the provision which was tucked into a massive bill. The intent is likely to reduce the amount of lead in those products to a level that still allows for proper functioning of keys while also minimizing the amount of lead and cadmium in the products.

[4] https://www.revisor.mn.gov/statutes/cite/325E.3892
[5] https://eur-lex.europa.eu/legal-content/EN/TXT/?uri=COM:2023:451:FIN

We sympathize with the MPCA's herculean task of drafting regulations for [Minn. Stat. § 325E.3892] and stress that the issues we've addressed above are of paramount concern. The regulations you write today could have a major impact on manufacturing and sales in the state of vehicles that are essential to society, and on the economy of Minnesota as a whole. Thank you for your consideration and we stand ready to answer any questions and to work with you on additional sensible and targeted relief for the powersports industry from this overly broad PFAS and lead law.

Sincerely,

Scott P. Schloegel
Senior Vice President Government Relations
Motorcycle Industry Council (MIC)
Specialty Vehicle Institute of America (SVIA)
Recreational Off-Highway Vehicle Association (ROHVA)

MIC/SVIA/ROHVA Powersports Industry Currently Unavoidable Use (CUU) Designation Requests 2024

In addition to designation of our vehicles as CUU, we need CUU designation for replacement parts used to service our vehicles. Please see the list below.

Re: Minnesota's Planned New Rules Governing Currently Unavoidable Use Determinations About Products Containing Per- and Polyfluoroalkyl Substances ("PFAS"), Revisor's ID No. R-4837

Dear Commissioner Kessler:

PRBA – The Rechargeable Battery Association ("PRBA") appreciates the opportunity to respond to the Minnesota Pollution Control Agency's ("MPCA") request for comments regarding the planned new rules for currently unavoidable use determinations (CUU). As part of our responses to MPCA's request for comments, PRBA requests a CUU determination for rechargeable and non-rechargeable batteries.

PRBA is a non-profit trade association representing manufacturers of batteries and the products powered by them. Our members manufacture approximately 55% of the lithium-ion battery cells produced in the world today. Our membership also includes battery assemblers, battery recyclers, retailers, airlines, and leading manufacturers of mobile telephones, tablet and laptop computers, point-of-sale terminals, hand-held scanners, power tools, flashlights, outdoor power equipment, medical devices, electric vehicles, military defense products. We were established in 1991, when the portable consumer product revolution had just begun.

Unless a CUU exemption is granted, the state's 2032 ban will put an end to the sale or distribution of rechargeable and non-rechargeable batteries in Minnesota. The CUU exemption provision is part of Minnesota's law precisely to allow MCPA to anticipate and avoid the significant disruption to safety, health, and the functioning of society that would result. PRBA is pleased to provide responses to MPCA's questions listed in the request for comments. Our responses reference PRBA's request for a CUU exemption submitted to Maine,[1] which was prepared with the need to be responsive to MCPA's questions, in mind (Attachment 1).

1. **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**

In Section 2 of Attachment 1, PRBA explains in detail the criteria by which rechargeable and non-rechargeable batteries are essential to the safety and functioning of critical domestic

---

[1] Maine Department of Environmental Protection, *PFAS in Products: Currently Unavoidable Uses* (Last visited February 29, 2024).

infrastructures such as transportation, communications, construction, and for transitioning to a clean energy-based economy. They are used in automobiles, phones, computers, security systems, safety lighting, life-saving medical devices, military equipment. Rechargeable and non-rechargeable batteries meet the definition of "essential" at every industrial, institutional, and consumer level product. Merriam Webster defines the term essential as "something necessary, indispensable, or unavoidable."[2] Given the diversity of products impacted by this law, we request that MPCA allow industry the ability to make their own case for how their products are essential with the common meaning of the term essential as a guidepost.

2. **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

PRBA submits that MPCA should consider all associated costs that companies incur over the time it takes to implement alternatives across the complex supply chains for batteries and the products in which they are used. In Section 4 of Attachment 1, PRBA describes the state of alternatives for PFAS in rechargeable and non-rechargeable batteries and the length of time that will be needed to explore and adopt other options.

3. **Should unique considerations be made for small businesses with regards to economic feasibility?**

PRBA supports having MPCA take into consideration the important concerns of small businesses in administering the CUU exemption.

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

In determining the safety of potential PFAS alternatives, PRBA supports a risk-based approach, as described in Section 3 of Attachment 1.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

PRBA supports CUU determinations that are not time limited. As described in Section 4 of Attachment 1, to identify alternatives for PFAS in rechargeable and non-rechargeable batteries will take many years. The myriad of products that batteries power do not align with a single transition period. Projected timeframes for research and development often have to be adjusted to reflect changing circumstances. MPCA should not expend additional resources meeting with industry, reviewing requests for extensions, or engaging in additional rulemakings for this purpose.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

PRBA supports exemptions for broad product categories. PRBA would like MPCA to focus its resources on making CUU determinations, and avoid the additional time and resources

---

[2] "Essential", Merriam-Webster.com (2024). **Error! Hyperlink reference not valid.**

associated with responding to requests for other kinds of determinations. It is not clear these other determinations are permitted by the law. Product manufacturers are in the best position to know their products, whether alternative ingredients are feasible, and the time and resources associated with transitioning ingredients. We think the information in Attachment 1 meets the needs for such requests.

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

PRBA respectfully requests that MPCA grant an exemption for the product category of rechargeable batteries and non-rechargeable batteries. PRBA believes that these products fulfill all the requirements for a CUU determination, as explained in Attachment 1.

8. **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

PRBA supports having MPCA make initial CUU determinations that are not time limited as part of this initial rulemaking. We request that rechargeable and non-rechargeable batteries be one of the categories included in the rulemaking. PRBA believes that due to the essential nature of rechargeable and non-rechargeable batteries, the lack of available alternatives prior to the 2032 ban, and growing uncertainty around the negative socio-economic consequences of a ban, CUU determinations should be made as soon as possible.

9. **Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.**

PRBA believes that a CUU exemption should apply to the ban as well as the reporting requirement, set to become effective in Minnesota as of January 1, 2026.

* * *

PRBA would welcome an opportunity to discuss these comments with you and answer any questions. PRBA respectfully requests that MPCA grant our request to provide a currently unavoidable use exemption in proposed and final regulations for rechargeable and non-rechargeable batteries. For further information about these comments, please do not hesitate to contact George Kerchner, PRBA Executive Director, who can be reached at (202) 719-4109 or gkerchner@wiley.law.

Respectfully submitted,

George Kerchner, Executive Director

PRBA - The Rechargeable Battery Association

Re: Request to Maine for a Currently Unavoidable Use ("CUU") Exemption for the Product Category of High Performance, Advanced Rechargeable and Non-rechargeable Batteries

Dear Commissioner Loyzim:

PRBA – The Rechargeable Battery Association ("PRBA") appreciates the opportunity to submit to the Maine Department of Environmental Protection's ("MDEP") a request to exempt the product category of high performance, advanced rechargeable batteries and non-rechargeable (primary) batteries as a currently unavoidable use pursuant to 38 M.R.S. §1614.

PRBA is a non-profit trade association representing manufacturers of rechargeable and non-rechargeable batteries and the products powered by them. Our members manufacture approximately 55% of the rechargeable lithium-ion battery cells produced in the world today. Our membership also includes battery assemblers, battery recyclers, retailers, airlines, and leading manufacturers of mobile telephones, tablet and laptop computers, point-of-sale terminals, hand-held scanners, power tools, flashlights, outdoor power equipment, medical devices, hybrid and electric vehicles, and military defense products. We were established in 1991, when the portable consumer product revolution had just begun.

A 2030 ban on the use of rechargeable and non-rechargeable batteries would significantly disrupt the health, safety and functioning of society in Maine, and raises concerns with respect to national security and the stability of our domestic infrastructure. There are no safe or feasible alternatives for their per- and polyfluoroalkyl substances ("PFAS") components that could be made available by this deadline. The following information explains how the exemption criteria specified by MDEP are met in this case.

1. **Type Of Product Including Global Product Classification ("GPC") Brick Category and Code, or If Not Applicable, The Harmonized Tariff System ("HTS") Code.**

The scope of this document includes the following types of high performance, advanced rechargeable and non-rechargeable batteries:

- **Rechargeable Batteries**

    - Lithium ion
    - Nickel cadmium
    - Nickel metal hydride
    - Metal air
    - Sodium ion
    - Zinc ion
    - Lithium metal
- **Non-rechargeable Batteries**
    - Lithium metal
    - Zinc air
    - Silver oxide

The GPC brick category for the rechargeable and non-rechargeable batteries listed above is Brick 10000546 Batteries; the specific codes are provided with this submission as Attachment A. The GPC brick category/codes for the products that contain rechargeable and non-rechargeable batteries are too numerous to list. The applicable six-digit HTS codes are shown in **Figure 1** below. Details for these listings are also included in Attachment B.

Figure 1. HTS Classifications for Rechargeable and Non-rechargeable Batteries

Non-rechargeable Batteries		**Rechargeable Batteries**
8506.10 Silver oxide		8507.30 Nickel cadmium
8506.50 Lithium metal		8507.50 Nickel metal hydride
8506.60 Zinc air		8507.60 Lithium ion
		8507.80 Other
		8507.90 Parts (cells)

2. The Intended Use and How Batteries are Essential for the Health, Safety, and Functioning of Society.

Rechargeable and non-rechargeable batteries are essential to the safety and functioning of critical domestic infrastructures such as defense, aerospace, transportation, communications, and construction, and for transitioning to a clean energy-based economy. They are used in automobiles, satellites, phones, computers, security systems, lighting, life-saving medical devices, and military equipment. Many rechargeable batteries provide back-up power for critical industrial and institutional assets from power plants to data centers to hospitals and schools and serve as energy storage systems for electrical grids. The major consumer market segments for rechargeable and non-rechargeable batteries are automotive (*e.g.*, cars, trucks, marine vessels and navigation, e-scooters, e-bikes, golf carts), consumer electronics (*e.g.*, smartphones, laptops, computers, tablets), medical devices (*e.g.*, hearing aids, pacemakers, and other wearable devices), and energy storage systems, with consumer electronics accounting for the largest revenue share (in excess of 31.0%).[1] Other key segments include rechargeable power tools, flashlights, LED lighting, vacuum cleaners, digital cameras, wristwatches, and calculators.

With respect to the essential role of rechargeable and non-rechargeable batteries to critical domestic infrastructures, the U.S. Department of Defense ("DOD"), in its August 2023 Report on Critical Per- and Polyfluoroalkyl Substance Uses, includes rechargeable batteries among the sectors of strategic importance.[2] DOD explains the critical uses of batteries manufacturing, and concludes that "the battery industry's ability to make products for a broad range of commercial and military applications would be greatly impacted if PFAS were no longer available for use in these components."[3]

In accordance with Section 6(g) of the Toxic Substances Control Act ("TSCA"), EPA also recently concluded that rechargeable batteries are essential to serve critical infrastructure such as transportation systems, security systems, as well as to energize the national defense base.[4] To reach such a conclusion, EPA must find that (1) a specific condition of use is critical or essential, (2) that no technically and economically feasible safer alternative is available, and (3) that discontinuing the use would significantly disrupt the national economy, national security, or critical infrastructure or that the specific condition of use of the chemical substance or mixture, as compared to reasonably available alternatives, provides a substantial benefit to health, the environment, or public safety.[5]

Rechargeable and non-rechargeable batteries support the functioning and climate control necessary to operate large scale data centers for information management by Maine's state and local governments, businesses, and institutions. They serve in backup generator power sources to ensure the safe operation of hospitals in Maine during severe weather events and power outages and protect public health by powering essential medical equipment. Lithium ion batteries are the leading technology in the emergence of large-scale energy storage systems ("ESS"), which are one of the lynchpins needed for renewable energy sources to power Maine's businesses, institutions, and households.

[5] 15 U.S.C. 2605(g)(1) (2016).

Rechargeable and non-rechargeable batteries make a great many essential contributions to consumer health and safety and the functioning of society among consumers. It has taken 30 years to develop and commercialize batteries for electric vehicles ("EVs").[6] The expansion of this automotive sector in Maine and across the country is contributing to environmental health and the functioning of society by reducing our dependence on fossil fuels and lowering our carbon footprint. Batteries that power pacemakers keep these individuals safe, contribute to their improved health and wellness, and reduce the societal burdens of intensive medical care as a whole. The performance of batteries in hearing aids also keep people safe and provide enhanced opportunities to function and interact with others.

Each year from 2010 through 2020, the worldwide sale of rechargeable lithium ion batteries increased by no less than twenty five percent.[7] This increase in use has created a highly competitive global market for both domestic battery manufacturers and the companies that use these batteries in their products. Manufacturers of rechargeable lithium ion batteries must continuously improve technology and be responsive to customer needs to successfully attract business opportunities away from the global competition. An exponential increase in the use of rechargeable lithium ion batteries in products is expected to continue on a global scale. A market report from Grand View Research states:[8]

> "The global lithium ion battery market size was estimated at USD 54.4 billion in 2023 and is projected to register a compound annual growth rate (CAGR) of 20.3% from 2024 to 2030. Automotive sector is expected to witness significant growth owing to the low cost of lithium ion batteries. Global registration of electric vehicles (EVs) is anticipated to increase significantly over the forecast period. The U.S. emerged as the largest market in North America in 2023. Increasing EV sales in the country owing to supportive federal policies coupled with the presence of several players in the U.S. market are expected to drive product demand. Federal policies include the American Recovery and Reinvestment Act of 2009, which established tax credits for purchasing electric vehicles."

Other federal policy drivers include New Corporate Average Fuel Economy ("CAFÉ") standards, mandated fuel economy standards for passenger cars and commercial vehicles, and

efforts to reduce carbon emissions. According to Grand View Research, the market for lithium ion batteries is projected to grow from the current level of $60 billion to $182.5 billion in 2030 – the same time that Maine's ban is scheduled to go into effect.[9] Similar projections are consistently echoed by other economic analyses. A 2019 report co-authored by McKinsey and Company projected yearly growth of 25 percent by 2030,[10] while a more recent analysis by McKinsey's Battery Insights team in 2022 projects that the larger value chain (*i.e.*, from mining to reclamation) could grow by over 30 percent annually to a value of more than $400 billion by 2030.[11] These larger forces at play need to be taken into consideration by MDEP.

3. **How the Specific Use of PFAS in the Product is Essential to the Function of the Product. If This Use of PFAS is Required By Federal or State Law or Regulation, Provide Citations To That Requirement.**

To understand the potential magnitude of Maine's ban on health, safety, and the functioning of society requires an explanation of the function of PFAS in rechargeable batteries. A detailed scientific and technical description of the PFAS used in rechargeable batteries is provided in the report included as Attachment C. This report was prepared by the trade association for the rechargeable battery industry in Europe, RECHARGE, for derogation from the proposed restrictions on PFAS under consideration by the European Commission. ("RECHARGE report"). Resistance to chemical degradation and tolerance at elevated temperatures are crucial for battery performance to protect public safety, which necessitates the use of PFAS in all rechargeable battery technologies in these key components:[12]

- Active material masses;
- Cathode binders;
- Separator coatings,
- Electrolytes;
- Casings, valves, gaskets, washers & membranes; and
- Coatings.[13]

---

[11] *Id.*

[12] Recharge, *Application for derogations from PFAS REACH restriction for specific uses in batteries* (April 2023), p.7.

[13] *Id.*

For example, rechargeable battery manufacturing involves the use of fluoropolymers (*e.g.*, polytetrafluoroethylene ("PTFE")) and polyfluoroalkyl acids ("polyFAAs") in multiple subcomponents.[14] Table 1 on page 8 of the RECHARGE report provides a list of current binder formulations used in active material masses in which PFAS are used. These formulations often include PTFE as well as and Polyvinylidine difluoride ("PVDF") as binder materials in the active material masses in electrodes in a wide range of battery technologies.

The use of PFAS is state-of-the-art for high performance batteries today due to both performance and safety. There are no commercialized alternatives to PTFE and PVDF to make cathode binders function properly in terms of mechanical stability, electrochemical stability, oxidation resistance, and processability. PTFE offers mechanical cohesion for electrode integrity throughout the battery lifecycle, provides uniform electrode density for consistent performance, and contributes to a low moisture content, which is absolutely essential for battery integrity.[15] Among many other attributes, PVDF's high ignition temperature of 346° C makes it highly stable and ideal for consumer product applications. There are a number of other specific uses of these materials that are both complex and essential, such as avoiding hydrogen fluoride emissions, provide dependable insulation, resistance to weathering and deterioration, and ultraviolet ("UV") light resistance.[16]

PRBA supports a risk-based approach to regulation. Rechargeable and non-rechargeable batteries do not use PFAS types such as Perfluorooctanoic acid ("PFOA"), Perfluorooctanesulfonic acid ("PFOS") and Perfluorohexane sulphonic acid ("PFHxS"). In contrast, the potential toxicity of PTFE and PVDF polymers is classified as lower than any potential (and lower performing) alternative chemistry.[17] Importantly, PFAS components are enclosed within the rechargeable or non-rechargeable battery. The battery is most often enclosed in the product. Therefore, there is little to no likelihood of human exposure and there is no release to the environment during the useful life of the product. Maine has already recognized that it is appropriate to regulate the disposal of PFAS-containing products through the state's waste management laws, rather than through a law instituting a PFAS ban. Therefore, the likelihood of improper end-of-life disposal is minimized significantly by Maine's recycling programs for rechargeable batteries, such as the Call2Recycle program.[18] Batteries are typically

[14] Department of Defense, *Report on Critical Per- and Polyfluoroalkyl Substance Uses, Pursuant to Section 347 of the James M. Inhofe National Defense Authorization Act for Fiscal Year 2023 (Public Law 117-263)* (August 2023), p. 6.

[15] Recharge, *Application for derogations from PFAS REACH restriction for specific uses in batteries* (April 2023), p.11.

[16] *Id.* at p.13.

[17] Korean Battery Industry Association, KBIA Comments on the PFAS Restriction Proposal (August 25, 2023), p. 18.

[18] Maine Department of Environmental Protection, *Battery Recycling* (last visited Feb. 12, 2024).

recycled via pyrometallurgical/hydrometallurgical processes, in which the temperatures destroy all PFAS types, resulting in the disassociation of the fluorine moieties. Perfluoromethane, one of the most stable forms of PFAS, disassociates at 1380° C, well below the process temperatures at recycling facilities that are more in the range of 1400° C – 1600° C.[19]

4. Whether There Are Alternatives For This Specific Use Of PFAS Which Are Reasonably Available.

Pursuant to 38 M.R.S. §1614(1)(B), a "currently unavoidable use" means a use of PFAS that the department has determined by rule under this section to be essential for health, safety, or the functioning of society and for which alternatives are not reasonably available. We refer MDEP to the RECHARGE report for understanding the lack of feasible and safe alternatives in rechargeable batteries. At present, there are no reasonably available alternatives for each and every component. Table 2 on page 19 of the RECHARGE report summarizes the the status of alternatives under development; in most cases, no feasible alternative to exists.

The transition away from these materials will take many years. During the stakeholder engagement process in the EPA rulemaking mentioned earlier in these comments, battery separator companies indicated that a 25-year transition period would be necessary for just one, single solvent ingredient used as a processing aid. According to industry experts, at least 40 years is needed to commercialize a PFAS-free EV battery, and additional time may be necessary beyond that to confirm that the technology is dependable and achieves the same level of performance.[20] The number of components in rechargeable batteries makes for an even more complex transition period. Maine's ban is schedule to go into effect only six years from now, which is not enough time for our industry to find and implement alternatives at a commercial scale. There are numerous steps in the process of identifying alternatives. These include basic research and development, prototype testing, extended trial use to evaluate performance, safety testing, retooling, and customer vetting and approval. Every product in which the rechargeable battery is used must also undergo rigorous safety and performance testing. The downstream users of these batteries will require additional time to evaluate the quality, safety, and performance of their products, which often involves a period of additional years, at the research, pilot, and large commercial scale – for thousands of different applications.

Further, we request that MDEP clearly indicate that the exemption applies to the need to provide notification as well as the 2030 product ban. Based on the foregoing information, we respectfully recommend this exemption and offer the following language to capture the scope of the exemption coverage that is needed for rechargeable and non-rechargeable batteries:

---

[19] Korean Battery Industry Association, KBIA Comments on the PFAS Restriction Proposal (August 25, 2023), p. 11.

[20] *Id.* at 12.

Pursuant to 38 M.R.S. §1614(1)(B), the following product categories are exempt from notification and the prohibition on sale of products containing intentionally added PFAS:

* * *

Rechargeable and non-rechargeable batteries, whether contained in another product or not, and their ingredients and components, including but not limited to lithium ion, nickel cadmium, nickel metal hydride, metal air batteries, sodium ion, zinc ion, lithium metal, zinc air, and silver oxide batteries.

Moreover, due to the myriad and diverse products which these batteries power, there is no single time limit that would be suitable for an exemption for rechargeable and non-rechargeable batteries. MDEP can and should avoid the need to spend more resources to re-engage with industry and undertake additional rulemakings to extend specific product exemptions.

PRBA would welcome an opportunity to discuss these comments with you and answer any questions. We applaud MDEP for recognizing that in seeking to protect its citizens by regulating substances of global concern, exemptions are needed for products like rechargeable and non-rechargeable batteries that are essential for the health, safety, or functioning of society. PRBA respectfully requests that MDEP grant our request to provide a currently unavoidable use exemption in proposed and final regulations for rechargeable and non-rechargeable batteries. George Kerchner, PRBA Executive Director, can be reached at (202) 719-4109 or gkerchner@wiley.law

Respectfully submitted,

George Kerchner, Executive Director

Executive Summary

The PFAS (Per and polyfluoroalkyl substances) REACH restriction proposal will have a major impact on the battery industry. This document provides RECHARGE's feedback to the public consultation and the latest proposal of 22 March. For specific applications where PFAS are used in batteries, RECHARGE is **requesting derogations and additional transition times to provide sufficient time for the battery industry to identify and implement alternative non-PFAS solutions**.

Batteries are a main enabler for the transition towards low-emission mobility, decarbonised energy generation and digitalisation. Batteries power a wide range of general public applications such as smartphones, tablets, power tools, hearing aids, defibrillators, safety lighting in public buildings, and provide many services to industry such as back-up power for mission critical industrial assets (from nuclear power plants to data centres), energy storage systems for electrical grids, traction power to forklift trucks and AGV's, and deliver energy to a wide variety of machines such as drones, rockets, satellites and IoT objects. Batteries also provide power to an increasing number of mobility solutions such as e-bikes, e-scooters and electric vehicles. They generate significant economic growth and provide jobs for millions of people.

This document details what types of PFAS are used in batteries and why, whether there are non-PFAS alternatives available, what are the tonnages of PFAS consumed and emitted, the socio-economic impact assessment of the proposed PFAS restriction for the battery value chain and finally proposes best practices that the battery industry and legislators could implement to further minimise emissions. All statements provided in this document are supported by scientific evidence.

Contents

1 Introduction and scope

RECHARGE represents over 60 organisations spanning all aspects of the battery value chain. The scope of this document as feedback to the ECHA consultation includes the following types of high performance, advanced rechargeable and lithium batteries:

- Lithium-ion rechargeable batteries (also known as Li-ion batteries)
- Lithium (Li) primary batteries (also known as primary Lithium batteries)
- Nickel–based rechargeable batteries (Ni-Cd and Ni-MH)
- Metal air batteries
- Zinc oxide batteries
- Silver oxide batteries
- Sodium-ion (Na-ion) rechargeable batteries
- Zinc-ion (Zn-ion) rechargeable batteries
- Solid-state batteries
- Lithium metal rechargeable batteries
- Other battery technologies currently under research

The only type of rechargeable battery which does not use PFAS is lead-acid batteries. However, lead-acid batteries have a low energy density. Lead-acid batteries cannot be used as suitable alternatives for the technologies presented above and applications they serve. These technologies serve applications where a variety of performances are required, amongst which are high energy, high power, very long life, superior reliability, ability to withstand extreme temperatures. Lead-acid batteries have limited capacity in these respects and cannot be considered as suitable alternatives. In addition, lead compounds used for battery manufacturing and lead metal have been recommended by ECHA for inclusion on Annex XIV respectively in the 6th and 11th recommendations.

Batteries are a main enabler for the transition towards low-emission mobility, decarbonised energy generation and digitalisation. Batteries power a wide range of **general public** applications such as smartphones, tablets, power tools, hearing aids, defibrillators, safety lighting in public buildings, and provide many services to **industry** such as back-up power for mission critical industrial assets (from nuclear power plants to data centers), **energy storage systems** for electrical grids, traction power to forklift trucks and AGV's, and deliver energy to a wide variety of machines such as drones, rockets, satellites and IoT objects. Batteries also provide power to an increasing number of **mobility** solutions such as e-bikes, e-scooters and electric vehicles. They generate significant economic growth and provide jobs for millions of people. Batteries are essential to ensure the sustainable development of society and provide critical environmental and social benefits.

This document has been produced using information provided by our members, company reports, governmental publications, patent reviews and academic articles. All statements provided in this document are supported by scientific evidence.

This is a first submission. RECHARGE will update this document with additional information during the public consultation.

2 Why are PFAS used in batteries and where?

Batteries are comprised of two electrodes, a separator and an electrolyte, as schematized in Figure 1. Each electrode consists of an active material mass which is coated onto a current collector.

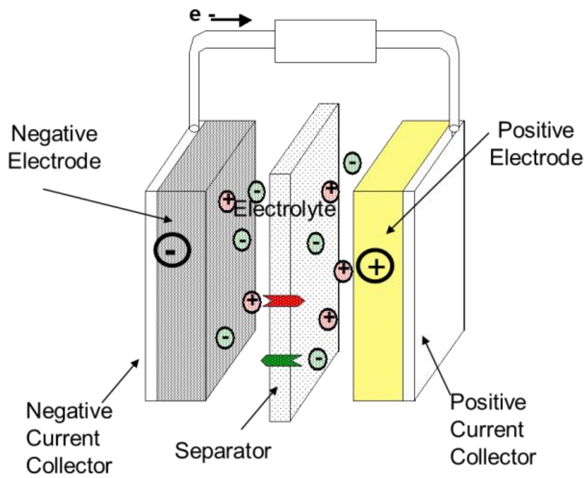

Figure 1. Components of a battery

PFAS have very unique properties:

- Water, oil and dirt repellent
- Durable under extreme conditions (high temperature, pressure, and aggressive chemicals)
- Electrical and thermal insulation.

As chemical resistance and tolerance to a high range of working temperatures are crucial for batteries, PFAS are used in key components for all high performance and lithium battery technologies. PFAS are used in key components in:

- Active material masses
- Electrolytes
- Valves, gaskets, washers & membranes
- Coatings

2.1 PFAS used in active material mass of electrodes

Each electrode is a composite which is manufactured by coating an active material mass onto a current collector (as shown in Figure 2). The active material mass comprises an active material, conductive additives (when needed) and a binder material.

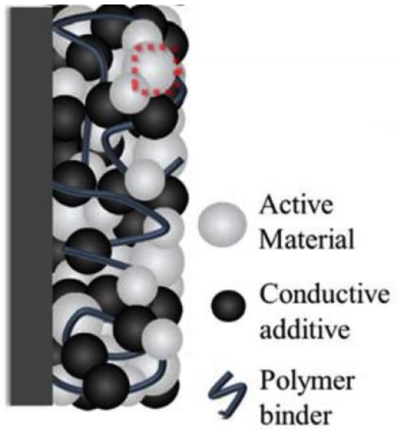

Figure 2: Composite electrode materials

Binder material is used to hold the active material particles together within the composite electrode and to provide a strong connection between the electrode and the current collector. The binder material plays an important role in the manufacturability of the battery and in the battery performance.

Due to their unique properties, both Polytetrafluroethylene (PTFE) and Polyvinylidine difluoride (PVDF – both homopolymer and copolymer) are used as binder materials in the active material masses in electrodes in a wide range of battery technologies, as detailed in Table 1.

Table 1. Binders used in active material masses for different battery technologies

Battery technology	Positive electrode	Negative electrode	Electrolyte
Li-ion (wet-process)	**PVDF** with NMC, NCA, LCO, LMO, LFP active masses	SBR/CMC with graphite anode, **PVDF** with LTO anode	Liquid organic electrolyte
Li-ion (dry process)	**PTFE** with NMC active mass	SBR/CMC with graphite anode	Liquid organic electrolyte
Na-ion	**PVDF** with PBA, Na-NFM and phosphate based active masses	**PVDF** with hard carbon anodes	Liquid organic electrolyte
Solid-state LMP	PEO with LFP active mass	No binder required for metallic lithium anode	Polymeric layer including PEO and **PVDF**
Ni-based rechargeable batteries	**PTFE** with Ni(OH)2 foam active mass	**PTFE** with Cd or MH electrode	Liquid alkaline electrolyte
Primary Li-SOCl2	**PTFE** with carbon anode	No binder required for metallic lithium	SOCl2 electrolyte
Primary Li-SO2	**PTFE** with carbon anode	No binder required for metallic lithium	SO2 electrolyte
Primary Li-MnO2	**PTFE** with Mn02 active mass	No binder required for metallic lithium	Liquid organic electrolyte
Primary Zn-Air	**PTFE** with MnO2 active mass	**PTFE**-membrane	Liquid alkaline electrolyte
Lithium metal rechargeable	**PVDF (and PTFE), with** with NMC, NCA, LCO, LMO, LFP	No binder required for metallic lithium	Liquid organic electrolyte, PE/PP or cellulose separator

2.1.1 PVDF used in active material mass of electrode

Although the PVDF binder comprises only a small portion of the composite electrode (typically 2–5% of the mass of the electrode[1]), the binder plays four important roles in battery performance. The PVDF binder:

- helps to disperse the active material and the conductive additive in the solvent during the fabrication process, enabling a homogeneous distribution of the slurry,
- holds the active material and the conductive additive together and connects them to the current collector, ensuring the mechanical integrity of the solid electrode without significantly impacting electronic or ionic conductivity (see Figure 2),
- acts as an interface between the composite electrode and the electrolyte. In this role, the PVDF binder protects the composite electrode from corrosion and the electrolyte from depletion while facilitating ion transport across this interface,
- tailors the viscosity of the slurry to allow a smooth coating onto the current collector during electrode manufacturing.

PVDF has several unique properties that enable it to fulfil these critical roles:

- **Mechanical properties**, including stiffness, toughness and hardness as well as good adhesion to the active material, the conductive additive, and the current collector. PVDF ensures the flexibility of electrode for cylindrical designs. The positive electrode binder must be able to withstand the forces that result from the expansion and contraction of active materials during charge/discharge cycles,
- **Thermal properties**, particularly thermal stability, are also important, both for the high temperatures commonly used for curing and drying during electrode fabrication and also for operation of the battery at various temperatures,

[1] Cholewinski, A., Si, P., Uceda, M., Pope, M., & Zhao, B. (2021). Polymer Binders: Characterization and Development toward Aqueous Electrode Fabrication for Sustainability. *Polymers*, *13*(4), 631–. https://doi.org/10.3390/polym13040631

- **Good dispersive capabilities** are important to help distribute the slurry evenly over the current collector during fabrication,
- **Chemical and electrochemical stability** are essential properties to enable the binder to function for long periods and over numerous cycles without degradation of the battery. The positive electrode binder must not react with any other components or intermediates formed during operation. In particular, the positive electrode binder must remain stable at the high and low voltage potentials experienced by the cathode. PVDF is the only proven material that can sustain a large voltage range from 0 to 5V at industrial scale for various battery designs (cylindrical, prismatic and pouch cell) and high-capacity cells. This stability guarantees its safe use in the electrochemical environment of the lithium cell.

All Lithium-ion battery manufacturing processes use PVDF as the binder material for all types of positive electrodes. Many other binder materials have been evaluated as replacements for PVDF, however all other materials have been found to oxidise at the high voltage at the positive electrode.

PVDF was previously also used as the binder material for all negative electrodes, however companies using graphite negative electrodes have successfully substituted PVDF with water-based CMC/SBR binder materials. For other types of negative electrodes using higher voltage materials such as lithium titanate oxide (LTO), NTO (Niobium Titanate Oxide)[2] the use of PVDF binder material is required because no research on alternative non-PFAS binders has proved sufficiently conclusive for transfer to industrialization to date.

For Sodium-ion rechargeable batteries, some research is ongoing regarding non-PFAS SBR/CMC binder materials for some hard carbon/PBA cells but this research work has not yet been scaled up. PVDF is preferred with some other PBA materials[3] and with hard carbon[4].

---

[2] Next-Generation SCiB^{TM} supporting smart mobility in the age of MaaS, Using Niobium Titanium Oxide (NTO) as a next-generation anode material. (n.d.). https://www.global.toshiba/ww/products-solutions/battery/scib/next/nto.html

[3] Wessels, C., D., Motallebi, S., (2020). Electrolyte Additives for Electrochemical Devices. Patent No.: US 10 862 168 B2. https://app.dimensions.ai/downloads/patents?ucid=US-10862168-B2

[4] Barker, J. & Heap, R., (2020). Metallate Electrodes. United States Patent. Patent No.: US 10 756 341 B2. https://patentimages.storage.googleapis.com/4e/07/f0/c9dd46a4691e63/US10756341.pdf

Next generation Lithium-ion battery developments are focussed on producing cathodes using a dry process which avoids the need for NMP solvent. This dry process will significantly reduce energy consumption and lower environmental footprint. However, the dry process requires the use of PTFE or PVDF as the cathode binder material[5,6].

2.1.2 PTFE used in active material masses of electrode

Industry outreach has confirmed that all leading manufacturers of primary batteries based on the technologies listed in Table 1 use PTFE, or another fluoropolymer, as the binder material for the positive electrode. PTFE is used as the binder material for the positive electrode in Lithium primary batteries to provide three main functions:

1. Mechanical cohesion between the positive electrode particles to enable electrode integrity during cell assembly and throughout the lifecycle of the battery storage and use,
2. Lubricant to allow the electrode particles to slide over each other during electrode formation (compression) giving uniform electrode density that is important to consistent battery performance and longevity,
3. Lower water absorption during mixing (PTFE is a hydrophobic material) and more complete drying during electrode baking - low moisture content is critical in Lithium chemistry.

PTFE provides a unique combination of properties that are essential for the performance and durability of Lithium primary batteries:

Li, Y., Wu, Y., Wang, Z., Xu, J., Ma, T., Chen, L., Li, H., & Wu, F. (2022). Progress in solvent-free dry-film technology for batteries and supercapacitors. *Materials Today (Kidlington, England)*, *55*, 92–109. https://doi.org/10.1016/j.mattod.2022.04.008;
Lu, Y., Zhao, C.-Z., Yuan, H., Hu, J.-K., Huang, J.-Q., & Zhang, Q. (2022). Dry electrode technology, the rising star in solid-state battery industrialization. Matter, 5(3), 876–898. https://doi.org/10.1016/j.matt.2022.01.011

- **High chemical stability** against the solvents used in Lithium primary batteries (such as thionyl chloride, sulphur dioxide and organic solvents),
- **High electrochemical stability**, which is necessary due to the high voltages (up to 3.9 V),
- **High temperature stability** to withstand the temperature necessary for drying the electrodes and provide stability in high temperature applications,
- **Good adhesion properties** to hold the active mass together in the electrode and provide adhesion to the current collector,
- **Good dispersion properties** to ensure the uniformity during the manufacturing of the electrodes,
- **Unique fibrillation properties**, very low concentrations are needed to hold the active mass in place without covering the active mass surface, this provides excellent porosity, which is needed for good penetration of the electrolyte,
- **Mechanical flexibility** to allow the winding of the electrode during cell assembly.

Polyvinyl alcohol (PVA, CAS 9002-89-5) or Poly(acrylic acid) (PAA, CAS 9003-01-4) may be added to the positive electrolyte binder material to create void volume after baking, this helps with electrolyte absorption.

PTFE is also used as the binder material for the positive and negative electrodes in industrial stationary Ni-Cd and Ni-MH rechargeable batteries.

2.2 PFAS used in electrolytes

PFAS is used in the electrolytes for Lithium-ion rechargeable, Lithium primary, Lithium metal rechargeable, and Sodium-ion rechargeable batteries.

In rechargeable batteries, LiPF6 (which is not a PFAS) has been widely used in older battery technologies for many years. However, recent advances in battery technology have established the use of PFAS substances as state-of-the-art for high performance batteries today, including as additives and as Lithium salt with PFAS anion. These include Lithium salts of PFAS monomers such as Li-Triflate

(CAS 33454-82-9), LiTFSI (CAS 90076-65-6), LiBETI (CAS 132843-44-8), LiFAP (LiPF3(CF2CF3)3n and LiTDI (CAS 761441-54-7). Examples of PFAS additives include Tris(2,2,2-trifluoroethyl)borate (TFEB CAS 659-18-7) and Trifluorotoluene (TFT CAS No. 98-08-8). PFAS substances are also used as gelifiers for Lithium-ion polymer batteries. Sodium bis(trifluoromethylsulfonyl)imide (NaTFSI CAS 91742-21-1) may be used for Na-ion batteries.

These advanced PFAS substances have properties which increase the electrolyte stability through chemical mechanisms such as capturing water and avoiding hydrogen fluoride emissions. The increased stability of the electrolyte provides significant increases in lifetime duration of the battery and battery operating temperature range. The PFAS substances are widely used in next generation Lithium-ion rechargeable batteries and particularly in the case of solid-state batteries.

For Lithium metal rechargeable batteries, polyfluorinated ether solvents, such as 1,1,2,2-Tetrafluoroethyl 2,2,3,3-tetrafluoropropyl ether, are essential to ensure adequate battery cycling lifetimes. This chemically inert solvent (in particular to Li metal) has unique properties that can reduce the viscosity of the cell and therefore the conductivity of the Lithium metal rechargeable batteries.

For Lithium primary batteries, the lithium manganese dioxide (Li-MnO2) electrochemical system is widely used in coin cells and cylindrical consumer cells such as CR2 and CR123A (one of the main electrochemical systems used for Lithium primary batteries), as well as in many cylindrical Lithium primary cell types for industrial applications. Li-MnO2 cells contain an electrolyte composed of organic solvents and a lithium salt. Lithium perchlorate (CAS 7601-90-3) has traditionally been used as the lithium salt, however lithium perchlorate has been found to act as an endocrine disruptor. Lithium perchlorate is the subject of ongoing regulatory management options analysis (RMOA) and is expected to become restricted. As a result, many manufacturers of primary Lithium batteries have already transitioned to using Li-Triflate (CAS 33454-82-9) and LiTFSI (CAS 90076-65-6) for cylindrical Li-MnO2 cells in general, and LiBETI (CAS 132843-44-8), LiFAP (LiPF3(CF2CF3)3n and LiTDI (CAS 761441-54-7) especially for high power Lithium primary cells (similar to the substitution observed in in rechargeable Lithium-ion cells). The use of the PFAS salts instead of lithium perchlorate also provides increased stability and performance as well as higher safety levels. Perchlorates in dry form are explosive materials which can explode in case of a thermal runaway of the battery or a fire.

2.3 PFAS used in valves, gaskets, washers, permeable membranes

PFAS is used in valves, gaskets, washers, and permeable membranes for Lithium-ion rechargeable, Lithium primary, solid-state batteries, Lithium metal rechargeable and Zinc air batteries.

Gasket sealings and washers, shown in Figure 3 for cylindrical cells and Figure 4 for prismatic cells[7], are critical components in batteries to prevent leakage of the electrolyte from the inside and penetration of moisture from the outside. Electrolyte leakages can cause short circuits and severe safety issues.

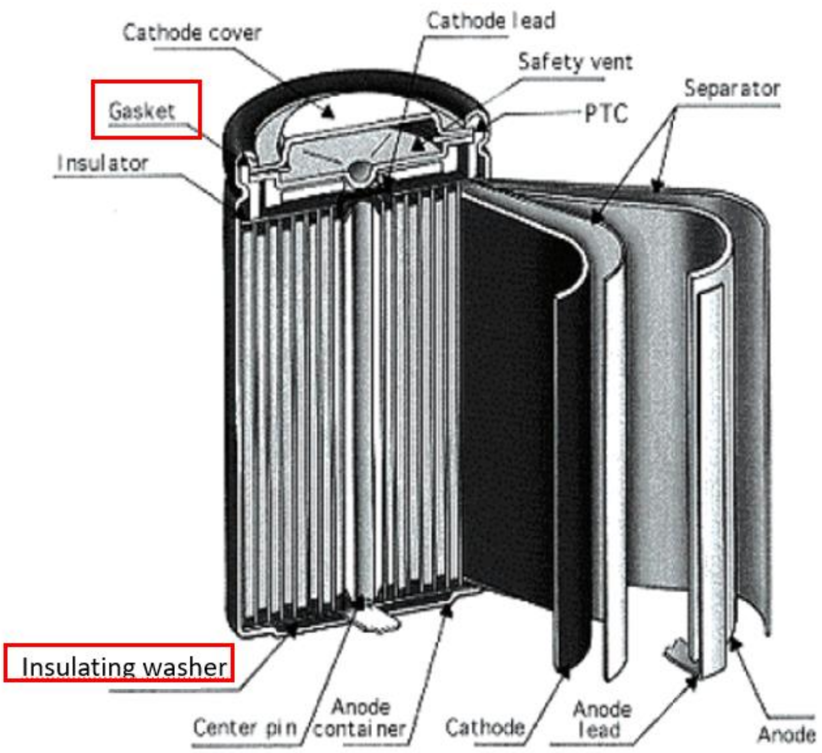

Figure 3. Gasket and washer in a cylindrical cell

[7] Arora, P., & Zhang, Z. (John). (2004). Battery Separators. *Chemical Reviews*, *104*(10), 4419–4462. https://doi.org/10.1021/cr020738u

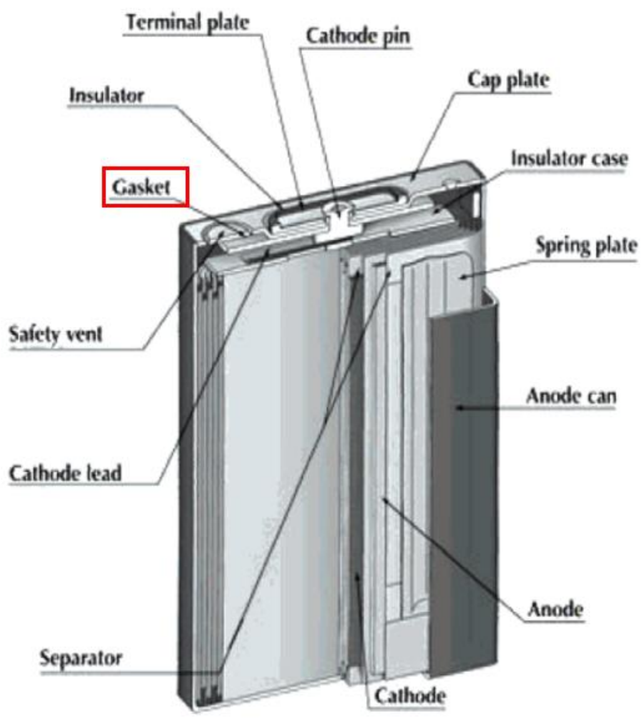

Figure 4. Gasket in a prismatic cell

For some applications used in mild temperature ranges, non-PFAS gasket sealing materials like PBT or PEI provide an adequate sealing performance. However, in high energy density Lithium-ion rechargeable and Lithium metal rechargeable batteries (e.g., high power batteries for automotive, industrial applications and power tools) it is crucial to employ very thin high-performance gaskets with high chemical and thermal stability, and high permeation resistance. This stability for high power and high temperature cells can only be provided by PFAS-based materials such as PTFE, PFA, FEP, VDF, HFP and FKM.

PTFE is not used for sealing gaskets in Li-MnO2 primary Lithium batteries. However, some industrial primary Lithium batteries use Li-SOCl2 and Li-SO2 electrolytes which are much more aggressive materials. SOCl2 is highly reactive and can violently release hydrochloric acid upon contact with water and alcohols. Sealing gaskets and washers for these much more aggressive materials require the use of PFAS-based materials such as FEP, PTFE, glass fiber with PTFE coating. These PFAS-based materials are critical to ensure the long lifetime of the battery, typically around 20 years. FEP is the preferred material for use in internal washers of high-power spiral primary Lithium Li-SOCl2 batteries because it provides excellent insulating properties and prevents internal shorts, thereby ensuring safe design and operation.

PTFE glass fiber washers are also used in Li-MnO2 and Li-SO2 industrial batteries to increase safety, especially in high temperature applications and safety-sensitive applications such as aviation. However, it may be possible to replace PTFE with another high-temperature non-PFAS polymer in these applications.

Zinc air batteries have the highest energy density of any practical battery system and operate by allowing oxygen to access the battery and react with the zinc. The oxygen is reacted on a catalytic surface inside the cell. Air permeable PTFE membranes are necessary to allow air to enter the battery whilst also preventing the release of the alkaline electrolyte from the battery. PTFE has unique hydrophobic properties and air permeability properties to achieve this critical function.

2.4 PFAS used in separator coatings

The separator is an indispensable part of batteries which separates the negative electrode from the positive electrode to prevent internal short circuits, whilst not participating in electrochemical reactions. At present, the most commonly used commercial separators are polyolefin separators, such as polypropylene (PP), polyethylene (PE) and multi-layer composite separators (PP-PE-PP)[8]. The layer materials are processed to make them porous by including tiny pores or voids at 35-45% porosity. The typical pore size is 200 nm - 1 μm which is large enough for the lithium ions to move smoothly through the separator.

Commercial tri-layer PP/PE/PP separators take advantage of the difference in the melting point of PP (165°C) and PE (135°C), using PE as the shutdown layer and PP to protect structural integrity. When the cell temperature rises near the melting point of the PE layer, the PE layer will melt at a temperature of 135°C and close the pores in the separator to stop the current flow while the PP layer, which has a

[8] Costa, C. M., Lee, Y. H., Kim, J. H., Lee, S. Y., & Lanceros-Méndez, S. (2019). Recent advances on separator membranes for Lithium-ion battery applications: From porous membranes to solid electrolytes. *Energy Storage Materials*, *22*, 346-375. https://doi.org/10.1016/j.ensm.2019.07.024

higher melting temperature than PE, remains solid. However, such protection is only effective below the melting point of PP.

To provide better thermal and mechanical stability, commercially available ceramic coated separators have been developed. Ceramic particles, such as alumina, silica, or zirconia can be mixed with polymeric binders and slurry-coated onto the polyolefin separators. In comparison to PP layers, ceramic coatings offer a better electrolyte wettability, which translates into better Li-ion transport through the separator and therefore a better performance of the battery. Although ceramic coatings have proven effective in improving the thermal stability of separators, the effectiveness of the protection is still limited by the thermal stability of the polymeric binder used.

Some companies use PVDF as the binder material for the ceramic coating to provide good adhesion to the electrolyte/composite electrode, as well as providing good adhesion of the ceramic coating to the separator. Other companies have developed non-PFAS binders which also provide good levels of adhesion to the separator and the electrolyte/composite electrode. Some organisations are researching the use of binder-free, thin-film ceramic-coated separators which may be able to provide improved safety for Lithium-ion batteries[9].

2.5 PFAS used in solid-state batteries

Several technical solutions are considered as fundamental to solid-state batteries, particularly for the development of solid-state electrolytes:

a. Polymer
b. Ceramic Sulfide
c. Ceramic Oxide

Polymer electrolyte is used in Lithium-metal-polymer (LMP) solid-state batteries and is already in production. Another solid electrolyte is based on ceramic sulfide. A third category of solid-state batteries are based on ceramic oxides. The last two are still under development at present.

[9] Gogia, A., Wang, Y., Rai, A. K., Bhattacharya, R., Subramanyam, G., & Kumar, J. (2021). Binder-Free, Thin-Film Ceramic-Coated Separators for Improved Safety of Lithium-ion Batteries. *ACS Omega*, *6*(6), 4204–4211. https://doi.org/10.1021/acsomega.0c05037

The architecture of LMP batteries is illustrated in Figure 3 and is based on using polymers as electrolytes and managing their chemical interfaces.

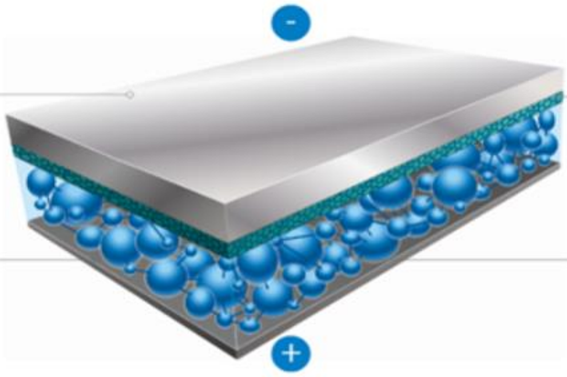

Figure 5. Schematic diagram of an LMP solid-state battery

The Lithium salt LiTFSI is used for the electrolyte and the cathode because it:

- has good conductivity allowing high power performance,
- is compatible with water (it does not hydrolyze and since there is water within the process, a salt that is stable in water is needed)
- is compatible with Lithium (also needed given the anode is Li-Metal)

PVDF is used as a binder in the electrolyte to provide mechanical strength and to act as an interface between the electrolyte and the electrodes.

These PFAS represent less than 5% of the cell's weight, but their role is crucial for the battery. PFAS are foreseen as even more important for the next generation of solid-state batteries. TFSI will be part of the cell recipe for its superior conductivity performances. PVDF is also expected to be a key component to ensure good adhesion between the cathode and the current collector.

3 Missing uses – analysis of alternatives

Table 2. Summary of derogation/transition period requests for various PFAS types, used in different types of batteries depending on current alternatives or alternatives in development

PFAS type	Where used in the battery	Type of battery	Alternatives available today?	Alternatives in development?	Derogation / transition period
PVDF	Binder in active material mass	Li-ion wet process (except for the graphite anode), Na-ion, Lithium metal rechargeable, solid-state	No	Preliminary research programmes funded by EU and Germany Govt	13.5 years
PTFE	Binder in active material mass	Li-ion dry process and semi-dry process, Lithium primary, Ni-Cd, Ni-MH, Zinc oxide, Metal air, Silver oxide, Zinc-ion rechargeable, Lithium metal rechargeable, solid-state	No	No	13.5 years
Various PFAS including LiTFSI, $LICF_3SO_3$ (triflate)	In electrolytes	Li-ion rechargeable, Lithium primary, Lithium metal rechargeable, Na-ion rechargeable batteries	Not for high performance/ next generation batteries	No - PFAS prevents 20% degradation of battery life.	13.5 years

PFAS type	Where used in the battery	Type of battery	Alternatives available today?	Alternatives in development?	Derogation / transition period
PTFE, FEP	Gaskets, washers	Chemically aggressive environments where PFAS is needed for electrochemical stability such as Lithium primary batteries using $Li\text{-}SO_2$ and $Li\text{-}SOCl_2$	No	No	13.5 years
PFA, VDF, HFP, FKM	Gaskets	High energy density batteries which require very thin high-performance gaskets such as Lithium-ion rechargeable batteries, Lithium metal rechargeable batteries	No other polymers have required mechanical properties and electrical insulation properties.	No	13.5 years
PTFE	Oxygen permeable membrane	PFAS hydrophobic properties are needed to facilitate air permeation and prevent alkaline electrolyte leakage in Zinc air batteries	No	No	13.5 years
PVDF, PTFE	Solid electrolyte/ gel polymer electrolyte	Solid-state batteries	No	No	13.5 years

PFAS type	Where used in the battery	Type of battery	Alternatives available today?	Alternatives in development?	Derogation / transition period
PTFE, PVDF	In coatings on the separator	Li-ion rechargeable, Lithium primary	Yes	Yes	Transition time of 6.5 years
PTFE, FEP, PFA, VDF, HFP, FKM	In valves, gaskets, washers	Li-ion rechargeable, Lithium primary, solid-state batteries where specific PFAS properties identified in section 3.1.4, 3.1.5 are not required	Yes	Yes	Transition time of 6.5 years

3.1 Uses where alternatives are not yet available

For the below uses where there are no alternatives available today, the chemicals industry will need to invest in research and development to build up the capacity and value chain for new innovative chemistries. The chemicals industry will need to make significant changes to existing research and development roadmaps which will be driven by industry demand for these new chemistries in Europe. In addition to research and development efforts, there is an immediate need for industrial investments to secure the manufacturing and the supply of chemicals to sustain the battery value chain in Europe. There is considerable uncertainty about the future of industry demand in Europe and therefore the timelines for these investments by the chemicals industry are not known. As a result, the battery industry requires derogation periods of at least 13.5 years for each of the below applications. If after the end of 13.5 years there are still no alternatives for specific applications, then the battery industry will need to apply to renew the derogation period for these specific applications.

3.1.1 Use of PVDF as the binder of the active material masses

PVDF is used as the binder material in the active masses for electrodes for Li-ion wet process (except for the graphite anode), Na-ion, Lithium metal rechargeable, and solid-state batteries. For the positive electrode, all attempts to replace PVDF binder materials with other polymers have caused cell performance and manufacturability issues. For the positive electrode, the degradation of alternative binder systems in the electrolyte has been demonstrated.

PVDF binder material is expensive (about 8-10 Euro/kg) and wet processes require the use of n-methyl-pyrrolidone (NMP) solvent (which is also expensive at about 2-6 Euro/kg) to dissolve the PVDF so that the slurry containing the binder material, active material and conductive additive can be dispersed evenly across the metal current collectors. NMP is classified in the EU as toxic to reproduction and its use is restricted under entry 71 of REACH Annex XVII. As a result, the use of NMP requires expensive solvent extraction and recovery systems. NMP also has a high boiling point of 210°C and so the curing and drying process has a high carbon footprint.

In view of the costs of PVDF and the health and safety concerns around the use of NMP solvent, many organisations have carried out research to try to find alternatives to PVDF as a binder material and NMP as the solvent. A peer reviewed academic article[10] indicates that PVDF as a latex can be used as the binder for the positive electrode with water as the solvent instead of NMP. Next generation Lithium-ion battery developments are focussed on producing positive electrodes using a dry process which avoids the need for NMP solvent. This dry process will significantly reduce energy consumption and lower the environmental footprint. However, the dry process still requires the use of PTFE or PVDF as the binder material for the positive electrode.

For Lithium-ion rechargeable batteries, PVDF was previously also used as the binder material for the negative electrode as well as for the positive electrode. For graphite negative electrodes, companies have successfully substituted PVDF with water-based CMC/SBR binder materials. CMC/SBR is now the most common commercially used binder material for the graphite negative electrodes due to its good

[10] Li, J., Lu, Y., Yang, T., Ge, D., Wood, D. L., & Li, Z. (2020). Water-Based Electrode Manufacturing and Direct Recycling of Lithium-ion Battery Electrodes—A Green and Sustainable Manufacturing System. *iScience*, *23*(5), 101081–101081. https://doi.org/10.1016/j.isci.2020.101081

cell performance, lower cost and reduced environmental impact[11]. For other types of negative electrodes using higher voltage materials such as Lithium titanate oxide (LTO), NTO (Niobium Titanate Oxide)[12] the use of PVDF binder material is required because no research on alternative non-PFAS binders has proved sufficiently conclusive for transfer to industrialization to date.

For Sodium-ion rechargeable batteries, some research is ongoing regarding non-PFAS SBR/CMC binder materials for some hard carbon/PBA cells but this research work has not yet been scaled up. PVDF is preferred with some other PBA materials[13] and with hard carbon[14].

The European Commission has recently funded the GIGAGREEN research project on dry alternatives and water-based binder systems for the positive electrode which propose to utilise a range of polymers including CMC/SBR, poly(acrylic acid), sodium alginate, polyurethanes and catechol-bearing polymers[15]. Whilst these initial research studies have indicated that these aqueous binder systems may have good adhesion properties, further research and development is required to investigate whether these alternatives have adequate chemical, mechanical, and electrical properties[16]. There are significant concerns about whether water-based CMC/SBR technology will have the necessary rheology and stability to match with today's positive electrode active materials such as LCO, NMC, NCA, LNMO, LFP. There are specific concerns about the use of water in the slurry production and the electrode coating, drying and calendaring processes, particularly if the water is not completely removed before the battery is assembled.

The Germany Government has funded the DigiBatt Pro 4.0[17] research project which also includes development of water-based binder systems for positive electrodes. As part of this research project, positive electrodes of around 100 metres in a lab scale with roughly 1/100 to 1/50 the scale of mass production have been produced using a nickel rich NCM cathode active material, $LiNi_{0.83}Co_{0.12}Mn_{0.05}O_2$. The cells could be successfully charged and discharged 1,000 times at 25°C before they fall below 80% of initial capacity. Whilst this research project appears to show promising results for very high nickel content batteries, correspondence with the project partners highlights that:

- Positive electrodes manufactured using water-based binder materials show increasing impedance/resistance with increasing numbers of charging and discharging cycles,
- The stability of the charging and discharging cycles is substantially lower than state-of-the-art positive electrodes using PVDF binder materials,
- The rapid increase in pH alkalinity of the water-based binder materials results in a very short shelf life for the mixed slurries, this would be very challenging for an industrial process as the mixture would go out of specification very quickly.

Further investigation of this research project confirms it focussed on a very specific high nickel NCM cathode active material at a moderate cell voltage of 4.2V. There is no evidence that this water-based binder material could be developed to meet the performance targets for positive electrodes with LCO chemistries operated at higher voltages, which is what many electronic devices use today.

It is also important to note that this research project focussed on a very specific cylindrical 21700 cell form factor used in certain automotive and power tool applications. Performance in this specific form factor is not directly transferrable to other cell form factors used in other applications. There are many unknowns which would need to be investigated before this technology could be adopted in other chemistries and other form factors, including:

- cycle life and calendar life and impedance growth under wide range of temperatures

[17] “*DigiBattPro 4.0 - BW*” - Digitized Battery Production 4.0 - Fraunhofer IPA. (n.d.). Fraunhofer Institute for Manufacturing Engineering and Automation IPA. https://www.ipa.fraunhofer.de/en/reference_projects/digibattpro.html

- swelling, fast charge cycling is unknown,
- electrode processibility for multilayer pouch cells and uniformity of coating is unknown,
- correspondence with the project partners highlighted that the positive electrodes manufactured using water-based binder materials show higher cell resistance and faster growth in resistance with increasing numbers of charging and discharging cycles with the high nickel NCM cathode active material. This trend is anticipated to become worse when industry moves to cathode active material operating at higher voltage, higher energy and higher power.

Furthermore, replacing the PVDF cathode binder likely requires the development of new cathode active material and Aluminium current collectors that are compatible with a new binder and solvent system. Water is known to cause poor cycle life and increased impedance growth in Lithium-ion cells. A new grade of active cathode powder may need to be developed to increase particle surface protection against water.

Replacing the PVDF cathode binder with new binder and solvent also requires development of a compatible electrode and cell manufacturing process and equipment. The necessary process and equipment change at mass production scale is unknown at this point and will be different for different companies depending on which alternative technology they pursue. The performance of mass production line produced PVDF free battery may have significant performance gaps compared with current batteries. Addressing these performance gaps may require a significant number of iterations of materials improvement, production process change and cell performance testing.

Given the above, we estimate that efforts to develop and commercialise high performance non-PFAS cathode binder, Al foil, active materials and corresponding cell manufacturing processes would take at least 10 years, followed by 5 years to commercialise the new technologies.

3.1.2 Use of PTFE as the binder of the active material masses

PTFE is used as the binder material in the active masses for electrodes for Li-ion dry process and semi-dry process, Li primary, Ni-Cd, Ni-MH, Zinc oxide, metal air, Silver oxide, Zinc-ion rechargeable, Lithium metal rechargeable and solid-state batteries.

There are currently no alternatives to PTFE due its unique combination of properties that are essential for the performance and durability of these batteries, especially for the:

- **fibrillation properties**, which produce an excellent mechanical electrode surface without covering the surface of the active material,
- **chemical properties**, including chemical stability in very aggressive environments,
- **hydrophobic properties**.

Alternative non-PFAS materials such as Polyvinyl alcohol (PVA, CAS 9002-89-5) and Poly(acrylic acid) (PAA, CAS 9003-01-4) have been tested as potential binder materials for the positive electrode and have been found to fail due to performance and manufacturability issues. The degradation of these alternative binder systems in the electrolyte has been demonstrated.

No research has been concluded on whether some of non-PFAS alternatives that are being investigated as potential replacements for PVDF as binders in Lithium-ion rechargeable batteries (see 3.1.1) may also be applicable to Lithium primary batteries. As a consequence, the timescale needed to investigate, develop and qualify alternatives for PTFE binder of the active material mass for Lithium primary batteries would be even longer than in the case of Lithium-ion rechargeable batteries.

3.1.3 Use of PFAS in electrolytes

Various PFAS substances are used in the electrolytes for Lithium-ion rechargeable, Lithium primary, Lithium metal rechargeable, and Sodium-ion rechargeable batteries. LiPF6 (which is not a PFAS) has been widely used in older battery technologies for many years. However, LiPF6 has been found to cause degradation in Li-ion cells, primarily from its thermal decomposition or hydrolysis to form acidic species. Recent advances in battery technology have established the use of PFAS substances as state-of-the-art for high performance batteries today, including as additives and as Lithium salt with PFAS anion.

PFAS electrolytes are used in advanced batteries to provide higher stability, increased performance and higher safety levels. This stability is provided by the high strength of the carbon-fluorine bond in the PFAS which is not present in the older electrolytes. As a result, the PFAS electrolytes provide 20% more battery life compared to LiPF6 electrolytes. This increased battery life provides sustainability benefits by extending the lifetime of the product.

In rechargeable batteries, Lithium salts of PFAS monomers such as Li-Triflate (CAS 33454-82-9), LiTFSI (CAS 90076-65-6), LiBETI (CAS 132843-44-8) and LiFAP (LiPF3(CF2CF3)3n are used to provide stability, performance and higher safety levels. There are no non-PFAS alternatives available today which provide similar stability, performance and safety levels. We estimate that research and development efforts to identify non-PFAS alternatives would take at least 10 years, followed by 5 years to commercialise the new electrolyte chemistry.

For Lithium primary batteries, Lithium salts based on monomolecular PFAS have been developed to replace the endocrine disruptor Lithium perchlorate and to improve the performance and durability of Lithium primary batteries (especially Lithium manganese dioxide batteries). Non-PFAS alternatives for Lithium perchlorate are currently not known and would have to be newly developed.

For Lithium metal rechargeable batteries, polyfluorinated ether solvents, such as 1,1,2,2-Tetrafluoroethyl 2,2,3,3-tetrafluoropropyl ether, are essential to ensure adequate battery cycling rates and lifetimes. This chemically inert solvent (in particular, inert to Li metal) has unique properties that can reduce the viscosity of the cell and therefore the conductivity of the Lithium metal rechargeable batteries. Non-fluorinated solvents can be used in combination with fluorinated ones, but not as a complete replacement primarily due to their lower chemical stability in conjunction with a metal Lithium electrode. There are no non-PFAS alternatives available today.

We estimate that research and development efforts to identify non-PFAS alternatives for electrolytes would take at least 10 years, followed by 5 years to commercialise the new electrolyte chemistries.

3.1.4 Use of PTFE & FEP in gaskets & washers in chemically aggressive environments

There are no alternatives to use of PTFE and FEP in gaskets and washers used in chemically aggressive environments such as the SO2 and SOCl2 substances used in electrolytes in primary Lithium batteries. SO2 and SOCl2 are very powerful oxidising agents which degrade almost all polymer types except PFAS materials. Degradation of the gasket and washer would result loss of battery component properties and release of the electrolyte. These primary industrial batteries using these electrolytes are required to operate for 20 years, significant research and development efforts will be needed to identify suitable alternatives which can provide the needed safety and long-term performance.

Polyimidazoles and fully chlorinated PVC may be some potential non-PFAS alternatives which may provide sufficient chemical stability against thionyl chloride in some applications. Thick bound fiberglass materials may also provide possible solutions. However, for chemically aggressive environments, more research on alternative materials is needed before the testing and final qualification can start, so that a derogation of 13.5 years is considered to be necessary.

3.1.5 Use of PFA, VDF, HFP, FKM in gaskets in high performance batteries which require very thin high performance gaskets

There are no alternatives to use of PFA, VDF, HFP, FKM in gaskets in high performance Lithium-ion rechargeable and Lithium metal rechargeable batteries (e.g., high power batteries for automotive, industrial applications and power tools) which require very thin high performance gaskets.

High power and high energy density batteries require very thin high performance gaskets[18]. Gaskets provide insulation between the positive and negative sides of the housings, a proper thermal functionality of the gasket is essential. This application needs a stable and compressive polymer which provides high levels of insulation to withstand the very high currents up to 280 amps which are found in these high performance batteries. Figure 6 compares the compressive properties of PFAS compared to other resins[19].

[18] Lui, J., Aoyama, T., Tsuda, H. & Sukegawa, M., (2019). Long-term reliability evaluation of fluororesin gasket for electrode of automotive lithium-ion battery using simulation. *VIII International Conference on Computational Methods for Coupled Problems in Science and Engineering*. https://upcommons.upc.edu/bitstream/handle/2117/190005/Coupled_2019-24-Long-term%20reliability%20evaluation.pdf

[19] Battery materials, Fluorochemicals, Daikin Global. (n.d.). https://www.daikinchemicals.com/solutions/products/battery-materials.html#anchor04

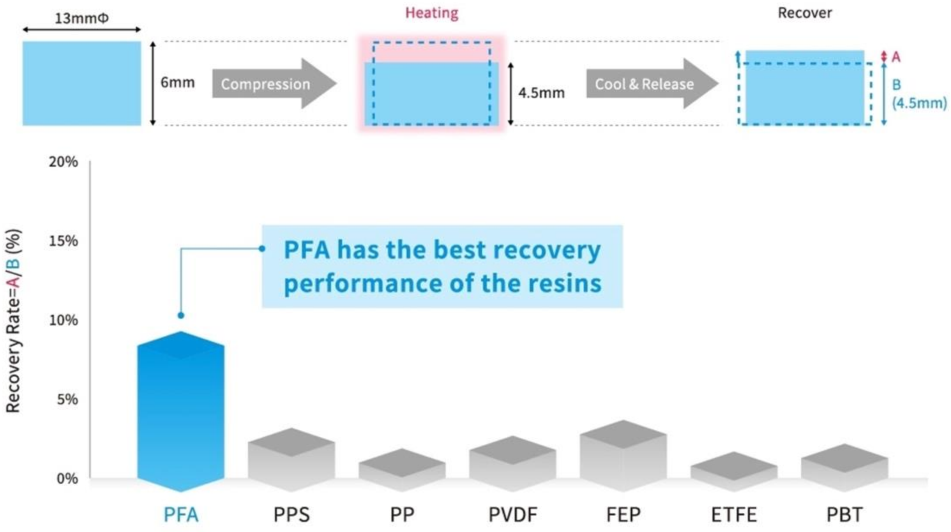

Figure 6. Compressive properties of polymer resins

PFAS provide a unique combination of electrical insulation and hydrophobic properties. Figure 7 compares the moisture permeation properties of PFAS compared to other resins[20]. As a result, the efficiency of the gasket performance is improved because of the reduced humidity absorption even when used at very low thickness.

[20] Ibid

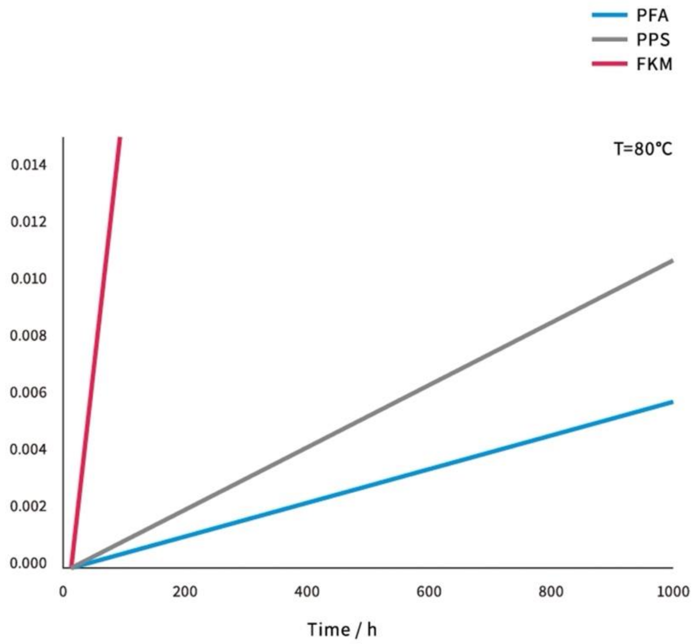

Figure 7. Moisture permeation of polymers

It will take significant time and effort for industry to investigate whether there are alternative polymers that can be used instead of PFAS in these gaskets. We estimate that research and development efforts to identify non-PFAS alternatives would take at least 10 years, followed by 5 years to commercialise the alternatives.

3.1.6 Use of PTFE in oxygen permeable membranes in Zinc air batteries

There are no known alternatives for use of PTFE in oxygen permeable membranes in Zinc air batteries or other types of alkaline metal-air batteries.

Zinc air batteries operate by allowing oxygen to access the battery and react with the zinc. The oxygen is reacted on a catalytic surface inside the cell. Air permeable PTFE membranes are necessary to allow air to enter the battery whilst also preventing the release of the alkaline electrolyte from the battery.

PTFE has unique hydrophobic properties and air permeability properties which allow gas molecules to pass through the membrane whilst at the same time preventing the release of the alkaline electrolyte. Extensive research would be needed to find alternatives. We estimate that research and development efforts to identify non-PFAS alternatives would take at least 10 years, followed by 5 years to commercialise the alternatives.

3.1.7 Use of PTFE / PVDF in solid electrolyte/ gel polymer in solid-state batteries

There are no available alternatives to the use of PVDF / PTFE as a binder in the solid electrolyte/ gel polymer in solid-state batteries. The PVDF / PTFE has unique properties that provide mechanical strength and act as an interface between the electrolyte and the electrodes in solid.

PVDF and co-polymers of PVDF are uniquely placed to enable solid electrolyte/gel polymers in batteries due to the presence of strong electron-withdrawing functional group (–C–F)[21]. These properties include high polarity, excellent thermal and mechanical strength, compatibility with organic solvents and chemical stability[22].

Extensive research would be needed to find alternatives. Research and development efforts to identify non-PFAS alternatives would take at least 10 years, followed by 5 years to commercialise the alternatives.

3.2 Uses where substitution is technically feasible but more time is required

As highlighted below, where substitution is technically feasible, the steps involved in substituting new materials into several subcomponents in a company's battery manufacturing process are considerably more complicated than in other industry sectors and therefore the battery industry requires a longer transition period of 6.5 years. Each new subcomponent needs to be developed and tested separately, and then the combination of the new subcomponents needs to be tested in the new battery and the product applications. Each company's battery manufacturing equipment and process lines also have unique aspects which are specific to that company's products and applications. Some companies may

[21] Manuel Stephan, A. (2006). Review on gel polymer electrolytes for lithium batteries. *European Polymer Journal*, *42*(1), 21–42. https://doi.org/10.1016/j.eurpolymj.2005.09.017

[22] Barbosa, J. C., Dias, J. P., Lanceros-Méndez, S., & Costa, C. M. (2018). Recent Advances in Poly(vinylidene fluoride) and Its Copolymers for Lithium-Ion Battery Separators. *Membranes (Basel)*, *8*(3), 45–. https://doi.org/10.3390/membranes8030045

need to make significant changes to their manufacturing equipment and process lines to accommodate the new subcomponents.

The below consecutive steps 1 to 4 are representative of the battery industry and present an optimistic scenario where no complications arise such as additional certification requirements or unforeseen customer validation requirements. For example, a significant amount of R&D resource will be needed to carry out the development of new subcomponents and the battery industry may face a shortage of qualified technical staff to carry out this work. In addition, a large amount of battery models and finished products containing batteries which are on the market today will need to be recertified and there may not be sufficient third-party certification companies available in the market today to provide these needed recertification services.

The battery industry will make every effort to work within a 6.5 years transition time. However, there may be some types of subcomponents where industry experience finds that it is not possible to achieve substitution within the 6.5 years and so the battery industry may need to apply for an extension to this transition period.

<u>Step 1: Substitute material identification for one subcomponent: up to 12 months</u>

Each company's battery manufacturing process is customised to meet the needs of that company's products. In many cases there are a range of chemistries that could be considered as alternatives for a specific subcomponent. The first step is assessment and laboratory verification to identify which target substitute material is likely to provide the best combination of properties for the specific subcomponent in the company's products. The identification of a target substitute material for one subcomponent alone can take up to 12 months. For example, in the case of the binder for the ceramic coating on the separator, companies which are currently using PVDF will need to evaluate several different alternatives to identify the best material for their application. There are several alternatives in use today which will need to be considered.

<u>Step 2: Separate development of each new subcomponent: 14 - 21 months</u>

This is the process of using the target substitute material to develop the new subcomponent and then to test it in a cell with an existing, already proven chemistry. This step is necessary to isolate the new subcomponent as the only variable that has changed in the cell. Once the cells are built, the testing of the cell cycling process can begin. It takes about 7 months to carry out 1000 test cycles of the cell build containing the new subcomponent, to check that it can meet swelling, impedance, capacity retention and other technical requirements after 1000 cycles. Some companies also need to carry out environmental testing of the subcomponent such as long-term storage at elevated temperatures. A cell build can fail the cycles tests, therefore most companies assume at least one additional iteration of the cell build will be required to refine the specific chemistry of the target substitute material. Therefore, this stage can take several multiples of 7 months, at least 14 to 21 months.

Step 3: Combination of all new subcomponents and chemistry development: 18 - 36 months

This is the process of integrating and developing all the new subcomponents into a next generation cell chemistry package. Each new subcomponent would need to be qualified as part of this larger chemistry package.

The integration and development process requires several cell builds to find a combination of components and process conditions that meets all electrochemical and safety requirements. Depending on the testing capacities at the company, some companies may need to carry out between 3 and 6 cell builds, as some cell builds may fail testing. It takes about five months to develop each cell build and carry out tests of the initial 250 cycles so that sufficient data can be collected to accurately inform the development of the next cell build. The final cell chemistry needs to be tested at 1000 cycles which takes 7 months. Therefore, it may take around 18 - 36 months to arrive at a validated battery chemistry which is ready to be integrated into a new product.

Step 4: Integration into existing product design and new product designs, and into manufacturing processes: 24 - 48 months

The next step is to integrate the new validated battery chemistry into existing product designs and new product designs, and to carry out testing on finished assembled products to ensure they meet all electrochemical, process, safety and reliability requirements and certifications. This requires requalification of the new battery in all existing products which are already in production in Europe. Companies will need to make changes to their manufacturing equipment and process lines to qualify the manufacturing of the new subcomponents, the integration of the new subcomponents into the cell and the integration of the new battery into existing and new products. These changes to manufacturing equipment and process lines may be significant and require extensive time and capital investment.

Product requalification is a very time-consuming exercise which will require extensive resources over many years. The completion of this task will require sufficient test house capacity and transition time to requalify all battery-powered products which are used in Europe for safety, performance and lifetime. Additionally, the process of re-certifying batteries for existing product designs may trigger other regulatory updates unrelated to the new subcomponents that could otherwise have been avoided. For a company with a wide range of existing product designs, this can take around 24 - 48 months.

4 PFAS consumption in tonnes and emissions during battery life cycle

4.1 PFAS consumption in tonnes

Further information will be provided in subsequent submissions.

4.2 Emissions during the battery life cycle

NOTE: This text repeats the information already provided by RECHARGE in the second call for evidence submitted in October 2021. Updated information will be included in subsequent submissions.

4.2.1 Emissions during battery manufacturing

For technologies using PVDF as binder

PVDF is mixed with its organic solvent NMP and other electrode components. A PDVF latex can also be used. This wet mix is then coated on a metallic foil. This electrode is further heated below the degradation temperature of PVDF. The dried electrode is then further used for cell manufacturing. Empty bags of PVDF, PVDF containing residues from the processes as well as scrap cathodes are collected as chemical wastes and disposed of according to applicable European regulations.

For technologies using PTFE as binder

PTFE dispersion is mixed with electrode components and carbon black. This wet mix is then processed and heated below the degradation temperature of the PTFE. The dried mix is then further used for cell manufacturing.

Empty drums of PTFE dispersion, PTFE containing residues from the processes as well as scrap cathodes are collected as chemical wastes and disposed of according to applicable European regulations.

Potential residues of PFAS from binders or electrolyte (either empty packaging or cleaning solutions) are always collected as chemical wastes and disposed of according to applicable European regulations**.** **No unintended and uncontrolled PFAS emissions are foreseen during battery manufacturing.**

4.2.2 Emissions during battery use

During battery manufacturing, active substances, binders (like PTFE and PVDF) and additives are embedded in a mechanical substrate to form electrodes. These electrodes are then further assembled with the other battery components such as separator, electrolyte, connectors, gaskets, washers and casing to obtain a finished battery. This battery is defined in the REACH regulation as "an article with no intended release" meaning that, **under normal and reasonably foreseeable conditions of use, no end-user of this battery will be exposed to any chemical substances. No PFAS emissions are foreseen during battery use.**

4.2.3 Emissions during battery recycling

Battery recycling is mandatory in Europe since 2006 according to the Battery Directive and will remain mandatory with higher recycling targets in the upcoming Battery Regulation. Fluoropolymers are totally decomposed (as compounds), during the pyrometallurgical recycling processes. The fluorine reports to the flue dust. Flue dust is further processed in a hydro-metallurgical process to extract specific remaining metal content. Also, the PFAS containing waste streams and product streams from the hydrometallurgical recycling process may be treated in high temperatures where fluoropolymers are totally decomposed (as compounds). **No unintended and uncontrolled PFAS emissions are foreseen during battery recycling.**

5 Socio economic impact assessment for battery value chain

Further information will be provided in subsequent submissions.

6 Why RECHARGE seeks derogations and additional transition times, and industry best practices

Further information will be provided in subsequent submissions.

Glossary

FEP	Fluorinated ethylene propylene
HFP	Hexafluoropropylene
LiCF3SO3	Lithium trifluoromethanesulfonate
Li-ion	Lithium ion battery
LiSO2	Lithium sulfur dioxide battery
LiSOCl2	Lithium-thionyl chloride
LiTFSI	also known as TFSIL,i Lithium bis(trifluoromethanesulfonyl)imide
LMP	Lithium-metal-polymer
LTO	Lithium titanate oxide
Na-ion	Sodium ion rechargeable battery
NFM	Layered oxide of Ni, Fe, Mn (for Na-ion)
Ni-Cd	Nickel Cadmium battery
Ni-MH	Nickel metal hydride battery
NTO	Niobium Titanate Oxide
PBA	Prussian Blue Analogues
PFAS	Per and polyfluoroalkyl substances
PTFE	Polytetrafluoroethylene
PVDF	Polyvinylidine difluoride (both homopolymer and copolymer)
VDF	Vinylidene fluoride
Zn-ion	Zinc-ion rechargeable batteries

KBIA comments on the PFAS Restriction Proposal

August 2023

First Submission

KBIA – Korea Battery Industry Association

Korea Battery Industry Association

About KBIA :

KBIA has 180 member businesses including world-leading battery manufacturers such as LG Energy Solution, Samsung SDI, and SK on, as well as companies in relevant materials, components, and recycling such as POSCO Future M and W-Scope. The association is committed to assisting Korea businesses in their responses to battery-related legislation with the aim to help them better run their business in the global markets.

The Korea Battery Industry Association and its member companies are very much in agreement with Europe's Green Deal policy and are working to achieve carbon neutrality. KBIA member companies are large-scale battery investors in Europe and contribute a lot to the promotion of the European battery industry, including the construction of manufacturing facilities in the EU. Korean battery manufacturer’s local production facilities is now significantly contributing to job creation in the Europe and be an essential part of the EU battery industry, playing pivotal roles in the global battery supply chain.

Due to the current PFAS regulations, the supply chain of LGES, Samsung SDI, and SKon has been disrupted, and we communicate the opinions collected from these companies as follows. We look forward to our views being positively considered to reflect Korea's opinion well.

KBIA – Korea Battery Industry Association

with LG Energy Solution, Samsung SDI, SK on

TABLE

A. Summary

KBIA member companies especially 'LG Energy Solution ("LGES"), Samsung SDI, and SK on' are the largest player in the European battery market. As such, we feels the urgency and responsibility to provide this comment addressing our grave concern that the proposed PFAS restriction will have adverse effects on the EU battery industry.

The Korean battery industry, led by LGES, Samsung SDI, and SK on has been the pioneer of the battery manufacturing sector since the beginning. It took 30 years to fully commercialize batteries for Electric Vehicles ("EV") and other important environment-friendly applications, such as Energy Storage Systems ("ESS"). From our over 30 years of experience, we know that **the currently suggested 13.5/6.5-year derogation period to replace PFAS materials in the battery industry is unrealistic and not achievable.**

Since replacing PFAS in batteries is practically impossible and any replacement will likely be an inferior solution, **the battery industry in its entirety should be excluded from the PFAS restriction** for the following compelling reasons:

① The scope of the restriction is overly extensive, resulting in the inclusion of PFAS substances that have **not been proven to be harmful** on the prohibited use list;

② Rechargeable batteries **release minimal amounts of PFAS** into the environment and provide little to no exposure to the human body throughout their life cycle;

③ It is not feasible to develop viable alternative PFAS-free materials and respective technologies for the battery industry within the currently suggested derogation period. The data that we have collected in our 30 years of extensive experience with the commercialization of EV, ESS and other industrial batteries compels the conclusion that **it will take at least 40 years to achieve a stable commercialization of PFAS-free EV batteries;**

④ Even those 40 years may however not be sufficient to verify cell performance and reliability. **An insufficient verification of cell performance and reliability for EV due to time constraints would risk user's safety**;

⑤ The proposed restriction creates **extreme market uncertainties, leading to a halt in EU investments across the entire supply chain and hindering the achievement of the EU's Carbon Neutrality target.**

⑥ Including batteries in the PFAS restriction strongly contradicts the EU's general policy on batteries, especially the new EU Battery Regulation which emphasize **the core importance of batteries for the EU's sustainability/climate/green mobility goals**.

Given these facts, the only reasonable option is to **exclude EV, ESS and other industrial batteries from the PFAS restrictions or have an unlimited derogation period.** A derogation period, even one of 40 years, would endanger urgently needed industry investments and render

a systematic manufacture planning impossible. **The exclusion of the 'Battery Industry' from the PFAS Restrictions is crucial to preserving the supply chain of lithium-ion batteries in the EU, supporting the realization of the EU's circular economy and a more sustainable eco-friendly environment**.

I. Introduction

The Korean battery industry and LGES, Samsung SDI, and SK on have been the pioneer of the battery manufacturing sector since the beginning.

We embarked on our first battery development research in 1992 and has been dedicated to creating unparalleled material technologies and next-generation batteries ever since. With outstanding technological capabilities in the fields of Advanced Automotive, Mobility & IT, and ESS batteries, we are actively pursuing new product developments and securing a world-class battery production capacity while expanding the next-generation energy market.

We have been bringing forward major investment in building manufacturing facilities in the EU. LGES, Samsung SDI, and SK on's local production facilities in Poland, Hungary will significantly contribute to job creation in the EU and function as an essential part of the EU battery industry, the latter playing a pivotal role in the global battery supply chain.

We have been recognized as the most environmentally cautious companies globally. For many decades, environmental concern and sustainable growth have been a high priority for us. Our aims to lead ESG management with the understanding that the consistent growth of the battery industry is the basis of the increasing use of green energy, contributing to a sustainable future for humanity. In particular, our aims to achieve carbon neutrality of its value chain by 2050. Ultimately, we strive to go beyond carbon neutrality with the goal of being carbon negative.

From our over 30 years of experience, we know that **the currently suggested 13.5/6.5-year derogation period to replace PFAS materials in the battery industry is unrealistic and not achievable.**

The new EU Battery Regulation creates a well-structured framework that addresses and eliminates potential health and environmental risks of end-of-life batteries. The new EU Battery Regulation is a cornerstone of the European Green Deal and aims to improve the circular economy, resource use and efficiency, and the life cycle of batteries in terms of climate neutrality and environmental protection.

II. Reasons why the complete exclusion from the PFAS ban is required

1. Environmental Perspective

1) Overly extensive scope of the restriction: inclusion of PFAS not proven to be harmful

The scope of proposed restriction is excessively broad, encompassing PFAS substances that have not been proven to be harmful, leading to their placement on the prohibited use list. As per Annex XVII to REACH, restrictions are intended to ban the use of substances that have been confirmed to be harmful through the rigorous REACH process of registration and evaluation. PFAS types such as PFOA (Perfluorooctanoic acid), PFOS (Perfluorooctanesulfonic acid), and PFHxS (perfluorohexane 1 Sulphonic Acid), which have been confirmed to be harmful, are appropriately restricted under Annex XVII.

However, it is extremely vital to ensure that **only additional PFAS substances that have been conclusively demonstrated to be harmful are selectively made subject to restrictions**. A targeted and evidence-based approach is required to strike the right balance between environmental protection and allowing for legitimate and safe uses of PFAS substances in various applications.

2) Rechargeable batteries release minimal amounts of PFAS into the environment and provide little to no exposure to the human body throughout their life cycle. [1]

It is essential to emphasize that rechargeable batteries release minimal amounts of PFAS into the environment and provide little to no exposure to the human body throughout their life cycle. PFAS substances are contained solely inside the battery and do not escape into the environment. **At each stage of the battery life cycle – production, usage, collection, and disposal – there in no significant or non-controlled risk of exposure to humans or the environment.**

The only moments of potential exposure during battery collection are effectively regulated and resolved through the **EU Battery Regulation**. The EU Battery Regulation mandates the collection/recovery and recycling of used batteries with increased target rates over time, particularly for EV, by 2030**.** By enforcing this Regulation, any – potential – exposure to PFAS during the collection/recycling and disposal stages is tightly controlled. Consequently, for the battery industry, the current proposed PFAS restriction appears excessive as it restricts the use of crucial materials despite the ability to manage potential negative effects effectively through other regulation.

---

[1] See RECHARGE's dossier submission to ECHA for detailed description.

2-1) Rechargeable batteries release minimal amounts of PFAS into the environment

Slide 24 from the 5 April 2023 ECHA webinar[2] on the PFAS restriction highlights that the energy sector represents between 0 and 1% of the total emissions of PFAS. Nevertheless, we present a detailed analysis of these emissions over the battery life cycle. Studies performed by Desotec demonstrate that all sources of emissions (not just PFAS) during the entire battery life cycle are tracked and controlled.[3]

2-2) In each stage of the battery's life cycle there is no significant risk of exposure to humans or the environment

(1) Battery Manufacturing Stage

There are no unintended or uncontrolled emissions of PFAS during the battery manufacturing process. During the battery manufacturing stage, PFAS handling facilities (input/mixer) are equipped with local exhaust systems, effectively preventing any scattering into the environment or the atmosphere. The use of sealed pipes during material transfer further minimizes exposure to the human body and the environment. Additionally, it is mandatory for workers handling PFAS substances to wear protective equipment, such as protective clothing, goggles, hats, and dust masks, ensuring their safety in the event of minimal emissions.

All battery manufacturing operations are conducted in facilities abiding by applicable permission requirements of the respective (EU Member) State, where any release of emissions is controlled and must be below regulation threshold limits. These include the limits of the Industrial Emissions Directive[4] ("IED"), aiming to prevent and limit levels of pollution. Under the EU Green Deal ("EGD"), the IED is in the process of being amended with a revision proposal released last year[5]. The proposed IED revision not only addresses PFAS limits but also clarifies requirements for reviewing and updating permits to comply with environmental quality standards, measures under the water legislation permits as well as reducing emissions of pollutants and greenhouse gas emissions. The proposed IED also specifically addresses the importance of the sustainable growth of batteries outlining all EU legislations in alignment to

[5] Proposal for a Directive of the European Parliament and of the Council amending Directive 2010/75/EU and Council Directive 1999/31/EC of 26 April 1999 on the landfill of waste (COM(2022) 156 final).

make this happen. In addition, the Chemicals Strategy for Sustainability Towards a Toxic-Free Environment[6] directly addresses the production of safe and sustainable chemicals for batteries.

(2) Battery Use Stage

During battery manufacturing, active substances, binders (like PTFE and PVDF), and additives are embedded in a mechanical substrate to form electrodes. These electrodes are then further assembled with other battery components such as separator, electrolyte, connectors, gaskets, washers, and casing to obtain a finished battery. Lithium batteries are sealed by design and do not have any openings. Some alkaline batteries may need to have water additions during their working life and therefore may be equipped with a valve opening system. Although gasses can be emitted during the working life of these batteries, the valves are designed to prevent any PFAS liquids or solids emissions leakage**. There are no PFAS emissions from any type of battery during normal use of the battery.**

(3) Waste Battery Collection Stage

The Batteries Directive 2006/66/EU, as amended by Directive 2013/56/EU, banned the disposal to landfill or incineration of automotive batteries and industrial batteries. Instead, **all automotive batteries and industrial batteries that become waste in the EU are collected and recycled in closed loop systems which minimize emissions.** The new EU Battery Regulation[7] states that all waste starting, lighting and ignition ("SLI") batteries, waste industrial batteries and waste EV batteries should be collected.

For this purpose, the producers of these batteries "*should be required to accept and take back free of charge, all waste batteries for their respective category from end-users*". Detailed reporting obligations should be established for all producers, waste management operators and waste holders involved in the collection of waste SLI batteries, waste industrial batteries and waste EV batteries (paragraph 112, page 70). The EU Commission Batteries FAQ[8] states that "***nearly 100% of automotive batteries and industrial batteries are already being collected***" and notes that the economic value of batteries motivates collection by professionals.

[7] Regulation of the European Parliament and of the Council of 12 July 2023 concerning batteries and waste batteries, amending Directive 2008/98/EC and Regulation (EU) 2019/1020 and repealing Directive 2006/66/EC.

[8] https://environment.ec.europa.eu/topics/waste-and-recycling/batteries-and-accumulat.

The European association of national collection schemes for batteries (Eucobat)[9] estimates that 19% of portable batteries placed on the EU market are exported in second hand or waste electrical products and therefore are not available for collection and recycling in the EU. Eucobat highlights that achieving a 65% collection and recycling target based on the quantity of batteries placed on the market is equivalent to achieving a 80% collection and recycling target based on the quantity of batteries that are available for collection.

In the meantime, Art. 59 sec. 3 EU Battery Regulation requires the industry to achieve the following collection and recycling targets based on the quantity of portable batteries placed on the market:

- 45% by 31 December 2023;
- 63% by 31 December 2027;
- 73% by 31 December 2030.

Achieving these targets will move the collection and recycling of portable batteries towards a closed loop system which minimizes emissions.

Increasing collection and recycling rates of portable batteries will also help with the large amounts of batteries stored by consumers. Surveys have shown that consumers tend to hoard electronic products that are old, broken, obsolete, or are no longer in use for different reasons. These waste portable batteries from consumer electronic products stored at home are currently not available for collection and recycling.

Once collected, the Waste Electrical and Electronic Equipment (WEEE) Directive[10] aims to achieve a separate recycling of Electrical and Electronic Equipment (EEE) and the batteries included in them. Art. 8 sec. 2 WEEE requires that the WEEE recycling process shall remove batteries from any separately collected WEEE, if possible. The removed batteries can then be recycled.

However, not all batteries can be removed from WEEE. Many electronic products include small batteries on the printed circuit boards to provide back-up power to clock functions and memory functions. The WEEE Directive requires (*inter alia*) the removal of printed circuit boards of mobile phones generally. These printed circuit boards are often sent for metal smelting including any batteries contained on the boards. The smelting of batteries at 1,600℃ destroys the PFAS entirely and does not result in any PFAS emissions. This explains why a large proportion of waste portable batteries in consumer electronic products are not available

[9] https://www.eucobat.eu/downloads/position-paper-collection-target-waste-batteries.

[10] Directive 2012/19/EU of the European Parliament and of the Council of 4 July 2012 on waste electrical and electronic equipment (WEEE).

for collection and battery recycling because they are not separately removed during the WEEE recycling process.

(4) Waste Battery Recycling Stage

The new EU Battery Regulation aims "*to make all batteries placed on the EU market more sustainable, circular and **safe***"[11] to achieve the EU circular economy and decarbonization ambitions from the sourcing of materials all the way through to battery collection, recycling, and repurposing. Once it enters into force, sustainability requirements such as disclosure of batteries' environmental footprint and recycled content will be introduced starting in 2024.

Batteries are recycled using pyrometallurgical processes and/or hydrometallurgical processes. All types of PFAS used in batteries are fully dissociated into fluorine compounds at these high temperatures. PVDF rapidly decomposes in the temperature range 400 – 510 ℃, followed by gradual decomposition between 510 – 700 ℃. The most stable PFAS, perfluoromethane (CF4), needs a temperature of 1380 ℃ to be dissociated. The temperature of the smelting reduction stage results in complete destruction of all these types of PFAS. **As the materials are smelted at between 1400℃ and 1600℃ during the pyrometallurgical process, there are no PFAS emissions from the pyrometallurgical process.**

All battery recycling operations are conducted in facilities which are permitted by the competent authority within each EU Member State, where any release of emissions is controlled and must be below regulation threshold limits. These limits include those set by the Industrial Emissions Directive[12] which sets limits on preventing and limiting levels of pollution.

2-3) By enforcing the new EU Battery Regulation, exposure to PFAS during the collection/recycling and the disposal stages can be tightly controlled.

The new EU Battery Regulation creates a well-structured framework that addresses and eliminates potential health and environmental risks of end-of-life batteries. The new EU Battery Regulation is a cornerstone of the European Green Deal and aims to improve the circular economy, resource use and efficiency, and the life cycle of batteries in terms of climate neutrality and environmental protection.

Regarding portable batteries – as the kind of batteries mainly used in EEE – it tightens the requirements for removability and sets new requirements to ensure replaceability. A battery will be considered

[11] https://ec.europa.eu/commission/presscorner/detail/en/ip_22_7588.

[12] Directive 2010/75/EU of the European Parliament and of the Council of 24 November 2010 on industrial emissions (integrated pollution prevention and control).

removable if it can be removed and replaced with a comparable battery without affecting the device. Such batteries in the future have to be removed and replaced, with the old battery requiring recycling under the new EU Battery Regulation. The enforcement of these new provisions will drastically decrease the number of EEEE-batteries being discarded by consumers and ensure their safe collection and professional recycling. This will significantly reduce the risk of improper treatment of end-of-life batteries which could potentially lead to PFAS exposure.

2. Technical Perspective

1) From our 30 years of extensive experience with the commercialization of EV, ESS, and other industrial batteries, we know that it would take at least 40 years to achieve a stable commercialization of PFAS-free EV batteries, and that the **currently suggested 13.5/6.5-year derogation period to replace PFAS materials in the battery industry is unrealistic and not achievable.**

The data that we have collected in the last 30 years of development of materials, optimization of the entire battery manufacturing process and supply chain **compels the conclusion that it would take at least 40 years to achieve a stable commercialization of PFAS-free EV batteries**.

This is especially due to the following reasons:

(1) Currently **no alternative cathode binder material**[13] **for PFAS (for example PVDF or PTFE) exists that simultaneously satisfies all required characteristics**, such as high voltage stability, thermal and chemical stability, mechanical properties, and processability. **The alternative material development period alone is predicted to be longer than 10 years at minimum.**

(2) After the alternative material is developed**,** it will **take at least 30 years to evaluate its commercialization,** which includes a new development and optimization of the entire battery manufacturing process as well as of the required facilities and equipment.

(3) The abovementioned minimum 40 years may not be sufficient to verify cell performance and reliability. **An insufficient verification of cell performance and reliability for EV due to time constraints would risk user's safety**.

(4) An **increased battery price** due to a decreased yield of battery manufacturing, an investment in mass production facilities/equipment, and binder supply shortage **will be an obstacle for the swift transition to carbon free EVs in the EU.**

At this point, it is unclear if and when a PFAS alternative for EV batteries can be found.

[13] The cathode binder indicates either the binder inside cathode itself or the binder added between the electrode and separator for adhesion during stacking or winding processes.

Even in the most positive scenario assuming that it will be found within reasonable time, the **total estimated time for the development and commercialization of PFAS-free EV batteries is at least 40 years**. It is however likely that no alternative exists or that processes will take significantly longer, especially to ensure safety for consumers. Therefore, any derogation period for EV batteries would have to be unlimited.

Given these facts, the only reasonable option is to exclude EV, ESS, and other industrial batteries from the PFAS restriction or have an unlimited derogation period. A derogation period, even one of 40 years, would endanger urgently needed industry investments and render a systematic manufacture planning impossible.

The battery manufacturers in Korea are consistently conducting technical reviews on alternatives for PVDF but have not found a material as good as PVDF in terms of productivity, quality, performance, and stability.

Recent academic research highlights materials such as polyimide, polyurethane, polyolefin, polyester, and epoxy, but as discussed in this report, none of these satisfies the desired processability, stability, and environmental aspects in the current lithium-ion battery design.

Some binders, for example, may seem feasible on a research level, but the actual commercialization involves various aspects not discussed in academic papers. This includes the productivity, quality, performance, safety, reliability, testing, and development, which will take at least 30 years based on our past experience.

In addition, in case the components of the lithium-ion battery need to be changed when the new binder is applied, the equipment, facility, and new material need to be developed and verified. This will further extend replacement times.

Also, the hazards of the newly introduced materials may be higher than those of PVDF and previous materials.

It therefore has to be concluded that replacing PFAS is practically impossible and that any replacement will likely be an inferior solution. **Therefore, the battery industry needs to be excluded entirely from the PFAS restrictions.**

1-1) No commercialized alternative candidate in the current market satisfies the most important characteristics of a cathode binder and it will take at least 10 years to develop an appropriate alternative.

There is **no commercialized alternative candidate** in the current market that satisfies the **following most important characteristics as a cathode binder, which need to be met simultaneously**: ① high chemical stability, ② electrochemical stability, ③ high thermal stability, ④ high mechanical properties, and ⑤ good processability.*14*

- **Minimum Requirements for Normal Lithium-Ion Battery Binders**

The primary function of a binder for lithium-ion battery is to provide mechanical strength and electrode stability. Cathode binders, for example, limit volume expansion during the lithium-ion battery intercalation process to maintain structural stability, while performing as a buffer during delithiation to support return to its original structure.

The bare minimum requirements for cathode binders in lithium-ion batteries are discussed below. These properties need to be considered in various perspectives, such as mechanical stability, electrochemical stability, and processability.

(1) Mechanical Stability

Carbonate electrolytes used in a lithium-ion battery are of high polarity. A binder must maintain its function and work as an adhesive and not dissolve in the electrolyte.

Without an appropriate binder, repeated expansion/contraction caused by charging and discharging can lead to structural deformation, meaning ohmic resistance induced by a weakened bond between active materials and conductive additives, which could lead to an overall decline of battery capacity. Even electrode dropout can happen, which could result in a serious safety issue.

Thermal resistance and flame retardancy are also required for a binder since the drying process of electrodes generally happens at around 200℃. Only a limited group of polymer substances qualifies for such requirements.

(2) Electrochemical Stability

Oxidation resistance is also required with respect to the generation of active oxygen in an overcharging state of metal oxide, such as cathode materials. Furthermore, a binder should have a lithium-ion conductivity without any side reaction while it is soaked in electrolyte. High-molecular substances that qualify for such requirements cannot be specified.

For example, compared to organic electrolytes such as ethylene

[14] The details regarding each property can be referred to Section 2.1.1 of RECHARGE 2nd draft.

carbonate(EC) (-12.46 eV) and propylene carbonate(PC) (-12.33eV), fluorine-based materials such as PVDF (-14.08 eV) and PTFE (-15.47 eV) have a comparative advantage in terms of oxidation potential.

(3) Processability

A. Homogeneity

A binder should uniformly paste/adhere with either active materials, conductive agents, or additives, while ensuring certain properties such as stable coating.

B. Contamination

A binder should not experience problems such as detaching from collector during the slitting and notching processes.

C. Viscosity

A binder with adequate viscosity is required to apply high shear force to mix the slurry uniformly.

D. Environment

Residue and solubility should be considered so that solvent can be recovered and reused.

E. Fibrillation (Dry electrode process)

A binder with enough fibrillation ability is required to paste/adhere with either active materials, conductive agents or additives uniformly in dry mixing condition.

- **No "alternative candidate material" satisfies the most important characteristics that have to be fulfilled simultaneously by a cathode binder.**

The materials most mentioned as cathode binder alternatives can be classified as aqueous and non-aqueous binders:

(1) Aqueous Binder

According to our research, the Ni-based cathode active material is easily degradable with only a minimum amount of moisture (several hundred ppm)[15], which consequently leads to battery performance degradation. It has been confirmed that the use of aqueous binder leads to a drastic decrease of the battery lifespan. This cannot be avoided by controlling/adjusting the aqueous binder type, content, configuration. It was also confirmed that **it is practically impossible to produce an electrode on an aqueous base.**

Therefore, the use of PFAS is inevitable for cathode binder.

(2) Non-Aqueous Binder

Both battery makers and researchers have made enormous efforts to develop binder for non-aqueous solvent application to replace PVDF over the past 30 years, but none have been commercially successful.

The use of PVDF is dominant in non-aqueous and commercialized cathodes in lithium-ion batteries, and numerous studies have been conducted to replace fluorine-based polymers in industries. The candidates for alternatives however have critical flaws that bar their commercialization and the currently available candidates cannot be utilized.

A. Polyimide: while showing good adhesion and thermal resistance, the imide bond is not suitable for the required characteristics.

B. Polyolefin (PE, PP): electrochemically not suitable due to high HOMO energy level (i.e. the oxidation potential value is too low).

C. Polyester: while showing good adhesion and thermal resistance, the ester bond is not suitable for the required characteristics.

D. Epoxy: time needed to induce curing is too long in processing perspective.

- **The unique property of PVDF is suitable for lithium-ion batteries and the recycling of the non-aqueous solvent is well established, which is environmentally desirable.**

(1) Processability

PVDF has a low crystallinity as a polymer, allowing it to have relatively

[15] Particularly, the extent of degradation becomes more severe as the content of Ni increases in the cathode material.

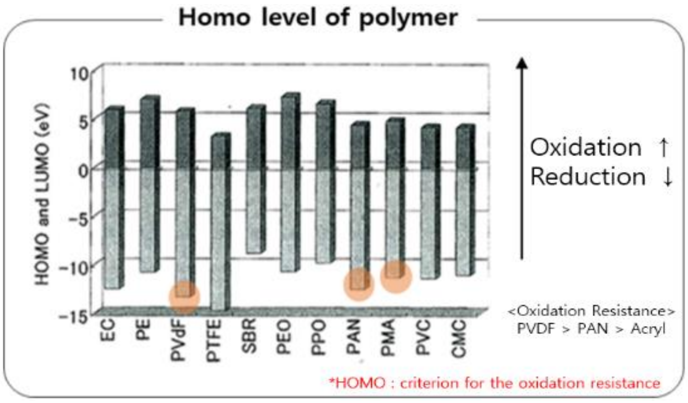
high solubility and great processability. The viscosity range is highly controllable, which is important in deciding the slurry viscosity suitable for the specific ratio of the active material. It is advantageous for coating quality and the adhesion to the electron collector is decent. In addition, the slurry made with PVDF exhibits appropriate flexibility and stiffness when pressed making it suitable for a high density pressing.

(2) Stability

PVDF, compared to other polymers, has an unusually high dielectric constant and exhibits an excellent lithium-ion conductivity ($10^{-6} \sim 10^{-5}$ S/cm) when swollen by electrolyte. Also, the strong bond between carbon and fluorine within the polymer makes it resistant to chemical changes under almost all carbonate electrolytes. Thus, PVDF satisfies all necessary properties as a cathode binder in lithium-ion batteries.

(3) Oxidation Resistance

During charging, the cathode is under a strongly oxidizing environment. Oxidation resistant properties are mandatory for a cathode binder. The oxidation resistant properties become better as the Highest Occupied Molecular Orbital (HOMO) energy level decreases, and the low HOMO energy can be achieved by introducing an electron acceptor. The fluorine-based functional group (-F, -CF2) is one of the strongest electron acceptors, and there is no polymer found that exhibits oxidation resistant levels that are similar to PVDF or PTFE, which are composed purely of the aforementioned functional group.



(4) Environment

PVDF, which is synthesized by polymerization, uses NMP as solvent and the solvent has an ignition temperature of 346°C, making it highly stable.

Also, the solvent recycling and reuse are well established and easier compared to other solvents. In addition, **PVDF exhibits relatively low toxicity compared to other aqueous alternatives suggested by RECHARGE.** [16] Overall, the toxicity and persistence – ECHA's main concerns – of PVDF are not much different from that of the alternatives.

Contents	PVDF	PTFE	SBR	CMC	polyacrylic acid

Although it depends largely on the processing control during lithium-ion battery manufacturing, the solvent recycling is generally easier for non-aqueous solvents with lower flash point, i.e. more volatile, compared to water that has strong bonds and less volatility. Thus, the use of **PVDF requires less energy for solvent recycling and reuse, resulting in lower Global Warming Potential ("GWP") and is therefore more eco-friendly**.

Meanwhile, the dry process in which no solvent is utilized during the electrode manufacturing process also requires the use of a different type of fluorine-based polymer material, PTFE, as a key component. The fibrilization property along with the aforementioned requirements such as thermal, chemical, and mechanical properties, makes PTFE an irreplaceable material for dry processing. **PTFE also exhibits relatively low toxicity compared to other aqueous alternatives suggested by RECHARGE**[17].

1-2) Even if an alternative binder for PVDF is developed, the actual commercialization will take at least 30 years.

Replacing PVDF is not equivalent to merely replacing one material with another. Rather, the entire process including the binder dissolution, slurry preparation and transfer, electrode manufacture, and cell assembly is affected in a complicated way by changing the binder, and **a great deal of time and cost must be invested to verify the manufactured cells**. In other words, **it is not only difficult to replace the binder but doing so will also largely affect the entire battery manufacturing process and cell performance**.

In our experience, the required development of new processes, equipment, and large-scale

[17] See RECHARGE's dossier submission to ECHA for detailed description.

facilities and the optimization of commercialization cannot be accomplished in less than 30 years. In addition, it will take decades to thoroughly evaluate the biological hazard and working environment safety, especially if the alternative has not already been evaluated for biohazard effects over generations.

It is also important to note that the 30 years period which was required for the first-time development of batteries did not even include the material development period. The battery industry has always utilized PFAS materials as key materials from the very initial stage of its development.

Thus, replacing PVDF with a new binder requires that all processes including the binder dissolution process, slurry preparation, electrode coating, drying, and electrolyte wetting are reviewed. During the 30 years of research for our current EV batteries, we have solved various problems of the electrode process and as a result, we have succeeded in the commercialization of EV batteries. A replacement of PVDF with a new binder would render these mass production experiences and efforts to base zero. We would also have to repeat endless trouble shooting for processing issues and require several decades to successfully commercialize again.

When the processes listed below return to base zero, a minimum of 30 to 35 years will be required to rebuild them. Building equipment for each process, developing the process recipe, and verifying the semi-product are mandatory. Also, each step needs to be verified in lab-scale, then proceed to scale-up and pilot, followed by mass production. Realistically, the processes listed below cannot be validated simultaneously; each needs to be validated on a step-by-step basis because each step will have a significant influence on the following step. Also, the resources such as human resources, cost, infrastructure etc. are limited for the below contents to be carried out at the same time in the process.

Based on this, the **minimum estimated time required to verify each process** is as follows:

- at least 2 years for binder dissolution equipment;
- at least 3 years for main mixer disperser;
- at least 4 years for coater;
- at least 3 years for pressing equipment;
- at least 3 years for notching equipment.

Thus, the total time required for the process development alone is a minimum of 15 years. After development, the following steps are required:

- at least 4 years to verify the assembly processability and cell performance, which are needed in the 4M processes for customers;
- at least 10 years to build a plant to expand to mass production;

- at least 3 years to stabilize the yield, overall equipment efficiency, and quality.

Therefore, the total time required for a transition is minimum 30 years, but likely more. It should also be noted that **if the newly developed alternative turns out to be hard to handle in processing, these time estimations might not be enough to stabilize mass production at the same level as currently PVDF**.

The following describes **typical past experiences of battery manufacturers where development/commercialization times took much longer than anticipated** due to difficulties of developing at each step of the process:

(1) Binder Dissolution

When manufacturing the cathode slurry, a process of pre-dissolving the PVDF binder is required to uniformly disperse the binder. At this stage, the state of the binder greatly affects the raw material storage, weighing, dissolution vessel type, selection of process equipment, and condition setting. If the new substitution binder is in the form of a bale such as rubber, there may be great difficulties in preparing the process including cutting and quantitative weighing, and a new facility investment for these may be inevitable. In addition, the bale form has a low specific surface area, so it may take more time and cost more energy to dissolve it sufficiently.

If the new alternative binder is in the form of a solution, a dissolution process would not be required, but the additional mass of the solvent needs to be reflected in the transportation cost and there is a high risk of binder property being compromised due to the high temperature when passing through the equator. In addition, the solution type requires a large storage space, and the existing dissolution facilities are likely to become unused facilities.

If it is a powder type such as PVDF, it is highly likely that the new substitution binder has a higher molecular weight to compensate for lower physical properties compared to PVDF, a more complex structure such as a copolymer, or a composite of one or more polymers. In this case too, in order to sufficiently dissolve the binder, more thermal energy and process time as well as a solvent change, additional dissolution equipment, and the like may be required.

(2) Cathode Mixing

When manufacturing a cathode slurry, the binder uniformly disperses the active material and the conductive material, thus contributing to appropriate rheological properties. However, if the binder is changed, there is a high possibility that both the existing solvent and the mixing process equipment themselves need to be changed for the slurry to have an equal or better processability. Asides from the dispersibility of the cathode slurry, the phase stability of the slurry is important as well and the viscosity of the slurry should not rapidly increase or decrease before coating or drying. PVDF has been developed and improved to obtain the slurry properties that are optimized to assure the desired slurry stability in a non-aqueous solvent through a long period of research and development, including the development of recycling technology for reuse of the solvent.

(3) Cathode Slurry Transfer

In addition, one of the factors that is easily overlooked is the slurry transfer step, which is directly related to productivity in manufacturing. In the case of applying a new alternative binder replacing PVDF, if the slurry viscosity is significantly increased, the entire transfer system of the pipeline may need to be replaced.

This change includes increasing the transfer pump power according to the physical properties, readjusting the line of balance, and evaluating a full review of new facility investment.

(4) Electrode Production

From the viewpoint of electrode production, the slurry must have appropriate rheological properties, which are also greatly affected by the binder. The binder change causes a large change in the flow and thermal properties of the slurry (particularly, it affects the drying temperature and drying time), and is highly likely to cause electrode quality problems in the coating and drying process after slurry preparation.

In addition, certain binders are likely to require the introduction of an additional process different from the existing process for coating/drying. For example, a high temperature curing process of 300°C or higher may be required to improve the performance of the binder. In this case, it is necessary to develop a new temperature control process and related process equipment that can ensure the uniformity of the electrode, not to mention the need to build a new facility for the large-scale and high temperature that uses much more thermal energy.

(5) Cell Assembly

The binder greatly affects the physical properties of the electrode such as electrode adhesion force and flexibility. If the adhesion force is lower than that of PVDF, it cannot easily proceed to the subsequent process stage due to electrode detachment and even if the cell is manufactured, the capacity and cycle performance are inevitably degraded. In addition, if a design change such as an increase in binder is made to make-up the insufficient adhesion force, the electrode may become stiffer and lose flexibility. For the mass production of electrodes, the electrodes are wound and unwound in the form of rolls, and at this stage, the electrodes with low flexibility and brittleness cause additional problems of being easily broken and detached.

(6) Electrolyte Wetting

Once produced, the electrode undergoes an electrolyte wetting process where the degree of wetting is greatly affected by the affinity of the binder and the electrolyte. If an electrolyte-friendly functional group is additionally introduced into the binder, it may be helpful to solve this problem, but mechanical properties of the binder may be compromised. Thus, other problems such as a decrease in electrode adhesion force or a decrease in cell life may be the result.

(7) Cell Verification

When changing the binder, the cell needs to be verified for its safety and life span. This process takes a very long time and is high cost. For EV cells, it has been taking decades to obtain data from field tests regarding cell safety upon sudden temperature change and impact. It is obvious that a newly introduced binder will have to go through the same verification steps as PVDF did, which will take just as long. For example, in the case of EV and ESS cells, life verification of 3,000 cycles or more is required to guarantee at least 10 years of lifespan, but it takes more than 2 years for the verification of one condition. This applies for the case of continuous charge/discharge, and the actual field test will take more than 10 years because charge/discharge will not be continuous.

2) The abovementioned minimum 40 years may not be sufficient to verify cell performance and reliability. **An insufficient verification of cell performance and reliability for EV due to time constraints would risk user's safety**.

In the beginning of the commercialization of batteries, there have been multiple fire incidents. The battery industry has invested around 30 years of research and development to ensure the reliability and safety of the batteries, and the EV and ESS industries are now blossoming due to the improved battery quality. **To assure the long-term reliability of EV and ESS, field test data under high temperature, low temperature, vibration, and impact was collected over 20 years through the Battery Management System ("BMS") embedded in the battery pack.** The battery industry has worked very hard to achieve the current level of reliability. The effort, time, and cost invested are valuable assets to the industry that cannot be calculated through a simple arithmetic. **If an alternative binder was applied without such extensive long-term verification, tremendous safety risks for end-users would be the consequence.**

3) Comprehensive exclusion from the ban is required for the entire battery industry

As it has been emphasized, developing viable alternative PFAS substances and their manufacturing technologies used in the battery industry within the currently suggested derogation periods is not feasible.

The proposed PFAS restrictions **not only affect the manufacturing of current cell materials, pack parts (used for electric vehicles and ESS), and electric/electronic devices but also hampers the development of key essential materials for the development of next-generation batteries.** Examples of these indispensable materials include "PVDF" and "PVDF Copolymer" utilized as cathode binders and separator binders, "PTFE" used as binders for dry process, and O-rings and gaskets employed in the top cap of cylindrical batteries.

These materials cannot be substituted with existing technologies or alternative materials. Over the course of more than three decades, the battery industry has dedicated extensive research and development efforts to optimize the performance and stability of these materials. **Replacing them with non-PFAS materials would inevitably impact the performance, stability, and – most importantly – the safety of the materials achieved through decades of innovation efforts.** The unique properties of PFAS substances played a crucial role in maximizing and ensuring the structural integrity, reliability, stability, and performance of lithium-ion batteries, making them suitable for EV applications. Korea's experience strongly suggests that without PFAS substances, the performance, reliability, and safety of EV batteries will be drastically compromised, hindering the growth of the EV industry, and impeding the progress towards the realization of the EU's long-term eco-friendly strategies and goals.

In particular, the development of alternative materials for lithium-ion battery binders is an intricate task that requires substantial time and resources. The current restriction proposal suggests derogation periods of 6.5 years or 13.5 years. Even when assuming the existence of alternative materials, considering the time required for the development period of alternative substances, sample testing, facility modification, etc., it is impossible to develop viable substitutes for PFAS substances that meet the stringent performance and safety requirements demanded by lithium-ion batteries within these extremely short time lines. The introduction of alternative PFAS substances without extensive evaluation will most likely have a negative impact on battery performance and lifespan, potentially hindering the progress of the EU's "Green Mobility" plans and impeding a successful transition towards EVs.

3. Socio-Economic Perspective

1) Problems linked to the time required to build a new supply chain, price increases, and supply shortage of EV, ESS, and other industrial batteries during the transition.

Even if a new alternative binder could be found, an entirely new binder supply chain would have to be established. In the meantime, PVDF usage has already been minimized to increase energy density. Even if it is assumed that the replacement is carried out only to the minimum required amount, securing the raw materials for a new binder, developing the commercially viable polymerization process, selecting the binder supplier capable of producing the required amount, investing for mass production, **and establishing a stable new supply chain requires an enormous amount of time and financial investment**.

2) The proposed PFAS restriction creates significant market uncertainties which prevent EU investments throughout the entire supply chain.

This situation poses a considerable obstruction to achieving the EU's long-term strategies, including the "Green Deal Industrial Plan for the Net-Zero Age", "Net Zero Industry Act", and "Green Mobility".

In a world where global attention is focused on expanding the EV market, a PFAS restriction would set unachievable requirements for the battery industry, thereby slowing down and even preventing battery and EV production. The consequence will be substantial losses not only for the companies of the EU's battery and EV supply chains, but also for the broader EU economy. Many other EU industries actively promoting green policies, such as the "2030 carbon neutrality" goal, would also be affected.

As of 2022, the EU EV battery market stands at 2.4 million units. However, to meet the EU's target of 100% of new vehicles sold being zero-emission by 2035, there is a need for a 250% increase in the battery market until 2027, and a 550% increase by 2034.

Unfortunately, the uncertain market conditions caused by the proposed PFAS restriction have led material companies to be hesitant to expand their investments. Such difficult investment climate makes it challenging to meet the rapidly growing demand for EV batteries, which must expand by 2 or 3 times the current size within the next 5 years to achieve the EU goals. Material companies usually plan new investments 4 to 5 years in advance, but due to the uncertainty brought on by the PFAS restriction proposal, these companies are currently delaying their investment plans.

3) The huge costs incurred to develop commercially suitable materials and relevant application processes will challenge a swift transition of the EV industry.

In addition, if the PFAS restriction is passed as currently discussed, companies making fluorine-based binders will most likely stop their investments into capacity expansion immediately. In the short term, especially given that currently there is not even a suitable candidate as an alternative, this will most likely to lead to a rapid increase in battery and EV prices as well as a battery supply shortage.

Finally, the financial investment required to develop a commercially suitable material, new mass production facilities, manufacturing processes, and cell verification is estimated to be multi-billion USD. The investment for new mass production facilities for the new alternative material alone is expected to reach more than 1 billion USD/10GWh. **These costs will be reflected in the price of EV batteries. As a result, the burden on EU consumers will increase, and the EV industry itself may be challenged.** This further exacerbates the challenges faced in meeting the ambitious EU targets.

4. Regulatory Perspective

1) Strong contradiction with the new EU Battery Regulation

Including PFAS in batteries in the PFAS restriction strongly contradicts the EU's general policy on batteries, as most recently expressed in the new EU Battery Regulation.

On several occasions, the Recitals to the new EU Battery Regulation emphasize the core importance of batteries for the EU's sustainability/climate/green mobility goals. The Recitals deliver strong arguments making it clear that an exclusion of the battery sector from the planned PFAS restriction is required:[18]

- The transition to e-mobility is indispensable for the EU to reach its 2050 climate goals;
- Batteries will make this transition possible;
- The EU expects the EV-battery market to grow "massively" in the next years due to increased e-mobility demand;
- Batteries have strategic importance;
- It is required to provide legal certainty to all operators on the battery market and to avoid discrimination and barriers to trade;
- Rules for battery performance and safety are required.

Against the background, including the battery sector in the PFAS restriction would strongly contradict the explicit wording and policy considerations of the new EU Battery Regulation.

2) Lack of basis for enforcement and compliance checks of PFAS restriction

Companies in the development/mass production stages typically check for hazardous substances to adhere to relevant regulations. However, the proposed PFAS restriction lacks specific CAS numbers for prohibited substances, making it challenging to identify their presence in the materials.

Furthermore, adequate assessment methods for detecting PFAS substances in most cases have not been established. As a result, besides the material manufacturers, no downstream users can confidently confirm the absence of PFAS substances in their products. To facilitate compliance with proposed regulations, it is imperative to develop methodologies for testing PFAS content in materials and revise relevant laws and regulations prior to incorporating PFAS into the Safety Data Sheet ("SDS") as part of foundation for companies to comply.

III. Conclusion

Based on the aforementioned it has to be concluded that replacing PFAS is practically impossible and that any replacement will likely be an inferior solution. **Therefore, PFAS used by the 'Battery Industry' need to be completely excluded from the restriction.** We sincerely hope that ECHA realizes the magnitude of the abovementioned issues and takes a more practical approach in agreeing with the battery industry that a permanent exclusion from the PFAS restriction for the Battery Industry as a whole is really what is required at this point in time.

---

NMMA National Marine Manufacturers Association   MRAA MARINE RETAILERS ASSOCIATION OF THE AMERICAS   wsia WATER SPORTS INDUSTRY ASSOCIATION

March 1, 2024

Commissioner Katrina Kessler
Minnesota Pollution Control Agency
520 Lafayette Rd, St Paul, MN 55155

Dear Commissioner Kessler,

I hope this letter finds you well. I am writing on behalf of the National Marine Manufacturers Association (NMMA), the Marine Retailers Association of the Americas (MRAA), and the Water Sports Industry Association (WSIA) to comment on unavoidable use in PFAS products, specifically in relation to Minnesota Session Law - 2023, Chapter 60, H.F. No. 2310.

NMMA is the trade association for the U.S. recreational boating industry, representing nearly 1,500 marine businesses, including recreational boat, marine engine, and accessory manufacturers. Our members are often U.S.-based small businesses, many of which are family owned. NMMA members collectively manufacture more than 85 percent of the marine products sold in the U.S. Furthermore, the recreational boating industry has a $230 billion impact on the nation's economy and in communities across the country, with nearly 700,000 American jobs across 35,000 U.S.-based marine businesses.

MRAA is the leading trade association of North American small businesses that sell and service new and used recreational boats and operate marinas, boatyards, and accessory stores. MRAA represents more than 1,300 individual member retail locations and conducts advocacy efforts on their behalf.

WSIA is the towed watersports industry's leading advocate, working to strengthen, grow boating and protect the interests of its member companies and recreational boaters across the country. The WSIA develops best practices, maintains waterway access rights, educates participants, and promotes safety on the water, including when participating in towed watersports. WSIA represents over 440 member companies, including boat, marine engine, and accessory manufacturers, as well as marine dealers.

Boating is big business in Minnesota, with an estimated annual economic impact of $6.9 billion, supporting over 25,000 jobs and 700 businesses. Moreover, we acknowledge the crucial work carried out by the Minnesota Pollution Control Agency (MPCA) in addressing environmental concerns and implementing necessary regulations.

Our members, most of whom are small businesses, face specific challenges in complying with Minnesota's PFAS reporting requirements. While we share the common goal of safeguarding the environment and human health, we believe that collaborative efforts are essential to strike a balance between regulatory demands and the economic feasibility of our industry.

In this letter, we aim to provide extensive insights and recommendations regarding the implementation of PFAS reporting requirements. We believe that collaborative efforts between the MPCA and stakeholders in the marine industry are crucial to achieving a balance between regulatory demands and the economic feasibility of our sector.

Our associations propose the following considerations for the implementation of PFAS reporting requirements, with a focus on a risk-based approach that addresses the unique considerations of small businesses, cost considerations, and the duration of Unavoidable Use determinations:

1. **Define Criteria for "essential for health, safety, or the functioning of society" based on a risk-based approach:** To ensure effective protection of human health and the environment, we request that the regulations adopt a risk-based approach. By focusing on actual environmental, health, and safety risks associated with PFAS chemistries, Minnesota can ensure that its regulatory efforts focus first on its highest priorities. To enhance the efficacy of this approach, we suggest incorporating a thorough evaluation of both hazard and exposure, considering the specific properties and uses of individual PFAS compounds.

   In addition, providing clear and reasonable timelines, coupled with extensive notices to stakeholders, is crucial to facilitate compliance without causing undue disruptions to supply chains and business continuity. The marine industry, with its complex and global supply chains, requires sufficient time for phaseouts and alternative analyses. Therefore, we urge the MPCA to establish realistic timelines, considering the intricate nature of our industry.

2. **Make unique considerations for Minnesota's small marine businesses:** Small businesses in the marine industry, many of which are based in Minnesota, play a vital role in assembling complex components, such as recreational marine engines, boats, trailers, and accessories. They face significant challenges in complying with the precise identification requirements outlined in Session Law - 2023, Chapter 60. For example, a typical 20-foot boat consists of more than 1,000 distinct stock keeping units (SKUs), making it impractical to identify 12,000 potential PFAS chemicals within each purchased component and subassembly. By and large, marine manufacturers are not actually responsible for directly manufacturing products that include PFAS, instead, during the manufacturing process, essential components that contain PFAS are assembled by the marine manufacture to create the final product.

   Moreover, the global and multi-tiered supply chain in the marine industry adds another layer of complexity. Minnesota marine dealers and manufacturers represent a minute fraction of the sales by their international importers and distributors who may be unaware of the ultimate destination of their products. Our members, who manufacture only a few of the components they use in their products, find themselves financially and logistically hard-pressed to acquire the information demanded by the proposed statute.

   Considering these challenges, we strongly urge that the MPCA view small marine businesses through a different lens when making unavoidable use determinations. Recreational boat building is generally driven by small businesses that assemble various purchased components that require a long useful life under harsh conditions. Recognizing the practical limitations faced by these businesses will contribute to a more realistic and feasible regulatory framework.

3. **Consider the costs of PFAS alternatives and develop a reasonable cost threshold:** we recommend the development of a reasonable cost threshold to prevent undue financial burdens on existing and developing marine businesses. The costs associated with developing chemical substitutions and identifying chemicals in a complex, global, multi-tiered supply chain will place an undue financial burden on marine businesses. It is essential that the regulations preserve industry sustainability, innovative capacity, and product diversity. We request that regulatory bodies protect these foundations of business and recognize the already-existing safe, durable, and essential products within the marine industry. A balanced approach that considers the economic

implications of PFAS alternatives will contribute to the long-term success of both environmental protection and the marine industry. Moreover, this approach aligns with international and federal precedents.

4. **Ensure CCU determinations remain in effect for the lifetime of each exempted product category:** Adding complexity to an already daunting task, the Environmental Protection Agency's (EPA) PFAS Master List encompasses over 12,000 potential chemicals falling within the reporting requirements. To address concerns over the ever-expanding PFAS master list, we propose that all Unavoidable Use determinations for a specific product category remain in effect for the lifetime of the product. Avoiding re-evaluation of unavoidable use products will provide much-needed stability for retailers and manufacturers facing substantial challenges in meeting the reporting requirements.

5. **Please share what uses and products you may submit a request for in the future and briefly why?**

   PFAS chemical entities assume a pivotal purpose in the maritime sector, including but not limited to paint, wiring harnesses, monitors, displays, seals, and lubricants. PFAS imparts unmatched thermal protection, water resistance, corrosion prevention, lubrication, and safety to specified marine equipment. Presently, there are notably scant viable alternatives to PFAS in these critical applications and efforts to develop alternatives for them have yielded suboptimal results. Our suppliers report that the substitutes they are testing degrade far quicker, require more frequent maintenance, and compromise the functionality, reliability, and safety of marine equipment. This underscores the importance of PFAS in upholding the integrity of marine equipment.

   For example, components integral to fuel systems, such as gaskets, O-rings, seals, and high-voltage battery cables commonly integrate fluoroelastomer (FKM). FKM is an essential additive and allows these core components to meet stringent design requirements, adhere to low-permeation evaporative emissions standards stipulated by the EPA and CARB, and provide the durability, chemical resistance, and heat resistance these products must have. FKM stands as a superior solution for many marine products, including primer bulbs. The multi-layered design of primer bulbs incorporates an internal FKM component to perpetuate compliance with both EPA and CARB evaporative emissions requirements established in 2010. These bulbs have manifested exceptional durability, reliability, and safety in daily use. Achieving the low permeability required by federal laws. While FKM as a fluoroelastomer may contain small amounts of PFAS chemicals used in its production, there are currently no available alternatives to the FKM component. Moreover, significant time and appropriate deadlines will be needed to allow manufacturers to complete rigorous validation and certification testing to ensure that the substitutes comply with required safety, performance standards.

   In consideration of FKM and its associated safe PFAS chemicals, manufacturers likely will apply for unavoidable use exemptions for a variety of marine equipment, such as marine engines and motors (HTS 8501.31.4000) and navigation gear (HTS 9014.80.4000). These applications will encompass a range of marine engine types, including outboard, inboard, stern drive, gas- and diesel-powered, and electric trolling motors. Manufacturers also foresee applying exemptions for indispensable navigation tools such as sonar, radar, electronic charts, tracking computers, compasses, and fish finders that provide indispensable functions that are integral to maritime operations. Notably, radar systems and electronic charts are essential to Public Safety and Rescue Operations. They must deliver precision and reliability under adverse conditions and require minimal maintenance during search and rescue missions and emergency scenarios. Marine engines and navigational tools play a pivotal role in environmental and marine research. For recreational use, these products propel Minnesota's recreational fishing economy, which boasts an annual economic impact of $10 billion. Furthermore, life jackets, also referred to as personal flotation devices (PFDs), throwable boat cushions, and boating survival gear are mandated by the United States Coast Guard and the International Maritime Organization (IMO) to meet certain harsh conditions and specifications. These products have a very long useful life and must remain intact and functional under robust conditions. The U.S. Coast Guard has statutory authority under Title 46, U.S. Code, Sections 3306(a) and (b), 4102(b), 4302(a) and (c), and 4502(a) and (c)(2)(B), to prescribe regulations for the design, construction, performance, testing, carriage, use, and inspection of lifesaving equipment on commercial and recreational vessels.

We request that the MPCA closely collaborate with Minnesota's marine businesses to ensure a pragmatic and feasible procedure for applying and gaining approval of unavoidable use exemptions. We believe together government and the marine industry can strike a balance that protects the environment and the economic sustainability of Minnesota's marine industry. We are confident that these regulations can be written to address the unique challenges faced by small businesses if they implement a risk-based approach, consider the costs of alternatives, and ensure stability in regulatory determinations, Even environmentally focused states, such as California, with its decades of experience regulating chemical classes, have minimized PFAS reporting mandates due to the massive scale and cost associated with such compliance.

In closing, we appreciate your consideration of these recommendations. We hope to have the opportunity to collaborate in their implementation for the betterment of both environmental protection and the economic sustainability of our industry.

Sincerely,

Chad Tokowicz

WILO USA LLC – W66 N1253 Forward Way, Cedarburg, WI 53012

Date: March 1st, 2024

To: Minnesota Pollution Control Agency

RE: Request for Comments: Planned new Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID number R-4837.

Wilo USA LLC stands firmly behind efforts to minimize the presence of Per- and Polyfluorinated Substances (PFAS) in the environment. However, we express concern regarding the potential economic, social, and health ramifications of current PFAS restrictions. It's important to acknowledge that PFAS play a vital role in ensuring product functionality in critical applications in order to meet stringent safety standards. Major end markets and applications served are as follows:

- Building Services Pumping Equipment, Systems & Accessories for Plumbing and HVAC in commercial and residential buildings.
- Water Management Pumping Equipment, Systems & Accessories for municipal water supply and wastewater handling treatment.
- Agricultural & Groundwater Pumping Equipment for irrigation, fertilization, weed and pest control, flood management.

In line with our commitment to finding balanced solutions, we have worked through our industry associations: Hydraulic Institute, Fluid Sealing Association, Valve Manufacturers Association, the Water and Wastewater Manufacturers Association (a.k.a. the Flow Control Coalition) which have developed a comprehensive Currently Unavoidable Uses (CUU) proposal, that is being submitted to the states of Maine and Minnesota. This proposal is founded upon expert knowledge of the design of critical processes, and incorporates valuable insights gathered from diverse stakeholders including design engineers, end-users and manufacturers of critical system components.

By engaging engineers and experts from the various segments of the fluid handling industry, the Associations have applied a collaborative, systems level approach to this complex issue. Highly corrosive materials, high temperatures, harsh environments, accessibility and life-cycle considerations along with intended, efficient sustainable performance, are all part of the design criteria of the industrial and other process systems which currently require PFAS as there are no viable alternatives to handle toxic substances, prevent hazardous leaks and fugitive emissions, ensure clean air and water, etc.

WINDOW & DOOR MANUFACTURERS ASSOCIATION
WDMA

March 1, 2024

Commissioner Katrina Kessler
Minnesota Pollution Control Agency
520 Lafayette Road North
St. Paul, Minnesota 55155

Re: Planned New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

Dear Commissioner Kessler:

The Window and Door Manufacturers Association (WDMA) is a national trade association representing the leading producers of commercial and residential doors, windows, and skylights for domestic and export markets. Our members sell to distributors, dealers, builders, remodelers, homeowners, architects, contractors, and other specifiers in the residential, commercial, and institutional construction markets. WDMA members manufacture high-quality products designed and constructed to performance-based standards that provide improved safety, comfort, and energy efficiency in residential and commercial buildings.

Last year, the Minnesota legislature passed a law banning products containing intentionally added PFAS that are sold, offered for sale, or distributed in the state beginning January 1, 2032 unless the MPCA determines by rule that the use(s) of PFAS they contain are currently unavoidable uses. We are writing in response to the Minnesota Pollution Control Agency's (MPCA) request for comment related to its planned new rules governing "Currently Unavoidable Use" (CUU) determinations about products containing per-and polyfluoroalkyl substances (PFAS).

Under the law, CUU determinations can be accepted for product uses that are deemed essential for health, safety, or the functioning of society. Windows, doors and skylights play a vital role in the functioning of society and these products should be recognized as essential, warranting special consideration for regulatory exemptions by the MPCA.

Windows, doors, and skylights are indispensable components of buildings and critical infrastructure, necessary for the safety, security, and functionality of homes, businesses, hospitals, and other facilities. These products provide not only protection from external elements but also provide natural light, ventilation, and emergency egress routes, contributing significantly to public health, safety, and the functioning of society. They serve multifaceted functions that are integral to the well-being and operation of commercial and residential communities. Any regulatory measures that impede the production or availability of these

essential building products could have far-reaching consequences, including disruptions in construction projects, increased costs of housing for consumers, and compromised safety standards.

Notably, historical precedent clearly establishes that windows, doors and skylights are essential for health, safety, and the functioning of society. During the COVID-19 pandemic, when lockdowns and stay-at-home orders were in place, access to safe and secure shelter became even more crucial. Construction and maintenance activities, including the manufacture, installation, repair, and replacement of windows, doors and skylights, were allowed to continue to ensure the integrity and safety of buildings. The designation of window, door and skylight manufacturers as essential during the COVID-19 pandemic was based on the recognition of their critical role in supporting public health, safety, infrastructure, and the economy, ensuring that essential services and functions could continue despite the challenging circumstances.

Windows, doors and skylights also adhere to stringent safety and energy codes mandated by the state of Minnesota that provide reliable structural performance and reduced emissions using components that rely on PFAS chemicals to meet existing regulations.

Please note that WDMA is responding to MPCA's request for comment based on its current assessment, recognizing that its manufacturer members are in the early stages of gathering and analyzing information from suppliers that will enable a more detailed analysis. We would welcome the opportunity to provide supplementary comments as WDMA member companies learn more from its suppliers.

As such, WDMA is submitting comments as MPCA develops the PFAS in Products Currently Unavoidable Use Rule. MPCA requested specific feedback on the following questions:

1. **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**

   It is imperative that MPCA establishes criteria defining "essential for health, safety, or the functioning of society" when making determinations for CUU exemptions. Clarity with CUU exemptions is critical to orderly compliance and administration of a law with such broad societal impact.

   In developing this criteria, MPCA should recognize that a foundational aspect of a functioning society is shelter, and further recognize that windows, doors, and skylights are component parts of Minnesotans' homes that are essential for the functioning of society. MPCA should also consider relevant guidance from the state of Maine for PFAS CUU exemptions, which released criteria for "essential for the functioning of society" that includes construction materials and critical infrastructure.

To be considered necessary for "the functioning of society," products with PFAS should satisfy an equally critical policy objective such as: security, sustainability, energy efficiency, availability of housing, and ease of use for all people, such as disabled and aging populations in Minnesota that rely on products with properties provided by PFAS that lessen the operating force of windows, doors and skylights. WDMA's members' products provide these societal needs, and thus windows, doors, and skylights should be deemed necessary for the functioning of society and receive a CUU determination.

A balanced approach is necessary, even with legislation aimed at safety. MPCA should focus criteria on other equally critical needs satisfied by the products at issue. For example, during the COVID-19 pandemic, many manufacturers, like WDMA's members, were deemed essential workers critical to the functioning of society. Those same considerations that were used to draw lines during COVID safety protocol can guide the MPCA here. WDMA's members were critical workers during the pandemic for the same reason that their products are necessary for the functioning of society.

Here, there a number of critical needs and policy objectives aided by the window and door products containing PFAS. For example, the use of PFAS increases durability, and durable products inherently generate less waste, aiding sustainability efforts. Many of our member companies have product warranties of ten years or longer. PFAS removes friction points in WDMA's members' products because PFAS lowers the necessary operating force. This is more than a marketing pitch. The ease with which individuals can operate their home furnishings like windows, doors, and skylights allows disabled and aging Minnesotans to vibrantly remain independent and in their homes. For this segment of the community, PFAS continues to provide autonomy. Removing their options from the market may have a disparate impact on disabled and aging populations.

Further, in the state of Minnesota, adherence to specific performance and energy standards for windows, doors, and skylights is mandated by the Minnesota State Building Codes. These regulations are in place to ensure that Minnesota's commercial and residential buildings meet rigorous criteria for energy efficiency, sustainability, and performance standards. The Minnesota State Building Codes are based on national model codes developed by the International Code Council (ICC) and the American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE). The codes provide specific criteria for the design, energy-efficiency and installation of windows, doors and skylights to ensure they meet safety and functionality standards.

Windows, doors, and skylights play a pivotal role in the overall thermal performance of structures, influencing heating, cooling, and lighting demands. The energy codes stipulate stringent requirements for factors such as U-factor, solar heat gain, air tightness, and overall energy efficiency ratings. By establishing and enforcing these standards, the state aims to enhance energy conservation, reduce environmental impact, and promote the construction of buildings that contribute to the overall well-being of residents and the broader community in Minnesota. These are all criteria that MPCA should recognize as "essential for health, safety, or the functioning of society."

WDMA member companies manufacture products that contain thousands of various components that are essential for commercial and residential construction. There are many components that go into producing high-quality windows and doors to meet the energy and safety standards mandated by the state of Minnesota, including coatings and sealants that are integral for sealing out weather and protecting homes from harsh environmental conditions and serve to block dust, sound, and heat transmission. Prohibiting the use of PFAS in adhering to these standards will be immediately detrimental to the commercial and residential construction markets in Minnesota. Coatings and sealants that contain PFAS offer unique properties that enhance the performance of windows, doors and skylights that contribute to their durability, resistance to environmental elements, and overall performance.

For the reasons mentioned above, MPCA should determine that existing building safety and energy codes appropriately regulate windows, doors and skylights and that these products are "essential for health, safety, or the functioning of society."

2. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.**

WDMA assumes MPCA will accept representative samples similar to other environmental programs like ENERGY STAR. Products manufactured by WDMA members are highly customized with literally millions of product combinations due to size, shapes, wall depth, building construction type, glass package, material types and other considerations. The parts that go into such products accordingly vary. Because of customization, feasibly, WDMA members will seek hundreds of thousands of requests for CUU determinations. The massive number of product iterations will certainly cause a backlog to the MCPA and delay the ability of Minnesotans to purchase windows, doors, and skylights that are needed for home repair projects, remodeling, and larger scale residential and commercial developments.

MPCA should also recognize that windows, doors, and skylights achieve high-performance and energy efficiency standards mandated by the state of Minnesota using PFAS-containing components, such as coatings and sealants, that currently have no reasonable alternative. These components are essential to the overall performance of commercial and residential structures using window, door and skylight products that must meet various energy efficiency ratings. Window, door and skylight manufacturers will seek numerous CUU determinations for fenestration products that must adhere to rigorous standards mandated by the Minnesota State Building Codes.

3. **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

   Yes, the law expressly allows specific products or product categories to receive a CUU determination. WDMA believes this authority from lawmakers to exempt specific products and product categories is part of the necessary recognition that there are critical, essential services, like housing, that cannot be unduly burdened, despite the utility of the law. Further, the fact that the law disallows exemptions for the products listed in the statute underscores that exemptions for products or product categories is feasible and appropriate when the products are outside the ambit of human consumption.

   MPCA should prioritize CUU determinations for product categories that pose low risks to personal health, such as products that are disconnected from human ingestion, and that are not in constant and close contact with the human body. Compare windows, doors and skylights to the prohibited items listed in the law and it is apparent that our members' products do not belong. Windows, doors and skylights are not single-use products, and they are not ingested nor applied to human skin.

   The immediacy of the PFAS reporting requirements and the total ban on products with PFAS additives will severely and adversely impact the ability of our members to conduct business in the state of Minnesota and will have material consequences for both consumers and the commercial and residential construction industries that rely on our products. This warrants a CUU determination that exempts windows, doors and skylights with PFAS from being banned in Minnesota.

Thank you for your consideration of these comments. WDMA recognizes that there will be an obligation to report information on products containing PFAS beginning January 1, 2026. Our members are working diligently to comply with these obligations and look forward to being a collaborative partner with MPCA as these regulations are implemented. For any questions, please contact WDMA's Director of Government Affairs Jacob Carter at jcarter@wdma.com.

Sincerely,

Michael P. O'Brien, CAE

St. Paul, MN 55155-4194

Re: **<u>Georg Fischer Piping Systems Americas Comments on MPCA's Planned Rulemakings for PFAS-Containing Products</u>**

Dear Commissioner Kessler:

On behalf of Georg Fischer Piping Systems Americas, we write to offer comments on the proposed regulations on per- and polyfluoroalkyl substances (PFAS) being developed by the Minnesota Pollution Control Agency (MPCA or the Agency), as authorized in Minn. St. § 116.943 (Section 116.943). These comments discuss the MPCA's planned rules governing currently unavoidable use determinations about products containing PFAS.

Georg Fischer (GF) is a global corporation, founded in 1802, and headquartered in Switzerland, with a presence in more than 34 countries distributed across more than 80 facilities. GF employes over 15,000 employees worldwide and generated sales of 3,998 million CHF in 2022. GF is divided into three divisions, which includes its largest division, Piping Systems.
GF Piping Systems Americas (GFPS) is a leading provider of high-quality piping system products. GFPS employes approximately 2250 employees and has sales of $750 Million. GFPS Americas serves a wide range of industries and applications including Data Centers, Microelectronics, Life Sciences, Food and Beverage, Water & Gas Distribution, Water Treatment, Energy, Chemical Processing, Mining, Agriculture, Aquaculture and others.

GF globally is committed to sustainability and considers this to be an essential pillar of its business framework. GF was recognized by the Wall Street Journal (2020) as the 9th most sustainable company, lending credence to our commitment to our sustainability practices Swiss ingenuity and responsible business processes. While GF supports the goal of limiting the release of PFAS into the environment and reducing Minnesotans' exposure to PFAS, we are concerned about the potential scope and reach of these regulations as well as their incompatibility with the Minnesota's own economic interests.

GFPS does not sell direct-to-consumer based products, as our primary focus is on industrial users, most of which produce products that do not contain PFAS. We believe it is important for MPCA to understand that a prohibition of our broad prohibition of PFAS will impact many industries, including:

- Semiconductor and microelectronics manufacturing
- Industrial chemical processing
- Energy production and energy-related applications
- Marine
- Mining

- Drinking water and wastewater treatment
- Food and beverage production
- Pharmaceutical manufacturing
- Life science industries

Accordingly, GFPS would like to offer its recommendations below to help inform future rule drafting in a way that would avoid negatively impacting the quality of life and the economic prospects of Minnesotans.

1. FLUOROPOLYMERS ARE UNIQUE AMONG PFAS

GFPS must stress that fluoropolymers as a class of substances are significantly different than other PFAS. The lack of such differentiation in Minn. St. § 116.943 is misguided as it will ban substances simply for their similarity to some substances that have been shown to pose a risk to human health and the environment. Although we would prefer to see a full exemption of fluoropolymers from the ban on PFAS in products, we hope that at the very least MPCA will consider the tremendous difference between fluoropolymers and other PFAS when evaluating CUU designations.

Fluoropolymers (covering fluoroplastics such as PVDF, ECTFE, FEP, PFA, PTFE, etc., as well as fluoroelastomers, such as FKM, FFKM, etc.) have unique properties that distinguish them from other PFASs, and they do not have the same environmental and toxicological profiles associated with some substances in this class of chemicals that are of concern.

Fluoropolymers are durable, stable, and mechanically strong in harsh conditions in a variety of sectors including but not limited to automotive, aerospace, chemical processing, environmental controls, energy production and storage, and electronics. They are also stable in air, water, sunlight, chemicals, and microbes, and chemically inert, meeting the requirements for low levels of contaminants and particulates in manufacturing environments critical for the food and beverage, pharmaceutical, medical, and semiconductor industries.

Finally, fluoropolymers are biocompatible, non-wetting, non-stick, and highly resistant to temperature, fire, and weather. These unique characteristics make them a critical material for a broad range of industries and sectors, playing a diverse and crucial role for society, with few, if any, viable alternatives, and making them essential in numerous technologies, industrial processes, and everyday products.

Beyond their socio-economic value for industry, their unique stability means that they are low-risk polymers for human health and their environment.[1,2] Trying to replace them in their many applications would lead to substitution with alternatives (when available) that do not provide the same advanced performance and safety as fluoropolymers. Furthermore, any alternative that may be suggested to replace fluoropolymers will need to perform at least at some degree (even if at lower levels) of chemical

---

Integr Environ Assess Manag, https://doi.org/10.1002/ieam.4646.

and temperature resistance, which means that such alternatives will likely be persistent materials like fluoropolymers.

Since fluoropolymers are different from the other families of PFAS, there is no scientific, economic, or social basis to justify regulating them in the same way as all other PFAS. We hope that MPCA will consider these facts in their CUU determinations, as well as in future rulemaking.

2. WITHOUT CAREFUL DRAFTING, THE RULES WILL DAMAGE CRITICAL INDUSTRIES AND THE HIGH-TECH ECONOMY

a. Fluoropolymers are Essential to the Semiconductor Industry

Below we provide an example of the importance of fluoropolymers to just one of the industries we serve, semiconductor manufacturing. A similar case can be made for each of the industries in which our products are used, and we look forward to an opportunity to do so in the future with more detail.

Fluoropolymers (FPs) are essential to the semiconductor industry because of their low surface tension, high heat and chemical resistance, high thermal stability, radiation stability, electrical characteristics, compatibility with other chemicals, and other unique properties. These properties enable FPs to fulfill the purity criteria required for semiconductor manufacturing. FPs are used by the industry to meet many needs within the manufacturing process and can be found in various equipment, materials, and other critical components, including in the following:

- Control and distribution systems (pipes, pumps, valves, etc.)
- Various components in a wide range of processing tools and sensors
- Ancillary articles (such as tubing, gaskets, containers, and filters)
- Facility systems in semiconductor manufacturing factories such as water and chemical distribution, waste removal systems, and exhaust systems

In short, the semiconductor manufacturing process is enormously dependent on fluoropolymers, the majority of which currently have no viable alternatives. In fact, GFPS sells a large variety of non-fluoropolymer materials, both in this application and elsewhere. Typically, products and solutions containing PFAS are being used for their performance characteristics in order to satisfy industry requirements. Our experience is that the industry requirements drive the choice of material rather than cost, as non-PFAS alternatives are generally less costly.

3. RESPONSES TO QUESTIONS FROM MPCA REGARDING CUU DETERMINATION PROCESS

i. Should criteria be defined for “essential for health, safety, or the functioning of society”? If so, what should those criteria be?

GFPS suggests that the MPCA should promulgate objective standards regarding the determination of whether uses of PFAS in products are currently unavoidable and that such standards should interpreted flexibly and broadly. We are providing the following background information on uses of PFAS in our products that we believe is currently unavoidable and “essential to health, safety, and the functioning of society” in the hopes that it will help inform MPCA’s decision making as to what these terms should include.

Fluoropolymers in GFPS products are primarily in industrial applications including semiconductor manufacturing, life sciences, pharmaceuticals, and chemical manufacturing. These products are not end-use articles sold to consumers, but rather components used in large, complex industrial systems. As previously stated, the use of products containing PFAS is generally driven by industry and process requirements. In many cases the use of non-PFAS known alternatives may be available but would result in lower performance capabilities, for example, more frequent maintenance requirements. Increased maintenance frequency could result in more frequent exposure to other chemicals and hazardous conditions as well as an increase in the risk of unintended releases of dangerous chemicals in the environment. The performance capabilities of our fluoropolymer-based products is a large part of why our customers choose these materials, as they have the proper functional characteristics to ensure safer, long-term operation.

In the case of semiconductor manufacturing, the impact of a PFAS ban on the semiconductor industry cannot be overstated, as semiconductors simply cannot be made without PFAS materials. The devices are made with the help of our products are used in computers, data centers, mobile phones, automobiles (300 to 1000 per vehicle), aerospace (airplane components), process control systems, medical devices (pacemakers, insulin pumps), to name just a few applications. Our society has come to be dependent on these items in our daily lives, and it is quite clear that they are essential to health, safety, and the functioning of society. We hope that this example illustrates to MPCA the importance of ensuring that all products and process required in the supply chain to produce “essential” end products are also deemed “essential” themselves.

ii. Should costs of PFAS alternatives be considered in the definition of “reasonably available”? What is a “reasonable” cost threshold?

In the case of GFPS products, PFAS-based materials are not used because of cost but for their functionality. In fact, PFAS materials are far more expensive than currently available non-PFAS potential alternatives (which don’t have the same functionality). Current “alternatives” would at best significantly reduce service life and production yield, in situations where they are usable at all.

Besides simply comparing costs, potential alternatives must be commercially available and demonstrated to be usable in practice, beyond theoretical and academic assertions that they exist.

To provide a specific example, a valve used in a sulfuric acid peroxide mixture should use FFKM o-rings. FKM o-rings will work to some extent, but they will have a much shorter service life (< 6 months vs > 3 years for FFKM). The FFKM version of this product is 10X the cost of FKM, ($25.00 vs $2.5) yet customers still use FFKM to ensure system uptime and product quality.

Another example is the use of stainless steel pipes in lithium mining operations. PVDF pipes cost 10X as much as stainless steel, but last >5 years, compared to 6 months for steel pipes. In this case, the cost is measured in up-time, replacement costs, and reduced maintenance versus simply material costs. This

DocuSign Envelope ID: 99E74F43-753D-4403-B2E0-082034FF25BC

example should also serve to illustrate the environmental ramifications of banning such long-lived materials, requiring alternatives that must constantly be manufactured and disposed of.

iii. Should unique considerations be made for small businesses with regards to economic feasibility?

Yes. The cost to develop alternatives is beyond the ability of small businesses to absorb. Even if a larger company could provide a new material, it would take significant effort to test and qualify a new material in a component (article). Most small businesses are not equipped to do this testing, nor can they afford to have it done. For example, testing the impact on a process would require having at least a pilot scale process available, which is not practical for most small businesses.

iv. What criteria should be used to determine the safety of potential PFAS alternatives?

It is difficult to recommend criteria for hazard evaluations of potential alternatives when no such criteria have been applied to the PFAS substance(s) being banned. In the case of fluoropolymers, significant evidence (discussed in section 1 of this document) exists that indicates they are "polymers of low concern" in terms of their risk to human health or the environment. If such substances are to be prohibited, certainly their alternatives must demonstrate extraordinary safety profiles.

Additionally, evaluation of the safety of potential alternatives should not only consider their toxicological profile as a substance, but also the safety impact of replacing currently used substances with said alternative. For example, hydrofluoric acid (HF), which is essential to the semiconductor manufacturing process, is highly hazardous to workers. If the materials used to handle HF are substituted with less resistant/shorter service-life alternatives that must be frequently replaced, the resulting increase in worker exposure to HF will have a tremendous negative impact on worker safety.

v. How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

Arbitrary timeframes for CUU determinations do not reflect the reality of research and development time necessary to identify and commercialize an alternative material. For applications such as ski wax or raincoats, a new material can be identified and produced to fill the need for PFAS-based products relatively quickly.

However, for applications that require extreme precision, such as semiconductor manufacturing, or those that have significant safety implications like aerospace components, simply declaring that in 15 years an alternative substance must be used does not manifest such a material into existence.

Additionally, even in the best case where alternatives are rapidly identified or developed, qualification and commercialization of new substances in such fields can easily take a decade itself. For example, the

DocuSign Envelope ID: 99E74F43-753D-4403-B2E0-082034FF25BC

semiconductor manufacturing process consists of nearly 1400 steps, with each having a number of variables that can impact the entire process. Evaluating the impact of a potential new material on this entire process requires controlled, step-by-step experimentation that takes years to conduct.

Rather than providing a suggesting for arbitrary timeframes for CUU determinations, we recommend the following: Uses of PFAS determined to be currently unavoidable should not be prohibited until a commercially viable alternative has been demonstrated to exist.

vi. How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA?

Of the approximately 100,000 unique product numbers that GF offers, we sell approximately 5000 unique PFAS-containing or entirely PFAS-based products. To provide an example, for PVDF piping systems, we offer 16 different sizes of product with 9 of those having 2 designs, resulting in 25 different product categories. Each of these ranges has about 50 different components, meaning that we offer 1250 products simply for piping systems made from this one material alone. For this reason, we believe that MPCA should group such products by broad use categories, rather than evaluating CUU proposals by individual materials/products.

Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?

If so, they should be required to demonstrate that either a practical, commercialized alternative exists on the market, or that the use does not benefit health, safety, or the functioning of society.

vii. In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

Our company sells piping systems that consist of pipes, fittings, valves, seals, gaskets, and sensors. There is tremendous variety in the sizes, shapes, and configurations of these systems based on the needs of individual customers. However, all of the PFAS-containing products we sell fall under these categories, and they are all made from fluoropolymers, including PVDF, ECTFE, FKM, FFKM, and PTFE.

GF intends to seek currently unavoidable use determinations for all of its products containing PFAS. As stated above, even where we have non-PFAS products available, these products do not necessarily constitute a commercially feasible alternative for our customers.

Our products are relatively similar across industries, but their applications are highly diverse. The following table presents most of the industry sectors for which we intend to seek CUU designations and their specific sub-uses.

Industrial Sector	Specific Application
Energy	Production of green hydrogen by electrolysis
	Automobile battery production Metal working/Steel manufacturing Chlor-alkali electrolysis Gasoline
	Cleaning and etching of metal surfaces Purifying metals Rocket fuel
	Metal pickling Glass etching and cleaning Oil refining Uranium fuel production for nuclear reactors
	Fracking process Oil production Metal pickling
Chemical processing	Chlor-alkali electrolysis Intermediates for fertilizers Gasoline Paper bleaching Cellulose fibers Coloring agents Sulfonation agents Amino acid intermediates
	Fertilizer production Organic dyes and lacquers Fungicides Household cleaning products
	Steel pickling Leather tanning process Manufacturing of PVC Production of household cleaners

INTERNAL

Microelectronics	Manufacture of semiconductor wafers, flat panel displays, and solar photovoltaic cells: -Production/transport of ultrapure water -Handling sulfuric acid/hydrogen peroxide solution
	Microelectronics industry: - to clean photoresist or organic material residue from silicon wafers - wet etching of wafers in the semiconductor fabrication process.
Drinking- and industrial waste water treatment	Drinking water treatment plants Large disinfection plants for industrial wastewater Disinfection plants for public infrastructure (hospitals, hotels, schools, swimming pools, ships, etc.)
Food & beverage	Primary, secondary and tertiary food processing Beverage manufacture and transport
	Additive dosing for food industry Salt purification Bleaching agent handling
Pharmaceuticals	Reverse osmosis (RO/DI) water
	Production of pharmaceuticals
	Synthesis of chemical active ingredients of API drugs Virucide Fungicide
	Production of pharmaceuticals
Life Science	Reverse osmosis (RO/DI) water
	Handling Laboratory Waste

viii. Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

Georg Fischer requests that MPCA make a currently unavoidable use designation for all industrial uses of fluoropolymer materials and systems in the manufacturing processes and supply chains of semiconductor manufacturing, energy industry, water treatment, agriculture/aquaculture, industrial chemical processing, food and beverage production, mining, marine, pharmaceutical manufacture, life sciences, and other more niche markets. Until MPCA has the time and resources to fully evaluate and understand the complex value chains and processes that make up these sectors, industrial uses of fluoropolymers therein should be considered currently unavoidable.

4. COMMENTS ON FACILITATING PRODUCTIVE ENGAGEMENT WITH INDUSTRY

Georg Fischer appreciates MPCA's proactive outreach to the regulated community in advance of issuing draft rules and encourages the agency to maintain this approach going forward. Engaging interested stakeholders from the early stages of the rulemaking process through listening sessions, webinars, and other venues will afford them the opportunity to inform the MPCA's rulemaking activities in a way that empowers the agency to meet its regulatory mandates while more effectively ensuring the long-term viability and competitiveness of the affected industries.

Building on these early-stage engagement activities, Georg Fischer recommends that the MPCA institutionalize the communication stream between itself and its regulated industries. One way to accomplish this would be through the creation of a workgroup, comprised of stakeholder representatives, which would inform the drafting and implementation of the planned rules, further examine affected products, and identify ways to ease administrative burdens without sacrificing the public health and environmental imperatives that prompted passage of Section 116.943 in the first place.

5. CONCLUSION

GFPS is committed to balancing the need for environmental protection and the sustainability of all the industries and applications referenced in this document. GFPS supports the responsible use of these materials in applications where the specific material characteristics are required. We welcome the opportunity to engage with MPCA to better explain the critical role that these substances have in the sectors and industries our company serves.

GFPS is grateful for the opportunity to engage with MPCA on planned rulemakings and is available to meet at your convenience to further elaborate on the issues discussed in these comments. If you have any questions or would like to discuss our positions, please do not hesitate to contact us.

Sincerely,

LEECH LAKE BAND OF OJIBWE
DIVISION OF RESOURCE MANAGEMENT

Via Web Submission:
Katrina Kessler
Commissioner, Minnesota Pollution Control Agency
520 Lafayette Road N St. Paul, MN 55155-4194

March 1, 2024

RE: Proposed New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS), Revisor's ID Number R-4837

OAH Docket No. 71-9003-39667

Dear Commissioner Kessler,

As a sovereign Tribal government located in Northern Minnesota, the Leech Lake Band of Ojibwe (LLBO) is taking this opportunity to comment on proposed new rules governing how MPCA determines Currently Unavoidable Uses of PFAS. This proposed rule, and the legislation which has prompted its creation, is of great importance to the Leech Lake Band of Ojibwe.

The continued production, use, and distribution of PFAS are an immediate and grave threat to the Leech Lake Band of Ojibwe, our treaty-guaranteed rights to hunt, fish, and gather, our lifeways, and our health, and the health of the environment and all people. PFAS have been found in the drinking water of our Tribal school, in our lakes, and in the fish we eat, and are surely present and continue to be introduced to other parts of the environment we have not yet analyzed. As long as PFAS continue to be manufactured and used, our bodies and environment will continue to be poisoned for decades to come.

The PFAS contamination present on our Reservation is the result of countless small sources, such as airborne deposition, product wear, and improper disposal of small quantities of household waste containing PFAS. There are no manufacturers or other facilities using, producing, or discharging PFAS within the Reservation. The uses this rule will allow are the very reason that Leech Lake Reservation is contaminated by PFAS today, and how it will continue to be polluted.

This proposed rule will outline the means of determining which products will continue to be sold with PFAS "intentionally added" to them. For the purposes of this rule, the terms "intentionally added," "product," and "product component" should be understood as broadly as possible in order to limit the use of PFAS to essential uses only. Contamination of water or soil by PFAS is harmful to human health at extremely low levels, and the intentional use of manufacturing, storage, or distribution processes which may introduce any amount of PFAS to a product, such as material transfer by Teflon (PTFE) coated hoses, will contribute PFAS compounds to products.

The below paragraphs will address the bolded questions MPCA requested:

Should criteria be defined for “essential for health, safety, or the functioning of society”? If so, what should those criteria be?

The phrase “essential for health, safety, or the functioning of society” should be narrowly defined to ensure that PFAS is only used when it is actually essential. Defining “essential” to include uses of PFAS intended to reduce maintenance, lengthen product life, or provide other perceived benefits when ANY alternative exists would be a mistake. Claims that a use of PFAS is “essential for health, safety, or the functioning of society” should be weighed against the value of clean air, water, and food for “health, safety, or the functioning of society.”

Should costs of PFAS alternatives be considered in the definition of “reasonably available”?

The cost of PFAS alternatives should not be considered when defining “reasonably available.” The harms caused by PFAS to the environment and human health, and the associated costs with remediating PFAS contamination, in the cases it is possible, are so great that any cost increase from a safe PFAS alternative will be cheaper than continuing to pollute our environment and ourselves.

Should unique considerations be made for small businesses with regards to economic feasibility?

Small businesses should not be given unique considerations, as any accounting of continued PFAS use which considers the negative externalities borne by society would show PFAS are never economically feasible. Additionally, because small businesses are the majority of businesses, such an exception would dramatically increase the allowed future PFAS pollution.

What criteria should be used to determine the safety of potential PFAS alternatives?

The safety of PFAS alternatives should be determined prior to their introduction to the market and use. Criteria to be considered should be their effects on human health and the environment, the ability of alternatives to disperse in the environment, and how readily they can be removed from the environment if they are found to be harmful in the future. Any safety determination should also consider by-products created during the production of alternatives and any product decomposition.

How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?

Currently unavoidable use determinations for PFAS should be valid for a period of one (1) year. If MPCA chooses to set a longer period for currently unavoidable use determinations, the period should be as short as possible, and should absolutely be no longer than three (3) years. A short determination period will ensure that the determinations are actually current and will encourage the competition and development of PFAS alternatives and research of PFAS. Any significant changes in available information about alternatives and/or new impacts should trigger a re-evaluation of currently unavoidable use determinations.

What information should be submitted in support of currently unavoidable use determination requests?

Requests to determine a PFAS use as currently unavoidable should include all potential alternatives, and should include a “no use” alternative. For example, an application describing the use of a PFAS coating in a nozzle to prevent clogging would be required to include a “no use” alternative in which the nozzle is mechanically cleaned or an alternative coating is used. Members of the public should also be able to request a currently unavoidable use determination be denied or revoked based on new information or technology. Manufacturer applications for a currently unavoidable use determination should include the specific PFAS(s) to be used, the environmental fate of the PFAS, estimated amount of PFAS to be used/sold during the reporting period, known environmental and health effects of specific PFAS, specific use of PFAS in the product, and justification of need for that specific product.

Should currently unavoidable use determinations be made for individual products or for product categories?

Currently unavoidable use determinations should only be made for specific products. The review period for all determinations based on product category must be shorter than for individual products. If entire categories of products are determined to have currently unavoidable uses of PFAS, the state will be giving free rein to industry to continue using these toxic chemicals without pressure to identify and implement alternatives.

Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?

No initial determinations of currently unavoidable use should be made as part of this rulemaking. If MPCA makes currently unavoidable use determinations as part of this rulemaking, that will greatly undermine the market incentives and pressure on industry to develop and implement safe alternatives.

Our environment and our bodies are being already being harmed by PFAS. Continued use of PFAS-containing products will exponentially increase this harm. Any exceptions to Minnesota's ban on the continued use of PFAS should be for the rare circumstances where their use is truly unavoidable and there is a genuine need for that specific product and use and that use can be measured and limited. If **any** PFAS alternative exists for a specific use or product, MPCA should determine that the use is **avoidable**.

LLBO would like to thank MPCA for the review and consideration of our comments on the Proposed New Rules Governing Currently Unavoidable Use Determinations about Products Containing Per-and polyfluoroalkyl substances (PFAS) (Revisor's ID Number R-4837) and would like to reemphasize that coordination between MPCA and Tribes is paramount in achieving sound environmental policy and should be as extensive as necessary to address issues of concern that exist among all involved parties. We look forward to continued communication on this important matter and the inclusion of our input in the proposed rule.

If you have any questions or require clarification please do not hesitate to contact my Deputy, Craig Tangren, at (218) 335-7429 or at craig.tangren@llojibwe.net.

Regards,

Brandy Toft (Mar 1, 2024 14:55 CST)

Appendix 1

Functions of PFAS, the uses and substitutions of Specialist Equipment

Appendix 1-1 The characteristics and functions of PFAS

This document is the appendix 1 of the general comment to the Restriction report on Per- and polyfluoroalkyl substances (PFAS) from

Japan Electric Measuring Instruments Manufacturers' Association (JEMIMA)

submitted on February 29, 2024

Table of content

The characteristics and functions of PFAS

Summary

PFASs have many functions. The characteristics and functions of PFAS which are mainly used in Specialist equipment are described in this section.

PFAS has excellent properties such as, chemical resistance, electric insulation, heat resistance, repellency from water and oil, non-adhesion, weatherability, and others. PFASs are used where multiple of these properties are required simultaneously. We recognize that the ability to provide these various properties in a single material is the most important property of PFAS, and at present we do not have information on any other substance with this function other than PFAS.

Excellent: 30 days of constant exposure causes no damage. Plastic may tolerate for 30 years.
Good: Little or no damage after 30 days of constant exposure for the regent
Fair: Some effect after 7 days of constant exposure to the reagent. The effect may be crazing, cracking, loss of strength or discoloration.
Not recommended: Immediate damage may occur. Depending on the plastic, the effect may be severe crazing, cracking, loss of strength or dis coloration, deformation, dissolution or permeation loss.

"Cleanliness" is defined as the fact that fluoropolymers are not easily eluted by acids, alkalis, or solvents (chemical resistance), do not contain other materials such as plasticizers in the molding process, and do not contain products that would thermally decompose during the material molding process.

Ozone resistance

Ozone is known to degrade plastic materials in two ways:

A: Substances with double bonds (C=C) in their structures (such as natural rubber, chloroprene rubber, butadiene rubber, etc.) undergo decomposition in which ozone reacts with the double bonds to produce ketones, when they come into contact with ozone.

B: When ozone exists in water, peroxy radicals are generated. Non-fluorine materials (eg polyethylene, polypropylene, etc.) deteriorate even if they do not have double bonds.

Fluoropolymers does not have decomposition pathways such as A and B even if it comes into contact with ozone, so it can be used for a long time without deterioration.

Table 3 Comparison of ozone resistance properties of plastics

Repellency from water and oil / non-adhesion

Since the fluoropolymers have a small polarizability, the intermolecular force is small. Because of its characteristics, fluoropolymers have repellency and non-adhere properties on the surface. In general, the repellency from various liquids is evaluated by the contact angle, and the larger the contact angle, the higher the repellency.

Contact angle θ

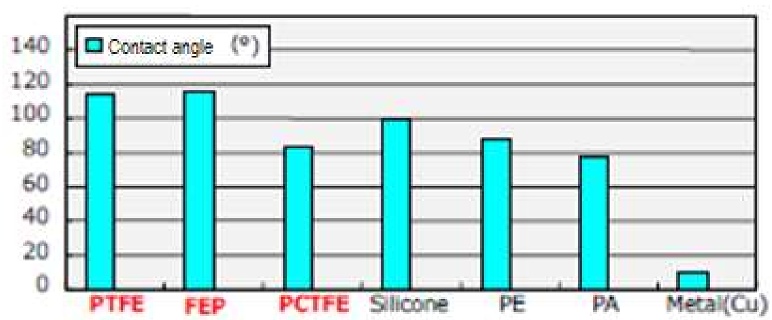

Figure 1 Contact angles with water

Adhesion energy refers to the amount of work required to pull a liquid contacting a solid away from the solid. The larger the contact angle, the smaller the adhesion energy. It means that a liquid in contact with a small adhesion energy solid easy to separate from the solid.[2]

Material name	Contact angle with water (°)	Adhesion energy (dyn/cm)
PTFE	114	43.1
FEP	115	42.0
Silicone resin	90~110	47.8~72.7

Phenolic resin	60	109.0
Copper(electropolishing)	9.6	144.2
Aluminium(electropolishing)	4.6	145.0

Table 4 Surface properties of various plastics and metals

This characteristic is sometimes called "mold releasability". It can also be expressed as antifouling because it does not easy to adhere.

Heat resistance

Fluoropolymers have high heat resistance as follows. They have higher heat resistance compared to other general-use resins

	Fluoropolymers						Other general-use resins	
Heat resistance : maximum operating temperature (C)	PTFE	PFA	FEP	ETFE	PCTFA	PVdF	PP	PVC
	260	260	205	150	120	120	100	60

Table 5 The heat resistance of Fluoropolymer [3]

Electric insulation

When the dielectric constant is low, the insulation in electrical components can be made thinner, leading to downsizing and weight reduction of the equipment. In applications where downsizing and weight reduction are necessary, it is an essential feature

Table 6　The dielectric constants of various resins

Low friction, self lubrication

Friction coefficient of fluorine resin is lower than that of other resins. It is because polarizability (Mobility of electrons in an electric field) of C-F bonding is low (0.68) and the intermolecular force is weak. (Reference: polarizability of C-Cl bonding is 2.59) [4]

Types of plastic	Plastic / Plastic	Plastic / Steel	Steel / Plastic
PTFE	0.04	0.04	0.10
PE	0.10	0.15	0.20
PS	0.50 *)	0.30	0.35
PMMA	0.80 *)	0.50 *)	0.45 *)

*) indicates occurrence of stick-slip motion.
Measurement condition: Bowden-Laden type measurement equipment, load: 9.8-39.2N, sliding speed: 0.01cm/s
Plastic/Steel indicates sample material/pin material
PE: polyethylene PS: polystyrene PMMA: polymethylmethacrylate

Table 7　Comparison of friction coefficient among PTFE and other materials[5]

As an example of low friction, Table8 shows friction coefficient of PTFE.

Type	ASTM test method	Measurement condition		Unit	PFA	PTEF	FEP
Coefficient of static friction	-	Against polished steel		-	0.05	0.02	0.05

Table 8 Comparison of static friction coefficient among PFA, PTFE and FEP[6]

One of the characteristics related to friction is “self lubrication”. The molecules of PTFE separate from molding of PTFE due to friction. The molecules in crystals of PTFE separate easily because intermolecular forces are weak. PTFE moves and attaches to the friction mating surface and generates friction between them. It lowers friction coefficient. [7]

Low refractive index

Amorphous fluoropolymer resin has high transmittance. This is utilized for optical components and optical fibres.

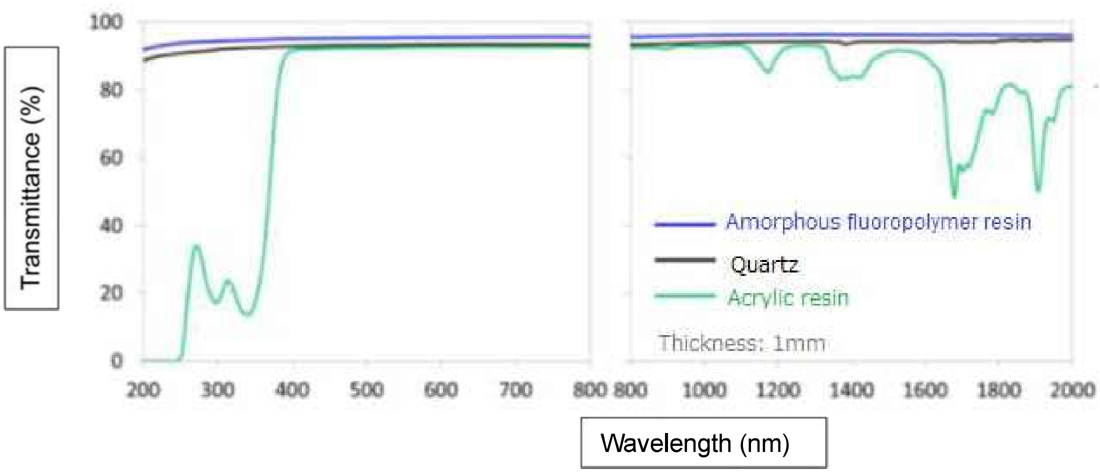

Figure 3 Comparison of transmittance

Weatherability

Fluoropolymer resin has high weatherability and can be used outdoors. It does not react to sunlight such as ultraviolet rays. It is not susceptible to oxidizing effects of atmospheric oxygen and other substances (see "chemical resistance"). It can be used in a wide temperature range from low to high (see "heat resistance"). It has high water repellency and does not absorb water, so it is not affected by humidity changes. It can be said that fluoropolymer resin has high weather resistance because it has the above points.

Durability

It means that it can be used for a long time. Due to its high chemical resistance and high weatherability, PFAS can achieve high durability.

Resistance to creep / Compression set

When a constant load is applied to a polymeric material, creep occurs, in which deformation progresses over time. Similarly, compression set occurs where the deformation does not recover when the force is removed. Both properties are known to be correlated. When rubber materials are used in elastic applications such as packings or diaphragms, it is required to minimize the effects of both properties.

Experimental examples of "30% creep time (Hour)" for major rubber materials are shown below. Creep is known to be worse at higher temperatures, Experiments have shown that FKM and silicon exhibit good properties.

	50 degree Celsius	70 degree Celsius	100 degree Celsius	120 degree Celsius	150 degree Celsius
NR	190	103	3.8	—	—
SBR	1250	203	14	—	—
CR	4200	550	45	7.4	—
NBR	3900	380	41	12.2	—
IIR	—	—	2.7	—	—
FKM	—	—	1650	305	180
Silicon	—	—	—	1550	190

Table 13

Quoted from the journal of “the Society of Rubber Science and Technology, Japan”, 1960(Vol33), P882-892, “Stress relaxation and creep properties of various vulcanized rubbers”.

Examples of compression set test results are shown below. In general, it is difficult to quantitatively compare materials because the measured values differ depending on the compounding and hardness of the rubber. Here, the compression set of the materials was compared by comparing the minimum value of each material in the database. FKM and silicon showed relatively good properties, showing the same tendency as creep.

	Compression set JISK6301 100 degree Celsius×70h
NR	—
SBR	Min 20%
CR	Min 23%
NBR	Min 9%
IIR	—
EPDM	Min 23%
FKM	Min 11%
Silicon	Min 6%

Table 14

The minimum value of each material was quoted from the data described in "Material Database / Organic Materials" (1989), The Nikkan Kogyo Shimbun”.

Appendix 1

Functions of PFAS, the uses and substitutions of Specialist Equipment

Appendix 1-2　Uses of PFAS in Specialist Equipment

This document is the appendix 1 of the general comment to the Restriction report on Per- and polyfluoroalkyl substances (PFAS) from

Japan Electric Measuring Instruments Manufacturers' Association (JEMIMA)

submitted on February 29, 2024

Table of content

Uses of PFAS in Specialist Equipment

Summary

PFAS are a very important group of substances for Specialist Equipment, which depends on these uses to maintain safety, as they are highly effective in chemical resistance, Repellency from water and oil, and electric insulation.

PFAS polymer resins are two to ten times more expensive than other commodity plastics. There is no use other than where the equipment does not work without the use of PFAS.

General electronics components are not covered in this document. However, since our equipment also uses common electronic circuit parts, we also use parts common to information equipment and general consumer EEE. For usage and non-substitutable information for such parts, please refer to Japan 4EE Input to Submission Requirements on Currently Unavoidable Uses (CUUs) under Maine law 38 M.R.S. §1614. Semiconductors are also used in our products. Many PFASs are used in semiconductors and semiconductor manufacturing equipment. Comments on most of the items in this section have been submitted by industry associations that specialize in the respective items. We hope that dossier submitters consider the manufacturer's opinions.

In this chapter, the use of PFAS in components and materials are explained. Then the some examples of the uses follows. These examples are not exhaustive.

Electric wires and insulation

An electric wire is a linear member for transmitting electricity. Metal, which is a good conductor, is used for the part that transmits electricity, and plastic resin that has electric insulation is used around the wire in order to block the influence on anything other than the transmission destination of electricity.

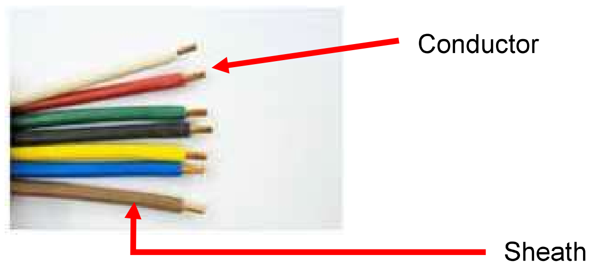

Figure 1

Polyvinyl chloride is generally used for covering parts where plastic resin is used, which is called as sheath, but PTFE, PFA, FTPE, etc. are selected depending on the suitability of use and electric insulation requirements. Since these are more expensive than polyvinyl chloride, they are used only when it is difficult to use other materials such as polyvinyl chloride.

PFAS functions required by PFAS wires and availability of alternatives.

Wires using PFAS for coating have high electrical insulation when the coating is thin (100 μm or less). PFAS also has a high heat resistance of 150-200°C. In addition, PFAS wires can be used even when there are chemicals around the device because PFAS has chemical resistance.

Examples of devices equipped with electric wire and insulation

<u>Cables for Sapphire Capacitance Diaphragm Gauge</u>

The components use electric insulation with PFAS.

・Temperature sensor for control

・Heater board connection cable and thermistor

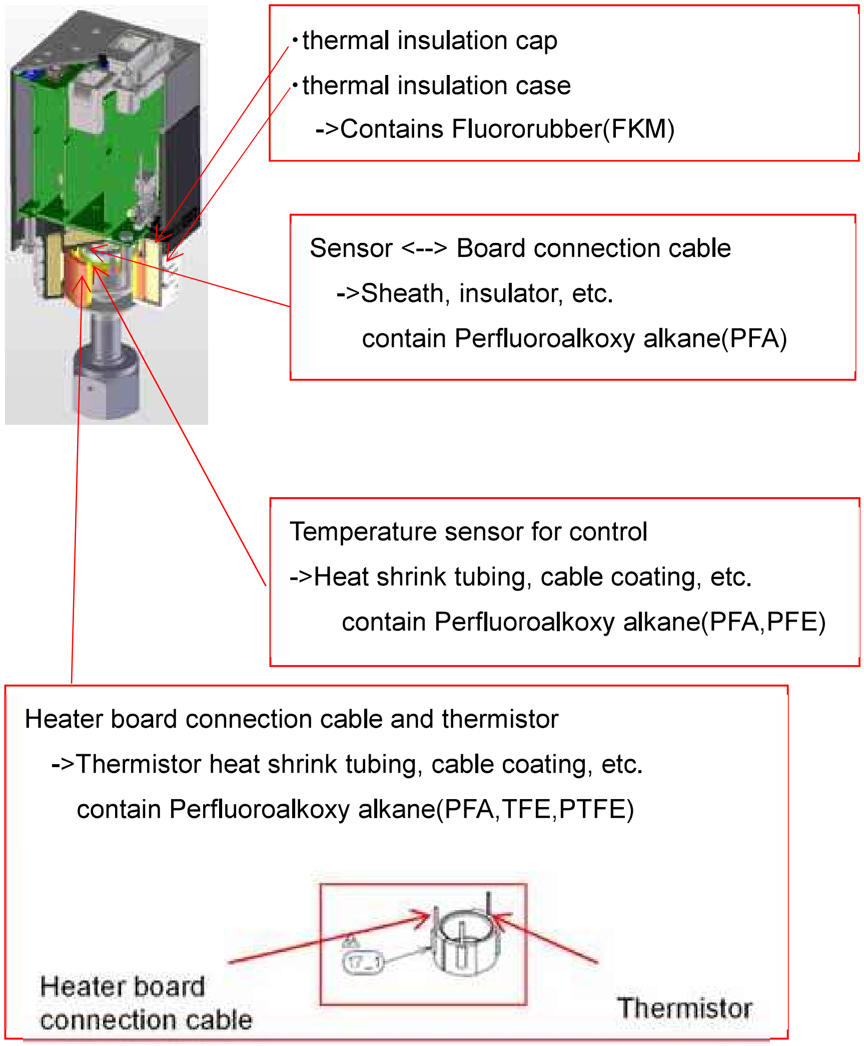

Figure 2

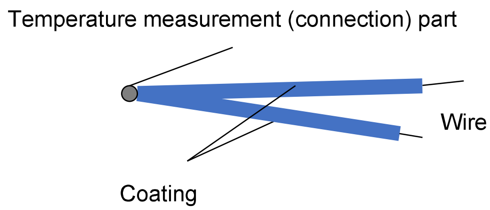
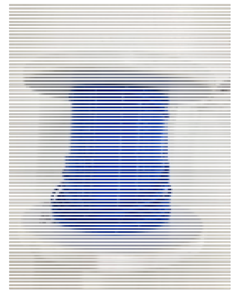
There is no fluorine-free material with equivalent heat resistance.

<u>Temperature sensor (thermocouple)</u>

A thermocouple is a temperature sensor that measures using the principle that a thermoelectromotive force is generated by connecting the tip of a metal wire made of different materials and the temperature difference between the tip and the other end.

Temperature sensors can measure a wide range of objects, including acids, alkalis, and organic solvents, and can also measure a wide range of temperatures, including applications that measure chemicals at 100°C or higher. The thermocouple wires are coated with FEP and PFA to ensure accurate measurement without negative effects from chemicals or high temperatures. There is no material other than fluoropolymers that combines chemical resistance and heat resistance to realize such applications, and it is difficult to replace them.





Coated temperature sensor wire

Figure 3 thermocouple

Heat shrink tubing

By putting a thin and long object to be covered in a tube, heating it, and shrinking the tube, the object is covered. It prevents parts from coming off or falling off, and strengthens the covered part. Fluoropolymer resin heat-shrink tubing is thin but has high electric insulation performance. PTFE and PFA are used as fluoropolymer resins.

Functions of PFAS required by heat-shrinkable tubing and availability of alternatives

Fluoropolymer resin heat-shrink tubing is thin but has high electric insulation performance. It can be used in applications where there is not enough space for electric insulation, and there is no alternative material available for applications that require tight spaces.

Examples of the products which incorporate heat shrinking tubes

<u>Thermistor protection for Sapphire Capacitance Diaphragm Gauge</u>

Components corresponding to a heater operating temperature of MAX 250°C

For the picture of this products, please see the explanation in electric wires and insulation.

Fluoropolymer resin is used in the heat-shrinkable tube to protect the thermistor

There is no fluorine-free material with equivalent heat resistance.

Sealing materials

Parts description

- Packings, gaskets, and O-rings

Packings and gaskets exist to connect and seal by placing/placing them between parts. As an example, they are used in piping and pipe connections. Gases and liquids that pass through pipes leak out through the smallest gaps, and packing gaskets exist to prevent this. Packing in the narrow sense is used for power system parts, and those used for non-moving parts are called gaskets. Various innovations have been made in molding and realizing functions, such as spiral

gaskets made of alternating layers of thin metal strips and PTFE sheets, and wrapped gaskets made of 0.4~0.8 mm hot PTFE, covering gaskets of metal or other materials.
Those with a circular/round cross section are called O-rings.
In addition to PTFE, fluoropolymer rubbers such as FKM and FFKM are also used for this application.

Figure 4 Packings, gaskets, O-rings

- Bearings

A bearing reduces friction between two parts to make movement smoother. Bearings are classified into radial bearings, thrust bearings, and linear bearings, depending on whether rotational or linear motion is involved. A bush is also a type of bearing.
Fluoropolymer bearings such as PTFE have a low coefficient of friction and can maintain a constant torque within various tolerances, while minimizing rattling and noise. In particular, PTFE must be used for bearings near chemical fluids such as acids, alkalis, organic solvents, and ozone, and for food contact applications, where oil is not preferred.

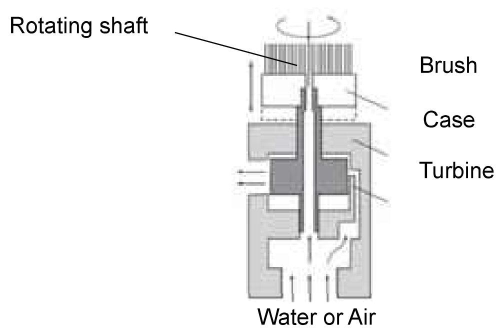


Figure 5 Bearing used for the rotating shaft sliding part of the sensor cleaning brush

- Sealing tape

Sealing tape, made of PTFE material, is an adhesive tape used to secure parts within equipment. It is employed to fasten parts that could pose safety risks if dislodged, as well as to seal mounting parts. Additionally, the tape serves as a filler to address gaps in the joints or connections of pipes for flowing liquids or gases, such as water pipes, air pipes, and hydraulic pipes. Notably, the tape can establish liquid- or gas-tight connections with tapered pipe threads by directly filling the voids between the threads.

Figure 6

The functions of sealing materials of PFAS and alternatives

Functions of PFAS Required by Sealing Materials and the Feasibility of Alternatives to PFAS

- Required Functions for Sealing Materials

Liquids and gases flowing in pipes, or near parts, often consist of strong acids, alkalis, or organic solvents. Therefore, the sealing materials used must be resistant to these chemicals. Fluoropolymer is highly resistant to such chemicals, and additionally, it is ozone-resistant, making it an ideal choice when ozone is present in the piping.

If the liquid or gas in the piping, or the equipment itself, operates at high temperatures, PTFE or PFA are good options due to their high heat resistance of up to 260°C, a limit higher than other resins. FFKM and FKM rubbers also exhibit high heat resistance, withstanding temperatures up to 250-300°C.

For applications where sealing materials, such as gaskets, are used on sliding surfaces, where lubricating oil is unsuitable (particularly in contact with food), or where play and noise must be avoided, sealing materials must also possess low friction and self-lubrication properties.

In the restriction report on seal tape, paste-like sealing materials are mentioned as alternative materials. However, if these sealing materials contain hydrocarbon substances, reactive functional groups may decompose. This could pose a risk of contamination in the surrounding area due to the produced decomposition products. For sealing tape used for equipment operating in clean environments, where such contamination is unacceptable, paste-like sealing materials cannot be used as alternatives.

As a sealing material that combines outstanding chemical resistance, ozone resistance, heat resistance, water and oil repellency, low friction, self-lubrication, and cleanliness, there is no substitute for fluoropolymers. The substitution of fluoropolymers with other materials poses a significant challenge. Non fluorine elastomers might be considered as potential replacements for fluorine rubbers like FKM rubber. However, their heat resistance, low friction, and chemical resistance do not measure up to those of fluorine-rubbers like FKM rubber. Therefore, substituting fluorine -rubbers with non-fluorine elastomers is unfeasible.

Examples of the products which uses sealing materials

Pressure Transmitter

Pressure transmitters are measuring instruments mainly used in factories and plants. It measures pressure for process fluids such as liquids, gases and steam and outputs analog or digital signals corresponding to the measurement results. It is also used to measure flow rate and liquid level based on measured pressure.

The process fluid to be measured has various characteristics such as temperature, pressure, and properties. If the sealing performance is not maintained, not only correct measurement results not be obtained, but the factory or plant may stop. In addition, if the process fluid is high temperature, extremely low temperature, or toxic or corrosive, the outflow of the fluid may cause great damage to the surrounding environment and workers, so the sealing performance is very important.

Many sealing materials that use PFAS materials have excellent heat resistance and chemical resistance, and it is considered difficult to replace them when considering the above safety assurance.

- O-R
  - It is used for sealing the mating part of the product.

Figure 7 Wetted O-RING

Collar

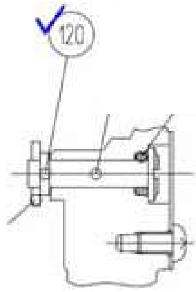

Figure 8

Junction unit for vacuum environment / O-ring for seal for air and vacuum environment

Optical Junction unit for vacuum environment is used for a photoelectric sensor that enables detection inside a vacuum chamber by transmitting light from a fiber amplifier through a fiber unit.

The optical coupler is provided with sealing ability to pass the detection light through the wall of the vacuum device.

The O-ring for sealing are made of fluorine rubber to keep high temperature, high seal and high cleanliness

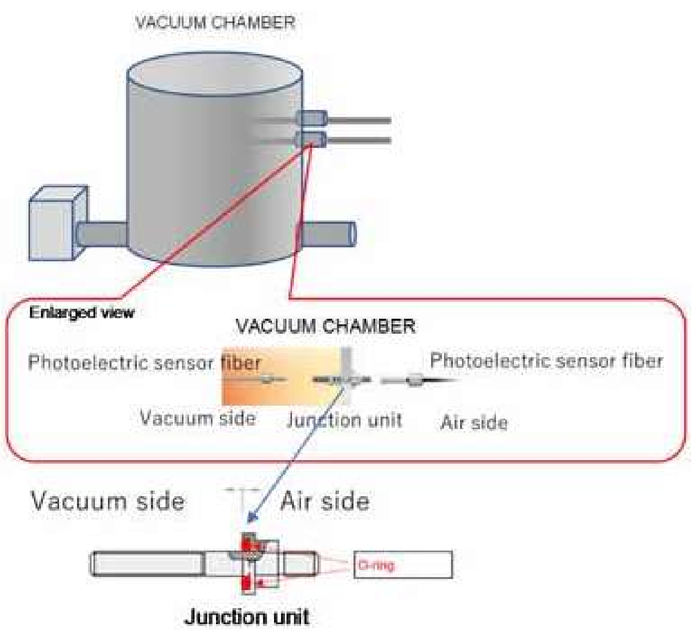

Figure 9

To keep high temperature, high seal, and high cleanliness in a vacuum environment, materials other than fluorocarbon rubber are not appropriate.
O-rings are used as sealing parts to prevent external leakage at joints between different parts.

Mass Flow Controller / Mass Flow Meter

O-rings are used as sealing parts to prevent external leakage at joints between different parts.

<Mass flow controller usage example>

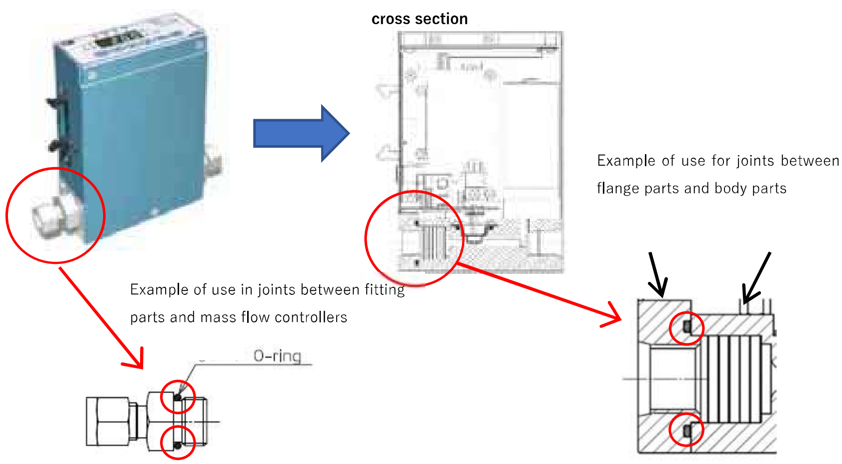

Figure 10

FKM is used for various gases with excellent heat resistance, chemical resistance, ozone resistance, etc., especially when using flammable oxygen gas, it is used due to its high heat resistance and ozone resistance, and the alternative product is a special rubber material, but it becomes a fluorine-based rubber material and the use of fluorine-based substances is unavoidable.
If fluorine-based materials are not used, safety is significantly impaired.

Plumbing
Plumbing is any system that convey fluids or energy for any application. Pipes, tubes, joints, fittings, are used for plumbing. Fluoropolymer resins, such as, PTFE, PFA, PVDF, are used. Some international standards mention uses of fluoropolymer resins for plumbing. [1]

- Tubes (not heat shrink tubes)
  Tubes are used for convey fluids to the places.

[1] Example of international standards: ISO 12039:2019 mentions that the sampling line shall be made of PTFE, PFA.

Figure 11

- Joints / fittings
  Joints / fittings are components to connect tubes to units and/or tubes to tubes.

Figure 12

The functions and alternatives which plumbing requires:

The material of plumbing is determined by the types of fluids flowing through tubes. Fluoropolymers can be used as piping for fluids in the temperature range of -10°C to 200°C (PTFE) and about -40°C to 160°C (PFA), including acids, alkalis, organic solvents, ozone, and oils. Fluoropolymers (PTFE, PFA, PVDF) are the only plumbing materials that can be used when the fluids of flowing the tubes meets one or more of these characteristics.

Fluoropolymer resins are the only materials that can simultaneously provide and express multiple functions required for the proper functioning of chemical resistance/ cleanliness, repellency from water and oil, and heat resistance.

Examples of the products which incorporate plumbing

<u>Magnetic Flowmeter</u>

An Electromagnetic Flowmeter is a type of flow meter that applies a magnetic field in the perpendicular direction to the flow of the measured fluid. As a result of the flow and the magnetic field, an electromotive force is generated in directions perpendicular to both the flow and the magnetic field. This electromotive force is extracted by a pair of electrodes, and the output signal is sent to a converter. The electromagnetic flow meter is a flow meter that applies Faraday's law of electromagnetic induction to moving objects.

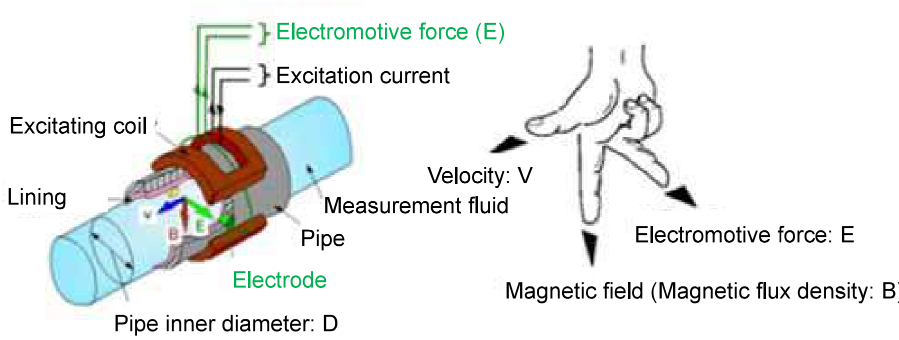

Figure 13

The resin lining, known as lining, is applied to pipes (metal piping), and materials such as PFA and PTFE are used.

The purposes of this lining are as follows:

Electrical insulation: The lining ensures electrical insulation between the measured fluid and the electrodes or the pipe, preventing electrical short-circuiting of the signal electromotive force.

Chemical resistance: The lining provides resistance to chemical substances such as acids and alkalis when the measured fluid contains them. This prevents corrosion and degradation caused by the fluid's characteristics and the environment, thereby improving the accuracy and reliability of the measurement.

Wear protection: The lining plays a role in protecting the pipe from internal friction and impacts. It reduces wear and damage caused by solid particles and abrasives in the fluid, maintaining measurement performance over an extended period of use.

Heat resistance: The lining exhibits stable performance even in high-temperature environments. It resists degradation when exposed to high-temperature fluids and environments, ensuring consistency and reliability in the measurements.

NOx measuring equipment

For accurate measurement, dehumidify the sample with a dryer unit before measuring. It is dehumidified by the Flemion tube of the dryer unit, but it is necessary to purge dry gas around the Flemion tube. Cover the Flemion tube with a PFA tube, purging dry gas in between.

Also, PFA tubes are used to connect the dryer unit and piping.

Since NOx is highly adsorbable, PTFE, which does not easily adsorb, is used as a sampling tube.

Used to connect flow sensor and PTFE tube.

Micro flow rate liquid flow meter

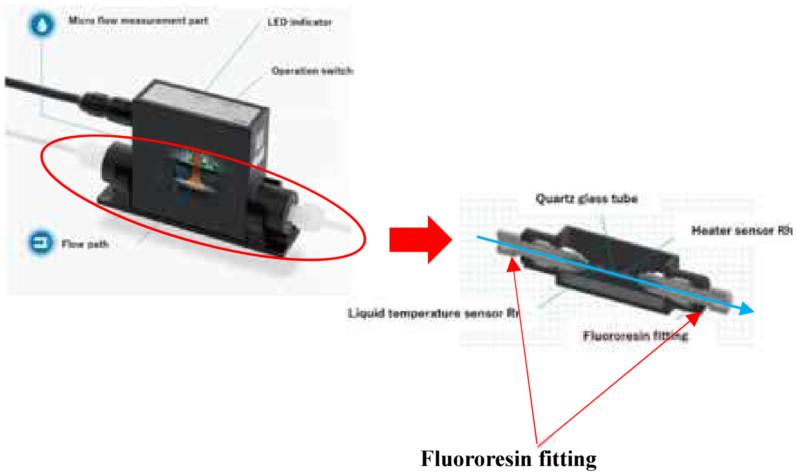

Figure 14

◆Characteristics of PFA,PTFE

・Inert to many chemicals

・Resistance to aging

・Less additives

・Soft

・Easy to process

◆Benefits of using PFA,PTFE

Semiconductor manufacturing process is required high level chemical controls, due to chemical contamination makes negative influences on quality of products. PTFE and PFA which are inert to various chemicals and also include low additives, are suitable materials for flow paths in semiconductor manufacturing process.

◆Impact of prohibition using PFA,PTFE

It will be impossible to keep miniaturization technology used in current semiconductor manufacturing process.

To avoid this problem would require a great deal of effort and technical innovation.

Fuel Cell Performance Testing Equipment

Fuel cells generate electricity and heat through a chemical reaction between hydrogen and oxygen. Fuel cell performance testing equipment evaluates the performance and durability of fuel cells. Fuel cells contribute to carbon neutrality by improving energy efficiency and reducing CO2 emissions.

The following characteristics are required for the piping of the fuel cell performance testing equipment.

- The piping serves as a flow path for alkaline substances used as materials for hydrogen and acidic substances produced as a result of the reaction. (Chemical resistance)
- Since the polymer membrane used in the fuel cells requires wet condition, water vapor is added to the hydrogen. The flow path is heated to approximately 150°C to prevent condensation of water vapor in the piping. (Heat resistance)
- Hydrogen in the exhaust gas after the reaction may be reused, which requires an additional supply of hydrogen, resulting in large pressure changes inside the piping. Therefore, the piping needs to be strong. (Durability).

In case of condensation in the piping, the concentration of water vapor added to hydrogen cannot be maintained at the required level and normal operation will be disturbed. In addition, a transparent pipe with chemical resistance may be used as a liquid level gauge to check the liquid level in the tank where the alkali solution is stored.

For these reasons, the fuel cell performance testing equipment needs to be made of transparent, chemical (acid, alkali) resistant, heat resistant, and durable materials. Currently, PTFE and PFA are the only such materials available, and they are difficult to replace.

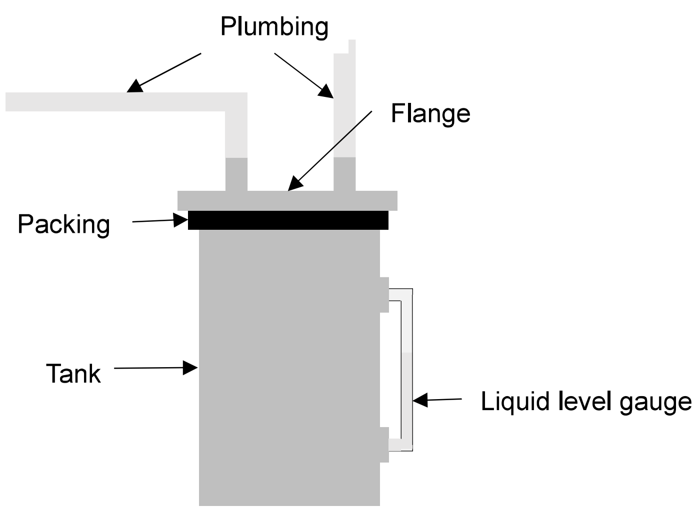

Figure 15

Valves

Valves are general for equipment with a movable mechanism that can open and close flow paths in order to go through, stop, and control the flow of fluids.

They are used in a wide variety of products, from relatively small devices with flow paths and valves to large-scale manufacturing processes and chemical plants. There are many types of valves. Some valves, which are often incorporated in specialist equipment, are discussed. They are not exhaustive.

The functions and alternatives which valves require:
The chemical resistance against acids, alkalis, organic solvents oils, and ozone, which flows through valves, is essentially required. Valves, which opens and close frequently required the property of low friction, repellency from water and oils, non-adhesion. Any failure of valves can cause serious accidents. Therefore, the durability of fluoropolymer resin is required for valves PTFE and other fluoropolymer resins are frequently used. Fluoropolymer resins, such as, PTFE are the only materials that can simultaneously provide and express multiple functions required for the proper functioning of valves.

- Solenoid valve

A solenoid valve is electromehanically operated. One of the operations is to open and close a valve using the principle that when an electric current is applied to an electromagnet (solenoid), an iron piece called a plunger is attracted and released when the electric current is cut off. Diaphragms divide into a valve compartment that opens and closes flow paths and a functioning compartment that drives. Fluoropolymer resins, such as, PTFE, FKM, FFKM, and FEPM, are frequently used for flow paths, diaphragms, and sealing materials in solenoid valves. Solenoid valves have wide variety of types, such as, liner action, pilot operated, the combination of liner action and pilot operated.

- Ball valves

A ball valve opens and closes a flow path by rotating a hollow ball. In automatic valves, an electric motor is used to rotate the ball. A large cross-sectional area of the flow path can be obtained, and the resistance of the path can be kept low. Fluoropolymer resins, such as, PTFE, are frequently used

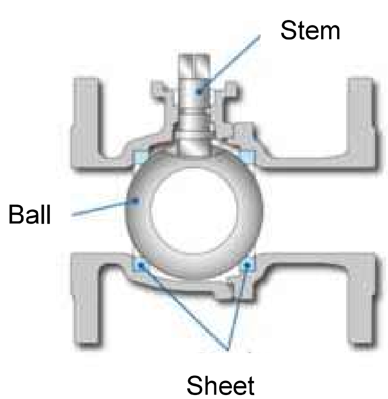

Figure 16

- Check valve

A check valve is installed on gas or liquid piping where the fluid back pressure closes the valve plug to prevent reverse flow. A check valve is called as non-return valve, reflux valve, retention valve, foot valve, or one-way valve There are disc check valves that blocks backflow by closing the O-ring valve with a disc and duckbill check valves that uses a valve plug shaped like a duck's beak.　Fluorinated materials such as PTFE, FKM, FFKM and FEPM are used for the valve plug and the sealing materials of the housing.

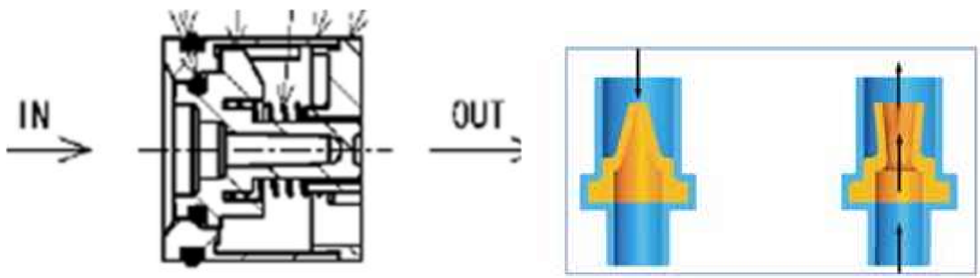

Figure 17

- Relief valves/safety valves

A relief valve is a valve that automatically releases pressure when excessive pressure occurs in the pipes. A spring keeps the valve plug such as O-rings or diaphragms closed, and it opens (released) when a pressure exceeding the spring force occurs.
Fluorinated materials such as PTFE, FKM, FFKM and FEPM are used for the valve plug and the sealing materials of the housing.

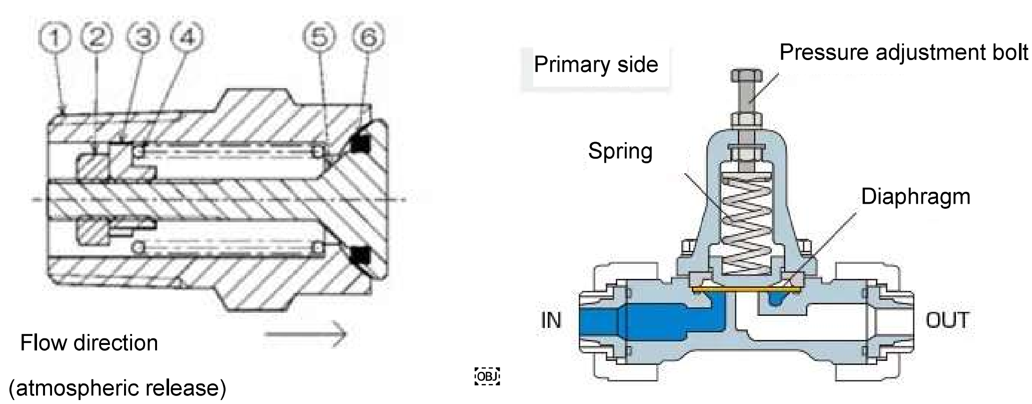

Figure 18

Examples of the products which incorporates valves

Control valve of mass Flow Controller

Mass flow controllers are used for flow control of various industrial gases.

PTFE is used as the material of the valve body of the flow control valve of mass flow controller.

See part (10) in the figure24 below (the right is a partial enlarged view).

Performance requirements for materials.

・Heat resistant to withstand operation from -10°C to +60°C.

・Chemical resistance to withstand components contained in combustible gases.

・Resistant to ozone gas.

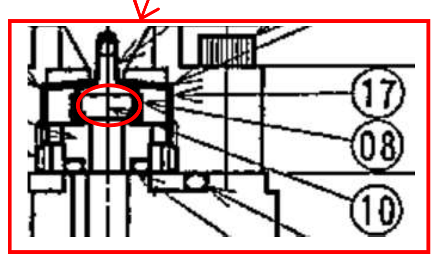
Cross-sectional view of the valve



Enlarged vie

Figure 19

Mass flow controller for semiconductor manufacturing

Mass flow controller for semiconductor manufacturing

PFA coating is applied to the valve that functions to accurately supply the amount of etching gas in the etching equipment for semiconductor manufacturing. When the valve is closed, it must be tightly closed and impermeable to gas. Low friction is necessary because it must not wear out even with the impact of continuous opening and closing of the valve.

The friction ecoefficiency of silicone is low, and silicone cannot be used for this application.

Fluoride ion measuring equipment

This equipment is mainly used to measure the concentration of fluoride ions in factory wastewater. Fluoride ions are detected by an ion electrode, and the concentration can be monitored continuously by sending the sample to the flow cell holding the ion electrode with a liquid sending pump. The sample water is an aqueous solution such as factory wastewater. Various ionic components and insoluble solids are included depending on the type of production.

Used as a switching valve for the solution feed channel

The valve is used as a switching valve for the solution feeding flow path, and the body and diaphragm valve are PTFE solenoid valves.

NOx measuring equipment

NOx meter utilizes chemiluminescence generated in the process that NO and ozone react to produce NO2. Since the emission intensity is proportionally related to NO concentration, NO concentration is obtained by measuring the emission intensity. Since NO2 does not emit light, it is converted into NO by a converter, and NOx(NO+NO2) is measured, and then NO2 concentration is obtained from the difference between NOx density and NO density. So the NOx meter requires switching between the NO measurement line and the NOx measurement line. Also, during calibration, it is necessary to switch between the sample line and the calibration line. Since NOx has high adsorptivity, PTFE is required for NOx passing part, and therefore, a solenoid valve is used for switching.

The NOx meter requires switching between the NO measurement line and the NO2 measurement line. Also, during calibration, it is necessary to switch between the sample line and the calibration line. A solenoid valve is used for switching.

Control valves

Control valves are used in a variety of different markets that controls fluid flows in plumbing installed in air conditioning system of building, and Industrial plants, for example petrochemical and power plant.

Examples of control valve products

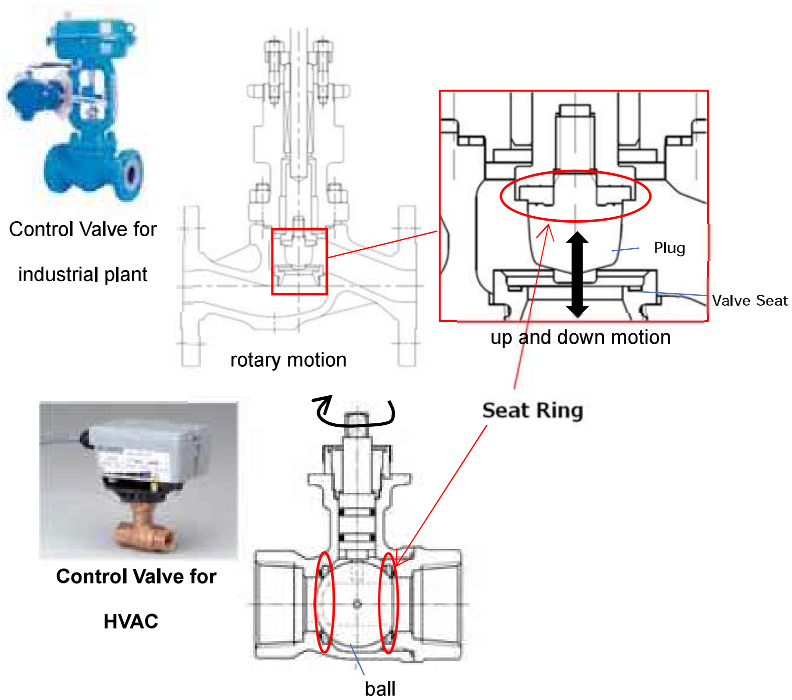


Figure 20

PTFE seat ring is a component of control valves that has a function of stopping the flow by contacting with the plug when it is fully closed.

In general, the friction coefficient of PTFE (0.1 or less) is approximately 1/5 that of metal (approximately 0.5), and the torque required to rotate the plug is approximately 1/5 in proportion to the friction coefficient.

Add that, corrosive and high temperature fluid flows through control valves. So, excellent chemical and heat resistance are required to control valves. PTFE fills all of characteristics aforementioned. Furthermore, it has proven track record of long-term use in various fields.

<u>Material for scraper rings in industrial control valves</u>

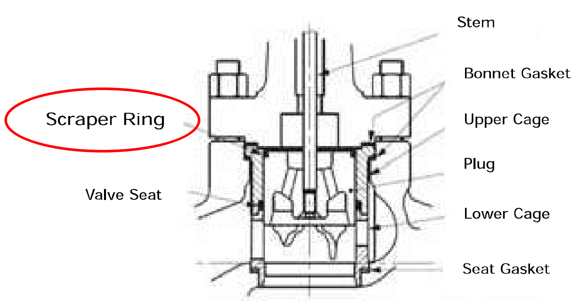

Figure 21

The PTFE scraper ring scrapes off the fluid adhering to the cage of the control valve and prevents sticking of the plug and cage.
Industrial control valves are used to control corrosive fluids such as chemicals, and are required to have performance that can withstand the control of corrosive fluids.
On the other hand, in identifying corrosive fluids, there are many fluids that are difficult to determine physical properties such as intermediates of chemical substances, and materials that have a wide range of chemical resistance are required.

In order to control corrosive fluids with industrial control valves, scraper rings made of PTFE are required in the flow passages where corrosive fluids come into contact.
Other polymer materials, such as rubber and resin, might be able to substitute for PTFE as the material of scraper rings. However, it is considered that the alternative materials are not suitable, because they do not have enough resistance to various chemicals of chemical plants.

Lining and throttling mechanism materials for industrial control valves

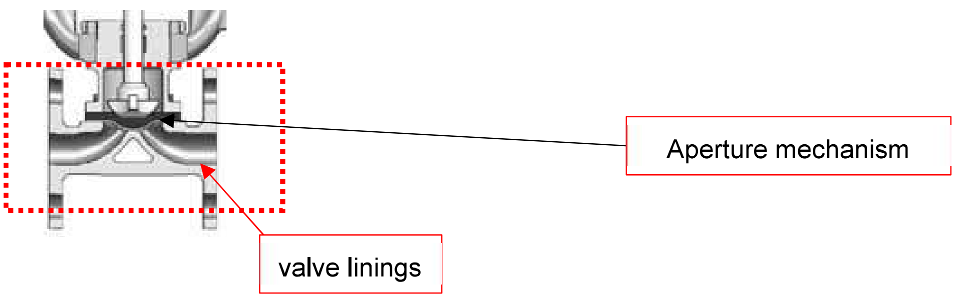

Figure 22

Industrial control valves are installed in pipes of various industrial plants, that are used to control flow of fluids. Industrial control valves are used to control corrosive fluids such as chemicals.

Industrial control valves are required to be able to withstand the control of corrosive fluids at high temperatures (approximately 140°C).

In order to control corrosive fluids with industrial control valves, main body linings and throttle mechanisms made of PFA, ETFE and PTFE are required in the flow passages where corrosive fluids come into contact.

Depending on the fluid used, PFA and ETFE are used in the body lining, and PTFE is used in the throttle mechanism.

- It is possible that other polymer materials such as rubber and resin can be used as alternative materials for body lining and throttle mechanism using PFA, ETFE, and PTFE. However, alternative materials have poor resistance to a wide variety of chemicals in industrial chemical plants and cannot withstand corrosive fluids.

-
- If it is assumed that metal materials such as chromium and nickel alloys will be substituted, it is necessary to periodically stop the equipment and check the corrosion status of the control valves connected to the pipes. When corrosion occurs, fluid control becomes impossible, so it is necessary to replace the industrial control valve itself.

Pumps

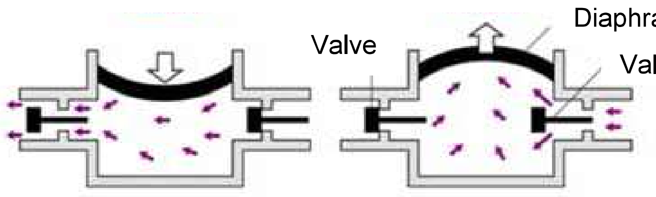

Figure 23 Explanation on Pumps [2]

A pump is a device that transfers, pumps, and stirs liquids and gases under the action of pressure. It is divided into two types according to the difference in structure: non-positive displacement pumps and positive displacement pumps. Non-positive displacement pumps are pumps that impart energy to liquids by rotating impellers, and include centrifugal pumps, propeller pumps, and viscous pumps. A positive displacement pump is a pump that pressurizes and energizes a liquid that is within a certain volume, and there are plunger pumps, diaphragm pumps, gear pumps, etc. In pumps, fluorine rubber such as FKM, FFKM, and FEPM is used for the sealing members and diaphragms of the housing. PTFE is used for the impeller bearings.

PFAS functions which pumps require and alternatives

Pumps used to transfer fluids such as acids, alkalis, organic solvents, oils, and ozone require high chemical resistance for each member in contact with the fluid. Especially in the case of diaphragms, durability that can withstand repeated bending are also required. Fluorine materials such as FKM, FFKM, and FEPM are used as materials to satisfy these requirements, and it is difficult to replace them with other materials.
In the case of bearings, low friction, self-lubrication, and wear resistance are also required. Fluorine materials such as PTFE are used as materials to satisfy these requirements, and it is difficult to replace them with other materials.

Coating/Lining

Part Description

A surface treatment in which the surface or inner surface of a base material is covered with a fluoropolymer is called a coating or lining. A relatively thick covering is often referred to as a lining, while a thin covering is often referred to as a coating. There are various methods such as molding, bonding a sheet to the base material, bonding powder, or covering with a liquid. Fluoropolymers used include PTFE, PFA, PCTFE, FEP, and ETFE.
Metal plating and surface treatment containing fluoropolymer resins are used to adhere to metals. Coatings and linings are applied to parts in contact with fluids. The parts include the inner surface of the piping and parts in contact with the fluid. Coatings may be applied to areas where water repellency to water and oil, low friction, self-lubrication, and non-adhesion are desired.

Examples of coating / lining

Piping inner surface

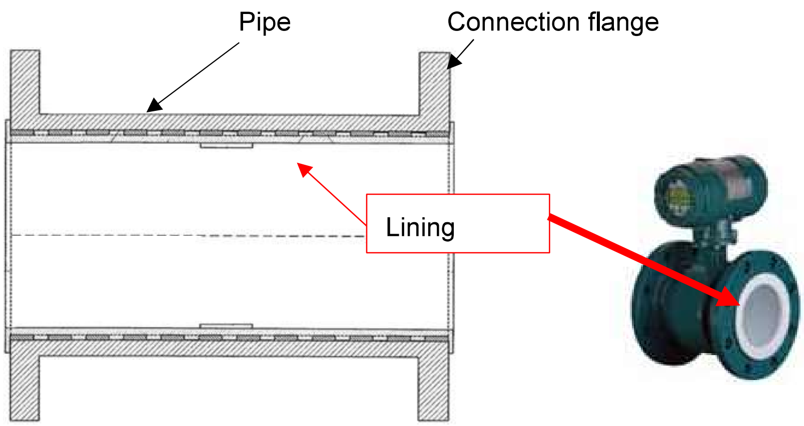

Figure 24

Coating and lining section of parts (diaphragm) in contact with fluid

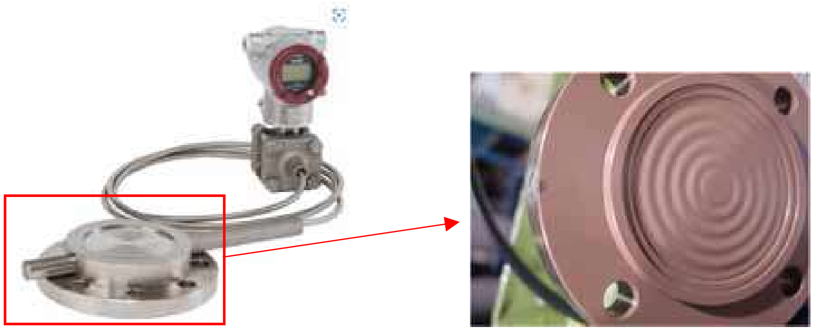

Figure 25

PFAS functionality required by coating/lining and possible substitutions

By covering the surface with a fluoropolymer, PFAS gains chemical resistance/cleanliness and mold-releasing properties that the base material does not have. Coatings and linings in contact with fluids can withstand corrosion and operate stably without maintenance for long periods of time (10 years). For example, fluorine coatings and linings on low-hardness rubber materials provide both high flexibility and chemical resistance. When the fluid is a powder, it is difficult for the fluid to adhere to the coating/lining area due to non-adhesion of fluoropolymers.

Coatings for instruments and tools for analysis and measurement
Analysis and measuring instruments are required to have chemical resistance because they may analyze and measure any kinds of chemical substances, including strong acids, strong alkalis, organic solvents, and oils, as samples. For correct analysis and measurement, no specimens or reference materials should remain in instruments or pipettes, tubes, etc. If residues remain, subsequent analysis and measurement will not be accurate. In order to prevent residues from remaining, coating should be applied to the areas where the specimens and reference materials are likely to remain. The fluoropolymer resins have the functions, such as, repellency from water and oils, and non-adhesion. These functions can prevent residues from remaining, which resulting in accurate analysis and measurement.

Examples of Parts and Equipment Using Lining and Coating
There are a great many devices that coat base materials that come in contact with fluids.

Lining for fluid contact parts of electromagnetic flowmeters and pressure transmitters

Equipment around piping such as electromagnetic flowmeters and pressure transmitters cannot maintain their performance without fluoropolymer resin linings and coatings in order to withstand various fluids such as acids and alkalis.
Linings using ETFE or PFA can operate stably for 10 years without maintenance.
Accidents may occur if the equipment continues to operate with the fluid flowing through the piping without noticing that it has been corroded by the fluid.
In order to maintain the work environment and safety management, it is necessary to use fluoropolymers that can be safely used for a long period of time without replacement for devices that pass corrosive fluids.

Environment-resistant photoelectric switch with built-in amplifier

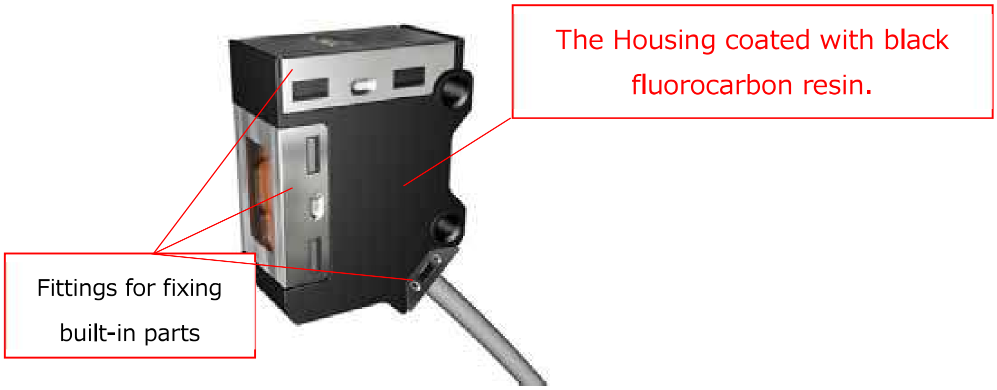

Figure 26 External View/ Detection of work piece seating in machine tool

Improved corrosion resistance of housing

The housing of Environment-resistant photoelectric switch is made of zinc die-cast. Zinc die-casting has advantages such as high fluidity, easy dimensional accuracy, low molding temperature, and long service life of metal mold, but it has low chemical resistance.

Therefore, it cannot be used in machine tools and automobile parts machining lines, which are users of this switch, unless corrosion resistance is improved by painting and plating. Water-soluble coolant (basic) is often used in machine tools and automobile parts machining lines, and zinc die-cast housing is highly likely to be corroded unless surface treatment such as painting is performed (Figure 26).

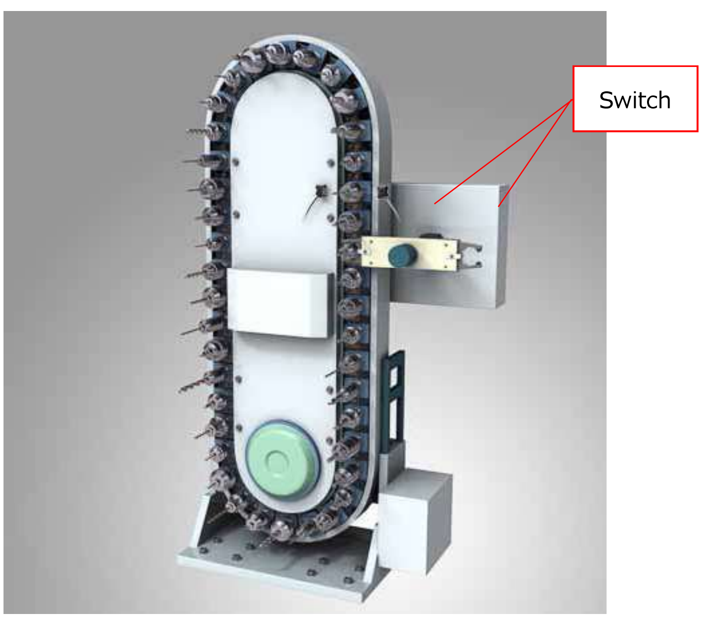

Figure 27 Confirmation of Existence of Tool in Machine Tool

Prevention of crevice corrosion and dissimilar metal contact corrosion

The H2B housing is assembled with a metal stopper (SUS plate (zinc plated)) (Figure 26) and attached to an accessory SUS bracket or the mounting surface of the user side (metal, resin, etc., materials cannot be specified) (Figure 27). Therefore, it is necessary that the metal surface of the housing is not exposed in order to prevent electrolytic corrosion due to gap corrosion and contact between different metals.

The former model number of this switch had adopted acrylic coating, but it was changed to fluorine coating due to low resistance to water-soluble coolant. The surface of the housing must be free from exposed metal. Therefore, coating by coating is necessary instead of plating. For the same reason, coating is necessary even if the housing is changed to a highly chemical resistant metal material such as SUS.

There are concerns about the following impacts due to the unavailability of this technology

・ Affects machining with machine tools that use water-soluble coolant and parts machining and production on automotive parts production lines

・ There is no alternative technology. When a switch without fluorine coating is used, corrosion of the switch causes contamination of corrosion products (foreign matter) into parts, generation of rust in processed parts, and increase of stoppage period of machine tools and production lines due to increase of sensor replacement frequency.

For the above-mentioned reasons, the prohibition of coatings with fluorine-based paints should be exempted indefinitely from this restriction because of the economic burden due to the increased frequency of replacement and the serious degradation to the finished product.

In terms of disposal, restrictions should not be applied as coatings by fluorinated paints generally lead to a reduction in waste.

Spatter-guarded proximity switch

Part of the housing of the spatter-guarded proximity switch used in a welding environment.

Cap：Fluoropolymer resin PFA sensing surface

Housing：Coated with fluoropolymer resin.

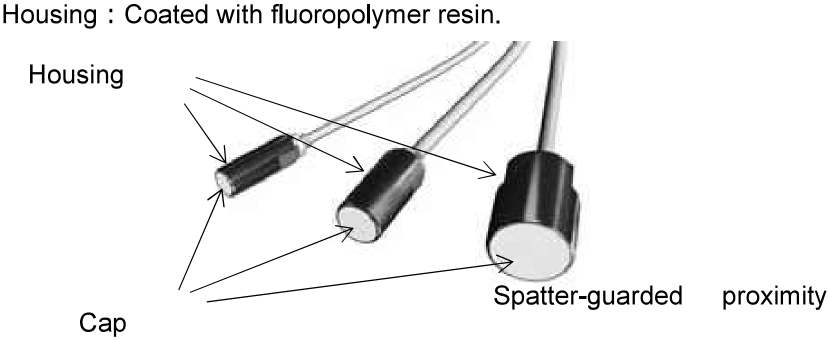

Figure 28

The following features can be obtained by using Fluoropolymer resin.

Cap：It can withstand the heat of welding spatter. It is difficult for spatter to stick.

Housing：It is difficult for spatter to stick.

Flame arrestor (sintered metal) surface

Figure 29

Sintered metal flame arrestor is used to prevent the internal gas sensor element from becoming an ignition source. Surrounding gas reaches the sensor element through fine gaps in the sintered metal, but when water is adsorbed on the sintered metal, the flow path of the gas narrows. Therefore, in order to prevent water adsorption and corrosion on sintered metal, a fluorine coating is applied for the purpose of adding repellency from water and chemical resistance.

- Inside the metal nipple

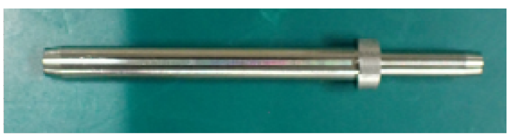

Figure 30

Fluorine coating is applied to the inside of the metal nipple which is part of the gas flow path for the purpose of adding non adhesion in order to prevent the gas concentration from decreasing due to the adsorption of highly adsorptive gases.

Repellency from water

The flame arrester (sintered metal) is given water repellency by applying a fluorine coating to prevent clogging due to water adsorption and corrosion.

Non-adhesion

Fluorine coating is applied to parts of metal pipes that cannot be used due to insufficient strength of fluoropolymer resin pipes, such as when it is necessary to cut threads to fix them.

Chemical resistance

Fluorine coating is applied to the parts used in the gas flow path to provide chemical resistance. Fluorine coating can be used in acids, alkalis, organic solvents, ozone, and oils.

Fuel cell performance testing equipment: Coating of tank

Fuel cells generate electricity and heat through a chemical reaction between hydrogen and oxygen. Fuel cell performance testing equipment evaluates the performance and durability of fuel cells. Fuel cells contribute to carbon neutrality by improving energy efficiency and reducing CO2 emissions.

The Fuel cell performance testing equipment supplies hydrogen obtained from an alkaline substance to the fuel cell. It stores the alkaline liquid to obtain hydrogen in a stainless steel tank, which cannot be used for a long period of time because the stainless steel is corroded by the alkali. Therefore, the tank surface is protected by coating with PTFE. Moreover, hydrogen gas used for fuel cell is necessary to add water vapor. The tanks for to control the dew point of the added water vapor can reach temperatures above 150°C. Thus the coating material must be heat resistant. So far, PTFE is the only material which has both chemical and heat resistance.

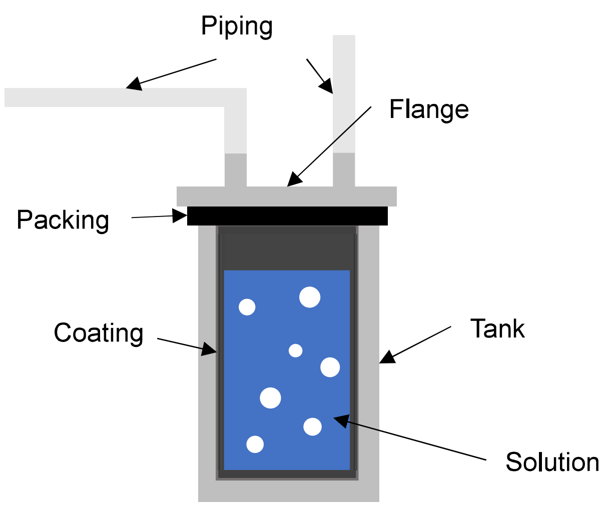

Figure 31

Temperature sensor

Contact type temperature sensors can measure temperature by contacting the object to be measured and reaching to the same temperature. The sensor measures the temperature using the element itself or an element inserted into a protective tube for strength.

Temperature sensors can measure a wide range of objects, including acids, alkalis, and organic solvents, and can also measure a wide range of temperatures, including applications that measure chemicals at 100°C or higher. Therefore, sensor elements, wires themselves, and protective tubes are coated with FEP or PFA to eliminate the adverse effects of chemicals and high temperatures and realize accurate measurement.

There is no material other than fluoropolymers that combines chemical resistance and heat resistance to realize such applications, and it is difficult to replace them.

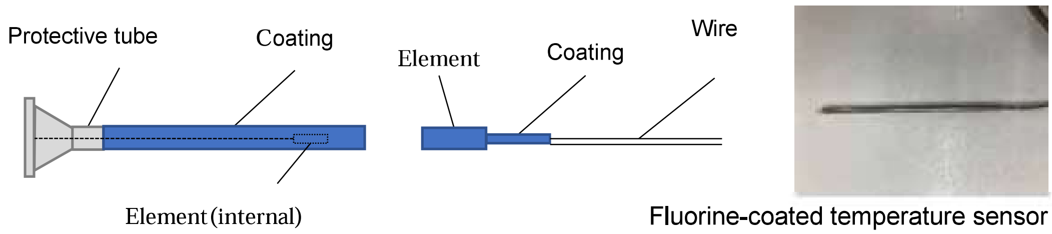

Figure 32

<u>Coatings/linings for tools for analysis and measurement</u>

Analysis and measuring instruments are required to have chemical resistance because they may analyse and measure any kinds of chemical substances, including strong acids, strong alkalis, organic solvents, and oils, as samples. For correct analysis and measurement, no specimens or reference materials should remain in instruments or pipettes, tubes, etc. If residues remain, subsequent analysis and measurement will not be accurate. In order to prevent residues from remaining, coating should be applied to the areas where the specimens and reference materials are likely to remain. The fluoropolymer resins have the functions, such as, repellency from water and oils, and non adhesion. These functions can prevent residues from remaining, which resulting in accurate analysis and measurement.

<u>Coatings for the interior of X-ray analysis detector</u>

Fluorescence X-ray analysis (XRF) is designed to analyze elements by measuring the X-ray fluorescence produced after each element is excited by X-rays. X-rays generated from components close to the sensor are also detected, so that X-rays of fluorescence generated from sources other than the sample being measured interfere with accurate analysis.

The lower the atomic number, the lower the energy of the X-ray fluorescence. Conversely, elements with higher atomic numbers tend to absorb X-rays more easily.

Therefore, metallic materials such as Nickel, which are the internal components of the detector, are coated with a metal with a lower atomic number, such as Aluminum (Al), and then coated with a fluoropolymer resin less than 100 μm thick to absorb the fluorescent X-rays generated from Al. Fluoropolymers also emit fluorescent X-rays, but their low energy has no effect on the analysis.

If coatings other than fluoropolymers are used, epoxy resins and carbon coatings are available. But these have a lower X-ray absorption than fluoropolymers. For the same absorption capacity, a coating three times thicker for graphite (C) and seven times thicker for polypropylene (C_3H_6) is required to absorb the fluorescence X-ray from Al (See the figure38). The thicker coating interferes with the sensor, reducing detection sensitivity and increasing analysis time.

For accurate X-ray fluorescence analysis, it is difficult to use anything other than fluoropolymers for the internal coating of the detector.

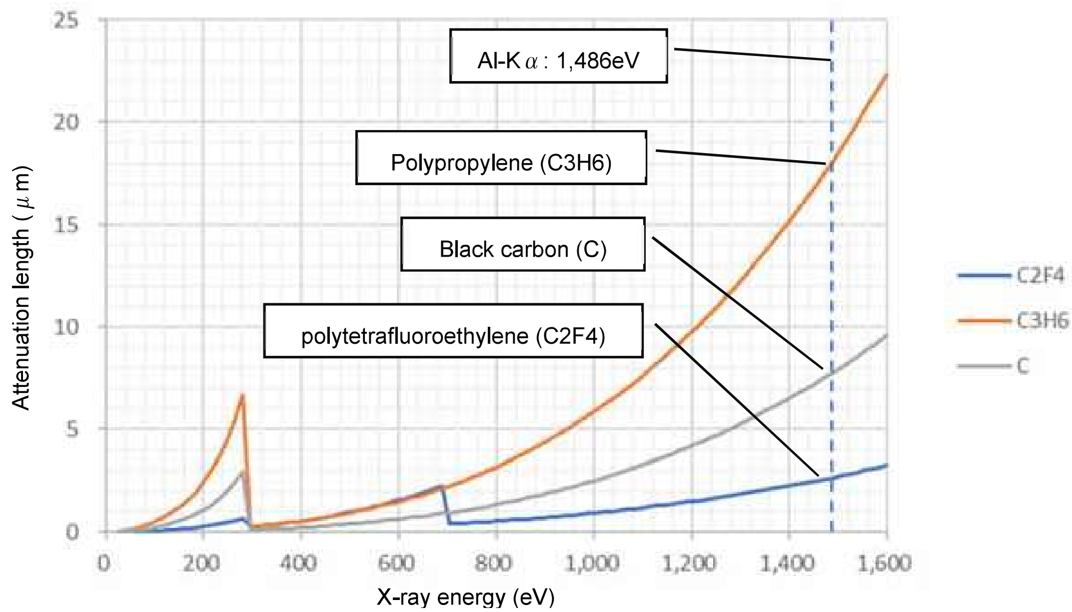

Figure 33 X-ray attenuation lengths from Aluminum [3]

Membrane filters

Membrane filters are to remove and separate specific substances or objects from fluids. A wide variety of materials are used. If fluorine compounds are necessary, PTFE, FEP, ETPE and PFA are frequently used.

Membrane

Dissolved oxygen electrode

Electrolyte

Electrochemical gas sensor

Figure 34

Measurement method of pH meter and diagram of membrane filter

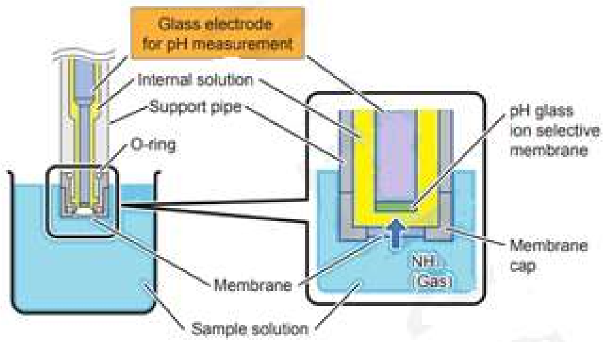

Figure 35

1. Gas components in the sample are go into the electrode through the membrane.
2. The pH of the internal solution changes according to the amount of the gas taken in, and the change of pH is read by a glass pH electrode.
3. The pH change of the internal solution is converted to gas concentration in the sample.

The following properties are required for the membrane used in this application.
There is currently no other material that possesses these properties at a level that can be used in products.

・Gas permeability
Membrane must have sufficient gas permeability even under conditions of no pressure.
・Chemical resistance
Membrane must have sufficient chemical resistance that will not deteriorate after immersion in various samples.
・Repellency from water
Repellency from water is required in order not to permeable water.

PVC, glass and PEEK are too high much gas barrier property to separate gases. PE is weak for acids. Glass is melt down by hydrogen fluoride and some gases. Fluorine compounds such as PFAS are the only materials that can simultaneously provide and express multiple functions required for the proper functioning of membrane filters.

PTFE filter used in the ozone decomposition catalyst unit of NOx measuring equipment
A NOx meter needs to generate ozone to measure NOx by the chemiluminescence method. For accurate measurements, ozone is generated in excess of NOx in the sample. An ozone decomposition catalyst is used to decompose ozone remaining after NOx measurement, and a PTFE filter is used to remove the catalyst powder.

PTFE filter is a filter with little adsorption and decomposition. Use is recommended in the Environmental Air Constant Monitoring Practices Promotion Manual. It also has better ozone-resistance than PVC and PE and is less priced than PEEK.

PTFE porous membrane electrochemical gas sensor

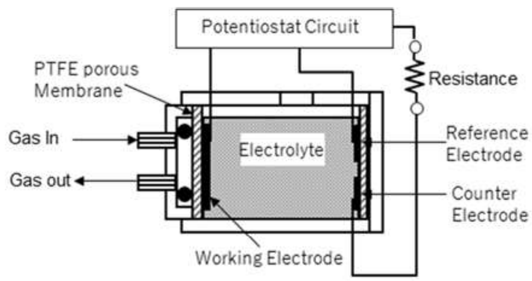

Figure 36

1. Electrochemical gas sensor is constituted by a working electrode formed on a PTFE porous membrane, a reference electrode, a counter electrode, electrolyte and a housing which is holding other components.
2. Every electrode is connected to a potentiostat circuit and the working electrode is implied fixed potential to that of the reference electrode.
3. The PTFE porous membrane is in contact with atmosphere which may contain intended gas to be detected.
4. The gas to be detected goes through by diffusion in the membrane and reaches the interface of the working electrode and the electrolyte.
5. The gas is electrochemically oxidized or reduced.
6. The oxidized or reduced reaction involves transfer of electrons between chemical species and the working electrode, hence current flows in the circuit.
7. The current is measured to determine the concentration of the gas to be detected

The following properties are required for the membrane used in this application.

There is currently no other material that possesses these properties at a level that can be used in products.

・Gas permeability

The membrane must have gas permeability at atmospheric pressure.

・Water resistance

The membrane must have sufficient water resistance not to leak electrolyte.

・Corrosion resistance

The membrane must have corrosion resistance. Examples of corrosive gases are NOx, SOx, halogen and halogen halide.

・Chemical resistance

・Heat resistance

The membrane must have sufficient heat resistance over 150 degree Celsius to coat electro catalyst.

・Non-adsorptive

The membrane must have sufficient non-adsorptive. If the gas to be detected is adsorbed on the membrane, the gas can’t go through the membrane, or it takes time to go through the membrane.

Galvanic oxygen sensor

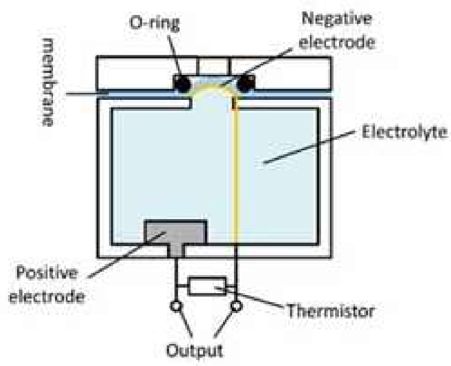

Figure 37

1. Oxygen gas in the sample reaches through the membrane into the sensor.
2. The oxygen gas taken in is reductively decomposed at the cathode. A current flows according to the oxygen amount taken in.
3. The current is read as a voltage through a resistor such as a thermistor.

The following properties are required for the diaphragm used in this application.

Gas permeability

The gas to be measured is taken into the electrode. This measurement is not possible without sufficient oxygen permeability even under conditions of no pressure. Among fluorine compounds, FEP has superior oxygen permeability compared to other polymer membranes.

Chemical Resistance

FEP is used in environments where it is in constant contact with various gases (acids, alkalis, organic solvents, etc.). The membrane filter does not deteriorate in these environments, does not elute components of the membrane filter when in contact with any sample, and must be resistant to chemicals.

Water repellency and water resistance

The membrane filter must be hydrophobic and water resistant to prevent water from permeating into the electrode.

The material must not change after 10 years of exposure test as a material.

Electrode

-Parts in contact with liquid other than electrodes in electrode structure (of instrument that measures the physical quantity of a liquid by electrical means)-

The electrode in a measuring instrument is a part to be electrically contacted with an object and to measure for the purpose of measuring the electrical signal of the measurement object.

The instrument to measure the physical quantity of a liquid by electrical means is equipped the electrode(s).

In that type of instrument, the purpose of the electrodes is to detect the electrical potential or charge at limited area in the liquid. Therefore,

(In the electrode and surrounding structure,) parts in contact with liquid other than electrodes must be non-conducting.

For non-conducting material, high hardness materials such as glass or ceramics can be used only very limited usage. because these high-hardness materials are inferior in workability and impact resistance.

Therefore, in many cases, resin is used for parts in contact with liquid other than electrodes.

And there is no resin material other than PFAS that can withstand the temperature and corrosiveness of liquids.

Examples of the products which incorporates electrodes

Internal junction and filers in electrodes for pH liquid measurement

Internal solution determines the standard of electric potential for pH liquid measurement. Small amount of internal solution is diffused in the sample. It is necessary to reduce the amount of diffusion of the internal solution to reducing the impact to samples, and stable measurement. Fluoropolymer gels and porous resins which impregnant fluoro-monomer internal solution minimise the amount of the diffusion.

Samples could be strong acids, alkalis, organic solvents, and others. The liquid junction of electrodes requires chemical resistance. PFASs are chosen for internal solutions, gels and porous resins in the liquid junction for pH measurement. PFASs have repellency from water and oils, which resulting in less stains in the electrodes. This is particularly useful for continuous operations. Internal junctions require PFASs which have the function of chemical resistance and repellency from water and oils for accurate and stable measurement.

Optical coating

A water-repellent coating layer which contains Perfluoroalkyl or perfluoropolyether compounds is formed with a thickness of less than tens of nm on the outermost surface of coating layers of the ophthalmic lens surfaces.

The water repellent coating provides superior properties such as water repellency, oil repellency, lubricity, smoothness and chemical resistance to the ophthalmic lens. These properties improve prevention of water discoloration on anti-reflection coatings, scratch resistance, ease of wiping off stains (fingerprints, sebum, etc.) on the lens surface and maintainability. As the results, these high performances enable to extend substantially the product life of lenses.

And the water-repellent coating layer is coated on anti-reflection coating layers to eliminate the ghost and flare phenomena in lens optical systems.

The one of valuable features is having both properties of low refractive index (n<=1.40) and high transparency of the coating layer which composed of perfluoroalkyl or perfluoropolyether compounds.

*1 Ghosting/flare: Reflected light generated on the lens surface is repeatedly reflected in complex ways, resulting in the appearance of light images that are not actually there. The higher the reflectivity of the lens surface, the more likely it is to appear.

*2 Anti-reflection coating: A film with a function to reduce reflected light. In ophthalmic lenses, reflection is reduced by alternately layering materials with different refractive indices to utilize light interference.

*3 Low refractive index: Since the lower the refractive index of the film of the top surface layer of an antireflection coating, the greater the effect of reducing reflections from the lens surface, a film material with a lower refractive index is required. The refractive index of general glass is 1.52, and the refractive index of base materials for eyeglass lenses is 1.50~1.90 (including plastic and glass).

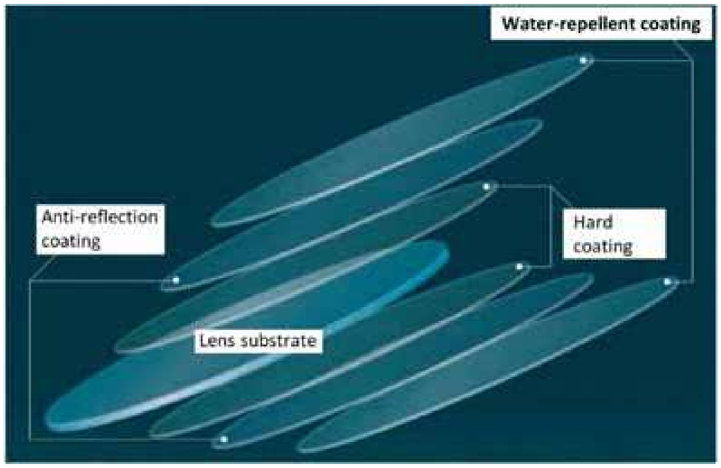

Figure 38

Functions of PFAS that required for lens coating and their alternatives.

Ophthalmic lenses

Ophthalmic lenses are daily exposed to sunlight, rain, sweat, and washed with detergents. So, high level repellency from water and oil are required for the coating of ophthalmic lenses. PFAS-based coatings are widely used because of their excellent weatherability, low friction, and repellency from water and oil. The water-repellent coatings have been developed since the 1980s, but it is still very difficult to achieve the target performances with non-fluorine compounds. Even after more than 30 years effort, no coating without PFAS, which can pass abrasion resistance, chemical resistance, and weather resistance tests assuming everyday use, has been developed yet.

As the proposal alternatives, silicone-based water repellents are representative material, though they can achieve fluorine-based equivalents in terms of contact angle to water, they have not been able to achieve fluorine-based equivalents in terms of contact angle to oil, chemical resistance, and low refractive index.

<Test results>

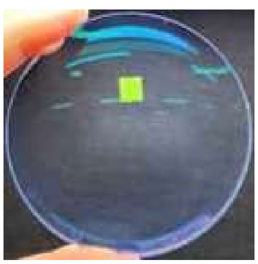
Performance comparison of fluorine-based perfluorinated polyether water-repellent coating and silicone-based polydimethylsiloxane water-repellent coating

		Perfluorinated polyether	Polydimethylsiloxane
Contact angle	To water (H_2O)	108°	104°
	To oil (Oleic acid $C_{18}H_{34}O_2$)	80°	52°
Scratch resistance	Steel wool load 500g 50 round-trip	Good	Bad
Chemical resistance	After 6hr dipping in alkali（NaOH aq. pH:11）	Good	Bad
	After 6hr dipping in acid（HNO_3 aq. pH:1）	Good	Bad

Table 1

＜Details＞

Pictures of appearance after scratch test



perfluorinated polyether

Table 2

Water repellent effect by coating

Without coating With Coating

Figure 39 Difference among lens with coating and without coating [4]

Period required for replacement: About 1.5 to 2 years, if a non-fluorine material with PFAS-equivalent performance is produced.

Volume of PFAS to be placed on the EU market : car camera 0.32μg/year

Amount of PFAS entering in the EU as water-repellent coating materials on ophthalmic lenses

The amount of PFAS entering the EU as water-repellent coatings on ophthalmic lenses is estimated to be 300 kg/year*1. The amount of PFAS entering the EU through water coating*2 is much smaller (1 ppm to 2 ppm) than the total amount of PFAS entering the EU through all applications (140,000 to 310,000 ton/year).

<Explanation for estimating the amount of PFAS entering the EU as water-repellent coating materials of ophthalmic lenses>.

The amount of PFAS entered in the EU as ophthalmic lenses was calculated from the product of the annual sales volume of eyeglass lenses in the EU and the amount of PFAS coated as hydrophobic coating film per lens.

[4] Cannon optron https://optron.canon/ja/evaporation/pickup01.html accessed on 31 May 2023.

1. Hypothesis

・Assume that all vision corrective spectacle lenses sold in the EU have a hydrophobic coating on both sides.

2. Estimate

1) Annual sales volume of eyeglass lenses in the EU

200,000,000 pcs/year (200 million pcs/year) *1,*2

2) Amount of PFAS per lens (both sides) **

1.5 x 10-3 g/pcs

3) Amount of PFAS entering the EU through spectacle lenses

1) × 2) = 300 kg/year

4) Total amount of PFAS entering the EU

140,000 to 310,000 tons/year *3

5) PFAS content ratio by spectacle lens

9.7E-07～2.1E-06 (1ppm～2ppm)

**The net PFAS amount is the solid content coated as the water-repellent coatings on both sides of the lens, excluding the solvent. Assuming that the total amount a is deposited on the total number of lenses b that are put in. The amount of PFAS per lens is calculated as a/b.

Therefore, The PFASs amount entering in EU countries as water-repellent coating materials for ophthalmic lenses is much smaller than that entered in EU as other industrial application.

Examples of devices with lenses

PFAS is mainly used for outdoor sensors, lenses of surveillance cameras, etc., and protective panels on the surface of smartphones and other devices.

Without the use of PFAS, it would not be possible to meet the required specification of water contact angle (100° or more). As a result, the visibility of the image will be poor, and the function of the sensor or surveillance camera will not be established.

Examples

Fiber unit for Measurement use

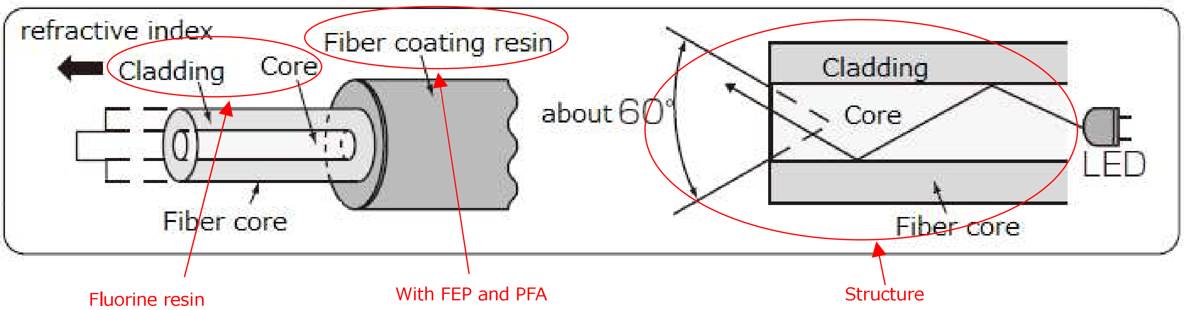

Figure 40

・This is a step index type multimode fiber (using the refractive index difference between core and clad). Fluorine resin is used for the clad. No alternative material has been proposed by the manufacturer at present. In this type of fiber, the basic optical characteristics of the fiber are determined by the refractive index difference between core material and clad material, and the material is selected by the manufacturer in consideration of the manufacturing method. Users use commercially available fiber. FEP is used for the clad and jacket, and PFA is used for the jacket and outer coating.

	Detection method and part of use	Purpose and materials used	Principle using PFA characteristics
Liquid level detection		The tip detection part is made of PFA, and the tube material which may come into contact with liquid is also covered with PFA, a material which is easily fused with the tip. In order to make the tip small and non-electric, a commercially available plastic optical fiber cable is used for guiding the detection light, and fluorine resin (specific material is not disclosed by the manufacturer) is also used as the clad material.	Use refractive index difference between PFA and liquid  It uses the difference in refractive index between liquid and liquid. Detection principle ・ It utilizes the return light difference due to the refractive index difference (hereinafter referred to as n) between the material of

			the tip cone and the external contact material. ・ Without liquid : In a state of lower refractive index than PFA (n ≒ 1.35) (air n ≒ 1), most of the light emitted from the projection is reflected by the inner surface of the cone and returns to the light receiving portion to enter. ・ Liquid : The liquid has a large refractive index equal to or higher than that of PFA (water n ≒ 1.33, ethyl alcohol n ≒ 1.36), and the amount of light that is substantially transmitted through the conical surface and returns to the light receiving portion decreases. ・ The presence or absence of liquid is determined by this light amount difference.
Leak detection		The detection head and cable, which may come into contact with liquid, are covered with PFA.	Use refractive index difference between PFA and liquid  Detection principle is the same as "liquid level detection"
Chemical resistance	Transparent example 	The detection head and cable, which may come into contact with liquid, are covered with PFA.	Sealing performance is ensured by fusing the tip of the PFA detection head and the tube. 
Figure 41

Due to the housing made of PFA resin, this fiber unit has higher stability against organic solvents than other products.

・The following characteristics can be obtained by using PFA resin for the fiber unit.

- This fiber unit functions stably for the detection of organic solvents.
- There is no alternative to this function

・This leakage sensor is used for the following applications.

- Liquid leakage detection in semiconductor wafer cleaning and developing processes
- Detection of tank leakage

・There are concerns about the following effects due to the unavailability of this technology :

- Cleaning and development of a semiconductor wafer using an organic solvent cannot be carried out safely.

・For the above reasons, the prohibition of PFA resin in leakage sensors affects safety and should be exempted from this restriction indefinitely.

Heat medium

Refrigerators, compressors, centrifuges

Refrigerators are used for the units require temperature control, and pretreatment for measurement and analysis. Fluorinated gases are the only materials that can simultaneously provide and express multiple functions required for the proper functioning of refrigerators, such as, thermodynamic efficiency, surface tension, electrical insulation, inactivity, heat conductivity, and a wide range of operating temperature.

HFCs as F-gas will be restricted by the EU F-gas regulation and international treaties. HFCs will be replaced by organic fluorine compounds that their GWP are smaller than carbon dioxide. In that case, the substituted organic fluorine compounds (GWP>1) will be further substituted.

A succession of substitutions in a short period shortens the lifetime of specialist equipment, which is originally long-life. Refrigerators, compressors, centrifuges are used as units of specialist equipment, the derogation as spare parts should be considered. Specialist equipment cannot be repaired, it will be discarded, and its lifetime will be shortened.

Refrigerants must not leak from the unit, the units that uses refrigerants such as refrigerators, compressors, and centrifuges require the sealing materials mentioned in this document.

5(f), (g), and (h) of proposal wordings are written in Annex A of the restriction report. Specialist equipment with a long lifetime cannot be sufficient grace periods. The grace periods should be examined.

Example of a product using a refrigerator:

<u>Compressor calorimeter</u>

A Compressor calorimeter is an equipment that measures the performance of compressors, which is the heart of air conditioner. It is used by compressor manufacturers for development and quality control, and contributes to the development of compressors that are compatible with natural refrigerants and more efficient energy-saving compressors.

Figure 42 Compressor calorimeter

Some of equipment such as calorimeters are equipped with a temperature chamber to maintain a constant environmental temperature for measuring EUT, and refrigeration units using CFC refrigerant (HFC, HFO) are used to cool the temperature chamber. Compressor endurance testing equipment, system performance test equipment, environmental test chambers, and other equipment are also equipped with a refrigerator for the same purpose.
Natural refrigerants such as ammonia and CO_2 are candidates to replace CFC refrigerants, but they have the following problems.

・When natural refrigerants are used, the refrigerator becomes too large and cannot be replaced.
・The system cannot be configured because there is no option of peripheral equipment for refrigeration equipment that is compatible with natural refrigerants.
・Many natural refrigerants are flammable, toxic, and unsafe. Especially for CO2, the use of CO2 is more hazardous due to its high pressure.
For these reasons, CFC refrigerants are difficult to replace.

Lubricating oil

Lubricating oil is used to control friction and wear of metal contacting parts when machines are combined to rotate, reciprocate, or otherwise operate. In addition to suppressing friction and wear, this oil also suppresses corrosion and frictional heat, and its sealing and cleaning properties allow the machine to operate smoothly.

Lubricating oil formulated with PFAS have the following characteristics

・Low friction: Reduces the adverse effects of friction on the lifetime and performance of components.

・Heat resistance: Resistance to chemical changes even when used in high-temperature environments. Resistance to ignition.

・Weatherability: Excellent oxidation stability and resistance to adverse effects of oxygen. Not decomposed by moisture.

・Chemical resistance: Resistant to chemicals such as acids and alkalis.

・Chemical resistance/cleanliness: Almost no deterioration of rubber and plastic materials.

There is no other lubricant besides fluorinated synthetic lubricants that can satisfy all of the above characteristics.

Lubricant oils in the products.

<u>Mass Flow Controller / Mass Flow Meter</u>

Mass flow controllers and mass flow meters are used for flow control and flow measurement of various industrial gases.

Lubricating oil is applied to joint screws and O-rings to prevent screw galling and improve the assembly of O-rings.

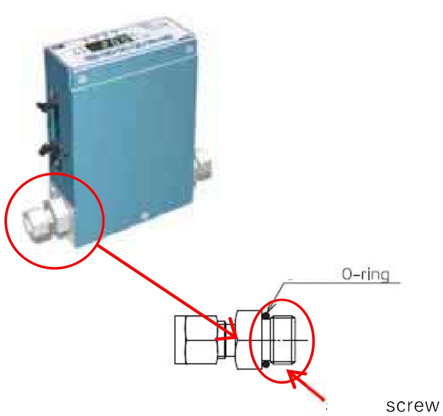

Figure 43

Ordinary grease and oil cannot be used because they may become a source of ignition when flammable oxygen gas is used, so their safety is significantly impaired.

<u>Pressure Transmitter</u>

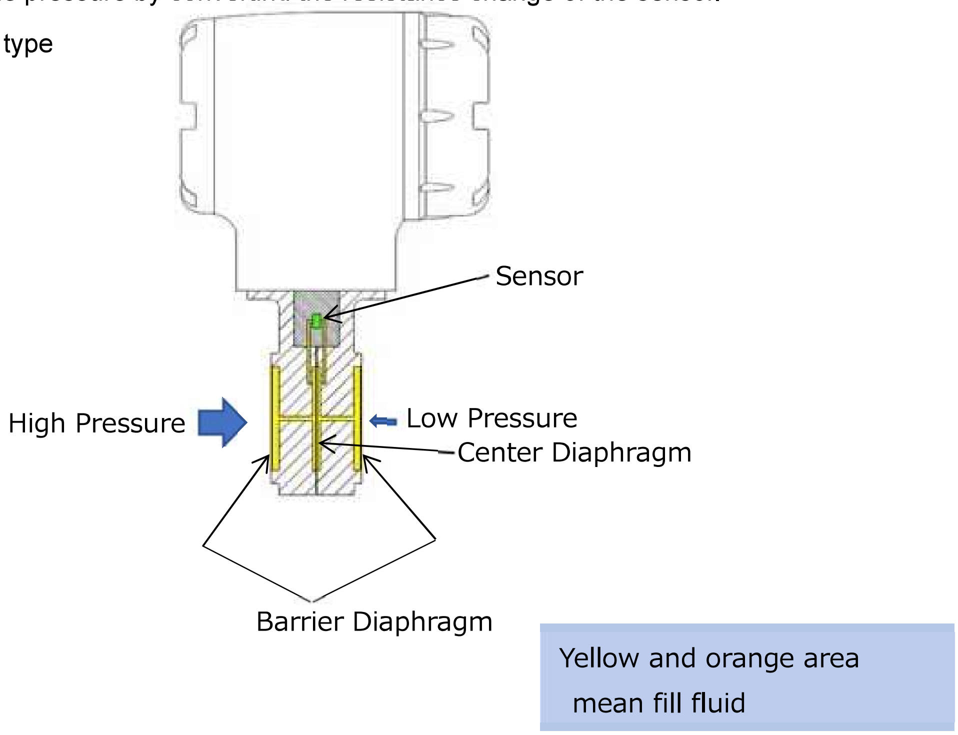
Measuring Principal

A pressure transmitter consists of a barrier diaphragm that contacts the process pressure, a center diaphragm that protects the sensor, and a sensor that detects the pressure.

If there is a difference in pressure on each barrier diaphragm, the fill fluid that carries the pressure creates a pressure difference on either side of the sensor, which distorts the sensor and changes its resistance.

Measure the pressure by converting the resistance change of the sensor.

Standard type



Remote type

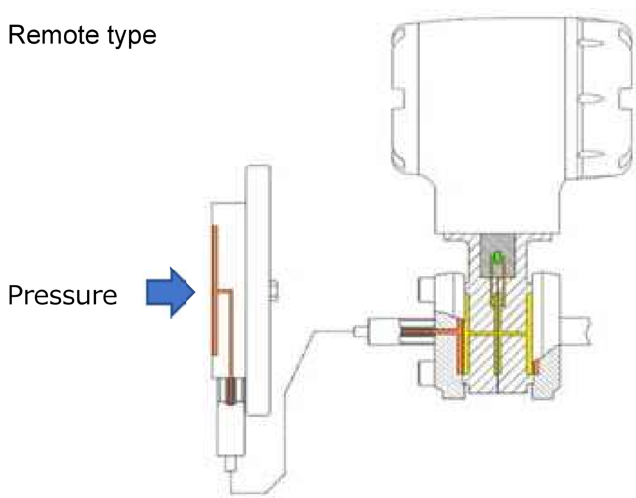


Figure 44

In addition to the following items, the properties required for the fill fluid include fluidity even at low temperatures, low viscosity, and non-flammability. The only fill fluid that offers all of these is the fluorinated fill fluid, and there is no alternative.
The diaphragms that come into contact with process fluids may be damaged due to corrosion or abrasion during use. When broken, the fill fluid comes into direct contact with the process fluid, but otherwise does not leak into the environment.　This product is a WEEE target model and is in a controlled state for disposal.
Shipping volume information：Less than 1000kg par year
Since the fill fluid is in direct contact with the sensor, high electrical insulation performance is required.
PCTFE can use up to 120 degree Celsius, Perfluoropolytrimethyleneoxide can use up to 260 degree Celsius.
Stable against strong corrosive acids and alkalis.
Does not react with chlorine and oxygen even under high temperature and pressure.
Surface tension:26～28mN/m
Silicon oil: Most likely fill fluid but reacts with chlorine and oxygen at high temperatures and pressures, and in the worst cases explodes.

Coding for sliding rubber parts of industrial controllers

A PTFE-coated lubricant is applied to the outer circumference of the packing to make it easier to separate the front bezel from the case.　Since the housing is made of resin, there is a risk of solvent cracking, and grease cannot be used.

Figure 45 Overall product

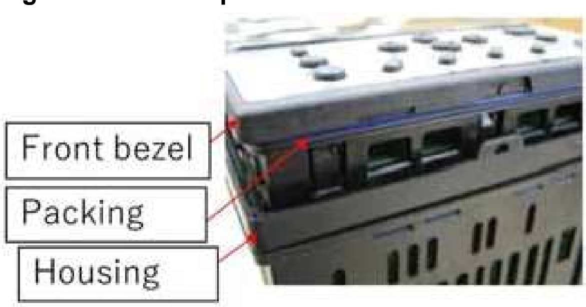

Figure 46 Packing installation explanatory diagram

Others

Solvent for oil content analyzer

Solvent for oil content analyzer is chlorotrifluoroethylene (CAS RN 9002-83-9). (hereinafter "specific chlorotrifluoroethylene solvent")

Solvent extraction-nondispersive infrared absorption method is used for oil content measurement. The light from the light source enters the cell filled with the oil-extracted solvent. After that, an interference filter introduces only the absorption wavelength range (3.4 to 3.5 μm) attributed to stretching vibration between carbon-hydrogen bonds (C-H) into a detector (pyrosensor). As the oil content in the oil extracting solvent increases, the light transmitted through the cell is decreased, and the current value generated by the pyroelectric effect decreases. The oil content can be calculated using this current value.

Infrared absorption method for oil content analysis is standardized in ASTM standard D7066-4.

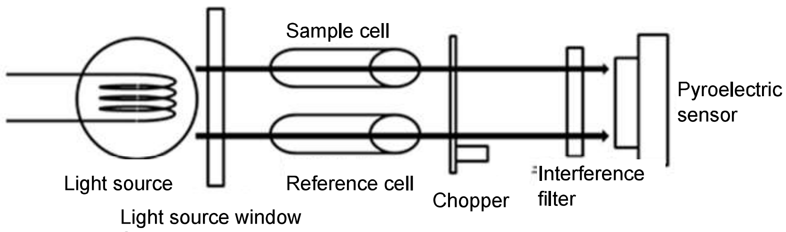

Figure 47 Oil content analyzer bench structure

Extraction of oil from solid samples is performed by immersion as shown in the figure below.

Figure 48 Method for extracting oil from solid samples

Functions of PFAS required by solvent for oil content analyzer and substitutability.

The oil content is quantified by Beer-Lambert law using absorption attributed to carbon-hydrogen stretching vibration at 3.4 to 3.5 μm (2941 to 2857 cm^{-1}). Therefore, the extraction solvent must not have absorption in this wavelength range. Chlorotrifluoroethylene has no carbon-hydrogen bond (C-H) in its molecular structure and has no absorption at 3.4 to 3.5 μm, so it is suitable as a solvent for oil content measurement using the solvent extraction-nondispersive infrared absorption method.

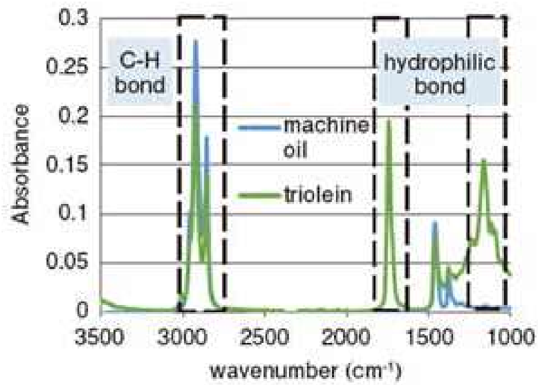

Figure 49 IR spectrum of oil

Existing solvents used for cleaning parts and general reagents that do not have carbon-hydrogen bond (C-H) in their molecular structures were verified, but it could not be adopted because it did not meet the following performance requirements.

- Influence of infrared absorption
  From the principle of the analyzer, it is necessary to have no absorption higher than that of the specific chlorotrifluoroethylene solvent in the wavelength range of 3.4 to 3.5 μm (2941 to 2857 cm^{-1}).
- Safety
  The specific chlorotrifluoroethylene solvent is not listed in the Montreal Protocol and the Kigali Amendment and are not classified in the EU CLP Regulation Hazard Classification.
  With a boiling point of 134°C and a vapor pressure of 1.33 (kPa), it does not easily volatilize during use, so it can be used with normal ventilated environment. Similar safety and operability are required for alternative material.

- Analyzer performance cannot be achieved
  The measurement range of the oil content analyzer is 0-200 mg/L. The light source and the detector are designed and adjusted to achieve the specified performance in the range of 0-200 mg/L when measured using the specific chlorotrifluoroethylene solvent.
  Therefore, as with the influence of infrared absorption, a low absorption rate equivalent to that of the specific chlorotrifluoroethylene solvent is required for measurement in the analyzer range of 0-200 mg/L

Table 3 comparison of solvents

Solvent PFAS Release Risk

Using: With a boiling point of 134°C and a vapor pressure of 1.33 (kPa), it does not easily volatilize during use. And the specific chlorotrifluoroethylene solvent is not listed in the Montreal Protocol and the Kigali Amendment and are not classified in the EU CLP Regulation Hazard Classification, so safe to use.

After use: Only the oil can be removed from used specific chlorotrifluoroethylene solvent with a dedicated equipment and can be reused

Existence and Possibility of Alternatives: There is no alternative solvent that can ensure the same performance and safety as the current one.

Period required for substitution when a substitute material is developed: 4-5 years

Solvent: There is no alternative solvent that can ensure the same performance and safety as the current one.

Limit switch button, housing and rubber seal

1. Internal switch button
2. Painting the housing
3. Used for each rubber seal of limit switch

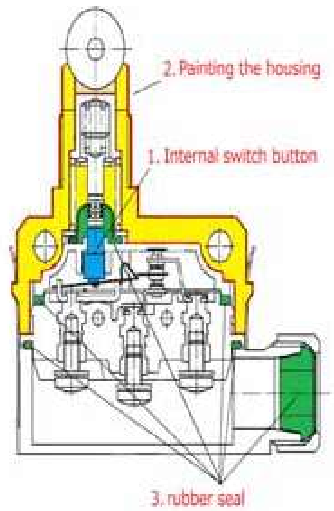

Figure 50

Although the exterior coating can be changed to other coatings, fluorine is the lowest and most suitable for internal sliding properties.

Sliding : plunger and housing

Sliding: internal switch button and internal switch cover

Addition of fluorine improves slidability.

	Fluoropolymer	Resin	
	PTFE	PE	POM
Dynamic friction coefficient (ud)	0.09	0.13	0.18
Heat-resistant(degree Celsius)	260	70-110	80-120

Table 4 [5]

The retention of seals at high temperatures is superior to other rubbers.

Switching to silicone rubber is difficult to adopt because of the risk of contact failure.

In addition, it is often used for applications such as cutting fluid that damage silicon rubber, so it cannot be used.

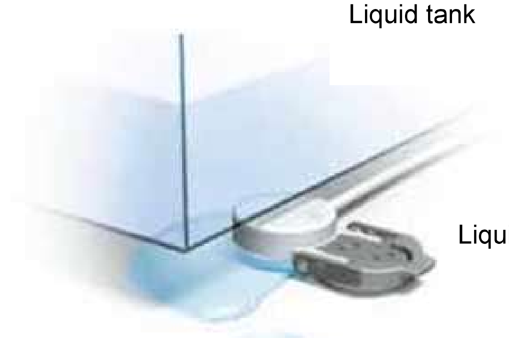
Liquid leak sensor

Liquid tank



Liquid leak sensor

The sensor housing is made of PFA resin.

Figure 51

Schematic diagram of sensor structure
The sensor housing cover, case and tube are made of PFA resin.

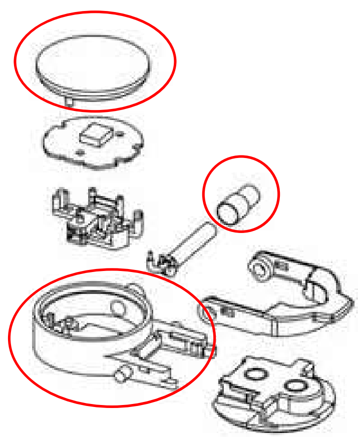


Figure 52

Due to the housing made of PFA resin, this leakage sensor has higher stability against organic solvents than other products.

・The following characteristics can be obtained by using PFA resin for the leakage sensor.

- This leakage sensor functions stably for the detection of organic solvents.

・This leakage sensor is used for the following applications.

- Liquid leakage detection in semiconductor wafer cleaning and developing processes
- Detection of tank leakage

・There are concerns about the following effects due to the unavailability of this technology :

- Cleaning and development of a semiconductor wafer using an organic solvent cannot be carried out safely.

Cutting parts

(Example of finished products: diaphragm galvanic oxygen sensors, oxygen detectors)

It is a part manufactured by cutting a block of resin. Because it is a small-lot production product, it is produced by cutting that does not require mold costs. Another reason for cutting is that there are places where sealing properties are required.

Here, I will touch on the machined parts used in the casing of the galvanic oxygen sensor. There are various materials, but we will describe the case where PTFE and PFA, which have higher chemical resistance, are used.

Figure 53 Example of Fluoroplastic Cutting Parts

Please see “Membrane filters” for galvanic oxygen sensors

Fluoropolymer casing are required when parts require chemical resistance. There is a need to measure oxygen concentration even in places where acids, alkalis, and organic solvents are always present. In this application, it is necessary to have chemical resistance such that it does not deteriorate even when it comes into contact with various gases (acids, alkalis, organic solvents), does not elute components even when it comes in contact with any sample.

Also, as a material, it is necessary to have weather resistance properties such as not changing in a 10-year exposure test and not softening or deforming in the surrounding environment of -40 to 70 °C.

If you try to perform the same function with other materials, for example, phenolic resins and polyamide resins can be mentioned as resins that are resistant to acetone as a general organic solvent, but phenolic resins are resistant to strong alkalis. Polyamide-based resins cannot be used as a substitute because they do not have durability against strong acids.

Figure 54

Humidity element for humidity sensor and dew point temperature sensor

Sector "Electronics and semiconductors (Annex E.2.11.)" "Construction products (E.2.13.)"

Sub uses :Monitoring and control instruments Heating, Ventilation and Air Conditioning(HVAC)

Polymeric PFAS /Fluorinated polyimide

Generic name for the final product: Humidity sensor, Dew point temperature sensor

Common name for application parts: Humidity element

Detailed application description:

The humidity sensor chip used for a humidity sensor and a dew point temperature sensor measures humidity by capacitance change between electrodes sandwiching the moisture sensitive film. The thickness of the moisture sensitive film is several μm.

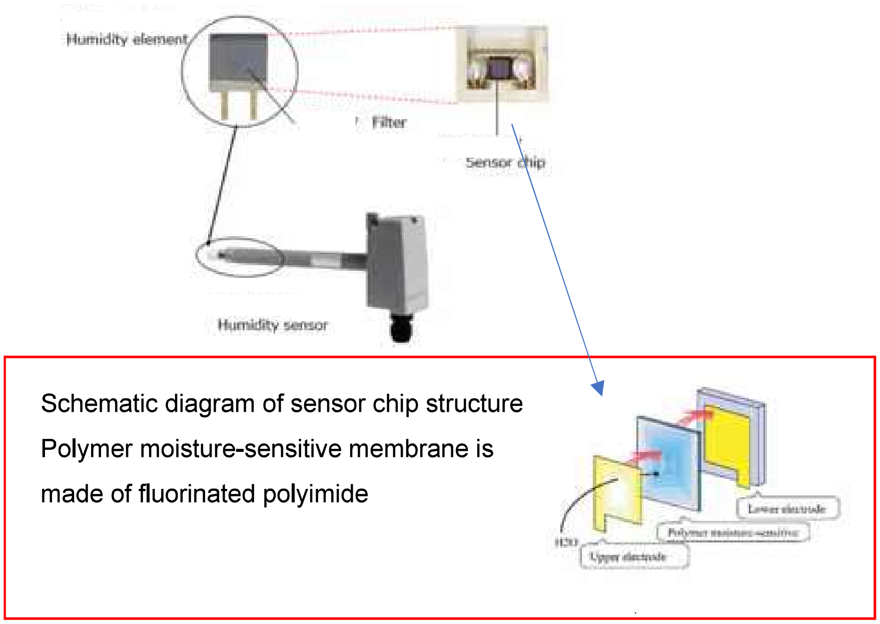

Figure 55

・This humidity sensor is used for the following purposes

・Humidity sensor installed in an environment in which condensation appears on the sensor itself, such as inside the HVAC duct and the outside air intake section.

The following features can be obtained by using fluoride polyimide for humidity sensor

・The humidity sensor works stably for a long period in an environment where the sensor is condensed (100% humidity).

・Nothing to replace this function.

The humidity sensor has higher stability under high temperature, high humidity and condensation than other products due to the humidity sensitive membrane using fluorinated polyimide.

・The prohibition of this technology is concerned about the following effects.

・It won't be able to properly measure and control humidity on HVAC system in an environment in which condensation appears on the sensor itself.

・Other polymer materials such as methyl methacrylate resin (PMMA), polyimide, polysulfone, etc. can be candidates as alternative technologies and materials.

・However alternative technology requires replacement of the sensor every time condensation occurs. For example, it is known that condensation appears on a humidity sensor which is inserted into an outside air intake duct several times a year depending on the weather. Humidity sensors without moisture sensitive membrane using fluorinated polyimide for this application will require replacement at least once a year. Moisture sensitive membranes using fluorinated polyimide can withstand at least 8 years of use.

Performance requirements for materials (PFAS)

Heat-resistant: 180 degree Celsius as a humidity sensitive element

Repellency from water: Electrical insulation in condensing environments

Chemical resistance: Resistant to organic solvent atmosphere

Alternative Considerations: No substitute material

Required derogation period: 13.5 years or more

Valve for air volume and room pressure control

Materials for ensuring sliding, corrosion resistance, chemical resistance, and solvent resistance for air volume valves.

Use sector: "Medical devices (Annex E.2.9.)", "Construction products (E.2.13.)"

sub-uses: Control valve, Heating, Ventilation and Air Conditioning(HVAC)

PFA：26655-00-5

PTFE：9002-84-0

PVDF：24937-79-9

ETFE：25038-71-5

Generic name for the final product: Valve for air volume and room pressure control

Common name for application parts: Body, Pivot arm, S-link, Shaft, Spring, Cone, Brackets, Seal), Tap, e-crip), Bush, Slider, Sleeve, Cap, Bolt

Detailed application description

The two main applications of valves are below.

(1) To be installed as a local exhaust ventilation system to prevent workers from being exposed to substances harmful to the human body, such as in chemical manufacturers and biotechnology research laboratories.

For example, when a worker opens or closes the door of the local exhaust device (red dotted frame in Figure 56), the differential pressure across the valve suddenly changes, but by taking advantage of the good sliding property, the valve can be instantly changed to the appropriate valve opening position to maintain exhaust at a constant air volume.

In addition, since valves must control fluids containing various chemicals and solvents, they must be resistant to corrosion, chemicals, and solvents.

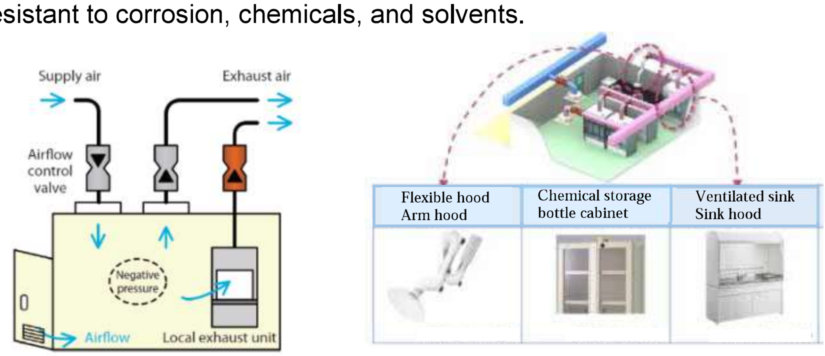

Figure 56 Example of air volume control in a chemical/ Other exhaust applications

(2) The device is installed in hospital rooms and wards as a negative-positive pressure control device to secure hospital beds for patients with infectious diseases and to protect healthcare workers from infection risk.

Even when the differential pressure across the valve suddenly changes due to the opening and closing of the hospital room entrance door, etc., the air supply and exhaust valves respond instantly by taking advantage of their good sliding characteristics and change to the appropriate opening position, thereby always maintaining the pressure difference between the room and outside.

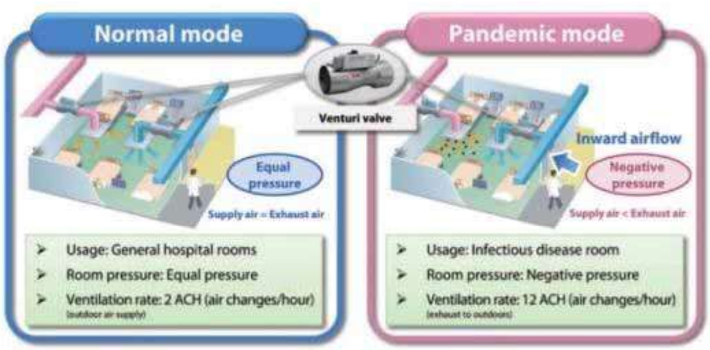

Figure 57 Image of negative and positive pressure control in a hospital room

The parts used in valves that include candidates for regulation are below.

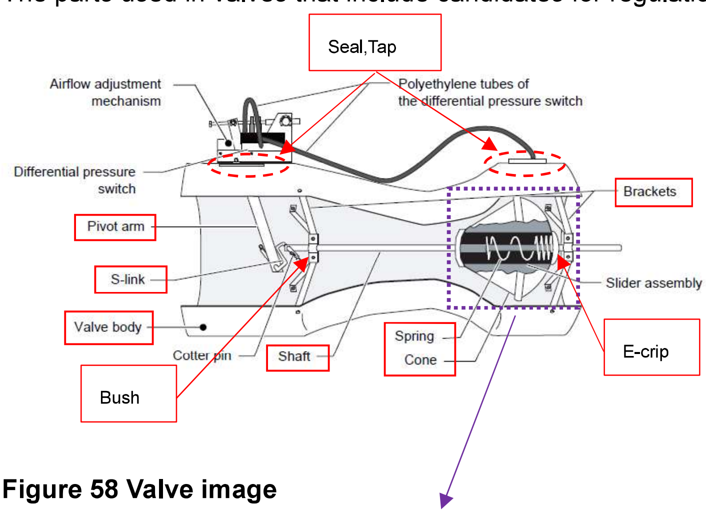

Figure 58 Valve image

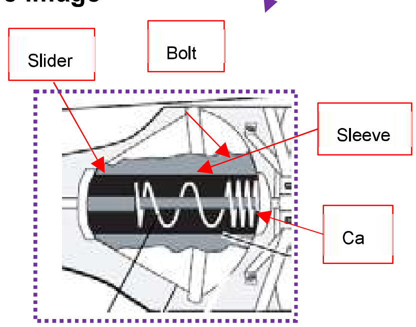

Figure 59 Slider assembly

(1) For valves that do not require corrosion resistance, chemical resistance, or solvent resistance, parts (Slider, Sleeve, Cap) containing PTFE should be used to ensure sliding properties.

(2)Valves that require corrosion resistance, chemical resistance, and solvent resistance use the following parts to ensure the above three functions and sliding properties.
・Parts containing PTFE (Slider, Sleeve, Cap, Bush, Seal, Tap)
・Parts containing PFA (Shaft, Spring)
・Parts containing PVDF or ETFE (Body, Pivot arm, S-link, Cone, E-crip, Bolt)

Technical Description of Essential Uses
As mentioned above in “Detailed application description”, valves must have the sliding property required to respond instantly to sudden disturbances, and the corrosion, chemical, and solvent resistance required to control fluids containing various chemicals and solvents.
Therefore, it is necessary to place parts containing PTFE, PFA, PVDF, and ETFE for mechanisms that need to ensure sliding properties and for channel parts that are in contact with the control fluid.
(1) Ensure sliding properties
Other polymeric materials may be used as an alternative to PTFE for ensuring sliding properties. However, since there is no material with lower sliding resistance than PTFE, the sliding resistance force will increase and the sliding performance required for valves cannot be ensured.
(2) Ensure sliding properties, corrosion resistance, chemical resistance, and solvent resistance
Other polymeric materials, such as rubber and resin, may be used as alternatives to PFA, PTFE, PVDF, and ETFE for the purpose of ensuring the above four functions.
However, the alternative materials cannot ensure the sliding properties, corrosion resistance, chemical resistance, and solvent resistance required for valves due to the deterioration of sliding properties as described in (1) and the lack of resistance to various chemicals and solvents.
The following effects are feared as a result of the unavailability of these technologies.
The inability to use PFA, PTFE, PVDF, and ETFE for valves will make it impossible to carry out normal operations at chemical manufacturers, biotechnology research facilities, hospitals, and other facilities.
This will have a profound impact on the production and supply of medicines, the progress of research in biotechnology, and isolated medical treatment, including coronas.

For the above reasons, the prohibition of the use of parts containing PFA, PTFE, PVDF, and ETFE in valves should be exempted from this restriction in terms of ensuring safety for the human body.

In terms of disposal, the restriction should not be applied to valves containing PFA, PTFE, PVDF, and ETFE, since these components can be used until the product reaches its original service life, leading to a reduction of waste in general.

Performance requirements for materials (PFAS)
Heat-resistant: Heat-resistant max93 degree Celsius
Chemical resistance: Resistant to chemicals, solvents and corrosive fluids
Sliding performance: Wear resistance due to sliding, sliding performance
Non-adhesion: Non-adhesion of foreign matter

Mechanical parts for sliding or releasing applications used in "Specialist equipment"

Fluoropolymers with excellent low friction, and self-lubrication and mon-adhesion. Properties are often used in mechanisms that require sliding with plastic and metal parts or releasing from sticky materials.. The following common characteristics are related to the reason why fluoropolymers are particularly selected for "Specialist equipment".

1) Some final products handled by "Specialist equipment" require use in special environments. For example, in facility environments where foods, liquids, powders, etc. are handled, consideration must be given to high temperature, high humidity, generation of dust, or hygiene management.
2) Equipment used in social infrastructure such as factories is required to have performance such as automatic operation, trouble-free operation, easy preparation and setup changes. This enables us to provide society with high-quality, low-cost products and services.
3) When handling products with equipment, it is required to minimize the impact on product quality, such as damage or adhesion of foreign matter.

From the above, the mechanical parts for sliding applications used in "Specialist equipment" are required to have the following properties.
・Repellency from water and oil / non-adhesion
・Low friction, self-lubrication
・Heat resistance
・Chemical resistance (Acid resistance, Alkali resistance, Oil resistance, Ozon resistance)

Table 5 summarizes the performance of major alternative materials with respect to the required performance.

Material		PTFE	POM	HDPE	PA66
Material or Coating		Material/ Coating	Material	Material/ Coating	Material/ Coating
Low friction	Coefficient of friction	0.04	0.2~0.3	0.2~0.3	0.18~0.4
Repellency from water and oil	Contact angle of water [deg]	114	(Equivalent to PA66)	88	77
	adhesion energy [dyne/cm]	43.1		75.2	97.7
Oil resistance	Contained in food	◎	○	◎	◎
Acid resistance	Contained in food	◎	×	◎~○	△~×
Alkali resistance	Contained in detergents, etc.	◎	×	◎	◎
Ozon resistance	Special cleaning	◎		△	×
Heat resistance	Hot food	◎	△	△~×	△

Table 5

* Non-adhesion and Repellency from water and oil are according to the above-mentioned property table. Others are summarized by the author of this section based on multiple documents.

Appropriate materials are selected and used according to the required performance that varies depending on the work environment and target product. From the table, PFAS shows good properties with respect to water/oil repellency and heat resistance. Cases where PFAS is used as an irreplaceable material include, for example, use in environments where food and liquids are handled, as well as guide parts or blade surface coatings where adhesion is undesirable.

Instrument example (Packaging machine for food industries)

Heating pressure bar with knife of packaging machine (with PTFE Coating)

Figure 60

Food Contact Parts of Measuring Instruments

The following performances are required for the food contact parts of measuring instruments for pre-packaging food.

1) Conformity with (EC) No 1935/2004, (EU) No 10/2011, etc. is required for safety when materials used are exposed to the body through food.
2) For the purpose of reducing food waste and cleaning burden, and ensuring supply by automating production, it is required that food does not adhere easily.

There are two technical approaches to the anti-adhesion performance of 2). The first is "a) reducing the contact area with food" and the other is "b) using water- and oil-repellent, non-adhesive materials." The Table 6 summarizes the performance of the main means currently in practical use considering the operating environment conditions. Each means is provided in the form of material or coating.

Technical approach		(1)contact area	(2) water- and oil-repellent, non-adhesive materials		
Means		Stainless steel embossed structure	PFAS(PTFE,PFA)	Ceramic	HDPE
Material or Coating		Material	Material/Coating	Coating	Material
Repellency from water and oil	Does not adhere to water or oil	× Oil hardens and accumulates.	◎	◎~〇	〇
Non-adhesion (for hard foods)	Food does not remain on equipment.	◎~〇	◎	〇~△	〇
Non-adhesion (for soft foods)		△~×	◎	〇~△	〇
Oil resistance	Contained in food	◎	◎	◎	◎
Acid resistance	Contained in food	◎	◎	◎	◎~〇
Alkali resistance	Contained in detergents, etc.	◎	◎	〇	◎
Ozon resistance	Special cleaning	◎	◎	◎	△
Heat resistance	Hot food	◎	◎	◎	〇
Durability	Hard to wear	◎	△	〇	△

Table 6

*PFAS and PE are according to the above-mentioned property table. SUS and ceramics are summarized by the author of this section based on multiple documents.

In terms of technology in the practical stage, PFAS is superior in all items except durability. Since the required performance differs depending on the type of food and the factory environment, means other than PFAS may be selected. However, it is clear from the above table that substitution is not possible in all cases, which is the reason why exclusion is necessary. Also, the determination of substitutability must be tried in all cases using actual food in a real working environment, which is why the substitution period is necessary.

Instrument example (Weigher for food industries)

Example of oil accumulation (Food contact part is a flat stainless steel without coating)

Example of stainless steel embossed structure

Coalition of Manufacturers of Complex Products

March 1, 2024

Katrina Kessler, Commissioner
Minnesota Pollution Control Agency
520 Lafayette Rd. N.
St. Paul, MN 55155-4194

Via eComment at https://minnesotaoah.granicusideas.com/

Re: Planned New Rules in Minnesota Governing Currently Unavoidable Use Determinations About Products Containing Per- and Polyfluoroalkyl Substances, Revisor's ID No. R-4837

Dear Commissioner Kessler:

The Coalition of Manufacturers of Complex Products (Coalition) appreciates the opportunity to respond to the Minnesota Pollution Control Agency's (MPCA) request for comments regarding the planned new rules for the MPCA's determination of currently unavoidable uses (CUU) of per- and polyfluoroalkyl substances (PFAS) in products. Additionally, the Coalition submits requests a CUU determination for complex consumer and durable goods, their components and replacement parts, as part of this rulemaking.

Coalition members manufacture equipment and products by assembling tens to hundreds or thousands of parts, components, and raw materials to provide, in many cases, critical services to society. These include commercial and consumer products such as appliances, vehicles, vessels, motors, heating, ventilation, air conditioning, refrigeration, and water heating equipment (HVACR- WH), electronics, and their replacement parts. Coalition members serve and support nearly every major sector in the nation, providing critical products and services for government agencies, the military, law enforcement, first responders, and public safety, food and agriculture (including commercial fishing and sea farming), energy, transportation and logistics (including for commuting and for island residents), public works and infrastructure support services, critical manufacturing, the defense industrial base, conservation, and life-saving climate control and ventilation in homes, hospitals, schools, and eldercare facilities, or food preservation and processing and for critical health and life sciences. Services dependent on refrigeration include everything from the prevention of dangerous food spoilage to life-giving medicines, vaccines, proteomics, therapeutics, blood plasma, and other temperature-dependent elements in the life sciences and pharmaceutical sectors. Collectively these products and services constitute a vital part of the economy, at all levels, including for public safety..

A ban on the use of complex consumer and durable goods in Minnesota would significantly disrupt the safety, health, and functioning of society in Minnesota, national security, and critical infrastructure. The Coalition is pleased to provide additional input below, in response to MPCA's questions listed in the request for comments. In addition to our responses, the Coalition is including comments submitted on establishing currently unavoidable use exemptions in Maine (Attachment 1). Please note that the information there was developed with both Maine and Minnesota's programs in mind.

1. **Should criteria be defined for "essential for health, safety, or the functioning of society"? If so, what should those criteria be?**

In Section 1 of Attachment 1, the Coalition provides the definition for "complex consumer and durable goods." In Section 2 of Attachment 1, the Coalition explains the criteria by which complex consumer and durable goods are essential to the safety and functioning of critical domestic infrastructures such as national defense, transportation, communications, and construction, and are used in security systems, safety lighting, and life-saving medical devices.

2. **Should costs of PFAS alternatives be considered in the definition of "reasonably available"? What is a "reasonable" cost threshold?**

The Coalition submits that MPCA should not only consider the costs of PFAS alternatives, but all associated costs, such as the costs that companies incur over the time it takes to implement alternatives across the complex supply chains for these products. In Section 4 of Attachment 1 the Coalition describes the length of time it takes to identify and implement alternatives across complex supply chains.

3. **Should unique considerations be made for small businesses with regards to economic feasibility?**

The Coalition supports taking small business considerations into account in providing exemptions from reporting and the law's product ban.

4. **What criteria should be used to determine the safety of potential PFAS alternatives?**

In determining the safety of potential PFAS alternatives, the Coalition supports a risk-based approach, as described in Section 3 of Attachment 1.

5. **How long should PFAS currently unavoidable use determinations be good for? How should the length of the currently unavoidable use determination be decided. Should significant changes in available information about alternatives trigger a re-evaluation?**

The Coalition supports CUU determinations that are not time limited. As described in Section 4 of Attachment 1, identification of and transition to safer feasible alternatives for PFAS in complex consumer and durable goods takes many years. The variety of ways in which PFAS components are used and the myriad of products does not align with a single transition period.

6. **How should stakeholders request to have a PFAS use be considered for currently unavoidable use determination by the MPCA? Conversely, could stakeholders request a PFAS use not be determined to be currently unavoidable? What information should be submitted in support of such requests?**

The Coalition supports exemptions by product category. The Coalition does not support redirecting limited state resources to requests for not unavoidable determinations. Product manufacturers are in the best position to know their products and whether alternatives are feasible. The Coalition supports having the same criteria that Maine requires for CUU exemptions.[1]

7. **In order to get a sense of what type of and how many products may seek a currently unavoidable uses determination, please share what uses and products you may**

---

[1] Maine Department of Environmental Protection, *PFAS in Products: Currently Unavoidable Uses* (Last visited February 29, 2024).

submit a request for in the future and briefly why. There will be a future opportunity to present your full argument and supporting information for a possible currently unavoidable uses determination.

The Coalition respectfully requests that MPCA grant an exemption for the product category of complex consumer and durable goods, as defined in Section 1 of Attachment 1. The Coalition believes that this product category fulfills all of the requirements for a CUU determination.

8. **Should MPCA make some initial currently unavoidable use determinations as part of this rulemaking using the proposed criteria?**

Yes. Due to the essential nature of and the additional time needed to find alternatives, CUU determinations should be part of the proposed rule. We ask that complex consumer and durable goods be included. To avoid uncertainty around the extremely negative socio-economic consequences of a ban on complex consumer and durable goods, CUU determinations should be made as soon as possible. The proposed rule should include a process for requesting additional exemptions.

9. **Other questions or comments relating to defining currently unavoidable use criteria and the process MPCA uses to make currently unavoidable use determination.**

The Coalition believes that a CUU exemption should apply to the 2032 ban and the reporting requirement, set to become effective in Minnesota as of January 1, 2026.

* * *

The Coalition would welcome an opportunity to discuss these comments with you and answer any questions. The Coalition respectfully requests that MPCA grant our request to provide a currently unavoidable use exemption in proposed and final regulations for complex consumer and durable goods, their components and replacement parts. For further information about these comments, please do not hesitate to contact Martha Marrapese, Partner at Wiley Rein LLP, at (202) 719-7156 or mmarrapese@wiley.law.

65000000	Computing		65010000	Computers /Video Games		65010100	Computer/ Video Game Accessories		10001112	Computer Tools/Tool Kits	Includes any products that can be described/observed as a collection of tools specifically designed to be used with computer equipment.	Excludes products such as DIY Toolkits.						
65000000	Computing		65010000	Computers /Video Games		65010100	Computer/ Video Game Accessories		10001115	Card Readers	Includes any products that can be described/observed as a compact portable device that allows for fast viewing, sharing, transferring and e-mailing of various data, such as pictures.	Excludes products such as Computer Drives and Cards.	20002649	Type of Card		30007885	MEMORY CARD	
65000000	Computing		65010000	Computers /Video Games		65010200	Computer Components		10001118	Computer Components - Replacement Parts/Accessories	Includes any products that can be described/observed as replacement parts and accessories that can be applied to various computer components.	Excludes all other products currently catered for within Computers segment.						
65000000	Computing		65010000	Computers /Video Games		65010200	Computer Components		10001119	Computer Components Other	Includes any products that can be described/observed as a Computer Component, where the user of the schema is not able to classify the products in existing bricks within the schema.	Excludes all currently classified Computer Components.						
65000000	Computing		65010000	Computers /Video Games		65010200	Computer Components		10001120	Computer Components Variety Packs	Includes any products that can be described/observed as two or more distinct Computer Component products sold together which exist within the schema but belong to different bricks, that is two or more products contained within the same pack which cross bricks within the Computer Components class. Includes products such as Computer Memory and Computer Motherboards sold together. Items that are received free with purchases should be removed from the classification decision-making process.	Excludes products such as Computer Processors sold individually.						
65000000	Computing		65010000	Computers /Video Games		65010200	Computer Components		10001123	Computer Motherboards	Includes any products that can be described/observed as the primary printed circuit board in a PC, which contains all of the basic circuitry and components required for a PC to function. The motherboard typically contains the system bus, processor and coprocessor sockets, memory sockets, serial and parallel ports, expansion slots and peripheral controllers but can be sold with or without these components attached.	Excludes products such as Peripherals.	20001709	Target Use/Application	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the target use and/or application.	30007587	DESKTOP	
65000000	Computing		65010000	Computers /Video Games		65010200	Computer Components		10005683	Computer/ Video Games Mass Storage	Includes any products that can be described/observed as a mass storage device on which data is held and from which data can be retrieved. Includes devices such as tapes, cartridges and disks specifically for use with computers and video consoles. Includes products such as ZIP and JAZZ disks.	Excludes products such as random access memory (RAM).	20002579	Storage Medium/Device	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of device used for storage.	30013000	DATA CARTRIDGE/TAPE	
65000000	Computing		65010000	Computers /Video Games		65010300	Computer Drives		10001133	Hard Disc Drives	Includes any products that can be described/observed as a storage device that uses a set of rotating, magnetically coated discs called platters to store data or programs, hermetically sealed to prevent airborne contaminants from entering and interfering with these close tolerances.	Excludes products such as Floppy Disc Drives and CD/DVD Drives.	20002710	If Multimedia	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product uses a combination of text, audio, still images, animation, and video.	30002960	NO	

65000000	Computing		65010000	Computers /Video Games		65010400	Computer/ Video Game Software		10001138	Computer Software (Non Games)	Includes any products that can be described/observed as a program that instructs a computer how to process data and documentation and that explains how these programs should be used. Includes products such as Word Processing Software, Spreadsheet Software, Presentation Software and Desktop Publishing Software.	Excludes products such as Computer Games.	20000045	Consumer Lifestage	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the period or stage in the consumer's life during which the product is considered to be suitable.	30000147	ADULT	
65000000	Computing		65010000	Computers /Video Games		65010400	Computer/ Video Game Software		10006236	Computer Software (Non Games) - Digital	Includes any products that can be described/observed as a programme which is downloaded or streamed that instructs a computer how to process data along with documentation that explains how these programs should be used. Includes products such as Word Processing Software, Spreadsheet Software, Presentation Software, Fonts, and Desktop Publishing Software.	Excludes products such as Computer Games and Digital Mobile Apps.						
65000000	Computing		65010000	Computers /Video Games		65010500	Computers		10001141	Computers - Replacement Parts/Accessories	Includes any products that can be described/observed as replacement parts and accessories that can be applied to various computer products.	Excludes all other products currently catered for within the Computers/Video Games segment.						
65000000	Computing		65010000	Computers /Video Games		65010500	Computers		10001142	Computers Other	Includes any products that can be described/observed as a Computer article, where the user of the schema is not able to classify the products in existing bricks within the schema.	Excludes all currently classified Computers as well as articles to be found within the Communication segment.						
65000000	Computing		65010000	Computers /Video Games		65010500	Computers		10001147	Servers	Includes any products that can be described/observed as a computer in a network that provides access to other computers in the network to programs, web pages, data, or other files and services, such as printer access or communications access.	Excludes products such as Personal Computers not specifically designed for use as Servers as well as servers for home automation or smart devices.	20001709	Target Use/Application	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the target use and/or application.	30007678	DATABASE SERVER	
65000000	Computing		65010000	Computers /Video Games		65010600	Computer/ Video Game Control/Input Devices		10001152	Computer/ Video Game Control/Input Devices - Replacement Parts/Accessories	Includes any products that can be described/observed as replacement parts and accessories that can be applied to various Computer/Video Game Console Control and Input Devices.	Excludes products classified in other bricks of Computer/Video Game Console Control and Input Devices class.						
65000000	Computing		65010000	Computers /Video Games		65010700	Computer/ Video Game Peripherals		10001155	Computer/ Video Game Peripherals - Replacement Parts/Accessories	Includes any products that can be described/observed as replacement parts and accessories that can be applied to various Computer/Video Game Peripherals.	Excludes products classified in other bricks of the Compute/Video Game Peripherals class.						
65000000	Computing		65010000	Computers /Video Games		65010700	Computer/ Video Game Peripherals		10001156	Printer Consumables	Includes any products that can be described/observed as being specifically designed to periodically replace/refill components of a printer that have been depleted or worn out by use, such as ink cartridges. These products also includes refills such as ink, which is just added to the original cartridge in order to refill it rather than replace it. Cartridges may contain only black ink or one to five colours of ink. The products include Photo Ink Cartridges that contain special lighter Cyan and Magenta Inks, which help re-create more lifelike flesh tones.	Excludes products such as Printers, Type Writer and Fax Machine Consumables.	20002605	Dedicated Usage	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the application/usage to which the product is dedicated.	30000720	COMBINATION	

65000000	Computing		65010000	Computers /Video Games		65010700	Computer/ Video Game Peripherals		10001156	Printer Consumables	Includes any products that can be described/observed as being specifically designed to periodically replace/refill components of a printer that have been depleted or worn out by use, such as ink cartridges. These products also includes refills such as ink, which is just added to the original cartridge in order to refill it rather than replace it. Cartridges may contain only black ink or one to five colours of ink. The products include Photo Ink Cartridges that contain special lighter Cyan and Magenta Inks, which help re-create more lifelike flesh tones.	Excludes products such as Printers, Type Writer and Fax Machine Consumables.	20002605	Dedicated Usage	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the application/usage to which the product is dedicated.	30007730	PRINTER	
65000000	Computing		65010000	Computers /Video Games		65010700	Computer/ Video Game Peripherals		10001158	Printers	Includes any products that can be described/observed as a computer/games console printer that produces hard copies. Includes products such as photo printers and video games printers.	Excludes products such as multifunctional devices that include a printer and which are classified with office machinery, as well as any other computer peripherals.	20002615	If Photo Printer	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is a photo printer.	30002960	NO	
65000000	Computing		65010000	Computers /Video Games		65010700	Computer/ Video Game Peripherals		10001158	Printers	Includes any products that can be described/observed as a computer/games console printer that produces hard copies. Includes products such as photo printers and video games printers.	Excludes products such as multifunctional devices that include a printer and which are classified with office machinery, as well as any other computer peripherals.	20001080	Type of Printer	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of printer.	30002518	UNIDENTIFIED	This term is used to describe those product attributes that are unidentifiable given existing or available product information.
65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001163	Gateways	Includes any products that can be described/observed as a device that enables two dissimilar systems that have similar functions to communicate with each other.	Excludes products such as Switches, Hubs, Routers and Firewalls.						
65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001168	Network Routers	Includes any products that can be described/observed as a device that determines the next network point to which a data packet should be forwarded enroute toward its destination.	Excludes products such as Hubs, Switches and Gateways.	20002061	If With Modem	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether or not the product is supplied with a modem.	30002960	NO	
65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001168	Network Routers	Includes any products that can be described/observed as a device that determines the next network point to which a data packet should be forwarded enroute toward its destination.	Excludes products such as Hubs, Switches and Gateways.	20001092	Type of Network Router	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of network router.	30007770	DYNAMIC ROUTER	
65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001168	Network Routers	Includes any products that can be described/observed as a device that determines the next network point to which a data packet should be forwarded enroute toward its destination.	Excludes products such as Hubs, Switches and Gateways.	20001092	Type of Network Router	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of network router.	30007771	STATIC ROUTER	
65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001168	Network Routers	Includes any products that can be described/observed as a device that determines the next network point to which a data packet should be forwarded enroute toward its destination.	Excludes products such as Hubs, Switches and Gateways.	20001092	Type of Network Router	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of network router.	30002515	UNCLASSIFIED	This term is used to describe those product attributes that are unable to be classified within their specific market; e.g. goat's cheese - goat's cheeses is often generically labelled and cannot be further classified.
65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001168	Network Routers	Includes any products that can be described/observed as a device that determines the next network point to which a data packet should be forwarded enroute toward its destination.	Excludes products such as Hubs, Switches and Gateways.	20001092	Type of Network Router	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of network router.	30002518	UNIDENTIFIED	This term is used to describe those product attributes that are unidentifiable given existing or available product information.
65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001169	Network Switches	Includes any products that can be described/observed as a computer networking device that filters information/data between network segments.	Excludes products such as Hubs, Routers and Gateways.						
65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001170	Computer Networking Equipment Other	Includes any products that can be described/observed as Computer Network Equipment, where the user of the schema is not able to classify the products in existing bricks within the schema.	Excludes all currently classified Computer Network Equipment.						

65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001171	Computer Networking Equipment Variety Packs	Includes any products that can be described/observed as two or more distinct Computer Networking Equipment products sold together which exist within the schema but belong to different bricks, that is two or more products contained within the same pack which cross bricks within the Computer Networking Equipment class. Includes products such as Computer Firewalls and Gateways sold together. Items that are received free with purchases should be removed from the classification decision-making process.	Excludes products such as Network Access Points sold individually.						
65000000	Computing		65010000	Computers /Video Games		65010800	Computer Networking Equipment		10001172	Computer Networking Equipment - Replacement Parts/Accessories	Includes any products that can be described/observed as replacement parts and accessories that can be applied to various Computer Networking Equipment.	Excludes all other products currently catered for within Computers segment.						
66000000	Communications		66010000	Communications		66010100	Communication Accessories		10001379	Communication Accessories Other	Includes any products that may be described/observed as Communication Accessories products, where the user of the schema is not able to classify the products in existing bricks within the schema. Includes all products (e.g. military, emergency service, industrial or other special specifications) which fit the product definition.	Excludes all currently classified Communication Accessories products.						
66000000	Communications		66010000	Communications		66010200	Fixed Communication Devices		10001383	Fixed Communication Devices Other	Includes any products that may be described/observed as a Fixed Communication Device, where the user of the schema is not able to classify the products in existing bricks within the schema.	Excludes all currently classified Fixed Communication Devices.						
66000000	Communications		66010000	Communications		66010200	Fixed Communication Devices		10001384	Fixed Communication Devices Variety Packs	Includes any products that may be described/observed as two or more distinct Fixed Communication Device products sold together, which exist within the schema belonging to different bricks but to the same class, that is two or more products contained within the same pack which cross bricks within the Fixed Communication Devices class. Includes products such as a Telephone sold with a separate Answering Machine. Items that are received free with purchases should be removed from the classification decision-making process.	Excludes products such as a Telephone sold with a Caller ID Display.						
66000000	Communications		66010000	Communications		66010300	Mobile Communication Devices/Services		10001385	Mobile Communication Devices/Services Other	Includes any products that may be described/observed as Mobile Communication Devices and Services products, where the user of the schema is not able to classify the products in existing bricks within the schema.	Excludes all currently classified Mobile Communication Devices and Services products.						
68000000	Audio Visual/Photography		68020000	Photography/Optics		68020100	Photography		10001487	Digital Cameras	Includes any products that can be described/observed as a digital device specifically designed for taking photographs that are stored on either an internal memory or memory cards/chips. Images taken on a digital camera can be viewed on products such as televisions or computers. Unwanted images can be erased from the memory.	Excludes products such as Analogue Cameras.	20003040	Can Directly Print Photos	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether or not the product can produce pictures from the camera.	30002960	NO	
68000000	Audio Visual/Photography		68020000	Photography/Optics		68020200	Optics		10001505	Optics - Replacement Parts/Accessories	Includes any products that can be described/observed as a replacement part or an accessory for products within the Optics class.	Excludes products such as Batteries and all Optics Products currently catered for in the Optics class.						

68000000	Audio Visual/Photography		68020000	Photography/Optics		68020200	Optics		10001506	Optics Other	Includes any products that can be described/observed as Optics products, where the user of the schema is not able to classify the products in any existing bricks within the schema.	Excludes all currently classified Optics products as well as Interchangeable Lenses to be found in the photography class.						
68000000	Audio Visual/Photography		68040000	Audio Visual Media		68040200	Recordable Media		10001452	Memory Cards	Includes any products that can be described/observed as a computer chip on which electronic information can be stored and accessed quickly. Memory cards may be installed in equipment such as phones or cameras. These products can hold various capacities of data and can transfer this data at various speeds to or from an external device. Includes products such as Games Console Memory Cards as well as Universal SD, and Smart Media Cards, which can be used with a number of electronic products.	Excludes products such as Computer/Video Mass Storage and USB Flash Drives/Thumb Drives.	20002598	Storage Capacity	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the storage capacity.	30016034	<1 GIGABYTE	
68000000	Audio Visual/Photography		68040000	Audio Visual Media		68040200	Recordable Media		10001456	Floppy Discs	Includes any products that can be described as a flat circular device, usually stored in a square plastic case, which has a magnetic covering and is used for storing computer information.	Excludes products such as recordable DVDs or CDs.						
68000000	Audio Visual/Photography		68040000	Audio Visual Media		68040200	Recordable Media		10001457	Recordable Media Variety Packs	Includes any products that can be described/observed as two or more distinct Recordable Media products sold together, which exist within the schema belonging to different bricks but to the same class, that is two or more products contained within the same pack which cross bricks within the Recordable Media class. Includes products such as Recordable CD's and Recordable DVD's sold together. Items that are received free with purchases should be removed from the classification decision-making process.	Excludes products such as Camcorder and Blank Video Cassettes Variety Packs.						
68000000	Audio Visual/Photography		68040000	Audio Visual Media		68040200	Recordable Media		10001458	Recordable Media Other	Includes any products that can be described/observed as Recordable Media products, where the user of the schema is not able to classify the products in existing bricks within the schema.	Excludes all currently classified Recordable Media Products.						
68000000	Audio Visual/Photography		68040000	Audio Visual Media		68040200	Recordable Media		10006398	USB Flash Drives/Thumb Drives	Includes any products that can be described/observed a solid state device with a computer chip on which electronic information can be stored and accessed quickly. A USB flash drive(also called a thumb drive) is a data storage device that includes flash memory with an integrated Universal Serial Bus (USB) interface. These products are typically removable and rewritable and can be linked to a computer's USB port. These products can hold various capacities of data and can transfer this data at various speeds to or from another device.	Excludes products such as Computer/Video Mass Storage and other memory cards.	20002598	Storage Capacity	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the storage capacity.	30016049	< 2 GIGABYTES	
72000000	Home Appliances		72020000	Small Domestic Appliances		72020600	Portable Air Control Appliances		10005317	Air Conditioners - Portable	Includes any products that may be described/observed as a portable device for controlling, especially lowering, the temperature and humidity of an enclosed space.	Excludes stationary air conditioners.	20001638	If With Integral Timer	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify if the product has an integral timer.	30002960	NO	
73000000	Kitchenware and Tableware		73040000	Kitchenware		73040300	Food Measuring Equipment		10002140	Food Thermometers	Includes any products that can be described/observed as an instrument for measuring temperature of food while cooking. Includes products such as digital thermometers, manually operated dial food thermometers, disposable temperature indicators designed for particular foods and pop-ups that are inserted into the food and pop-up when the desired temperature is reached.	Excludes products such as thermometers not specifically designed for measuring food temperature.	20001679	Type of Food Thermometer	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of food thermometer.	30009656	DIGITAL FOOD THERMOMETER	

73000000	Kitchenware and Tableware		73040000	Kitchenware		73040300	Food Measuring Equipment		10002141	Food Measuring Equipment Variety Packs	Includes any products than can be described/observed as two or more distinct kitchen measuring tools sold together, which exist within the schema belonging to different bricks but to the same class, that is two or more products contained within the same pack which cross bricks within the Food Measuring Equipment class. Includes products such as a cooking timer and thermometer sold together. Items that are received free with purchases should be removed from the classification decision-making process.	Excludes products such as a kitchen scale and kitchen utensils variety pack.						
73000000	Kitchenware and Tableware		73040000	Kitchenware		73040300	Food Measuring Equipment		10002142	Food Measuring Equipment Other	Includes any products that can be described/observed as food measuring equipment, where the user of the schema is not able to classify the products in existing bricks within the schema.	Excludes all currently classified Food Measuring Equipment as well as products such as personal scales classified in Healthcare.						
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020500	Electrical Connection		10005573	Connectors (Electrical)	Includes any products that can be described/observed as a coupling device for joining conductors of one electrical circuit together with those of another circuit. Connectors may facilitate a connection that can be easy established and separated or be a permanent fixture. Typically these products are either female or male, or in some case may comprise of both female and male parts.	Specifically excludes plugs, sockets connected to the mains/live electricity supply and terminal blocks/strips. Excludes products such as Conduit Connectors, Splitters, Extension Cables/Reels, Switches Transformers and Fuses.	20002566	Automatic/Mechanical	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product makes a connection automatically or through mechanical operation.	30006875	AUTOMATIC	The product manufacturer identifies that the product is operated automatically.
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10000547	Converters/Transformers	Includes any products that can be described/observed as an electrical apparatus designed to alter, convert, stabilise, regulate or transform an electric power supply characteristic, such as the voltage, current or phase. Includes products such as signal converters, power regulators and distribution power transformers.	Excludes products such as adaptors, switches and splitters.	20000658	If Waterproof	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify if the product is waterproof.	30002960	NO	
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10005568	Splitters	Includes any product that can be described/observed as a device that separates an electronic signal into two or more smaller and approximately equal signals and distributes them to a number of receivers simultaneously. Includes products such as power splitters, RF (radio frequency) signal splitters and microphone splitters.	Excludes products such as electrical adaptors, busways and cable splicing tools.	20002536	Type of Splitter	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of splitter.	30012961	DATA NETWORK SPLITTER	
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10005570	Relays/Contactors	Includes any products that can be described/observed as an electrical switching device that opens and closes under control of another electrical circuit. Relays are designed for switching loads on or off, whereas contactors are designed to "break" a high current load and are commonly fitted with overload protection. Includes products such as power relays, socket relays and alternating voltage relays, as well as vacuum contactors.	Excludes products such as switches, transformers and circuit breakers.	20002538	Type of Relay/Contactor	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of electrical relay or contactor.	30012788	ALTERNATING VOLTAGE RELAY	
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10005577	Electrical Distribution Accessories/Fittings	Includes any products that can be described/observed as an accessory or fitting used to assist or enhance the installation of electrical distribution products. Includes products such as wire terminal kits, terminal block covers and terminal block separators.	Excludes products such as pliers classified with hand tools and wall plates.	20002531	Type of Electrical Distribution Accessory/Fitting	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of electrical distribution accessory or fitting.	30012919	CEILING BOX FLANGE	

78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10005585	Surge Suppressors/Protectors	Includes any products that can be described/observed as a device used to protect electrical appliances and electronic equipment. Surge protectors regulate the voltage supplied to an electric device by either blocking, or shorting to ground, voltage above a safe threshold. Includes products such as external surge suppressors, which are installed on the electrical panel to protect home appliances such as refrigerators and washing machines, or point-of-use surge suppressors, which are connected to individual pieces of home electronic equipment such as computers and televisions.	Excludes products such as circuit breakers and fuses.	20002542	External/Point-of-use	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is installed externally where all electricity enters the home, or at point-of-use where connection is made to an individual piece of electronic equipment.	30007610	EXTERNAL	
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10005586	Switches	Includes any products that can be described/observed as a circuit interruption device used to control the flow of electricity to electrical lights, appliances, and outlets. The flow is controlled by either turning the electricity on or off or by changing the path along which it flows and can be managed mechanically, electronically by remote control or via an app (smarthome).	Excludes products such as dimmers classified with electrical lighting, relays and circuit breakers.	20001353	Installation Type	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify how/where the product is installed.	30012932	PANEL MOUNTED	
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10005586	Switches	Includes any products that can be described/observed as a circuit interruption device used to control the flow of electricity to electrical lights, appliances, and outlets. The flow is controlled by either turning the electricity on or off or by changing the path along which it flows and can be managed mechanically, electronically by remote control or via an app (smarthome).	Excludes products such as dimmers classified with electrical lighting, relays and circuit breakers.	20002537	Type of Switch	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of switch.	30012771	FLOW SWITCH	
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10005586	Switches	Includes any products that can be described/observed as a circuit interruption device used to control the flow of electricity to electrical lights, appliances, and outlets. The flow is controlled by either turning the electricity on or off or by changing the path along which it flows and can be managed mechanically, electronically by remote control or via an app (smarthome).	Excludes products such as dimmers classified with electrical lighting, relays and circuit breakers.	20002537	Type of Switch	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of switch.	30012779	LEVEL/FLOAT SWITCH	
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10005586	Switches	Includes any products that can be described/observed as a circuit interruption device used to control the flow of electricity to electrical lights, appliances, and outlets. The flow is controlled by either turning the electricity on or off or by changing the path along which it flows and can be managed mechanically, electronically by remote control or via an app (smarthome).	Excludes products such as dimmers classified with electrical lighting, relays and circuit breakers.	20002537	Type of Switch	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of switch.	30012766	LIMIT SWITCH	
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78020600	Electrical Distribution		10005682	Multi-use/Universal Electrical Timers/Controllers	Includes any products that can be described/observed as an electrical device that automates/controls the operational timing of a number of different home systems such as electrical lighting, central heating, water heating, security systems and audio visual equipment. Includes products with a plug-in connection as well as wireless digital, programmable switches and touch pads.	Excludes products such as cooking timers, clocks and control systems intended for a single application such as thermostats and audio visual remote controls.						

78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78021100	Batteries/Chargers		10000546	Batteries	Includes any products that can be described/observed as small electro-chemical cells specifically designed to produce an electrical current that can act as a conveniently sized portable power source for a range of electronic devices. Includes products such as rechargeable and non-rechargeable Battery Cells that come in different sizes dependent on power output.	Excludes products such as Battery Chargers, Transformers and Car Batteries.	20000664	Battery Constituent	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify a particular type of battery constituent.	30004177	ACID	
78000000	Electrical Supplies		78020000	Electrical Connection/Distribution		78021200	Electrical Generation		10008390	Inverters	Includes any products that can be described/observed as an electronic device that converts direct current (DC) electricity into alternating current (AC) electricity. In renewable energy systems, inverters are commonly used to convert the DC electricity produced by solar panels or wind turbines into AC electricity that can be used to power homes and businesses. Inverters are essential for renewable energy systems, as most electrical devices require AC power to function. In addition to converting DC to AC, inverters may also perform other functions, such as regulating the voltage and frequency of the AC output, providing grid-tie capabilities, and managing power quality.	Excludes products such as converters, charge/voltage regulators and transformers.						
78000000	Electrical Supplies		78030000	Electrical Lighting		78030400	Portable Electric Lighting		10005642	Electric Torches/Flashlights	Includes any products that can be described/observed as a hand-held or head mounted portable electric spotlight. Typically a torch/flashlight consists of a small electric lightbulb powered by electric batteries or rechargeable electric cell. The components are mounted in a housing that contains the necessary electric circuit and provides ease of handling, a means of access to the batteries for replacement, and a clear covering over the lightbulb for its protection. Includes products such as headlamps, which have elasticised straps and can be worn around the head leaving the hands free.	Excludes products such as all Lanterns, Lightbulbs/Tubes, Freestanding Lamps and Lighting Fixtures.	20002572	Type of Torch/Flashlight	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of torch or flashlight.	30002518	UNIDENTIFIED	This term is used to describe those product attributes that are unidentifiable given existing or available product information.
78000000	Electrical Supplies		78040000	Electrical Cabling/Wiring		78040100	Cabling/Wiring Management/Control		10005647	Cable/Wire Conduit/Ducting/Raceways	Includes any products that can be described/observed as an enclosure for wires and cables, generally formed with hard/solid materials. Includes products such as a surface raceway, a floor moulding wire track, a cable conduit, a wire duct, a cable tray and a strut channel. In the office, cord organisers and routers are particularly useful for the orderly realignment and consolidation of tangling wires, which exist with most electronic equipment.	Excludes products such as protective wrapping for wires and cables, conduit fittings, electrical busways and ducting used in the ventilation and plumbing of a building.	20002512	Type of Cable/Wire Conduit/Ducting/Raceway	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of cable or wire conduit, ducting or raceway.	30012950	CABLE LADDER	
78000000	Electrical Supplies		78040000	Electrical Cabling/Wiring		78040100	Cabling/Wiring Management/Control		10005650	Cabling/Wiring Protection/Wrapping	Includes any products that can be described/observed as a protective sheath or tube, generally formed with soft materials. These products are normally made of a protective material that offers safety properties such as heat, flame and abrasion resistance and in certain circumstances could also claim to be waterproof. Includes products such as spiral wrap, corrugated loom tubing and expandable sleeving and heat shrink tubing.	Excludes products such as insulation tape and cable conduit, ducting or raceways.	20000987	Safety Features	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the product safety features.	30009601	ABRASION RESISTANT	

78000000	Electrical Supplies		78040000	Electrical Cabling/Wiring		78040100	Cabling/Wiring Management/Control		10005660	Cable Conduit Fittings	Includes any products that can be described/observed as a fitting specifically designed for use with electrical conduit. Includes products such as conduit couplings, expansion fittings, locknuts and cable boxes.	Excludes products such as electrical wiring and cabling connectors and cable clips, grommets and ties, and light bulb fittings.	20002540	If Watertight	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether or not the product is watertight.	30002960	NO	
78000000	Electrical Supplies		78040000	Electrical Cabling/Wiring		78040300	Electrical Cables		10005758	Telecommunication Cables	Includes any products that can be described/observed as wires or optical fibres bound or twisted together into a single piece of cable that is used to carry an electrical current, audio and visual data to and from telecommunication equipment. These products may or may not have a protective jacket or sheath for insulation. Includes products such as telephone cables and fax/modem cables.	Specifically excludes all single stranded wires and all construction/building cables. Excludes products such as computer cables, audio visual cables and satellite installation cables.	20002660	Type of Telecommunication Cable	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of telecommunication cable.	30013529	FAX/MODEM CABLE	
78000000	Electrical Supplies		78040000	Electrical Cabling/Wiring		78040400	Electrical Wiring		10005541	Electrical Wires	Includes any products that can be described/observed as a conducting wire, made from one or more cylindrical strands/threads of elongated or drawn out metal. These products are used to carry an electrical current from one location to another. These products may or may not have a protective jacket or sheath for insulation, and can range in length from a short piece of wire used in fuses, to wire that is many meters long. Includes products such as bare wire and insulated copper wire.	Specifically excludes computer cables, telecommunication cables, audio visual cables, non-conducting and gardening wires. Excludes products such as Capacitors, Fuses, Wire Connectors, and Wire/Cable Sleeving.	20002508	If Insulated	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether or not the product has an insulating cover/wrapping.	30002960	NO	
78000000	Electrical Supplies		78050000	Electronic Communication Components		78050100	Electronic Communication Components		10005661	Circuit Assemblies/Integrated Circuits	Includes any products that can be described/observed as an assembly of electronic components containing many circuits built into a single device capable of many functions such as the controlling, processing and distribution of information and the conversion and distribution of electric power. Includes analogue and digital circuits.	Excludes electrical distribution boards and circuit breakers.	20001145	Analog/Digital	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is analog or digital.	30007712	ANALOG	
78000000	Electrical Supplies		78050000	Electronic Communication Components		78050100	Electronic Communication Components		10005661	Circuit Assemblies/Integrated Circuits	Includes any products that can be described/observed as an assembly of electronic components containing many circuits built into a single device capable of many functions such as the controlling, processing and distribution of information and the conversion and distribution of electric power. Includes analogue and digital circuits.	Excludes electrical distribution boards and circuit breakers.	20001145	Analog/Digital	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is analog or digital.	30006049	BOTH	
78000000	Electrical Supplies		78050000	Electronic Communication Components		78050100	Electronic Communication Components		10005661	Circuit Assemblies/Integrated Circuits	Includes any products that can be described/observed as an assembly of electronic components containing many circuits built into a single device capable of many functions such as the controlling, processing and distribution of information and the conversion and distribution of electric power. Includes analogue and digital circuits.	Excludes electrical distribution boards and circuit breakers.	20001145	Analog/Digital	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is analog or digital.	30005480	DIGITAL	
78000000	Electrical Supplies		78060000	General Electrical Hardware		78060100	General Electrical Hardware		10005599	Voltmeters/Multimeters	Includes any products that can be described/observed as a measuring instrument, used to measure electrical currents, voltage (potential difference between two points) or to measure currents, voltage and resistance. Typically these products are used for basic fault finding in electrical circuits. Includes products that use digital and analogue displays.	Excludes other electric measuring equipments.	20001145	Analog/Digital	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is analog or digital.	30007712	ANALOG	

78000000	Electrical Supplies		78060000	General Electrical Hardware		78060100	General Electrical Hardware		10005599	Voltmeters/Multimeters	Includes any products that can be described/observed as a measuring instrument, used to measure electrical currents, voltage (potential difference between two points) or to measure currents, voltage and resistance. Typically these products are used for basic fault finding in electrical circuits. Includes products that use digital and analogue displays.	Excludes other electric measuring equipments.	20001145	Analog/Digital	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is analog or digital.	30012965	ANALOGUE/DIGITAL	
78000000	Electrical Supplies		78060000	General Electrical Hardware		78060100	General Electrical Hardware		10008363	Monitors/Screens	Includes any products that can be described/observed as a monitor/screen in which images or text are displayed that provides guidance and monitoring about the specific appliance to the user. Includes products that use digital and analogue displays.	Excludes products such as Multimeters and Voltmeters.						
79000000	Plumbing/Heating/Ventilation/Air Conditioning		79010000	Plumbing/Heating/Ventilation/Air Conditioning		79010600	Air Conditioning/Cooling/Ventilation Equipment		10003982	Air Conditioners/Coolers - Fixed	Includes any products that can be described/observed as a fixed or installed device for controlling, especially lowering, the temperature and humidity of an enclosed space.	Excludes portable air conditioners, air dehumidifiers and air purifiers.	20002283	If with Adjustable/Rotating Louvres	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the item is equipped with adjustable and/or rotating louvres.	30002960	NO	
79000000	Plumbing/Heating/Ventilation/Air Conditioning		79010000	Plumbing/Heating/Ventilation/Air Conditioning		79010600	Air Conditioning/Cooling/Ventilation Equipment		10003984	Air Conditioning/Cooling/Ventilation Equipment Replacement Parts/Accessories	Includes any products that can be described/observed as a replacement part or accessory for an installed air conditioning system. Includes products such as air filters for an air conditioner or a wall bracket to hold a ventilator.	Excludes products such as a complete air conditioning system.						
79000000	Plumbing/Heating/Ventilation/Air Conditioning		79010000	Plumbing/Heating/Ventilation/Air Conditioning		79010600	Air Conditioning/Cooling/Ventilation Equipment		10004063	Air Conditioning Equipment - Multifunction - Fixed	Includes any products that can be described/observed as a fixed or installed unit that combines the work of several appliances such as, for example, air conditioner, dehumidifier and fan.	Excludes portable multifunction air controlling appliances.	20001531	Function	Indicates with reference to the product branding, labelling or packaging, the descriptive term that is used by the manufacturer to identify the intended usage of the appliance.	30011944	CHILLER/DEHUMIDIFIER	
91000000	Safety/Security/Surveillance		91030000	Home/Business Safety/Security/Surveillance		91030400	Home/Business Surveillance Equipment		10005412	Light/Motion/Sound Sensors	Includes any products that can be described/observed as an automatic light controller with sound and/or motion activation to detect intruders. A motion sensor detects "warm" infrared movement and a sound sensor detects voices several metres away. Includes products such as sensors with adjustable sound and motion lights, manual and automatic options and weather resistant casings.	Excludes products such as surveillance cameras and security lights that remain on during the night.	20002339	Automatic/Manual	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is operated automatically or manually.	30006875	AUTOMATIC	The product manufacturer identifies that the product is operated automatically.
91000000	Safety/Security/Surveillance		91030000	Home/Business Safety/Security/Surveillance		91030400	Home/Business Surveillance Equipment		10005413	Security Lights	Includes any products that can be described/observed as an exterior light, which illuminates the building exterior and property thus acting as a deterrent to intruders. Includes products such as low energy lights that can be left burning all night as well as floodlights that are more often used on business premises.	Excludes products such as motion and sound sensor lights and personal safety lights.	20000651	If With Remote Control	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether or not the product comes with a remote control device.	30002960	NO	
91000000	Safety/Security/Surveillance		91030000	Home/Business Safety/Security/Surveillance		91030400	Home/Business Surveillance Equipment		10005415	Home/Business Surveillance Equipment Variety Packs	Includes any products that can be described/observed as two or more distinct combinations of home/business surveillance products sold together, which exist within the schema belonging to different bricks but to the same class, that is two or more products contained within the same pack which cross bricks within the Home/Business Surveillance Equipment class. Includes products such as a light motion sensor sold with a floodlight. Items that are received free with purchases should be removed from the classification decision-making process.	Excludes products such as surveillance camera and door intercom variety packs.						

91000000	Safety/Security/Surveillance		91030000	Home/Business Safety/Security/Surveillance		91030600	Home/Business Safety/Security/Surveillance Variety Packs		10005417	Home/Business Safety/Security/Surveillance Variety Packs	Includes any products than can be described/observed as two or more distinct home or business safety/security/surveillance products sold together which exist within the schema but belong to different classes that is two or more products contained within the same pack which cross classes within the Home/Business Safety/Security/Surveillance family. Includes products such as burglar alarm and security lights variety packs. Items that are received free with purchases should be removed from the classification decision-making process.	Excludes products such as fire retardant and fire blanket variety packs.						
79000000	Plumbing/Heating/Ventilation/Air Conditioning		79010000	Plumbing/Heating/Ventilation/Air Conditioning		79010600	Air Conditioning/Cooling/Ventilation Equipment		10003985	Air Conditioning/Cooling/Ventilation Equipment Variety Packs	Includes any products that can be described/observed as two or more distinct air conditioning/cooling/ventilation products sold together, which exist within the schema belonging to different bricks but to the same class, that is two or more products contained within the same pack which cross bricks within the Air Conditioning/Cooling/Ventilation Equipment class. Includes products such as an air ventilation system sold with ducting and ducting boosters. Items that are received free with purchases should be removed from the classification decision-making process.	Excludes products such as extractor fan and stove variety packs.						
79000000	Plumbing/Heating/Ventilation/Air Conditioning		79010000	Plumbing/Heating/Ventilation/Air Conditioning		79010500	Heating Equipment		10002660	Central Heating Replacement Parts/Accessories	Includes any products that can be described/observed as a replacement part or an accessory for central heating products. Includes products such as replacement temperature pressure relief valves for boilers, radiator valves, gas connectors and accessories such as radiator covers and water heater blankets.	Excludes products such as complete central heating products.	20002475	Type of Central Heating Replacement Part/Accessory	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of central heating replacement part or accessory.	30013276	CHIMNEY BRUSH	
79000000	Plumbing/Heating/Ventilation/Air Conditioning		79010000	Plumbing/Heating/Ventilation/Air Conditioning		79010500	Heating Equipment		10005478	Fireplaces/Fireplace Surrounds/Mantels	Includes any products that can be described/observed as an appliance built into a home, consisting of a space designed to contain an open fire, generally for heating but sometimes also for cooking. A chimney or other vent allows gas and particulate exhaust to escape the building and a fireplace will normally be surrounded by decorative panels and a mantelshelf. Includes products such as wood/coal-burning fireplaces with a chimney and gas fires installed with a gas flue, as well as installed electric fires.	Excludes freestanding, portable fires or heaters that do not require installation.	20002004	Fuel Type	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of fuel that powers the product.	30004553	COAL	
79000000	Plumbing/Heating/Ventilation/Air Conditioning		79010000	Plumbing/Heating/Ventilation/Air Conditioning		79010500	Heating Equipment		10002653	Heating System Controls	Includes any products that can be described/observed as a mechanical or electronic device that controls a heating system within a building. It is capable of increasing comfort for personnel while delivering real cost savings through the use of a programmed time switch and thermostat. Time and temperature can be set according to building and user needs.Includes products that have control options for heating only, ventilation only, frost protection, seven-day programming, three on/off periods per day, holiday mode and overtime mode.	Excludes products such as the components of the heating system itself, such as pipes and the boiler as well as Smart Home/Home Automation Equipment - Temperature Regulation Appliances.	20002470	Manual/Digital	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is controlled by manual or digital operation.	30005480	DIGITAL	

79000000	Plumbing/ Heating/Ventilation/Air Conditioning		79010000	Plumbing/ Heating/Ventilation/Air Conditioning		79010500	Heating Equipment		10004002	Thermostats	Includes any products that can be described/observed as a device that automatically regulates temperature in a room or building by cutting off and restoring the supply of heat from the central heating system. Includes mechanical thermostats and digital thermostats that can be remotely controlled by a home automation system.	Excludes products such as thermostats not intended for the control of a building's central heating system.	20002478	Mechanical/Digital	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is operated mechanically or digitally.	30005480	DIGITAL	
79000000	Plumbing/ Heating/Ventilation/Air Conditioning		79010000	Plumbing/ Heating/Ventilation/Air Conditioning		79010800	Water/Gas Supply/Central Heating		10008010	Connectors Accessories/Replacement Parts - Water, Gas, Central Heating	Includes any products that may be described/observed as an accessory or replacement part for connectors. Includes products such as closing plugs, sealing wires, pinch nuts, cutting rings and gradient sets.	Excludes: Valves/Fitting accessories/replacement parts. Specifically Excludes Air Conduits/Air Conduit Fittings.						
79000000	Plumbing/ Heating/Ventilation/Air Conditioning		79010000	Plumbing/ Heating/Ventilation/Air Conditioning		79010800	Water/Gas Supply/Central Heating		10004057	Pipes/Tubing - Accessories/Replacement Parts	Includes any products that can be described/observed as an accessory/replacement part for Water/Gas Supply products. Includes products such as pipe hangers and clips, tubing brackets, rosettes and saddles.	Excludes products such Valves, Pipes/Tubing, Connectors, Hose Clamps and Pumps.	20002150	Type of Accessory/Replacement Part	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of accessory or replacement part.	30008043	BRACKET	
79000000	Plumbing/ Heating/Ventilation/Air Conditioning		79010000	Plumbing/ Heating/Ventilation/Air Conditioning		79010800	Water/Gas Supply/Central Heating		10005867	Pipes/Tubing Flanges	Includes any product that can be described/observed as an external or internal rib or rim, used to connect to another pipe or flange; to close a pipe; to add strength to a pipe or to hold a pipe in place. Includes products such as closet flanges, orifice flanges, long weld necks and reducing flanges.	Excludes products such as connectors.	20002733	Raised/Flat	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify whether the product is raised from the surface or flat.	30014602	FLAT/RING TYPE JOINT (RTJ)	
79000000	Plumbing/ Heating/Ventilation/Air Conditioning		79010000	Plumbing/ Heating/Ventilation/Air Conditioning		79010800	Water/Gas Supply/Central Heating		10004024	Valves/Fittings - Water and Gas	Includes any products that can be described/observed as a valve or fitting that regulates the flow of water and/or gas (i.e. propane; pneumatics; etc.) by opening, closing or partially obstructing the passageway within a water/gas supply system.	Specifically excludes Faucet/Tap and Shower Valves. Excludes products such as Pumps, Connectors, Pipe Accessories, Pipes and Tubing.	20002942	Type of Usage		30000720	COMBINATION	
79000000	Plumbing/ Heating/Ventilation/Air Conditioning		79010000	Plumbing/ Heating/Ventilation/Air Conditioning		79010800	Water/Gas Supply/Central Heating		10008011	Valves/Fittings Accessories/Replacement Parts - Water and Gas	Includes any products that may be described/observed as an accessory or replacement part for valves and fittings. Includes products such as drains for water and gas.	Excludes: Connectors Accessories/Replacement Parts						
91000000	Safety/Security/Surveillance		91030000	Home/Business Safety/Security/Surveillance		91030200	Door/Window/Perimeter Security Products		10005398	Access Control Security Systems	Includes any products that can be described/observed as an electronic system situated at the entry door or gate of a property that identifies the person through the use of a security code, business related personnel information or personal recognition factors such as a fingerprint or the iris of the eye. Includes products such as keypad entry that requires a security code, swipe card control that incorporates personnel information and biometric scan-in access control that recognises fingerprints.	Excludes products such as door intercoms, door viewers and computer access security control systems.	20002328	Type of Access Control Security System	Indicates, with reference to the product branding, labelling or packaging, the descriptive term that is used by the product manufacturer to identify the type of access control that is incorporated in the security system.	30012058	BIOMETRIC READER	
	Vehicle		77010000	Automotive Accessories and Maintenance		77014300	Automotive Electrical		10006846	Automotive Instruments and Measurement Systems	Includes any products that can be described/observed as automotive instrument systems or measurement systems.		20003008	Type of Automotive Instruments/Measurement Systems	Indicates with reference to the product branding, labelling or packaging, the descriptive term that is used by the manufacturer to identify the type of automotive instruments/measurement system.	30002515	UNCLASSIFIED	This term is used to describe those product attributes that are unable to be classified within their specific market; e.g. goat's cheese - goat's cheeses is often generically labelled and cannot be further classified.
	Vehicle		77010000	Automotive Accessories and Maintenance		77014300	Automotive Electrical		10006846	Automotive Instruments and Measurement Systems	Includes any products that can be described/observed as automotive instrument systems or measurement systems.		20003008	Type of Automotive Instruments/Measurement Systems	Indicates with reference to the product branding, labelling or packaging, the descriptive term that is used by the manufacturer to identify the type of automotive instruments/measurement system.	30002518	UNIDENTIFIED	This term is used to describe those product attributes that are unidentifiable given existing or available product information.

7318.16.00.85	4	Other
7318.22.00.00	2	Other washers
8405.10.00.00	1	Producer gas or water gas generators, with or without their purifiers; acetylene gas generators and similar water process gas generators, with or without their purifiers
8413.20.00.00	1	Hand pumps, other than those of subheading 8413.11 or 8413.19
8413.50.00.50	2	Diaphragm pumps
8413.60.00	1	Other rotary positive displacement pumps
	2	Hydraulic fluid power pumps:
8413.7	1	Other centrifugal pumps:
8413.81.00	2	Pumps
8413.91	2	Of pumps:
8414	0	Air or vacuum pumps, air or other gas compressors and fans; ventilating or recycling hoods incorporating a fan, whether or not fitted with filters; gas-tight biological safety cabinets, whether or not fitted with filters; parts thereof:
8414.10.00.00	1	Vacuum pumps
8414.30.40.00	2	Not exceeding 1/4 horsepower
8414.40.00.00	1	Air compressors mounted on a wheeled chassis for towing
	1	Fans:
8414.51	2	Table, floor, wall, window, ceiling or roof fans, with a self-contained electric motor of an output not exceeding 125 W:

8414.59.15.00	3	Fans of a kind used solely or principally for cooling microprocessors, telecommunications apparatus, automatic data processing machines or units of automatic data processing machines
8414.70.00.00	1	Gas-tight biological safety cabinets
	2	Air compressors:
8414.80.05.00	3	Turbochargers and superchargers
8414.80.16.05	6	Not exceeding <il>746 W</il>
8414.90.10	2	Of fans (including blowers) and ventilating or recycling hoods
8415	0	Air conditioning machines, comprising a motor-driven fan and elements for changing the temperature and humidity, including those machines in which the humidity cannot be separately regulated; parts thereof:
8418	0	Refrigerators, freezers and other refrigerating or freezing equipment, electric or other; heat pumps, other than the air conditioning machines of heading 8415; parts thereof:
	2	Compression type:
8418.10.00.10	3	Having a refrigerated volume of under <il>184 liters</il>
8418.21.00.10	3	Having a refrigerated volume of under <il>184 liters</il>
8418.21.00.20	3	Having a refrigerated volume of <il>184 liters</il> and over but under <il>269 liters</il>
8418.99.40.00	3	Door assemblies incorporating more than one of the following: inner panel; outer panel; insulation; hinges; handles
8421	0	Centrifuges, including centrifugal dryers; filtering or purifying machinery and apparatus, for liquids or gases; parts thereof:
	1	Centrifuges, including centrifugal dryers:
8421.29.00.05	3	Refrigerant recovery and recycling units
8421.39.01.15	4	Other
8421.91	2	Of centrifuges, including centrifugal dryers:
8443.32	2	Other, capable of connecting to an automatic data processing machine or to a network:
8443.32.10	3	Printer units
	4	Laser:
8443.32.10.20	5	Other
8443.32.10.40	4	Ink jet
8443.32.10.80	4	Dot matrix
8443.32.10.90	4	Other
8443.32.50.00	3	Other

8443.39	2	Other:
8443.91	2	Parts and accessories of printing machinery used for printing by means of plates, cylinders and other printing components of heading 8442:
8443.91.10.00	3	Machines for uses ancillary to printing
8470.21.00.00	1	Other electronic calculating machines:
8471.41.01	1	Other automatic data processing machines:
8471.41.01.10	2	Comprising in the same housing at least a central processing unit and an input and output unit, whether or not combined
8471.49.00.00	3	Other
8471.90.00.00	3	Other
	0	Parts and accessories (other than covers, carrying cases and the like) suitable for use solely or principally with machines of headings 8470 to 8472:
8473.21.00.00	1	Parts and accessories of the machines of heading 8470:
8473.3	2	Other
	1	Parts and accessories of the machines of heading 8471:
8473.30.11	2	Not incorporating a cathode ray tube:
8473.30.11.40	3	Printed circuit assemblies
8473.30.11.80	4	Memory modules suitable for use solely or principally with machines of heading 8471
8473.30.20.00	4	Other
8473.30.51.00	3	Parts and accessories, including face plates and lock latches, of printed circuit assemblies
8473.30.91.00	3	Other
	2	Other:
8481.8	1	Safety or relief valves
8481.80.10	2	Hand operated:
	3	Of copper
8481.80.10.20	4	Having a pressure rating under <il>850 kPa:</il>
8481.80.10.50	5	Supply stops
	5	Other
8481.80.10.60	4	Having a pressure rating of <il>850 kPa</il> or over:
8481.80.10.70	5	Gate type
8481.80.10.75	5	Globe type
8481.80.10.85	5	Plug type
8481.80.10.90	5	Ball type
8481.80.10.95	5	Butterfly type
8481.80.30	5	Other
	3	Of iron or steel
8481.80.30.10	4	Of iron:
8481.80.30.15	5	Gate type
8481.80.30.20	5	Globe type

8481.80.30.25	5	Plug type
8481.80.30.30	5	Ball type
8481.80.30.40	5	Butterfly type
	5	Other
8481.80.30.55	4	Of steel:
8481.80.30.60	5	Gate type
8481.80.30.65	5	Globe type
8481.80.30.70	5	Plug type
8481.80.30.75	5	Ball type
8481.80.30.90	5	Butterfly type
8481.80.50	5	Other
8481.80.50.40	3	Of other materials
8481.80.50.60	4	Pressure spray can valves
8481.80.90	4	Other
8481.80.90.05	2	Other
8481.80.90.10	3	Solenoid valves
8481.80.90.15	3	Ballcock mechanisms
	3	Regulator valves, self-operating, for controlling variables such as temperature, pressure, flow and liquid level
	3	Other:
8481.80.90.20	4	With electrical or electro-hydraulic actuators:
8481.80.90.25	5	Control valves designed for proportional operation by a signal from a control device
8481.80.90.30	5	Other
	4	With hydraulic actuators
8481.80.90.35	4	With pneumatic actuators:
8481.80.90.40	5	Control valves designed for proportional operation by a signal from a control device
8481.80.90.45	5	Other
8481.80.90.50	4	With thermostatic actuators
8481.9	4	Other
	1	Parts:
8481.90.10.00	2	Of hand operated and check appliances:
8481.90.30.00	3	Of copper
8481.90.50.00	3	Of iron or steel
8481.90.90	3	Of other materials
	2	Other
8481.90.90.20	3	Of valves of subheading 8481.20:
8481.90.90.40	4	Valve bodies
	4	Other
8481.90.90.60	3	Other:
	4	Valve bodies
8481.90.90.81	4	Other:
8481.90.90.85	5	Steel forgings

8484.10.00.00	0	Gaskets and similar joints of metal sheeting combined with other material or of two or more layers of metal; sets or assortments of gaskets and similar joints, dissimilar in composition, put up in pouches, envelopes or similar packings; mechanical seals:
8486.90.00.00	2	For lifting, handling, loading or unloading of boules, wafers, semiconductor devices, electronic integrated circuits and flat panel displays
8501	0	Electric motors and generators (excluding generating sets):
8501.1	1	Motors of an output not exceeding 37.5 W:
	2	Of under 18.65 W:
8501.10.20.00	3	Synchronous, valued not over $4 each
8501.10.40	3	Other
8501.10.40.20	4	AC
	4	DC:
8501.10.40.40	5	Brushless
8501.10.40.60	5	Other
8501.10.40.80	4	Other
8501.10.60	2	Of 18.65 W or more but not exceeding 37.5 W
8501.10.60.20	3	AC
	3	DC:
8501.10.60.40	4	Brushless
8501.10.60.60	4	Other
8501.10.60.80	3	Other
8501.4	1	Other AC motors, single-phase:
8501.40.20	2	Of an output exceeding 37.5 W but not exceeding <il>74.6 W</il>
8504	0	Electrical transformers, static converters (for example, rectifiers) and inductors; parts thereof:
8504.10.00.00	1	Ballasts for discharge lamps or tubes
8504.32.00.00	2	Having a power handling capacity exceeding <il>1 kVA</il> but not exceeding <il>16 kVA</il>
8504.4	1	Static converters:
8504.40.40.00	2	Speed drive controllers for electric motors
8504.9	1	Parts:
8517.62.00	2	Machines for the reception, conversion and transmission or regeneration of voice, images or other data, including switching and routing apparatus:
8517.62.00.10	3	Modems, of a kind used with data processing machines of heading 8471
8517.62.00.20	3	Switching and routing apparatus
8517.62.00.90	3	Other
8525.89	2	Other:
8531.10.00	1	Burglar or fire alarms and similar apparatus

8533.9	1	Parts:
8534.00.00	0	Printed circuits
8536.41.00	2	For a voltage not exceeding 60 V
8536.41.00.05	3	Automotive signaling flashers
	3	Other:
	4	With contacts rated at less than 10 A:
8536.41.00.20	5	Electromechanical
8536.41.00.30	5	Other
	4	Other:
8536.41.00.45	5	Contactors
	5	Other:
8536.41.00.50	6	Electromechanical
8536.41.00.60	6	Other
8536.50.40.00	2	Motor starters
	2	Other:
8536.50.70.00	3	Electronic AC switches consisting of optically coupled input and output circuits (insulated thyristor AC switches); electronic switches, including temperature protected switches, consisting of a transistor and a logic chip (chip-on-chip technology); electromechanical snap-action switches for a current not exceeding 11 amps
8536.50.90	3	Other
	4	Rotary:
8536.50.90.20	5	Rated at not over 5 A
8536.50.90.25	5	Rated at over 5 A
	4	Push-button:
	5	Rated at not over 5 A
8536.50.90.31	6	Momentary contact
8536.50.90.32	6	Other, gang switches
8536.50.90.33	6	Other
8536.50.90.35	5	Rated at over 5 A
8536.50.90.40	4	Snap-action, other than limit
8536.50.90.45	4	Knife
8536.50.90.50	4	Slide
8536.50.90.55	4	Limit
8536.50.90.65	4	Other
	1	Lamp-holders, plugs and sockets:
8536.90.85.10	3	Electrical distribution ducts
8537.1	1	For a voltage not exceeding <il>1,000 V</il>:
8538.9	1	Other:
	2	Printed circuit assemblies:
8538.90.10.00	3	Of an article of heading 8537 for one of the articles described in additional U.S. note 11 to chapter 85
8538.90.30.00	3	Other

8538.90.40.00	2	Other, for the articles of subheading 8535.90.40, 8536.30.40 or 8536.50.40, of ceramic or metallic materials, electrically or mechanically reactive to changes in temperature
	2	Other:
8538.90.60.00	3	Molded parts
8538.90.81	3	Other
8538.90.81.20	4	Of automatic circuit breakers
	4	Other:
8538.90.81.40	5	Metal contacts
8538.90.81.60	5	Other parts of switchgear, switchboards, panel boards and distribution boards
8538.90.81.80	5	Other
8543.20.00.00	1	Signal generators
8543.7	1	Other machines and apparatus:
8543.70.98.20	5	Special effects pedals for use with musical instruments
8544.42	2	Fitted with connectors:
8544.42.10.00	3	Fitted with modular telephone connectors
	3	Other:
8544.42.20.00	4	Of a kind used for telecommunications
8544.42.90	4	Other
8544.42.90.10	5	Extension cords as defined in statistical note 6 to this chapter
8544.42.90.90	5	Other
9001	0	Optical fibers and optical fiber bundles; optical fiber cables other than those of heading 8544; sheets and plates of polarizing material; lenses (including contact lenses), prisms, mirrors and other optical elements, of any material, unmounted, other than such elements of glass not optically worked:
9001.10.00	1	Optical fibers, optical fiber bundles and cables
	2	Optical fibers:
9002.19.00.00	2	Other
9011.80.00.00	1	Other microscopes
9013.20.00.00	1	Lasers, other than laser diodes
9013.80.91.00	2	Other
9016	0	Balances of a sensitivity of 5 cg or better, with or without weights; parts and accessories thereof:
9022.19.00.00	2	For other uses
9025.19	2	Other:
9025.19.80	3	Other
9025.19.80.10	5	Infrared thermometers of a kind described in statistical note 2 of this chapter
9025.19.80.60	5	Infrared thermometers
9025.8	1	Other instruments:

9025.80.10.00	2	Electrical
	2	Other:
9025.80.15.00	3	Barometers, not combined with other instruments
9025.80.20.00	3	Hydrometers and similar floating instruments, whether or not incorporating a thermometer, non-recording
9025.80.35.00	3	Hygrometers and psychrometers, non-recording
9025.80.40.00	3	Thermographs, barographs, hygrographs and other recording instruments
9025.80.50.00	3	Other
9025.90.06.00	1	Parts and accessories
9026	0	Instruments and apparatus for measuring or checking the flow, level, pressure or other variables of liquids or gases (for example, flow meters, level gauges, manometers, heat meters), excluding instruments and apparatus of heading 9014, 9015, 9028 or 9032; parts and accessories thereof:
9026.1	1	For measuring or checking the flow or level of liquids:
9026.10.20	2	Electrical
9026.10.20.40	3	Flow meters
9026.10.20.80	3	Other
	2	Other:
9026.10.40.00	3	Flow meters
9026.10.60.00	3	Other
9026.2	1	For measuring or checking pressure:
9026.20.40.00	2	Electrical
9026.20.80.00	2	Other
9026.8	1	Other instruments and apparatus:
9026.9	1	Parts and accessories:
9026.90.20.00	2	Of electrical instruments and apparatus
	2	Other:
9026.90.40.00	3	Of flow meters, heat meters incorporating liquid supply meters and anemometers
9026.90.60.00	3	Other
9027	0	Instruments and apparatus for physical or chemical analysis (for example, polarimeters, refractometers, spectrometers, gas or smoke analysis apparatus); instruments and apparatus for measuring or checking viscosity, porosity, expansion, surface tension or the like; instruments and apparatus for measuring or checking quantities of heat, sound or light (including exposure meters); microtomes; parts and accessories thereof:
9027.1	1	Gas or smoke analysis apparatus:

9027.10.20.00	2	Electrical
	2	Other:
9027.10.40.00	3	Optical instruments and apparatus
9027.10.60.00	3	Other
9027.2	1	Chromatographs and electrophoresis instruments:
9027.20.50	2	Electrical
9027.20.50.30	3	Electrophoresis instruments
9027.20.50.50	3	Gas chromatographs
9027.20.50.60	3	Liquid chromatographs
9027.20.50.80	3	Other
9027.20.80	2	Other
9027.20.80.30	3	Gas chromatographs
9027.20.80.60	3	Liquid chromatographs
9027.20.80.90	3	Other
9027.3	1	Spectrometers, spectrophotometers and spectrographs using optical radiations (ultraviolet, visible, infrared):
9027.30.40	2	Electrical
9027.30.40.40	3	Spectrophotometers
9027.30.40.80	3	Other
9027.30.80	2	Other
9027.30.80.20	3	Spectroscopes
9027.30.80.80	3	Other
9027.5	1	Other instruments and apparatus using optical radiations (ultraviolet, visible, infrared):
9027.50.10.00	2	Exposure meters
	2	Other:
9027.50.40	3	Electrical
9027.50.40.15	4	Chemical analysis instruments and apparatus
9027.50.40.20	4	Thermal analysis instruments and apparatus
9027.50.40.50	4	Photometers
9027.50.40.60	4	Other
9027.50.80	3	Other
9027.50.80.15	4	Chemical analysis instruments and apparatus
9027.50.80.20	4	Thermal analysis instruments and apparatus
9027.50.80.60	4	Other
	1	Other instruments and apparatus:
9027.81.00.00	2	Mass spectrometers
9027.89	2	Other:
9027.89.45	4	Electrical
9027.89.45.30	5	Chemical analysis instruments and apparatus
9027.89.80.30	5	Chemical analysis instruments and apparatus
9027.9	1	Microtomes; parts and accessories:

	2	Parts and accessories:
	3	Of electrical instruments and apparatus:
9027.90.45.00	4	Printed circuit assemblies for the goods of subheading 9027.81 or 9027.89
	4	Of optical instruments and apparatus:
9027.90.64.00	5	Of instruments and apparatus of subheading 9027.20, 9027.30, 9027.50, 9027.81 or 9027.89
9027.90.68.00	5	Other
	4	Other:
9027.90.84.00	5	Of instruments and apparatus of subheading 9027.20, 9027.30, 9027.50, 9027.81 or 9027.89
9027.90.88.00	5	Other
9028	0	Gas, liquid or electricity supply or production meters, including calibrating meters thereof; parts and accessories thereof:
9028.20.00.00	1	Liquid meters
9029.2	1	Speedometers and tachometers; stroboscopes:
9030	0	Oscilloscopes, spectrum analyzers and other instruments and apparatus for measuring or checking electrical quantities, excluding meters of heading 9028; instruments and apparatus for measuring or detecting alpha, beta, gamma, X-ray, cosmic or other ionizing radiations; parts and accessories thereof:
9030.10.00.00	1	Instruments and apparatus for measuring or detecting ionizing radiations
9030.2	1	Oscilloscopes and oscillographs:
9030.20.05.00	2	Specially designed for telecommunications
9030.20.10.00	2	Other oscilloscopes and oscillographs
	1	Other instruments and apparatus, for measuring or checking voltage, current, resistance or power (other than those for measuring or checking semiconductor wafers or devices):
9030.31.00.00	2	Multimeters, without a recording device
9030.32.00.00	2	Multimeters, with a recording device
9030.33	2	Other, without a recording device:
9030.33.34.00	3	Resistance measuring instruments
9030.33.38.00	3	Other
9030.39.01.00	2	Other, with a recording device
9030.40.00.00	1	Other instruments and apparatus, specially designed for telecommunications (for example, cross-talk meters, gain measuring instruments, distortion factor meters, psophometers)
9030.84.00.00	2	Other, with a recording device

9030.89.01.00	2	Other
9030.9	1	Parts and accessories:
	2	For articles of subheading 9030.10:
9030.90.25.00	3	Printed circuit assemblies
9030.90.46.00	3	Other
9030.90.89.61	5	Other
9031	0	Measuring or checking instruments, appliances and machines, not specified or included elsewhere in this chapter; profile projectors; parts and accessories thereof:
9031.41.00	2	For inspecting semiconductor wafers or devices (including integrated circuits) or for inspecting photomasks or reticles used in manufacturing semiconductor devices (including integrated circuits)
9031.41.00.20	3	For inspecting photomasks or reticles used in manufacturing semiconductor devices
	3	For inspecting semiconductor wafers or devices:
9031.49	2	Other:
9031.49.90.00	3	Other
9031.8	1	Other instruments, appliances and machines:
9031.80.80	2	Other
9031.80.80.60	4	For testing electrical characteristics
9031.80.80.70	4	Other
9031.80.80.85	3	Other
9031.9	1	Parts and accessories:
	2	Of other optical instruments and appliances, other than test benches:
9031.90.59.00	3	Other
	2	Other:
9032	0	Automatic regulating or controlling instruments and apparatus; parts and accessories thereof:
9032.10.00	1	Thermostats
	2	For air conditioning, refrigeration or heating systems:
9032.10.00.30	3	Designed for wall mounting
9032.10.00.60	3	Other
9032.10.00.90	2	Other
9032.20.00.00	1	Manostats
	1	Other instruments and apparatus:
9032.81.00	2	Hydraulic and pneumatic
	3	Industrial process control instruments and apparatus:
9032.81.00.20	4	Hydraulic
9032.81.00.60	4	Pneumatic
9032.81.00.80	3	Other
9032.89	2	Other:

	3	Automatic voltage and voltage-current regulators:
9032.89.20.00	4	Designed for use in a 6, 12 or 24 V system
9032.89.40.00	4	Other
9032.89.60	3	Other
	4	Control instruments for air conditioning, refrigeration or heating systems:
9032.89.60.15	5	Complete systems
9032.89.60.25	5	Other
	4	Process control instruments and apparatus:
9032.89.60.30	5	Complete systems
	5	Other:
9032.89.60.40	6	Temperature control instruments
9032.89.60.50	6	Pressure and draft control instruments
9032.89.60.60	6	Flow and liquid level control instruments
9032.89.60.70	6	Humidity control instruments
9032.89.60.75	6	Other
9032.89.60.85	4	Other
9032.9	1	Parts and accessories:
	2	Of automatic voltage and voltage-current regulators:
9032.90.21.00	3	Designed for use in a 6, 12 or 24 V system
9032.90.41.00	3	Other
9032.90.61	2	Other
9032.90.61.20	3	Of thermostats
9032.90.61.40	3	Of manostats
9032.90.61.60	3	Of instruments and apparatus of subheading 9032.81
9032.90.61.80	3	Other
9033	0	Parts and accessories (not specified or included elsewhere in this chapter) for machines, appliances, instruments or apparatus of chapter 90:
9033.00.90.00	1	Other

Alex Gordon (Semiconductor Industry Association) Attachment

Converted from Microsoft Excel to Adobe PDF 3/5/2024

Annex A - Table A.49. Uses and properties of PFASs in the semiconductor industry identified by stakeholders - Updated since the Call for Evidence/Royal Haskoning studies and initial uploads to the ECHA portal for the Annex XV public consultation
Semiconductor Manufacturing

Use Category	Sub-Use	Properties	Examples of PFAS	Estimated Timeframe To Substitute with Non-PFAS Alternatives (Timeline commences after an invention is identified)	Element
Photolithography	Photoacid generators	- Strong electronegativity of F atom in the complex resist/chemical matrix allows for controlled generation of strong acid upon exposure to UV light	Fluorinated salts	25+ years	Process Chemistries
Photolithography	Antireflection coatings	- Low dielectric constant - Low refractive index - Good thermal stability - Good barrier properties	Acrylate and methacrylate-based copolymers	15-20+ years	Process Chemistries
Photolithography	Topcoats and Embedded Immersion Barriers Layers	- Hydrophobicity	Fluoropolymers	25+ years	Process Chemistries
Photolithography	Surfactants	- Uniformity in coating with minimal effect on properties provided by other critical resist/chemical ingredients (i.e., without impact to refractive indexes)	Non-polymeric PFASs (non-ionic)	15-20+ years	Process Chemistries
Photolithography	Dielectric Polymers (PBO/PI)	- Hydrophobicity - Electrical non-conductivity - Thermal resistance	Water-insoluble C1 PFAS polymers	15-20+ years	Process Chemistries Semiconductor Device
Photolithography	Filters	- Chemical resistance ' - Low extractables against solvents	Fluoropolymers	15+ years	Process Chemistries
Nanoimprint Lithography		- Low surface adherence	Fluoropolymers	15-20+ years	Process Chemistries
Photoresist	Epoxy, case masking	- Resistance to fire, grease, stain, etc.	Fluorotelomer-related compounds	15-20+ years	Process Chemistries Semiconductor Device
Colour Filter photoresist for imaging semiconductor components "photopatterning"					
Plasma [Dry] Etch and Wafer Cleaning		- Anisotrophic etching capabilities	PFC, HFC and HFO gases	15+ years	Process Chemistries
Vapour deposition chamber	Cleaning	Less shedding	PFC, HFC and HFO gases	10+ years	Process Chemistries
Wet surface modification chemistries (e.g. Wafer)	Wet etch	- Wetting agents - Selective metal oxide removal	Fluorinated organic acids	3-15+ years	Process Chemistries
Advanced Semiconductor Packaging	Flux	- High-temperature thermal stability (>160 C)	Surfactants	5 years	Process Chemistries
Development of necessary chemistries and their packaging to be used for manufacturing of process recipes (Photo Acids, Polymer with Fluorine Groups, Monomers/prepolymers, Surfactants, Dyes etc.)	Semiconductor manufacturing - process chemistries				Process Chemistries
The use of fluoropolymers in process chemistry manufacturing equipment (Filtration system e.g. PTFE filters, Pump, etc.), production infrastructure (Blending Kettles, Piping, Valves, etc.) and evaluation tools (coating, exposure and development tools, NMR, IR, ICP/MS, Titrator, etc.)	Semiconductor manufacturing - process chemistries				Process Chemistries
The use of Consumable Materials for process chemistry development and manufacturing (air and wet chemical filters, seals/o-rings, piping/tubing, embedded lubricants (oils, greases, solids), non-process chemicals, replacement parts, release film for mold process etc.)	Semiconductor manufacturing	High temperature stability up to 180°C Low Young's modulus Low tensile strength (i.e. high stretchability with low tearing risk) Low adhesion strength Chemical inertness	Fluoropolymer		Semiconductor Manufacturing Equipment Semiconductor Manufacturing Infrastructure Semiconductor Manufacturing Support Equipment Process Chemistries
Articles to store, handle, and deliver liquid process chemicals (Bottle Cap Seals, PTFE inner, PTFE tape, Dip tube, O-ring, Packing, Connector, Valve etc.)	Semiconductor manufacturing				Process Chemistries
MEMS wafer process	Vapor HF Sacrificial Etch: Tool Parts, Seals, Fittings etc.	Chemical resistance to HF vapor, low particle generation	Fluoropolymer	at least 20+ years	Process Chemistries Semiconductor Manufacturing Equipment
Semiconductor Manufacturing Equipment (photolithography coaters, scanners and developers, dry etch, ion implant, deposition, CMP, assembly test, metrology, pumps, point of use abatement equipment, spare parts, equipment repair, maintenance of articles and mixtures used etc.)					Semiconductor Manufacturing Equipment
Semiconductor Manufacturing Equipment & Infrastructure - Enabling Uses of Fluoropolymer Articles (raw materials including precursors, fluoropolymer parts embedded within manufacturing equipment, spare parts, equipment repair, maintenance of articles and infrastructure, filters, piping, tubing, gaskets, cables etc.)	Data, Power & Fluid Delivery and Interconnects, sealants/piping, waste removal used in semiconductor manufacturing	- Chemical resistance - Low volatility/high stability - Thermal resistance - Cleanliness - UV resistance - Flame resistance - Inertness - Purity - Low flammability - Temperature stability - Resistance to chemical permeation - Low coefficient of friction - Optical properties - Low dielectric constant - Low dissipation factor - low outgassing factor - Stable electrical performance over high temperature	Fluoropolymers (i.e., Teflon ™, Viton ™, PTFE, PFA, FEP, ETFE, PVDF, FFKM, etc)	15+ years	Semiconductor Manufacturing Equipment Semiconductor Manufacturing Infrastructure
Plasma Etch and Wafer Cleaning	Filters Ozone functionalized water	Chemical resistance Thermal durability High retention and high flow Low extractables	Fluoropolymers		Semiconductor Manufacturing Equipment
Plasma Etch and Wafer Cleaning	Thermal insulation for wet solution	Low thermal conductivity Chemical resistance Thermal durability Less shedding Less gas	Fluoropolymers		Semiconductor Manufacturing Equipment
Wafer	Wet etch & clean filters	Chemical resistance Temperature resistance Low extractables	Fluoropolymers		Semiconductor Manufacturing Equipment

Heat Transfer Fluids	Equipment Chillers	- High precision temperature control imparted by thermal stability - Viscosity vs temperature characteristics - Specific heat - Electrical conductivity characteristics	Hydrofluoroethers, perfluoropolyethers (including PFPMIE), and other fully fluorinated liquids (perfluorinated amines and perfluoroalkylmorpholines, PFPE, Butane, 1-ethoxy-1,1,2,2,3,3,4,4,4-nonafluoro-, 2,3,3,4,4-pentafluoro-5-methoxy-2,5-bis[1,2,2,2-tetrafluoro-1-(trifluoromethyl)ethyl]tetrahydrofuran, Perfluamine, 1,1,1,2,2,4,5,5,5-nonafluoro-4-(trifluoromethyl)-3-pentanone PFCs HFCs HFOs	8-14+ years	Semiconductor Manufacturing Equipment Semiconductor Manufacturing Infrastructure
Thermal Testing of Semiconductor Devices (in-line and end of line)	Equipment Chillers	- High precision temperature control imparted by thermal stability - Viscosity vs temperature characteristics, - Specific heat and electrical non-conductivity characteristics - High boiling point - Low pour point - Non-flammability	Hydrofluoroethers, perfluoropolyethers (including PFPMIE), and other fully fluorinated liquids (perfluorinated amines and perfluoroalkylmorpholines, Reaction mass of 1,1,2,2,3,3,4,4,4-nonafluoro-N,Nbis(nonafluorobutyl)butan-1-amine and 1,1,2,2,3,3,4,4,4-nonafluoro-N-[1,1,2,3,3-hexafluoro-2-(trifluoromethyl)propyl]-N-(1,1,2,2,3,3,4,4,4-nonafluorobutyl)butan-1-amine	8-14+ years	Semiconductor Manufacturing Equipment
Vacuum pump	Vacuum fluid	- Thermally stable - Non-flammable and insoluble in water, acids, bases and most organic solvents - Inertness - Low off-gassing and particle generation	Fluorocarbon ether polymers of polyhexafluoropropylene oxide,	10+ years	Semiconductor Manufacturing Equipment
Plastics such as PC/ABS		- Flame retardancy	Perfluoroalkane sulfonic acids (PFSA), their salts and esters	15+ years	Semiconductor Manufacturing Equipment
Fluoroelastomers, polymers including polyimides, polyamides, polyesters, polycarbonate etc.		- Cross linking agent for fluoroelastomers, monomer, high temperature composites and electronic materials	Bisphenol AF and its salts	15-20+ years	
Adhesive, coating, lubricant		Solvability	Perfluoroalkylethers	10+ years	
Lubricants		- Inertness - Low off-gassing and particle generation	PFPE Fluorosilicone PCTFE PTFE	10+ years	Semiconductor Manufacturing Equipment Semiconductor Manufacturing Infrastructure
Semiconductor Manufacturing Equipment & Infrastructure - the design, manufacture and delivery of semiconductor manufacturing equipment	Semiconductor manufacturing	- Chemical resistance - Low volatility/high stability - Thermal resistance - Cleanliness - UV resistance - Flame resistance - Inertness - Purity - Low flammability - Temperature stability - Resistance to chemical permeation - Low coefficient of friction - Optical properties	Fluoropolymers (i.e., Teflon ™, Viton ™, PTFE, PFA, FEP, ETFE, PVDF, FFKM, etc)	15+ years	Semiconductor Manufacturing Equipment Semiconductor Manufacturing Infrastructure
Reticle and pellicle manufacturing and all of its required chemicals, materials and tooling etc.	Semiconductor manufacturing - photolithography				Semiconductor Manufacturing Equipment
Consumable Materials in semiconductor manufacturing equipment (air and wet chemical filters, seals/o-rings, piping/tubing, embedded lubricants (oils, greases, solids), non-process chemicals, replacement parts etc.)	Semiconductor manufacturing				Semiconductor Manufacturing Equipment Semiconductor Manufacturing Infrastructure
Development of semiconductor manufacturing equipment (fluoropolymers, PFAS in mixtures etc.)	Production of semiconductor manufacturing equipment				Semiconductor Manufacturing Equipment Semiconductor Manufacturing Infrastructure
The use of fluoropolymers and PFAS in mixtures in the production of semiconductor manufacturing	Production of semiconductor manufacturing equipment				Semiconductor Manufacturing Equipment
Semiconductor Manufacturing infrastructure (production and storage, high purity water manufacturing/delivery systems, high purity chemical & gas delivery systems, air filtration systems, bulk chemical delivery systems treatment and distribution, planar chemical delivery systems, liquid waste collection system, abatement systems, semiconductor wastewater treatment and HVAC including corrosive exhaust ducting and treatment, facilities systems controls, gaskets for pipelines, etc.)	Support of semiconductor manufacturing (Chemical transportation, air cleaning, waste removal, waste treatment, etc.)	- Inertness (no outgassing) - Chemical resistance - Mechanical stability - Low pressure drop (filters) - Low volatility/high stability - Purity - Low flammability - Temperature stability - Resistance to chemical permeation	Fluoropolymers (PVDF, PTFE, etc.)	15+ years	Semiconductor Manufacturing Infrastructure
Plasma Etch and Wafer Cleaning	Thermal insulation for gas supply and exhaust in Plasma Etch	Low thermal conductivity Chemical resistance Thermal durability Less shedding Less gas	Fluoropolymers		Semiconductor manufacturing Infrastructure
Vapour deposition chamber	Thermal insulation for gas supply and exhaust in Plasma Etch	Low thermal conductivity Chemical resistance Thermal durability Less shedding Less gas	Fluoropolymers		Semiconductor Manufacturing Infrastructure
Consumable Materials in semiconductor manufacturing infrastructure (air and wet chemical filters, seals/o-rings, piping/tubing, embedded lubricants (oils, greases, solids), non-process chemicals, replacement parts etc.)	Semiconductor manufacturing				Semiconductor Manufacturing Infrastructure
Development of semiconductor manufacturing infrastructure equipment (fluoropolymers, PFAS in mixtures etc.)	Semiconductor manufacturing				Semiconductor Manufacturing Infrastructure
Support equipment for SM Processes	Protection Equipment for Maintenance/Firefighting	Special requirements when F-containing gases come into play	Viton™ gloves, personal protective equipment for firefighters etc.	Not known	Semiconductor Manufacturing Infrastructure

Semiconductor Manufacturing Support Equipment (Automated Material Handling Systems, lab equipment such as Die yield/Failure Analysis, Pathfinding/R&D, Chemical evaluation, associated abatement systems etc.)	Support of semiconductor manufacturing				Semiconductor support equipment
Consumable Materials in semiconductor manufacturing support equipment (air and wet chemical filters, seals/o-rings, piping/tubing, embedded lubricants (oils, greases, solids), non-process chemicals, replacement parts etc)	Semiconductor manufacturing				Semiconductor support equipment
Development of semiconductor manufacturing support equipment (fluoropolymers, PFAS in mixtures etc.)	Semiconductor manufacturing				Semiconductor support equipment
Wafer processing and transportation semiconductor manufacturing support systems - cassettes from front end to back end	FOUPs - Front Opening Unified Pod/Front Opening Universal Pod	High airflow and low particle penetration Low outgassing Low particle emission Water spray washing resistance	Fluoropolymers		Semiconductor support equipment
Advanced Semiconductor Packaging	Encapsulants (epoxy underfills, mold compounds etc.)	Temperature resistance Beneficial material flow Wetting, degassing and composite homogeneity Electrical non-conductivity	Fluoropolymers	13 years	Semiconductor Device
Advanced Semiconductor Packaging	Thermal Interface Materials	High thermal conductivity/heat resistance Tear resistance High tensile strength Incorporation of various fillers into different resin systems - High-temperature thermal stability (>160 C) - Low surface tension	Fluoropolymers	20+ years	Semiconductor Device
Advanced Semiconductor Packaging	Adhesives	- Solubility in organic solvents, low dielectric constants, and high thermal and thermo-oxidative stability	Fluorinated Tetracarboxylic acid anhydride derivatives, aromatic diamines, acrylate and methacrylate-based copolymers	20+ years	Semiconductor Device
Advanced Semiconductor Packaging	Hydrophobic coating/hermetic seal packages	- Unique hydrophobicity	Fluoropolymers	10+ years	Semiconductor Device
Advanced Semiconductor Packaging	Substrates including buildup/dielectric material	- High-temperature thermal stability (>160 C) - Electrical non-conductivity/low dielectric constant - Surface roughness/adhesion - Low coefficient of thermal expansion	Fluoropolymers	10+ years	Semiconductor Device
Advanced Semiconductor Packaging	MEMS anti-stiction layer/coating	- Low coefficient of friction - Low surface energy - High thermal stability - chemical inertness - mechanical durability, - electrical insulation - low particle generation	Fluoropolymers Fluoroalkyl Silanes	15-20+ years	Semiconductor Device
Advanced Semiconductor Packaging	Die for chiplets				
Advanced Semiconductor Packaging	Release sheet for thermocompression bonding process of semiconductor chips	- Heat-resistant - Releasability - Flexibility - Tensile strength	PTFE	10+ years	Semiconductor Device
Advanced Semiconductor Packaging	Packaging (bump, test, sort & assembly)				Semiconductor Device
Advanced Semiconductor Packaging	Sintering of semiconductor chips to a heatsink	- Anti-stiction - High thermal stability (>280°C) - Contamination protection - Compensation of topology	Fluoropolymers	10+ years	Process Chemistries
Advanced Semiconductor Packaging	Vapour phase soldering	- High boiling point (>235°C) - Long term thermal stability - No reactivity to semiconductor under these conditions	PFPE	15+ years	Process Chemistries
MEMS sensor packaging	Passivation gels and coating materials	Unique property: simultaneous high chemical stability against polar, unipolar and oxidative agents and acids Low Young's modulus that is constant over very wide operational temperature range (-50°C to 175°C) High thermal stability No significant aging over product lifetime (up to 15 years)	Fluoropolymers	10+ years	Semiconductor Device
MEMS sensor packaging	Chemically robust adhesives for chip and package component attach	Unique property: simultaneous high chemical stability against polar, unpolar and oxidative agents and acids Low Young's modulus that is constant over very wide operational temperature range (-50°C to 175°C) High thermal stability No significant ageing over product lifetime (up to 15 years)	Fluoropolymers	10+ years	Semiconductor Device
MEMS sensor packaging	Soft adhesives for chip attach	Intermediate Young's modulus that is constant over very wide operational temperature range (-50 to 175°C) High thermal stability No significant aging over product lifetime (up to 15 years)	Fluoropolymers	7+ years	Semiconductor Device
MEMS sensor packaging	Air-permeable membranes, protective meshes, and their hydrophobic and oleophobic coatings	Unique property: simultaneous high chemical stability against polar, unpolar and oxidative agents and acids Unique property: simultaneous hydrophobicity and oleophobicity High thermal stability up to reflow solder temperature (>260°C)	Fluoropolymers	at least 20+ years	Semiconductor Device

Bruce Calder (Claigan Environmental) Attachment

CUU	Currently Unavoidable Use (CUU)	Products	HS Codes	Example Products	Essential Use of Product	Essential Use of PFAS	Comparison of Alternatives	PFOA	Alternatives Tab
1	Fluoropolymer and perfluoropolyether (PFPE) release agents used in manufacturing processes of plastic, rubber, and pressed wooden parts including foam.	Widespread use Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory, Building Products, and Security & Defence.	HS Code Chapters - 32, 39, 40, 56 83, 84, 85, 86, 87, 88, 89, and 90	Gaskets (401693), o-rings (401693), and molded rubber parts in electronics (40), pumps (841381), medical devices (9018), door locks (830140), pressed wood pallets (441520)	Widespread use. Used in the majority of manufactured products on the market.	Release agents are required to release rubber parts from their molds	Superior to other release agents. May be replaceable in the future by silicone. Wide verification and validation required. Silicone has higher friction and adhesion than fluoropolymer based release agents.	None	Release agent
2	PTFE used as an additive drip agent in plastics to meet flammability safety requirements	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 39, 40, 48, 49, 76 83, 84, 85, 86, 87, 88, 89, and 90	Electronics with plastic components (85). Examples- vacuum cleaners (850860), computers (847130), fans (841490), food processing equipment (843880), and electric cars (870380).	Widespread use. Used in the vast majority of complex electronics on the market to meet flame retardancy standards such as UL 94 and IEC 60695-11.	Provide required anti-drip flame retardancy required by fire regulation and standards. Currently no effective replacements for PTFE as an anti-drip additive. Virtually all electronics use PTFE anti-drip agents in one or more parts. Restriction of PTFE anti-drip agents would create a significant safety risk for electronics and require the redesign and re-qualification of safety of virtually every electronic product on the US market	Only additive widely approved for use to meet strict anti-drip flame retardancy requirements in plastics	None	Anti-Drip
3	PTFE, ETFE, PFA, PVDF, and FEP as a wire insulator.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90	Laptops (847130), medical endoscopes (901890), mass spectrometers (902781), car ignition (8708), tablets (847160), Pumps (8414), Data Machines (8517), Printers (8544), Analytical Instruments (9026), Photometers/Instruments (9027)	Widespread use. >100M products per year Used in the majority of complex higher performance electronics on the market.	Provide temperature and chemical resistance in combination with electrical insulation	Other materials do not have sufficient temperature and corrosive resistance, feasibility in dense electronics (too thick), and electrical insulation	None except PFA. PFA can be manufactured without residual PFOA but time will be required for conversion.	Wiring
4	Fluoropolymers (PTFE, ETFE, FEP, and PFA) used for electrical insulation purposes except wiring.	Hoses, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90	Coaxial cables (854420), audio ports (853669), chemical hoses (3917), antennas (852910), electrical transformers (850431), electric switches (853630)	Widespread use. >10M products per year. Common in most RF applications. Necessary for many radio frequency applications Also common to general electrical insulation, static dissipative hoses, and fire suppression.	Fluoropolymers have the best in class dielectric constants / electrical insulation while maintaining flexibility. This includes both electrical isolation but also in static dissipation and related safety activities.	Other polymers do not provide sufficient electrical insulation (poorer dielectric constants). Ceramics can provide sufficient dielectric constants for some RF applications, but do not have the flexibility required for most applications.	None except PFA. PFA can be manufactured without residual PFOA but time will be required for conversion.	Dielectric
5	Fluorosilicone, amorphous fluoro resins, and fluoroelastomers (including perfluoroelastomers) for electrical insulation purposes except wiring.	Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90; and HS Code 3917.	High voltage cables (854460), electric vehicles (870380), hoses (3917), (853340) electrical resistors (including rheostats and potentiometers) and industrial machinery (843890).	High voltage applications would be difficult without fluoroelastomers	Specialized uses requiring electrical isolation in a rubber	No other material has equivalent dielectric constant / electrical insulation capability with flexibility Fluoroelastomer use is more specialized and lower volume than PTFE and ETFE for the same purpose.	None	Insulator
6	Fluoropolymers in invasive, implantable, fluid, and gas contacting applications in medical devices.	Medical	HS Code Chapter - 90	Endoscopes (901890), surgical instruments (9018), surgical tubing, and pacemakers (902150), electrical components (854370)	Widespread medical use. Necessary for most invasive procedures	Low friction, flexibility, and high biocompatibility are essential for internal procedures	Alternatives do not have equivalent low friction, flexibility, and/or biocompatibility. Some polymers, such as silicone and polyurethane, have applications in invasive medical devices but not in situations requiring low friction or thin material. Silicone also contains over 100X higher concentrations of forever chemicals (D4, D5, and D6) than PFA fluoropolymer.	Yes. However PFOA presence is strongly linked to flexibility and will take time and validation to phase out.	Medical
7	PTFE as an additive up to 25% in plastics for the purpose of reduced friction and wear	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 28, 32, 38, 39, 40, 49, 73, 74, 82, 83, 84, 85, 86, 87, 88, 89, and 90	Bearings (848210), medical devices, drills (846721), manufacturing equipment, food processing equipment (820830), industrial vehicles and instruments for analysis (9027).	Widespread use. Very common in longer life products with moving parts. Without these products, there would be no more automation or automated assistance.	PTFE additive provides greatly reduced friction and wear in plastic parts. This property greatly extends their lifetime and time before replacement.	Alternatives do not have equivalent low friction or compatibility as an additive. No other additives are as effective in safely reducing the coefficient of friction of plastics. Restriction of PTFE additives in plastics for friction reduction would reduce the lifetime of many products, resulting in products going to waste or landfall sooner and more often. In addition, PTFE added plastics extend product life/service intervals thereby reducing potential fluid and gas releases/exposures. They also reduce power consumption compared to non-PTFE added counterparts.	No	Friction
8	PTFE, ETFE, and PCTFE for professional, industrial, or high temperature applications (>150C) requiring reduced friction, or chemical inertness.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 32, 39, 40, 83, 84, 85, 86, 87, 88, 89, and 90.	Chemical reactors (841989), breathing appliances (9020), chemical processing, oil and gas (847989), laboratory equipment, engines, electrical transformers (850450), and industrial equipment.	Widespread professional and industrial use. Requirement for industrial and laboratory machinery. Working at high temperatures or harsh environments would no longer be possible.	Fluoropolymers have tremendous chemical and temperature resistance combined with low friction. All three are essential for the operation and safety in industrial environments.	No other materials have the same low friction and chemical inertness properties as PTFE, ETFE and PCTFE at regular temperatures and at high temperature (150C). PTFE and PCTFE extend product life/service intervals thereby reducing potential chemical releases/exposures. They also can reduce power consumption compared to non-PTFE/PCTFE counterparts.	No	Harsh Env.
9	Fluoroacrylic coatings necessary for chemical or fire safety for fabrics including applications requiring extreme water repellancy for professional use.	Textiles	HS Code Chapters - 39, 42, 56, 62, and 63	Chemical aprons (6210), Splash shields (392690), motorcycle racing jacket (420310), and hazardous environment clothing (621010)	Safety clothing is necessary for worker safety in hazardous environments.	Fluoroacrylics provide adhesion to the fabric and protection from acid, water, and oil.	Alternatives do not have the combination of acid, water, temperature, and oil resistance sufficient for hazardous environments while maintaining permeability to air (breathability).	Yes from the fracturing of the C-O-C bond in the fluoroacrylic coatings. But in low concentration.	Fabric Coating
10	Fluoroacrylic coatings on fabrics necessary for the protection or storage of portable medical devices or laboratory equipment.	Textiles, Medical, Laboratory	HS Code Chapter - 84 and 90	Water resistance cases for pumps (841370), dialysis equipment (901890), CPAPs and other sensitive medical or laboratory devices (901920).	Water resistance provided by the carrying case is necessary for sensitive medical and laboratory requirement.	Fluoroacrylics provide adhesion to the fabric and significant protection from acid, water, and oil. The safety of the laboratory or medical device is dependant on their proper care from the environment.	Alternatives do not have the combination of acid, water, and oil resistance sufficient for complete protection of the sensitive equipment or medical devices.	Yes from the fracturing of the C-O-C bond in the fluoroacrylic coatings. But in low concentration.	Fabric Coating

11	PTFE, PFA, FKM, and PVDF membranes for gas and aqueous filtration, or particle retention.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 38, 39, 73, 84, 85, 86, 87, 88, 89, and 90.	Medical filtration membrane (901819), laboratory filtration membranes (8414), water purification / food processing equipment filtration membranes (842121), and drinking water filtration and laboratory membranes (9020)	PTFE, PVDF, FPA, and FKM membranes are hydro- (water) and oleo- (oil) phobic while still allowing air to pass. These membranes provide the ability to extract air components from liquids and solids in specialized environments. Fluoropolymer membranes perform well under pressure and are stable over time and resistant to corrosive cleaning reagents.	PTFE, PVDF, PFA, and FKM membranes are the only material with best in class air porousness and resistance to water and oils.	No other material has the same gas permeability while being hydrophobic, oleophobic, acid resistant, and alkali resistant. Fluoropolymer membranes also have the advantage of maintaining their performance characteristics even at elevated temperatures. Although it is theoretically possible to develop a porous gas permeable polyethylene frit for some applications, this would be a long project and is risky regarding tightness and reproducibility of the gas transfer. Safety and accuracy would degrade in these specialized medical, laboratory, or industrial applications.	Yes. From the fracturing ('rubberizing') of the fluoropolymer to create the membrane fibre. Low concentration: 1 to 4 ppm	Membranes
12	PTFE as a lubricant additive under 30% concentration not in contact with drinking water.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 34, 84, 85, 86, 87, 88, 89, and 90	Widespread use. Mineral or silicone oil with PTFE powder added. Used in a wide range of consumer, professional, and industrial machinery to maintain low friction. PTFE added oil lubricants are both found inside machinery and are sold independently for use on moving parts.	The PTFE added lubricants significantly decrease the wear and increase the lifetime of machinery parts.	PTFE powder added to oils safely provides lubrication in a large range of environments necessary for proper function and lifetime of machinery.	No other material has the same impact as a low friction additive to mineral or silicone oil than PTFE.	No	Lubricant
13	PTFE as a fused coating on cookware	Cookware	HS Code Chapters 73, 76 and 84	Frying pans, electric griddles, electric waffle machines. (7323, 761510)	Cooking appliances and frying pans are essential to the continued functioning of society. Non-stick cookware is necessary to reduce cooking and cleaning time for consumers and professionals.	Fused PTFE powder to create anti-stick coating on cooking surface	No polymer provides the same low friction at high temperature. Ceramic cookware can provide sufficient non-stick (low friction) but is not as durable as PTFE coated cookware, reducing the lifetime of the fry pan or cooking appliance.	No	Cookware
14	PTFE as a coating for chemical containers	Containers	HS Code Chapters - 39, 73, 84, and 86	Chemical containers (for storage or industrial machinery) for hazardous chemicals (7309-7311) (841989, 8609)	PTFE has the necessary acid, water, oil, and temperature resistance to handle some of the most hazardous chemicals.	PTFE provides excellent resistance to chemicals, acids, water, and oils - and temperatures.	Alternatives do not provide sufficient resistance to acid, water, oils, and temperature for all harsh chemicals. Ceramics have similar performance characteristics but could only be used to coat metal vessels. Ceramic coatings are more difficult to coat completely without gaps in larger containers, creating leakage or degradation risk.	No	Harsh Env.
15	Fluoroelastomers (including perfluoroelastomers), fluorosilicone, and amorphous fluoro resins as a sealing and packing material in situations requiring chemical resistance, oil resistance, oxidation resistance, decompression resistance, elasticity, high temperature (over 150C), and/or low temperature (<-20C).	Rubbers, Building Products, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 32, 34, 39, 40, 49, 59, 68, 72, 73, 83, 84, 85, 86, 87, 88, 89, and 90.	Widespread use. Pumps, oil and gas (848790), industrial machinery (848420), chemical tanks (7309), food processing, medical devices, laboratory equipment, aerospace, chemical processing, pharmaceutical and cosmetic processing equipment, and equipment for extreme environments	Products using fluoroelastomer seals can be found in virtually every industrial or machinery application world wide. Without fluoroelastomer seals, virtually all industrial applications would no longer be viable.	Fluoroelastomers (including perfluoroelastomers and amorphous fluoro resins) are the necessary sealing material for applications requiring temperature resistance, chemical resistance, flexibility, and water/oil resistance. Without fluoroelastomers, sealing on machinery would not be viable in many applications.	No other rubbers have equivalent hydrophobic and oleophobic properties, oxidation resistance, and chemical safety over a range of low and high temperatures as fluoroelastomers. Fluoroelastomers are also very resistant to explosive decompression. Fluoroelastomer use can extend product life/service intervals thereby reducing potential chemical releases/exposures. Alternative materials would need to be replaced monthly, as they begin to leak. PTFE has similar environmental properties, but is a plastic and is not suitable for applications requiring the conformity of a 'rubber' seal. Fluoroelastomers also have a higher coefficient of friction than PTFE and create a superior 'seal' in most applications.	No	Seals
16	Fluoroelastomers (including perfluoroelastomers), fluorosilicone, and amorphous fluoro resins as a sealing and packing material for drinking water or food contact if compliant with NSF, FDA, and State food and/or drinking water regulations.	Rubbers, Industrial, Machinery	HS Code Chapters - 40, and 84.	Widespread use. Seals in water purification facilities and laboratory equipment. Very common material in drinking water contact. (842121, 842199)	Water purification is essential to the functioning of society.	Fluoroelastomers provide flexibility, biocompatibility, temperature resistance, and water resistance.	No other rubbers have equivalent hydrophobic and oleophobic properties, UV resistance, and chemical safety over a range of temperatures as fluoroelastomers. The most common alternatives are not chemically compatible for direct contact for long exposure time (years). PTFE has similar environmental properties, but is a plastic and is not suitable for applications requiring the conformity of a 'rubber' seal. Fluoroelastomers also have a higher coefficient of friction than PTFE and create a superior 'seal' in most applications. Additionally, silicone has reduced biocompatibility and high forever chemicals due to its normal high concentration of residual D4, D5, and D6 forever chemicals.	No. However, fluoroelastomers can contain 6:2 fluorotelomer from their emulsion surfactant. Any presence of 6:2 fluorotelomer (and related short chain perfluorocarboxylate degradation products) must conform to drinking water standards.	Water Seals
17	PTFE tape for moisture insulation, or joining of fluid or gas components.	Self adhesive tape, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 40, 84, 85, 86, 87, 88, 89, 90, and HS Code 3919.	Widespread use. PTFE tape for home and professional use, plumbing, machinery with fluids or gasses, drinking water equipment, food production equipment, industry water processes, medical endoscopes, analytical instruments, and any other equipment requiring piping to be sealed together. (3919)	PTFE tape is the most effective joining materials in a fluid environment. Alternative materials do not have equivalent water and oil sealing in a thin coating.	PTFE rubber tape has the best in class water and oil resistance in a thin applicable tape.	Alternative materials do not provide the same water or oil seal in a thin tape.	Yes. The fracturing of the PTFE polymer chain to produce PTFE rubber commonly produces PFOA and LC-PFCA. Manufacturing of PTFE tape without PFOA is possible and PFOA containing PTFE can be phased out.	PTFE Tape
18	PTFE tape for reduction of friction.	Self adhesive tape, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 39, 40, 84, 85, 86, 87, 88, 89, 90, and HS Code 3919.	Industrial machinery or equipment with moving parts. (3919). Printing equipment (3215)	PTFE tape provides a thin coating to reduce friction between moving parts.	PTFE rubber tape has very low friction, reducing the wear, and extends the lifetime of moving parts.	No other tape materials has as low friction as PTFE tape and the ability to conform to uneven surfaces. Replacement of PTFE tape in a low friction application will negatively affect product performance and reduce lifetime of the product - causing earlier disposal or replacement of the product using the PTFE tape.	Yes. The fracturing of the PTFE polymer chain to produce PTFE rubber commonly produces PFOA and LC-PFCA. Manufacturing of PTFE tape without PFOA is possible and PFOA containing PTFE can be phased out.	PTFE Tape
19	Fluorocoating of rubber, metal, carbon, and plastic seals in high temperature, professional, or industrial applications where chemical resistance is required.	Rubbers, Building Products, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory, Aerospace	HS Code Chapters - 40, 83, 84, 85, 86, 87, 88, 89, and 90	Plunger in a syringe (901831), rubber plunger in industrial equipment (841319), rubber component in contact with chemicals.	Most standard rubbers are high friction (nitrile rubber, styrene rubber, EPDM) and require a fluorocoating for low friction. This is necessary for plungers and other rubber parts likely to encounter friction in operation.	Fluorocoating of standard rubber such as nitrile or butadiene rubber provides low friction to a standard rubber.	Alternative materials do not sufficiently reduce the friction of rubber to allow for the necessary movement of the rubber part. No other coating material provides the same environmental protection to rubber and metal seals.	No	Rubber coating

20	PTFE, ETFE, and PFA coating of metal for environmental or temperature resistance not in contact with food or drinking water.	Metal, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory, Aerospace	HS Code Chapters - 72, 84, 85, 86, 87, 88, 89, and 90	Widespread use. Outdoor machinery, construction vehicles, oil and gas platforms, industrial equipment (3208) (721070)	Metals and machinery used in harsh or outdoor environment need chemical, water, and oil resistant coatings to protect from the conditions.	Fluoropolymer coatings provide environmental resistant to metal parts. Resistance to water, acids, and oils extends the lifetime of the parts in outdoor and harsh environments.	No other coating materials provide the same environmental (water, oil, acid, and chemical) protection to metals. Replacement PTFE and PFA environmental coatings for metals will reduce the corrosion resistance (in particular over temperature) of many metals resulting in failure of these metals and/or reduced product lifetime (resulting in more products entering end of life disposal sooner).	No	Outdoor
21	PTFE, FEP, and PFA coating of metal for low friction, improved wetting, and/or wear resistance in machinery or tools	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Machinery or equipment with moving parts. Wood saw blade, pumps, and other moving components in contact with other materials. (721070). Machines and mechanical appliances (847989), pumps (8413), laboratory or plant machinery (841989), spectrometers (902730). Includes paint, anodization, and other coatings on metals.	Cutting, drilling, grinding, milling, and other activities with metal in contact with other materials requires low friction, high wear resistance and high temperature resistance.	Fluoropolymers coatings are nearly frictionless, have excellent wetting properties, and can withstand high temperature and wear.	Alternative materials do not have equivalent low friction, wetting, and/or temperature resistance. PEEK provides similar durability but not equivalent low friction. PFA does not have as low friction as PTFE, but is lower friction than PEEK. Replacement PTFE, FEP, and PFA environmental coatings will greatly reduce the performance of some machinery, increase wear, and reduce lifetimes on metal components. Liquid lubricants can be used, but they are temporary in nature, and the most effective lubricants for low friction in metal parts contain PTFE powder and are covered by another derogation request.	None except PFA. PFA can be manufactured without residual PFOA but time will be required for conversion.	Machinery
22	PTFE, PFA, FEP, and TFE copolymers in hoses in chemical, pump, or valve applications.	Tubing, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, 90; and HS Code 3917.	Widespread use. Pump hoses, chemical plants, gasoline hose, fuel lines, and oil and gas. (4009)	Transport of chemical or petroleum fluids requires specialized materials.	Fluoropolymers have excellent chemical, acid, and oil resistance - the requirements for transportation of many petroleum and chemical fluids. Fluoropolymers also have the flexibility necessary for hose (as opposed to rigid tube) applications.	No other polymer that can be formed into hoses or braided to transport chemicals has the equivalent acid, chemical, oil, fire, and temperature resistance with the necessary flexibility required for hoses.	None except PFA. PFA can be manufactured without residual PFOA but time will be required for conversion.	Hoses
23	Fluorocoatings on labels on products (excluding textiles) necessary for environmental resistance	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory, Personal Protective Equipment (PPE), Consumer	HS Code Chapters - 65, 84, 85, 86, 87, 88, and 90	Widespread use. Safety label on product, product serial number label, battery capacity and composition label, and other labels with indelibility and lifetime requirements. (482110)	Clear labels that do not degrade over time are required for safety and regulatory reasons on most electronic, personal protective equipment, professional, and industrial products. A thin fluorocoating protects the label from the environment, maintaining the legibility of the label and meet standards such as UL 969.	Fluoropolymer coatings provide water and oil resistance to labels - reducing, if not preventing legibility issues with the label's writing.	Alternative coatings do not have the equivalent water or oil resistance. Or, in the case of nitrile or EPDM rubber, do not have the required transparency to read the label's writing. PVC has nearly equivalent water and oil resistance, but has risks of other regulated substances (such as phthalates) and does not withstand temperature ranges as well as fluoropolymers.	No	Labels
24	PTFE, PFA, FEP, PVDF, ETFE, and fluoroelastomer (including perfluoroelastomer) tubing not in contact with drinking water.	Tubing, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, 90; and HS Code 3917.	Widespread Use. (391739) Transformers, power suppliers, laboratory equipment, medical devices (901839), accelerometers (903180), and servers	Electrical transformers are reliant on PTFE tubing to protect their wiring. Medical devices and laboratory equipment use fluoropolymer tubing for transport of fluids in situations where non-reactive materials are critical. Tubing and bellows are used in articulating joints in machinery and vehicles. Without which, the joints would be inflexible and would wear.	Fluoropolymers have flexibility, biocompatibility (low chemical reactivity), optical transparency, and high temperature resistance. For electronics, the flexibility and high temperature resistance is critical for power applications such as the leads in transformers. For medical devices, the flexibility, transparency, and low chemical reactivity are critical for human or laboratory processes.	Alternative polymers do not have equivalent low chemical reactivity, optical transparency, flexibility, and temperature resistance. Polyurethane and PVC tubing can be used in some applications, but have poor resistance to acids and bases, can release chemicals (isocyanates or phthalates) into the fluid, and both have poor temperature stability.	No	Tubes
25	Heat transfer fluids for industrial applications	Heat transfer fluids, Electronics, Vehicles, Industrial, Machinery, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, and 89; and HS Code 3824.	Servers, semiconductor manufacturing equipment, radar equipment, and large power supplies.	Specialized high performance products that require fast and efficient transfer of heat from the heat generation source.	Fluorinated fluids have best in class heat transfer properties.	No other fluids have equivalent heat capacity to transfer heat sufficiently in machinery. Replacement with other fluids would create safety and performance issues in industrial applications such as semiconductor manufacturing, data centers, and military/aerospace.	Unknown	N/A
26	PVDF and PTFE as the cathode binder in lithium batteries	Lithium batteries, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, 90; and HS Code 8507.	Lithium batteries in electronics, vehicles, medical devices, servers, power drills (846721), analysis equipment for water, and portable electronic equipment. (850760)	Lithium batteries are fundamental to electric vehicles, servers, and portable electronics / tools.	Fluoropolymer binders have high heat resistance and excellent electrical insulation - improving performance of lithium batteries and reducing delamination of the electrodes in the battery.	Alternative polymers do not have as good of temperature resistance and/or electrical insulation, reducing the performance and lifetime of lithium batteries. Other polymers could not maintain the rigorous performance requirements of a binder in a high density lithium battery. Lead acid batteries have similar performance to lithium batteries, but can release lead at the end of life and have a weight that makes them unusable for mobile applications including electrical vehicles.	No	Batteries/Cap
27	PVDF, PTFE, TFE, and sulfonated PTFE as a binder, separator, or spacer in capacitors (including copolymers)	Capacitors, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, 90; and HS Code 8532.	supercapacitors and other high capacitance capacitors have a broad use in electronics, electrical distribution, and industrial equipment. (8532)	Fluorinated binders in capacitors are fundamental to high performance / capacitance capacitors. The fluoropolymers fill a similar role in a capacitor as they do in a lithium battery.	Fluoropolymer binders, separators, and spacers provide the electrical insulation and temperature resistance needed in high capacitance capacitors.	Alternative polymers do not have as good temperature resistance and/or electrical insulation, reducing or preventing the performance of the high performance capacitors	No	Batteries/Cap
28	Surfactants in emulsion based bio-assays and dry-chemistry assays	Medical, Laboratory	HS Code Chapter 90	Specialized low volume use in laboratory assays. Research and development, and medical applications.	Surfactants are commonly needed in laboratory and medical assays. These assays are necessary for measurement of biological, human, and chemical properties.	Fluorinated surfactants have the best surfactant performance. High performance and critical measurements using bio and dry chemistry assays often have to use fluorinated surfactants for measurement accuracy.	Fluoro based surfactants are commonly used as the surfactants in specialized bio-assays and dry chemistry assays. Fluoro based surfactants are useful for membrane protein stabilization in subsequent purification steps as they do not strip natural lipids and other co-factors from the proteins. In addition, the bulky fluorinated tails can not penetrate into the interior and disrupt the structure. Fluorinated surfactants often decrease non-specific aggregation and are thought to result in improved distribution. Without fluoro based surfactants, many specialized laboratory or medical measurements would not be possible or, at least, not with the same accuracy.	Yes. The very small amount present is very low volume, specialized use, and has controlled disposal. No risk of impact to humans or drinking water.	N/A
29	PTFE foil coating of rubber for biotechnology or chromatography purposes.	Medical, Laboratory	HS Code Chapter 90	Specialized very low volume use in laboratory and medical testing. Research and development, and medical applications. (902720)	PTFE foil is a specialized use in gas (and other) chromatography. This is a low volume application necessary for very specialized tests.	By enclosing the gas / fluid path with PTFE, higher precision chromatography is possible due to the reduced friction and low chemical reactivity of the tubing.	No other polymer has as low reactivity and low friction as PTFE. Specialized biotechnology or chromatography applications require the highest possible performance for measurement accuracy and consistency.	No	N/A

30	Fluorinated polyethylene for chemical storage and handling.	Industrial, Machinery, Laboratory	HS Code 3904	Fluorinated polyethylene containers for hazardous or laboratory chemicals.	Certain laboratory and hazardous chemicals will dissolve standard polyethylene or other polymer containers. Fluorinated polyethylene containers are needed for transport and storage of these chemicals (pesticides, optical personal care products, and industrial cleaners).	Fluorinated polyethylene provides the chemical resistance to standard polyethylene containers necessary to contain and transport certain chemicals.	Alternative non-fluorinated polymers do not have the chemical resistance to safely contain or transport pesticides and industrial cleaners. PFA fluoropolymer has similar performance as fluorinated polyethylene, but is more flexible and not suitable for most applications of fluorinated polyethylene.	Yes. Small concentration of PFOA and LC-PFCA are created by the fluorination of polyethylene.	N/A
31	Fluorosilicone, fluoroacrylic, and nano-fluorocoatings for antismudge and antireflective coatings for plastics and glass.	Electronics, Building Products, Vehicles, Industrial, Machinery, Medical, Laboratory, Eyewear, Headwear	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90.	LCD screens (852859), ski goggles (900490), motorcycle helmets (65061030), sunglasses and eyewear (900410), refrigerator shelves (841899), and windows (761010).	Anti-smudge and anti-reflective coatings are necessary to maintain optical clarity in products that are touched by humans or are exposed to the environment. Without anti-smudge and anti-reflective coatings, safety and functionality could be compromised by lack of visibility.	Fluorinated coatings provide hydrophobic (water repellant) and oleophobic (oil repellant) properties to glass and plastics while maintaining optical transparency. Necessary for product safety, viewing clarity, and to meet state motor vehicle codes. Fluoroacrylic coatings are critical for optical clarity for motor vehicles and related safety optical elements.	Alternative materials do not have equivalent water or oil resistance with the necessary optical clarity (especially in harsh environments). In particular, oil (fingerprint) repellency of other materials are not equivalent. Other anti-fingerprint coatings exist, such as parylene, but they do not adhere to plastic substrates as effectively as fluoropolymer side chain polymers and have lower thermal stability.	No Except fluoroacrylic coatings. Fluoroacrylic coatings can have under 1ppm LC-PFCA from the fracturing of the C-O-C bond in the fluoroacrylic coatings.	Anti-smudge
32	PTFE, PCTFE, PVDF, FEP, ePTFE, PFA, and TFE (including copolymers) as a sealing or spacer material.	Seals (plastic, rubber, or metal), Building Products, Electronics, Vehicles, Industrial, Machinery, Pumps, Medical, Laboratory	HS Code Chapters - 28, 32, 38, 39, 40, 49, 59, 72, 73, 74, 82, 83, 84, 85, 86, 87, 88, 89, and 90	Widespread use. Pumps, oil and gas, industrial machinery, food processing, pharmaceutical and cosmetic processing equipment, medical devices, laboratory equipment, aerospace, chemical processing, electronic components, and equipment for extreme environments.	Products using fluoropolymer seals can be found in a wide range of industrial or machinery applications. Fluoropolymer seals are used in situations requiring a solid or vacuum seal versus the rubber seal of a fluoroelastomer, or added / impregnated into sealing material to provide the necessary performance properties.	Fluoropolymers have the acid, alkali, temperature, heat, water, and oil resistance needed for industrial sealing applications.	Alternatives do not provide sufficient resistance to acid, chemicals, water, oils, and temperature. In most of the applications listed in this entry, alternative sealing materials were tested, and no materials and closure systems showed positive results.	No Except PFA and ePTFE. They often contain PFOA and LCPFCA from the fracturing of the C-O-C bond of PFA, and the crosslinking of the polymer in ePTFE. Both can be designed without PFOA or LC-PFCA.	Seals
33	PVDF and ETFE as a component in fluid or gas systems	Plumbing, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90 - HS Code 3917	Pumps (841381), water circulation systems (842121), water purification system (842121), laboratory equipment (8419), and water heaters (8419).	Fluid and gas transportation is critical for a wide range of industries. Society cannot function without the ability to transport fluids and gases.	PVDF and ETFE provide significant performance advantages as components in a fluid or gas transportation system as either part of the tubing or as connector pieces in the system.	Alternatives do not have sufficient resistance to water, oil, and chemicals; and with the necessary durability and biocompatibility. The only other polymer with similar properties is PTFE. PTFE is higher density and has less abrasion resistance than PVDF. PVDF is preferred in industrial or heating applications for piping. ETFE has higher tensile strength than PTFE and can be used under harsher conditions that PTFE. The exception is the PEEK polymer. PEEK is technically a viable alternative to PVDF. Validation work needs to be completed to ensure replacement is viable in all circumstances.	No	Fluid/Gas Comp.
34	PTFE in coatings of labels for security or tamper evidence.	Tamper proof labels	HS Code Chapters - 84, 85, 90 HS Code 3923	Food packaging (3923), smart cards (8523.52), secure forms delivery, passports, self-adhesive plates, sheets, film, foil, tape (3919)	Abrasion and tamper proof labelling is needed for the security of personal information and product safety.	PTFE coatings provide abrasion and tamper proof protection for labels. PTFE cannot be modified by chemicals and shows physical wear if tampered. such as leaving a "Void" marking when the tamper evident label is pulled away/off.	For security - no other polymer provides the same tamper proof properties (chemical resistance) as PTFE as a coating. Use of another polymer would reduce the security of devices especially those for financial transactions or personal identification. For tamper evidence - PTFE material film (plus an adhesive) is used in the label in order to provide evidence. Other plastics do not have the combination of chemical resistance and visibility of tampering than irradiated (soft) PTFE.	No	Labels
35	Fluoroacrylic and PFA coatings (and PFPE solvents) for encapsulation of capacitors or semiconductor components.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8532 and 8542	Capacitors and integrated circuits used in computers, servers, machinery, and laboratory equipment	Electronics with advanced capacitors and integrated circuits are necessary for the continued functioning of society.	Very thin fluoroacrylic and PFA coatings provide water resistance at high temperature to sensitive electronics. There will be a very small amount of residual perfluoropolyether (PFPE) from application of the coatings	Alternative non-fluorinated materials do not have adequate chemical, water, and heat resistance in a high density / thin film application.	Below measurable levels due to small size of application	IC Coating
36	PTFE and fluorosilicone sprays for maintaining lubrication in industrial equipment.	Lubricants, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 34, 84, 85, 86, 87, 88, 89, and 90	Widespread use. Pumps (841381), oil and gas, industrial machinery, food processing, medical devices, laboratory equipment, aerospace, chemical processing, and equipment for extreme environments.	Widespread use. Very common in longer life products with moving parts. Without these products, there would be no more automation or automated assistance.	PTFE and fluorosilicone sprays provides lubrication in a large range of environments necessary for proper function and lifetime of industrial machinery, metal parts, and wire/cable.	No other spray is as effective in low concentrations and thickness in achieving reduced friction. Silicone spray is less effective than fluoro sprays and often contains D4, D5, and D6 forever chemicals (also regulated in the EU with further restriction expected). Silicone lubricants stay 'wet', apply thicker, do not have good high temperature resistance, and are less effective on moving parts.	No	Lubricant
37	Ionic fluoro fluids as electrolytes in capacitors or batteries	Lithium batteries, Capacitors, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8507 and 8532.	Lithium batteries and supercapacitors in electronics (8507), vehicles (870380, medical devices, servers, power drills (8467), and portable electronic equipment.	Lithium batteries, capacitors, and supercapacitors are fundamental to electric vehicles, servers, industrial equipment, and portable electronics / tools.	Fluoro ionic fluids provide great surfactant power, chemical/biological inertness, easy recovery and recyclability, low surface tension, extreme surface activity, no flammability, and high thermal stability. The surface activity and high thermal stability are excellent for high performance lithium batteries and supercapacitors.	Other ionic fluids can be used, but these fluids do not exhibit either/or the performance or flammability resistance of FILs.	No	N/A
38	Perfluorinated polyether (PFPE) as a lubricant for harsh (very low or high temperature) environments	Building Products, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 83, 84, 85, 86, 87, 88, 89, and 90.	Industrial machinery, components, and equipment uses at low and high temperatures.	Industrial machinery is required to work in low and high temperatures in laboratory and outdoor environments.	PFPE provides lubrication at very low temperatures which is not available for other materials. PTFE can offer high temperature lubrication equivalent to PFPE.	Silicone oil does not have the temperature range of PFPE and is not suitable for contact with some plastics. PFPE can handle a higher temperature range and is compatible with a wider range of rubbers.	No	N/A

39	PVDF polymers and PVDF terpolymers for ferroelectric films.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Specialized use of ferroelectric films in micromachines and memory devices. Use of PVDF terpolymer films in actuators for medical devices (e.g. catheters or other implantable devices).	Micromachines and memory devices are specialized use, but are necessary for miniature applications and memory storage. Medical devices such as catheters and other implantable devices have an essential medical use.	PVDF and similar films are fundamental to the specialized use of ferroelectric films. Without PVDF, ferroelectric films would not be possible. PVDF terpolymer ferroelectric films enable the construction of flexible actuators that assist medical devices in their function. Without PVDF films, flexible actuators would not be possible in medical uses.	Specialized PVDF films have the highest dielectric constant of polymers, are new innovations, and are not replaceable with other materials. Given the electroactivity, strength and flexibility of PVDF terpolymer films, they enable the construction of flexible actuators for which there is currently no alternative.	No	N/A
40	Fluoroethers for degreasing applications	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Metal components for electronics, medical, industrial, or laboratory equipment are commonly degreased with fluoroethers.	Clean high precision metal components are needed for electronics, laboratory, medical, and high precision applications.	Fluoroethers provide degreasing cleanliness necessary for metals in high precision applications.	Chlorinated and brominated solvents can be used to degrease metal parts, they have higher greenhouse gas and environmental emissions; and reduced solvency power - resulting in most environmental hazards and would reduce part quality.	No	N/A
41	Residual hydrofluoroolefins used as blowing agents for insulating foam internal to products	Polyurethane foam, Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90, and HS Code 392690	Blown foam for refrigerators, centrifuges, buildings, and shipping of fragile products.	Blow foam is necessary for thermal insulation for food safety and for transportation of valuable / fragile products.	Hydrofluorolefins used as a blowing agent for insulated foam leaves residual hydrofluorolefins.	HFOs (hydrofluorolefins) are the environmentally friendly replacements for hydrofluorocarbons (HFCs). To meet greenhouse gas emissions targets, companies need to continue to use and convert to HFOs.	No	N/A
42	PTFE as a manufacturing aid or tool for high temperature (> 150C) applications	Tools for manufacturing	HS Code Chapter 84.	Tools includes tools, jigs, and molds for high temperature manufacturing.	Industrial manufacturing processes often involve high temperatures which require tools that can withstand high temperature with strong chemical resistance.	PTFE withstands high temperatures and has very good chemical resistance.	Metals are too thermally conductive for most high temperature manufacturing processes. Other polymers either do not have the temperature resistance of PTFE (example - polyethylene) or are difficult to machine into custom tools (example - PEEK).	No	Harsh Env.
43	Fluorocoatings on laser fibers, laser fiber components, and fibers for optical purposes including light guidance.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Fibre optics in communication systems (854470), medical endoscopes (901890), industrial vehicles (8708), aerospace, and laboratory equipment.	UV curable coatings based on fluorinated polymers (amorphous fluoropolymers) are used in connecting optical fibres or fiber based components to maintain light guidance along a chain of fiber and fiber based components when making a device. For optical components, light guidance needs to be maintained with high reliability and precise optical matching to avoid losses and transmitting light between beam forming components.	Fluoropolymers have optical transparency, excellent optical matching properties, and can be used in thin or dense environments.	Alternative materials are not as transparent to visible light and have poorer optical matching properties.	None expected. The amount of amorphous fluoropolymer is not sufficient for measurable perfluorocarboxylates in the final device even for a potential degradation product.	Optical Coating
44	Fluorosilicone used as a surfactant or anti-foaming agent in semiconductor materials	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8532 and 8542	Integrated circuits used in computers, resistors, servers, industrial machinery, and laboratory equipment	Precision semiconductor products are fundamental to virtually all modern electronic applications.	The fluorosilicone surfactants are used in a manufacturing step for a microscopic material internal to a semiconductor device. The resulting chemical is only used in the manufacturing of the product and will not be present above 50 ppm organic fluorine in the final product.	Other surfactants are not as effective for this high precision application or as inert. In semiconductor manufacturing this surfactant cannot react without other materials.	No	N/A
45	F2 gas and PFA fluorinated plastics in capacitors and microchips	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 34, 39, 40, 48, 49, 73, 84, 85, 86, 87, 88, 89, and 90; and HS Code 8532 and 8542	Integrated circuits used in computers, servers, industrial machinery, and laboratory equipment	Precision semiconductor products are fundamental to virtually all modern electronic applications.	A microlayer of fluorinated material is created in capacitors and semiconductor devices by F2 gas fluorination (usually plasma fluorination) of a plastic such as polyethylene or polyphenylene sulfide The thin layer has amorphous fluorinated alkane molecules. This very thin internal fluorinated layer provides specialized capacitance curves and is useful in specialized applications. Capacitors and microchips require extreme chemical resistance or flexibility advantages.	Thin fluorinated plastics provide capacitance performance advantages plus environmental resistance not available in other materials, and temperature resistance necessary for dense electronics	No	N/A
46	PTFE filled die attach material for semiconductor devices	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90; and HS Code 8532 and 8542	Integrated circuits and semiconductor devices (854110) used in computers, servers, industrial machinery, and laboratory equipment	Precision semiconductor products are fundamental to virtually all modern electronic applications.	PTFE provides a chemical inertness and temperature resistance to microchip die attach material.	No other polymer powder is as chemically inert and has as high temperature resistance as PTFE powder.	No	N/A
47	PFBS (Perfluorobutane sulfonate) and its salts - for the purposes of optical clarity in flame retarded polymers.	Electronics, Vehicles, Industrial, Machinery, Medical, Laboratory	HS Code Chapters - 84, 85, 86, 87, 88, 89, and 90.	Refrigerator, computer display, kiosk terminal	Optically clear and flame retarded displays are important for displays used by consumers.	Flame retarded clear plastic tends to be slightly cloudy, reducing the transparency of the screen. By adding <0.01% PFBS, the plastic of the displays is 'clarified', and can be used easily and safety.	No information is available on a potential replacement for PFBS. Currently is it the only material effective for its specialized application.	No	N/A
48	PVDF, PTFE, PCTFE, FKM, ETFE, PFA, PVDF in chemical and pharmaceutical packaging	Diagnostic / laboratory reagents, Pharmaceuticals	HS Code Chapters - 38, 39, and 90.	Reagents (3822), chemical analysis instruments and apparatus (9027), plastic articles and materials (3926), pharmaceutical packaging	Pharmaceutical and chemical packaging has to be very chemical resistance, high purity, and have high biocompatibility (low leaching).	Fluoropolymers including PVDF, PTFE and other fluorinated polyethylenes, provide chemical resistance for corrosive and solvent chemicals. Heat or UV resistance needed during some uses. Fluoropolymers incorporated into liners and seals in chemical packaging, and through fluorinations of inner container surfaces maintains integrity of the containers, preventing potentially hazardous leaks and protecting human health and the environment.	No alternatives to fluorinated chemical containers currently exist. Replacement with non-fluorinated materials would create a safety hazard for workers. Non-fluorinated polymers such as polyethylene lack resistance to corrosive and solvent chemicals and harsh conditions.	No Except PFA. PFA often contains PFOA and LCPFCA from the fracturing of the C-O-C bond of PFA. Both can be designed without PFOA or LC-PFCA.	Chemical packaging

49	PTFE, PFA coated tubing to prevent clogging if compliant to applicable NSF, FDA, or State requirements	Analyzer reagent tubing, wastewater tubing, printer tubing	HS Code Chapters - 39, 40, 49, 73, 84, 85, 90	Printer system tubing & spigots, pumps (841381), water circulation systems (842121), water purification system (842121), laboratory equipment (8419), and water heaters (8419).	Water quality tubing, analyzers, printers.	Parts that require either low friction or have a role in hostile chemical environments. PTFE required to reduce friction to prevent clogs within a hostile environment.	No alternative material with required resistance to hostile environments.	No Except PFA. PFA often contains PFOA and LCPFCA from the fracturing of the C-O-C bond of PFA. Both can be designed without PFOA or LC-PFCA.	Tubes
50	Conductivity agent in continuous ink jet for coding and marking	Printing ink, ink cartridges	HS Code Chapters - 32 and 84.	Printer inks (321511, 844399)	Essential marking of information, tracing and tracking of product. Sell by dates for food, pharmaceuticals, bottling and packaging.	Lithium trifluoromethanesulfonat e is used as a conductivity agent in the ink formulation	No non-PFAS conductivity agents compatible with these formulations have been identified. Lithium trifluoromethanesulfonate is only used when other approaches are unsuccessful.	No	N/A
51	High temperature greases containing perfluoropolyether (PFPE)	Lubricating preparations	HS Code Chapter 34.	Fluorinated greases and oils (340399)	Assembly aid in production	Lubricant with high fluid resistance	No alternative material with required resistance to fluids	No	N/A
52	PTFE fibers and filtration disks used in corrosive gas filtration	Machinery, Electronics, Industrial	HS Code Chapter - 90 HS Code - 8421	Chemical analyzers, filtering or purifying machinery and apparatus for gases, others (8421)	These types of instruments are used to test if the water is safe for consumption or discharge in to the environment.The filtration allows successful conversion of these gases back to harmless forms that will not damage the environment or affect human health.	For filtration of corrosive or oxidizing gases the material is required to be very chemical resistant. The material must be able to separate particles from gas flow without damaging the filter.	Other polymers and filter material will react by dissolving and do not have the wide range of environmental resistance.	Yes. From the fracturing ('rubberizing') of the fluoropolymer to create the membrane fibre. Low concentration: 1 to 4 ppm	Membranes
53	PTFE Impregnated fabric for high temperature insulation	Electronics, Vehicles, Industrial, Machinery, Laboratory, Cooking Appliances	HS Code Chapters - 32, 39, 40, 83, 84, 85, 86, 87, 88, 89, and 90.	Insulation blankets in appliances, kilns, chemical reactors, conveyor belts	PTFE impregnated glass fabric is used as a heat insulating materials in high temperature professional and consumer products. The insulation fabric prevents heat from impacting other components including human contact surfaces.	PTFE provides additional insulation over glass fibre alone.	Silicone impregnated glass fibre does not have the temperature or chemical resistance of PTFE impregnated glass fibre.	No	Harsh Env.

JP4EE Attachment 1 - List of GPC Brick Codes covering EEE

Note: this list is prepared based on our best knowledge and non-exhaustive.

BrickCode covering EEE	BrickTitle covering EEE
10001686	Airbrushes (Powered)
10001742	Burning/Engraving Craft Tools (Powered)
10001694	Kilns (Powered)
10001732	Melter (Powered)
10001695	Pottery Wheels (Powered)
10001749	Printing Press (Powered)
10001693	Sculptors Tools (Powered)
10001707	Sewing/Knitting Tools (Powered)
10001754	Spinning/Weaving Tools (Powered)
10005726	Analogue/Digital Converters
10001467	Audio Headsets
10001483	Audio Visual Accessories - Replacement Parts
10001484	Audio Visual Accessories Other
10001482	Audio Visual Accessories Variety Packs
10005744	Audio Visual Labelling Systems
10001475	Converter Cassettes
10005204	Megaphones
10001476	Microphones
10005747	MP3 Docking Stations
10001468	Signal Boosters
10005809	Sound-active Effect Lighting
10001472	Switch-boxes
10001479	Television Internet Packs
10001470	Universal Remote Controls
10005735	Visual Distribution Amplifiers
10001469	Wireless Television Links
10001485	Audio Visual Equipment Variety Packs
10001429	Home Audio Amplifiers/Preamplifiers
10001432	Home Audio Cassette Decks
10001433	Home Audio CD Decks
10001443	Home Audio Effects Equipment
10001447	Home Audio Equipment - Replacement Parts/Accessories
10001448	Home Audio Equipment Other
10001446	Home Audio Equipment Variety Packs
10001440	Home Audio Jukeboxes
10001441	Home Audio Karaoke Systems
10001434	Home Audio MD Decks
10001437	Home Audio Receivers/Tuners/Radios
10001436	Home Audio Speaker Systems

10001435	Home Audio Speakers - Individual
10001442	Home Audio/Visual Mixers
10001430	Home Stereo Systems
10001431	Home Theatre Systems
10001444	Turntables - CD
10001439	Turntables - Vinyl
10001424	Clock Radios
10001425	Dictation Machines
10001419	Portable Audio Cassette Players
10001427	Portable Audio/Video - Replacement Parts/Accessories
10001428	Portable Audio/Video Other
10001426	Portable Audio/Video Variety Packs
10001416	Portable CD Players
10001421	Portable Digital Video Players
10001420	Portable DVD Players
10005765	Portable FM (Frequency Modulation) Transmitters

10001400	Televisions
10001402	Televisions - Hand-held
10001404	Televisions - Replacement Parts/Accessories
10001405	Televisions Other
10001403	Televisions Variety Packs
10001411	Aerials
10005841	Audio/Visual Receivers
10005736	Low-noise Block (LNB) Converters
10005760	Satellite Reception Accessories
10005829	Satellite/Terrestrial Antenna Systems
10001409	Set-top Boxes
10005739	Video Receiving/Installation Variety Packs
10005808	Audiograms
10001406	Camcorders
10001408	Combination Players/Recorders
10001407	DVD Players/Recorders
10005748	Memory Card Recorders
10001412	Video Cassette Players/Recorders
10001410	Video Hard Disc Recorders
10001414	Video Recording/Playback - Replacement Parts/Accessories

10001413	Video Recording/Playback Variety Packs
10006240	Audio (Non-Music) - Digital
10001464	Audio Cassettes - Pre-recorded
10001459	CD/MD - Pre-recorded
10003718	Dual Discs - Pre-recorded
10001460	DVD - Pre-recorded
10001466	Pre-recorded Media Other
10001465	Pre-recorded Media Variety Packs
10001463	Video Cassettes - Pre-recorded
10001449	Audio Cassettes - Recordable
10001450	CD/MD - Recordable
10001451	DVD - Recordable
10001456	Floppy Discs
10001452	Memory Cards
10001458	Recordable Media Other
10001457	Recordable Media Variety Packs
10006398	USB Flash Drives/Thumb Drives
10001455	Video Cassettes - Recordable
10003777	Audio Visual/Photography Variety Packs
10001533	Car Audio - Replacement Parts/Accessories
10001531	Car Audio Aerials
10001530	Car Audio Amplifiers
10005205	Car Audio Cassette Players/Changers
10001527	Car Audio CD Players/Changers
10001525	Car Audio Head Units
10001528	Car Audio MD Players/Changers
10001534	Car Audio Other
10001529	Car Audio Speakers
10005828	Car Audio Subwoofers
10001526	Car Audio Tuners/Receivers
10001532	Car Audio Variety Packs
10001519	Car DVD Players
10005749	Car GPS Antennae
10001517	Car Navigation Equipment
10005728	Car Radar Detectors
10001520	Car Video Cassette Players
10001518	Car Video Monitors
10001521	Car Video Receiving Equipment
10001523	Car Video/Navigation - Replacement Parts/Accessories
10001524	Car Video/Navigation Other
10001522	Car Video/Navigation Variety Packs
10003685	In-car Electronics Variety Packs
10001499	Binoculars

10001502	Microscopes
10001501	Monoculars/Telescopes
10001505	Optics - Replacement Parts/Accessories
10001506	Optics Other
10001504	Optics Variety Packs
10001486	Analogue Cameras
10005750	Camera Flash Accessories
10001489	Camera Flashes
10001487	Digital Cameras
10005700	Digital Photo Frames
10001491	Interchangeable Lenses
10005842	Mobile Photo Storage
10005755	Photographic Camera Filters
10001492	Photographic Slide Projectors
10005753	Photographic Studio Flash Gun
10001494	Photography - Replacement Parts/Accessories
10001498	Photography Other
10001496	Photography Variety Packs
10001508	Photograph Enlargers
10001512	Photography Dark Room Safelights
10001511	Photography Drying Equipment
10001515	Photography Printing/Dark Room Equipment - Replacement Parts/Accessories
10001516	Photography Printing/Dark Room Equipment Other
10001514	Photography Printing/Dark Room Equipment Variety Packs
10003686	Photography/Optics Variety Packs
10000807	Bath Massage/Toning
10000758	Body Massage/Toning - Replacement Parts
10000760	Body Massage/Toning Other
10000668	Body Massage/Toning Variety Packs
10000567	Body Toning/Firming Products (Powered)
10000759	Personal Warming/Massaging (Powered)
10000770	Oil Diffusers (Powered)
10000767	Nails - Accessories (Powered)
10000780	Nails - Aids (Powered)
10000828	Hair - Aids (Powered)
10000348	Hair - Perming
10000678	Hair - Styling (Powered)
10000830	Depilation/Epilation (Powered)
10000831	Shaving - Razors (Powered)
10008378	Gum Stimulator/Massager
10005839	Oral Care Centre - Brush/Cleanser/Storage (Powered)
10008374	Oral Cleaner System (Powered)

10008380	Tooth Stain Removers/Whitener (Powered)
10008373	Toothbrush (Powered)
10006246	Penetration Accessories (Powered)
10006248	Suction Devices (Powered)
10000806	Anti-spot Aids (Powered)
10000808	Cleansers/Cosmetics Removers (Powered)
10000809	Sunless Tanning (Powered)
10005560	Bells/Chimes/Buzzers
10006404	Gate/Garage Door Opener Replacement Parts and Accessories
10005673	Gate/Garage Door Opening Systems
10002551	Awnings - Powered
10007039	Window Shutter Motorisation
10002087	Camping Stoves/Grills/Ovens
10002077	Camping Heating/Lighting Equipment Other
10002078	Camping Heating/Lighting Equipment Variety Packs
10004099	Camping Water Heaters

10004003	Underfloor Heating Systems
10003994	Plumbing/Heating Ventilation/Air Conditioning Variety Packs
10006962	Bathroom Sink Accessories
10002610	Bathroom Suites
10002590	Bathtub/Shower Modules
10004029	Bathtub/Shower Modules - Jetted
10002596	Bathtubs - Jetted (Hot Tubs/Spas)
10007941	Faucet Replacement Parts/Accessories
10002602	Faucets/Taps
10007726	Shower Sets
10004044	Shower Spas
10006961	Toilet Accessories
10007017	Toilet/Bidet/Urinals Replacement Parts/Accessories
10002589	Toilet/Urinal Cisterns
10002586	Toilets
10002587	Urinals
10002611	Macerators
10004049	Septic Tanks
10004006	De-scalers (DIY)
10002649	Scale Inhibitors
10004016	Water Filtration Machines/Systems
10004012	Water Meters

10004008	Water Softeners (DIY)
10007038	Water Softeners Replacement Parts/Accessories
10004055	Pumps
10004024	Valves/Fittings - Water and Gas
10008011	Valves/Fittings Accessories/Replacement Parts - Water and Gas
10000791	Baby Safety Monitoring (Powered)
10006820	Baby Safety/Security/Surveillance - Other
10005385	Public Fire Alarms
10005389	Lifebelts/Life-Jackets/Lifesuits
10003427	Lightning Detectors - Powered
10005391	Lightning Rods/Accessories
10005872	Marine Electronic Chartplotters
10005874	Marine Navigation Radar Systems
10005873	Marine Navigation Software
10005474	Rock Salt/Ice Melting Products
10005394	Transponders
10005473	Alarm Systems Replacement Parts/Accessories
10005396	Burglar Alarms
10005397	Gas/Heat/Smoke Detectors
10007008	Glass Break Detector
10005398	Access Control Security Systems
10007007	Anti-Climb/Deterrent Security Product
10005401	Door Chains/Door Guards
10005399	Door/Gate Entry Intercoms
10005402	Door/Gate Viewers
10005403	Security Doors/Gates
10008069	Smart Doorbells
10005405	Window Burglar Bars/Panels/Shutters
10005407	Fire Blankets
10005408	Fire Extinguishers - Pressurised
10005409	Fire Hoses
10005410	Home/Business Fire Extinguishers Variety Packs
10005417	Home/Business Safety/Security/Surveillance Variety Packs
10005411	Bugging/Debugging Equipment
10005415	Home/Business Surveillance Equipment Variety Packs
10005412	Light/Motion/Sound Sensors
10005413	Security Lights
10005414	Surveillance Cameras/Recorders
10005373	Body Alarms
10005472	Emergency Survival Blankets/Sleeping Bags
10005374	Emergency Whistles
10005375	Key-ring Alarms
10005376	Personal Luggage Alarms

10005382	Personal Safety Devices Variety Packs
10005377	Personal Safety Flares/Signals
10005378	Personal Safety Lights
10006850	Remote Controlled Vehicles
10006851	Remotely Controlled Vehicle Replacement Parts and Accessories
10005380	Stun Guns
10005381	Wearable Wireless Webcams (Inverse Surveillance)
10005418	Safety/Security/Surveillance Variety Packs
10008110	Coin Operated Control Unit
10008109	Vending Machine
10004098	Fencing Sports Equipment (Powered)
10001813	Cycle Sports Equipment Other
10001812	Cycle Sports Equipment Variety Packs
10005815	Cycles (Powered)
10008275	Cycles Accessories - Computers/Navigation Equipment
10008276	Cycles Accessories - Other
10008260	Cycles Parts - Lighting
10001814	Exercise Machines (Powered)
10001822	Sports Exercise Monitors
10001843	Scooter/Skateboard Sports Equipment Other
10001842	Scooter/Skateboard Sports Equipment Variety Packs
10005814	Scooters/Skateboards/Hoverboards (Powered)
10001841	Skateboarding Sports Equipment - Replacement Parts/Accessories
10005703	Pumps (Powered)
10004111	Sports Scoring Equipment (Powered)
10001867	Target Sports Equipment - Replacement Parts/Accessories
10001869	Target Sports Equipment Other
10001868	Target Sports Equipment Variety Packs
10001865	Targets (Powered)
10001242	Calculators/Currency Converters (Powered)
10001243	Cash/Money Registers (Powered)
10001247	Laminating Machines (Powered)
10005229	Multifunctional Devices
10001248	Office Machinery Other
10001250	Office Machinery Variety Packs
10001251	Photocopier Consumables
10001252	Photocopiers
10005676	Typewriter Consumables
10001254	Typewriters (Powered)
10001262	Franking Machines
10001265	Letter Openers (Powered)

10001268	Postal Weighing Scales (Powered)
10005445	Overhead Projectors
10001277	Pointers (Powered)
10006406	Presentation Boards (Powered)
10001281	Presentation Equipment Accessories
10001280	Presentation Equipment Other
10001283	Presentation Equipment Variety Packs
10001288	Binding Machines (Powered)
10001300	Stationery Staplers (Powered)
10001312	Hole Paper Punches (Powered)
10005119	Paper Shredders (Powered)
10001231	Measuring/Geometrical Equipment
10001233	Pencil Sharpeners (Powered)
10006730	Electronic Cigarette Accessories
10006729	Electronic Cigarettes
10003461	Measuring Wheels
10003459	Micrometers
10006776	Moisture Meter (Soil)
10003458	Tape Measures (DIY)
10006777	Thermal Leak Detector
10008057	Military - Engineering Specialty Equipment - Powered
10003679	Hoists/Winches
10003749	Power Tools - Lifting/Handling Equipment Other
10003680	Power Tools - Lifting/Handling Equipment Replacement Parts/Accessories
10006779	Pulley Puller (Powered)
10005221	Wheelbarrows - Powered
10005230	Air Compressors - Stationary
10003597	Band Saws - Stationary
10003668	Belt Sanders - Stationary
10003598	Bench Grinders
10003604	Bench Jointers
10003611	Combination Sanders - Disc/Belt
10003609	Disc Sanders
10003613	Drill Presses/Mortisers
10003730	Jointer Planers - Stationary
10003605	Lathes - Stationary (Powered)
10003608	Power Tools - Stationary - Replacement Parts/Accessories
10003751	Power Tools - Stationary Other
10003603	Radial Arm Saws
10003602	Scroll Saws - Stationary
10003746	Shapers - Stationary
10003610	Spindle Sanders

10003729	Surface Planers - Stationary
10003601	Table Saws - Stationary
10008139	Tool Sharpeners (Powered)
10003596	Wet Saws/Tile/Glass Cutters
10007026	Abrasive Blasters/Sandblasters
10003555	Air Compressors - Portable
10003644	Angle Grinders
10003619	Angle Measurers (Powered)
10003651	Arc Welders
10005231	Band Saws - Portable
10003742	Belt Sanders - Portable
10005718	Biscuit Joiners
10003664	Caulking Guns (Powered)
10005214	Cement/Mortar Mixing Machines
10003643	Chisels (Powered)
10005223	Circular Saws
10003645	Cut-off Tools
10007028	Demolition Hammer
10003672	Detail Sanders
10005248	Disc Sanders/Drywall Sanders - Portable
10003618	Distance/Linear Measurers (Powered)
10003741	Drain Augers (Powered)
10003653	Drill/Drivers (Powered)
10003658	Drills - Combination (Powered)
10007029	Endoscope Camera (DIY)
10003669	Finishing Sanders
10003638	Foam Cutters - Powered
10005213	Glue Guns - Powered
10003663	Grease Guns (Powered)
10007027	Hammer Drill and Impact Driver Kit
10003659	Hammer Drills
10003662	Heat Guns
10007030	Hole Saw
10003655	Impact Drivers
10003656	Impact Wrenches
10007976	Industrial Wet/Dry Construction Vacuum Cleaner Filters
10007978	Industrial Wet/Dry Construction Vacuum Cleaner Heads
10007977	Industrial Wet/Dry Construction Vacuum Cleaner Hoses/Tubes
10007975	Industrial Wet/Dry Construction Vacuum Cleaners
10003631	Jigsaws - Powered
10003616	Jointer Planers - Portable
10003626	Laminate Trimmers

10003620	Laser Levels
10006277	Metal Detectors
10003738	Mitre Saws - Portable
10007031	Mixer/Vibrator
10003666	Nail Guns (Powered)
10003632	Nibblers/Shears - Metal (Powered)
10007032	Oscillating Multitools
10005653	Paint Applicators - Powered
10003640	Pipe Cutters (Powered)
10003750	Power Tools - Hand-held Portable Other
10003747	Power Tools - Hand-held Portable Replacement Parts/Accessories
10003629	Reciprocating Saws
10003660	Rotary Hammers
10007033	Rotary Multitools
10003641	Rotary Saws
10003737	Routers
10007034	Sanding Rollers (Powered)
10003657	Screw Guns
10003654	Screwdrivers (Powered)
10003649	Soldering/Brazing Irons
10003665	Staplers (Powered)
10003647	Straight/Die Grinders
10005869	Stud Finders/Detectors/Sensors
10003648	Surface Grinders
10003615	Surface/Thickness Planers - Portable
10003627	Table Saws - Portable
10007035	Wall Slotter (Powered)
10003884	Wall/Ceiling Covering Tools - Powered
10003744	Welding/Blow Torches
10007936	Welding/Blow Torches Replacement Parts/Accessories
10007937	Welding/Blow Torches Rods/Wire/Solder
10003682	Tools/Equipment - Power Variety Packs
10005134	Board Games (Powered)
10005136	Board Games/Cards/Puzzles Other
10005137	Board Games/Cards/Puzzles Variety Packs
10005139	Card Games (Powered)
10005141	Puzzles (Powered)
10005154	Baby/Infant Stimulation Toys (Powered)
10005155	Bath/Pool Water Toys
10005157	Communication Toys (Powered)
10005159	Developmental/Educational Toys Other
10005160	Developmental/Educational Toys Variety Packs
10005162	Push/Pull-along Toys (Powered)

10005164	Scientific Toys (Powered)
10005165	Spinning Tops/Yo-Yos
10005167	Toy Building Blocks (Powered)
10005712	Toy Computer Accessories
10005158	Toy Computers
10005442	Toy Drawing Boards/Accessories
10005169	Toy Model Construction (Powered)

JP4EE Attachment 3-List of EEE Functions needing PFAS

◆ List of the functions and properties necessary to electrical and electronic equipment (EEE), which need PFAS materials to attain required performances.

	Functions and properties required for EEE	Characteristic of parts and materials to achieve their functions and properties of EEE	Performance requirements for materials (PFAS)	(e.g.) Specific parts or components that accomplish the functions or characteristic of EEE	(e.g.) Typical EEE	Necessary applications of PFAS to attain the functions and properties (Linked with Column D of Attachment 5)
1	Optical function	No interference of light transmission (Transparency)	Low refractive index, High transmissivity + Water and oil repellency, Flexibility, Flame retardancy	Optical fiber, Optical Lens, LED, Monitor/Panel, Fiberglass, Optical adhesive, Protective coating material, Anti-reflective material, etc.	Camera, Lighting, Monitor/Panel, Optical cable, Smartphone, etc. Other products in EU RoHS categories 1- 11 would need this function if they use optical function in control panels for example.	2) Optical elements. 5) Optical elements for LCD panels. 25) Transparent electronic circuit board and circuit. 27) Optical elements. 29) Functional coatings.
2	High speed communication and transmission function	Low transmission loss at high frequencies and wide frequency range	Low dielectric constant and Low transmission loss + Water and oil repellency, Flame retardancy	Printed circuit boards (Smartphone, PC, Base stations, etc.), Antenna, Cable for High-frequency, Protective coating material, etc.	Smartphone, PC, Antenna, Base stations, etc. Other products in EU RoHS categories 1- 11 would need this function if they use communication function to operate or update it for example.	6) Electronic circuit boards for high-frequency applications. 29) Functional coatings.
3	Piezoelectric function (Conversion/Inversion between the mechanical power and electrical voltage) Refer to separate sheet "3. Piezoelectric function" for functional explanation.	Piezoelectricity (pressure-sensitive detection) and good workability and durability	High Piezoelectricity (High piezoelectric coefficient) + Heat resistance, Flexibility	Speaker, Touch panel, Sensor, Actuator, etc.	Touch panel, Speaker, Various sensor, etc. Other products in EU RoHS categories 1- 11 would need this function if they use touch panels or sounds for example.	3) Piezoelectric elements
4	Sliding function in mechanical section Refer to separate sheet "4. Sliding function" for functional explanation.	Lubricity and abrasion resistance, Elasticity, Low water absorption, Low moisture permeability	Lubricity, Abrasion resistance, Machineability + Flame retardancy, Durability, Low water absorption, Low moisture permeability	Sliding parts in mechanical section (Bearing, Gear, Roll), Seal material (Packing, O-ring, etc.), Grease, Lubricant, Protective coating material, Epilame, Sealing material, etc.	Motor, Printer, Industrial equipment, Camera, Display, etc. All the EEE in EU RoHS categories 1- 11 would need this function.	1) Sliding elements in mechanical section. 8) High performance materials for mold release and protection purposes used in the article molding process. 11) Hermetic sealant requiring low percentage of the compression set as well as simultaneously other functions such as excellent elongation followability, durability, flame resistance, heat and hot water resistance, low water absorption, low moisture permeability, chemical resistance and/or low outgassing. 29) Functional coatings. 30) Lubricants where the use takes place under harsh conditions or the use is needed for safe and intended functioning and/or safety of equipment.
5	Display function(Liquid crystal display / LCD)	Low voltage drive and fast response (Low anisotropic refractive index and low viscosity)	Low anisotropic refractive index, Low viscosity, Low voltage drive + Heat resistance, Durability	Liquid crystal panel (TV, various monitor), etc.	Liquid crystal display panel (TV, Monitor for various device), etc. Other products in RoHS categories 1- 11 would need this function if they use control panels or monitors for example.	26) Liquid crystal display (LCD) elements.
6	Safety and safety functions	Electrical insulation and flame retardancy, Chemical resistance, Heat resistance, Durability, Dripping prevention	Low dielectric constant, Flame retardancy, Machineability, Chemical resistance + Heat resistance, Durability	Cable, Pipe/Tube, Package, Seal material, Enclosure, Encapsulation, Protective coating material, Sealing material, Protection tube, etc.	Cable, Monitor, Medical equipment, Electric appliance, Industrial control equipment, Printer, etc. All the EEE in EU RoHScategories 1- 11 would need this function.	4) Insulating material requiring flame-retardancy and/or heat-resistant, where the use is needed for safe functioning and safety of equipment. 7) Anti-dripping agent used for safety and to enhance flame retardancy. 8) High performance materials for mold release and protection purposes used in the article molding process. 10) Film, sheet or membrane requiring surface performance which ensures multiple functions such as electrical insulation property, chemical resistance, heat resistance, flame resistance, flex resistance and excellent elongation followability at the same time. 12) Fluid tubes and containers requiring chemical resistance, high cleanliness. 16) High performance materials for mold release and protection purposes, which ensures multiple functions such as electrical insulation, heat resistance, chemical resistance or flame resistance, etc. at the same time. 29) Functional coatings. 30) Lubricants where the use takes place under harsh conditions or the use is needed for safe and intended functioning and/or safety of equipment.

7	**Functional surface**	**Releasability and Heat resistance, UV protection, Antifouling, Waterproof**	**Water and oil repellency, Heat resistance, Weather resistance**	Releasing and Protective coating material, Film, etc.	Cooking appliance, Touch panel, Smartphone, Printer, etc. All the EEE in RoHS categories 1- 11 would this function.	8) High performance materials for mold release and protection purposes used in the article molding process. 10) Film, sheet or membrane requiring surface performance which ensures multiple functions such as electrical insulation property, chemical resistance, heat resistance, flame resistance, flex resistance and excellent elongation followability at the same time. 16) High performance materials for mold release and protection purposes, which ensures multiple functions such as electrical insulation, heat resistance, chemical resistance or flame resistance, etc. at the same time. 29) Functional coatings.
8	**Semiconductor**	**Photoacid Generators (PAG) , Surfactants, anisotropic/isotropic etching and protective layer formation, low dielectric constants, high thermostability, chemical inertness (to acids, bases, and solvents), and low moisture absorption, low electric permittivity /dielectric loss, low water absorption, and low coefficient of thermal expansion(CTE), In heat transfer fluid uses, electrically non-conducive, and usability in very broad temperature range, and non-corrosive in closed-loop systems**	**Photoacid Generators (PAG) , Surfactants, anisotropic/isotropic etching and protective layer formation, low dielectric constants, high thermostability, chemical inertness (to acids, bases, and solvents), and low moisture absorption, low electric permittivity /dielectric loss, low water absorption, and low coefficient of thermal expansion(CTE), In heat transfer fluid uses, electrically non-conducive, and usability in very broad temperature range, and non-corrosive in closed-loop systems**	Photolithography and thin films formed thereby, dry etching, cleaning, heat transfer fluids, resins, manufacturing equipment materials	All the EEE in EU RoHS categories 1- 11 would use semiconductors.	13) PFAS used for semiconductor manufacturing process, semiconductor manufacturing equipment, and semiconductor. 17) Semiconductor manufacturing process. 21) Refrigerant, coolant, cleaning agent and solvent used for semiconductor process. 23) Chemicals for ultra-fine processing applications, as typified by semiconductor and MEMS manufacturing processes.
9	**Thin-film device manufacturing process**	**Semiconductor manufacturing process and similar microfabrication process Refer to item 8. Semiconductor**	**Refer to item 8. Semiconductor**	Thin-film device such as MEMS(Sensor, Gyroscope, Inkjet head), SAW filter, Angular velocity sensor, Moisture sensitive membrane, Capacitor, Resistor, etc.	Car navigation system, Sphygmomanometer (blood pressure meters), Inkjet printer, Smartphone, PC, etc. Other products in EU RoHS categories 1- 11 may use thin-film device.	14) PFAS used for thin-film device (Micro Electro Mechanical System/MEMS, SAW device, Capacitor, etc) manufacturing process, thin-film device manufacturing equipment, and thin-film device. 18) Thin-film device (Micro Electro Mechanical Systems/MEMS, SAW, Capacitor, etc) manufacturing process. 22) Refrigerant, coolant, cleaning agent and solvent used for thin-film device (Micro Electro Mechanical Systems/MEMS, SAW etc.) process. 23) Chemicals for ultra-fine processing applications, as typified by semiconductor and MEMS manufacturing processes.
10	**Energy supply (Batteries, Fuel cells, Solar cells)**	**[Batteries] Refer to comments from BAJ ＊BAJ ： Battery Association of Japan [Fuel cells] For core materials (Proton exchange membrane, catalyst layer (ionomer), electrode water repellent, rubber seal, etc.), resistance to strong acidity as well as high temperature steam are required to ensure a product life of 90 K hours in the harsh environment of the cell. [Solar cells] Surface materials (front sheet, back sheet) must be durable and weather resistant with UV, high temperatures, high humidity, steep temperature changes, and salt damage, and must also be fire resistant.**	**[Batteries] Refer to comments from BAJ [Fuel cells] Resistance to strong acidity as well as high temperature steam [Solar cells] weather resistant with UV, high temperatures, high humidity, steep temperature changes, salt damage, fire resistant**	[Batteries] Refer to comments from BAJ [Fuel cells] Proton exchange membrane, catalyst layer (ionomer), electrode water repellent, rubber seal [Solar cells] Frontsheet, Backsheet	All the EEE in EU RoHS categories 1- 11, automotive, aircraft, and industrial equipments would use batteries, Fuel cells, and Solar cells	4) Insulating material requiring flame-retardancy and/or heat-resistant, where the use is needed for safe functioning and safety of equipment 9) Batteries 10) Film, sheet or membrane requiring surface performance which ensures multiple functions such as electrical insulation property, chemical resistance, heat resistance, flame resistance, flex resistance and excellent elongation followability at the same time 29) Functional coatings.
11	**Refrigeration, Air-conditioning and heat pump sector RACHP (Refrigerant)**	**Refer to comments from JRAIA ＊JRAIA : Japan Refrigeration and Air Conditioning Industry Association**	**Thermodynamic properties and temperature tracking over a wide range + Low flammability and low toxicity**	Refrigerant	All the EEE in EU RoHS categories 1- 11, automotive, aircraft, and industrial equipments would use refrigerant	20) Refrigerant used in various appliances such as those for Refrigeration, Air Conditioning and Heat Pump (RACHP) products.
12	**Passive electronic components and manufacturing process**	**Safety, high reliability and high durability (Passive electronic components are essential components in the electrical circuits of electrical and electronic equipments that protect semiconductors, filter electrical signals, and attenuate, store, and release electrical energy.)**	**・Water and oil repellency, Electrical insulation, Heat resistance ・Binding properties, chemical and electrical stability + Reliability (heat resistance, moisture resistance, durability)**	Passive electronic components (Capacitors, transformers, etc.)	Essential Device for circuit configuration of electrical and electronic equipments All electrical and electronic equipment such as Automobiles, Medical equipment, Industrial/Infrastructure equipment, Information/Communication equipment, Home appliances, Solar power generation, etc. Other products in EU RoHS categories 1- 11, automotive, aircraft, and industrial equipments may use passive electronic components.	8) High performance materials for mold release and protection purposes used in the article molding process 10) Film, sheet or membrane requiring surface performance which ensures multiple functions such as electrical insulation property, chemical resistance, heat resistance, flame resistance, flex resistance and excellent elongation followability at the same time 29) Functional coatings.

JP4EE Attachment 5-List of PFAS essential uses in EEE: The list explains CUU in EEE by OECD categories of PFAS as chemical materials.
The list links the functions listed in Attachment 3 and includes the reasons why these PFAS cannot be substituted.

PFAS classification	Representative Chemical Materials	Ref. No.	Currently Unavoidable Use (CUU) in electrical and electronic equipment (EEE) [Derogations for EEE should be set at this level.]	Non-exhaustive examples of uses	Reasons why PFASs are un-replaceable	Functions of EEE requiring the use of PFAS (Link to Column C of Attachment 3)	Functions of EEE requiring the use of PFAS (Link to Column G of Attachment 3)
Fluoropolymers and Perfluoropolyethers	PTFE PFA FEP ETFE PVDF PCTFE FKM FFKM FEPM FFKO PFPE	1	Sliding elements in mechanical section	Plain bearings Conductive plain bearings Sliding parts of various electric components (motors, connectors, switches, etc.) Sliding parts of various mechanical components (bearings, gears, winder, etc.) Fixing and photoconductive components, etc., in printing equipment	Fluoropolymers with multiple functions such as excellent self-lubrication (low coefficient of friction), electrical insulation property, chemical resistance, releasability, heat resistance and flame retardancy are used in sliding elements in mechanical section of EEE and its components to function normally in various environments. The Non-PFAS alternatives listed in Attachment 6 cannot be used as they exhibit the worst performance. In addition, some components are required to maintain their indispensable sliding characteristics over a long period of time under severe conditions such as high temperature, high pressure, high voltage, and high friction. Fluoropolymers are the only materials that resist such severe conditions, and substituting other materials is impracticable.	4.Sliding function in mechanical section	Motor, Printer, Industrial equipment, Camera All the EEE in RoHS categories 1- 11 would need this function.
		2	Optical elements	Optical fiber materials, optical adhesives	Optical element used in EEE and its components requires fluorine materials with no absorption at specific wavelengths, high weather resistance, and low refractive index. Therefore, it is impossible to substitute to the Non-PFAS alternatives listed in Attachment 6.	1.Optical function	Camera, Lighting, Monitor/Panel, Optical cable, Smartphone Other products in RoHS categories 1- 11 would need this function if they use optical function in control panels for example.
		3	Piezoelectric elements	Piezoelectric elements pressure sensitive films, speakers, microphones, piezo pickups for acoustic guitar	PVDF and its copolymers with unique dielectric and piezoelectric properties, which are also excellent in durability, electrical insulation property, and heat resistance are used in piezoelectric elements used in EEE and its components. Therefore, it is impossible to substitute to the Non-PFAS alternatives listed in Attachment 6.	3.Piezoelectric function	Touch panel, Speaker, Various sensor Other products in RoHS categories 1- 11 would need this function if they use touch panels or sounds for example.
		4	Insulating material requiring flame-retardancy and/or heat-resistant, where the use is needed for safe functioning and safety of equipment	Cables, heat insulator, tubes, wire coating	Insulating material used for product safety of EEE and its components requires multiple functions of fluoropolymers such as electrical insulation property, heat resistance, flame retardancy, and durability. Therefore, product safety of EEE and its components cannot be guaranteed if the Non-PFAS alternatives listed in Attachment 6 are used singly or in combination.	6.Safety and safety functions 10.Energy supply (Battery,Fuel cells, Solar cells)	Cable, Monitor, Medical equipment, Electric appliance, Industrial control equipment All the EEE in RoHS categories 1- 11 would need this function.
		5	Optical elements for Liquid crystal display (LCD) panels	Anti-fingerprint layer on panel surface and anti-reflection (high light transmittance) layer	The fluoropolymer on the panel surface has a refractive index of 1.3, which is almost half the refractive index of 1.0 for air and 1.5 for TAC (Triacetylcellulose) film of the polarizer, and suppresses surface reflection. This translates to a 3% increase in backlight utilization efficiency (i.e. energy efficiency). In addition, since the visibility of the panel is improved by preventing fingerprint stains on the surface, the brightness of the panel can be reduced. Only fluoropolymer has the above properties. It cannot be substituted with silicone or other resins that are considered substitutes.	1.Optical function	Camera, Lighting, Monitor/Panel, Optical cable, Smartphone Other products in RoHS categories 1- 11 would need this function if they use optical function in control panels for example.
		6	Electronic circuit boards for high-frequency applications	Electronic substrate materials	Electronic circuit board used in high-frequency applications requires low dielectric constant and low transmission loss. Additionally it needs functions such as electrical insulation property, high water and oil-repellent property, thermal and flame resistance. Fluoropolymers are the only materials that have those multiple functions, therefore it is impossible to substitute to other materials.	2.High speed communication and transmission function 12.Passive electronic components and manufacturing process	Smartphone, PC, Antenna, Base stations Other products in RoHS categories 1- 11 would need this function if they use communication function to operate or update it for example.
		7	Anti-dripping agent used for safety and to enhance flame retardancy	Anti-dripping agent to enhance flame retardancy	PTFE is used as anti-dripping agent to enhance flame retardancy, as it is flame-retardant and has an extremely high melt viscosity. Product safety of EEE and its components cannot be guaranteed if the Non-PFAS alternatives listed in Attachment 6 are used singly or in combination.	6.Safety and safety functions	Cable, Monitor, Medical equipment, Electric appliance, Industrial control equipment All the EEE in RoHS categories 1- 11 would need this function.
		8	High performance materials for mold release and protection purposes used in the article molding process	Developer additives and resin additives used in electrical and electronics manufacturing processes Coating material (use as mold release agent)	Fluorine compounds such as PFAS are the only materials that can simultaneously provide and exhibit multiple functions, such as low dielectric constant, low dielectric loss tangent, low refractive index, oil repellency, electrical insulation, water repellency, heat resistance, chemical resistance, weather resistance, mold releasability, flame resistance, separability, wear resistance, surface properties (friction coefficient), bending strength, stretching properties, non-flammability, etc. which are necessary for electrical and electronic devices as well as manufacturing equipment of components for such devices to function normally under various environments, making substitution by other materials listed in Attachment 6 extremely difficult.	4.Sliding function in mechanical section 6.Safety and safety functions 7.Functional surface 12.Passive electronic components and manufacturing process	Motor, Printer, Industrial equipment, Camera Cable, Monitor, Medical equipment, Electric appliance, Industrial control equipment, Cooking appliance, Touch panel, Smartphone All the EEE in RoHS categories 1- 11 would need this function.
		9	Batteries *Please refer to the input from the battery industries, such as those from Battery Association of Japan (BAJ) for the concrete details.	Battery materials	Please refer to the relevant industry association's comments for details on the reasons why substitution is not possible. For example, please refer to the input from Battery Association of JAPAN (BAJ).	10.Energy supply (Battery,Fuel cells, Solar cells)	Battery All the EEE in RoHS categories 1- 11 would use batteries.

JP4EE Attachment 5-List of PFAS essential uses in EEE: The list explains CUU in EEE by OECD categories of PFAS as chemical materials.
The list links the functions listed in Attachment 3 and includes the reasons why these PFAS cannot be substituted.

PFAS classification	Representative Chemical Materials	Ref. No.	Currently Unavoidable Use (CUU) in electrical and electronic equipment (EEE) [Derogations for EEE should be set at this level.]	Non-exhaustive examples of uses	Reasons why PFASs are un-replaceable	Functions of EEE requiring the use of PFAS (Link to Column C of Attachment 3)	Functions of EEE requiring the use of PFAS (Link to Column G of Attachment 3)
		10	Film, sheet or membrane requiring surface performance which ensures multiple functions such as electrical insulation property, chemical resistance, heat resistance, flame resistance, flex resistance and excellent elongation followability at the same time	Film material, electrostatic adsorption belt, Waste Powder Collection Filter, Friction Reduction Tape, peeling tape, ventilation film, moisture permeable film, Dial (Polarizing plate, plastic raw material), protective film, release sheet Films for analytical testing	Multiple functions such as electrical insulation property, chemical resistance, heat resistance, flame resistance, flex resistance and excellent elongation followability are also required for films, sheets, and membranes that require performance based on low surface free energy (water repellency, oil repellency, lubrication, non-adhesiveness) used in the facilities for manufacturing EEE and its components. Fluoropolymers are the only materials that have those multiple functions at the same time, therefore it is impossible to substitute to other materials.	6.Safety and safety functions 7.Functional surface 10.Energy supply (Battery,Fuel cells, Solar cells) 12.Passive electronic components and manufacturing process	Cable, Monitor, Medical equipment, Electric appliance, Industrial control equipment Cooking appliance, Touch panel, Smartphone All the EEE in RoHS categories 1- 11 would need this function.
		11	Hermetic sealant requiring low percentage of the compression set as well as simultaneously other functions such as excellent elongation followability, durability, flame resistance, heat and hot water resistance, low water absorption, low moisture permeability, chemical resistance and/or low outgassing.	Gasket materials, sealing materials, rubber valves (umbrella valves, duckbill valves, etc.), four-way reversing valve, check valve, ball valve, O rings, buttons on the operating unit, sealing materials, encapsulating materials and tube element for various electronic component	The compression set of a material is the permanent deformation remaining after removal of a force that was applied to it. The percentage of the compression set of hermetic sealant used in the facilities for manufacturing EEE and its components to function normally in various environments must be low. And at the same time, sealant as EEE parts needs other functions such as excellent elongation followability, durability, flame resistance, heat and hot water resistance, low water absorption, low moisture permeability, chemical resistance (including resistance to chlorine contained in tap water), low outgassing (to avoid contamination of impurities and to maintain the vacuum of instrument). Fluoropolymers are the only materials that have those multiple functions at the same time. If the Non-PFAS alternatives listed in Attachment 6 are used singly or in combination, the worst performance is exhibited. Therefore, it is impossible to substitute to those alternatives.	4.Sliding function in mechanical section	Motor, Printer, Industrial equipment, Camera, Display All the EEE in RoHS categories 1- 11 would need this function.
		12	Fluid tubes and containers requiring chemical resistance, high cleanliness	Chemical supply tubes, Tube for flow path of analytical equipment Air tubes used in air piping, etc. tube for a chemical supply system chemical-resistant containers	Fluoropolymers with multiple functions such as chemical resistance, excellent fluid barrier properties, high cleanliness and low surface tension are used for fluid tubes and containers in the facilities for manufacturing EEE and its components. If the Non-PFAS alternatives listed in Attachment 6 are used singly or in combination, the worst performance is exhibited. Therefore, it is impossible to substitute to those alternatives.	6.Safety and safety functions	Cable, Monitor, Medical equipment, Electric appliance, Industrial control equipment All the EEE in RoHS categories 1- 11 would need this function.
		13	PFAS used for semiconductor manufacturing process, semiconductor manufacturing equipment, and semiconductor	Construction of polymer substrates and dielectric materials, manufacturing equipment for adhesives, underfills, filter, die bond resins, valve seals, etc., heat transfer fluids surface protection	Fluorine compounds such as PFAS are the only materials that can simultaneously provide and exhibit multiple functions, such as low dielectric constant, low dielectric loss tangent, low refractive index, oil repellency, electrical insulation, water repellency, heat resistance, chemical resistance, weather resistance, mold releasability, flame resistance, separability, wear resistance, surface properties (friction coefficient), bending strength, stretching properties, non-flammability, etc. which are necessary for semiconductor manufacturing processes, semiconductor manufacturing equipment and semiconductors to function normally under various environments, making substitution by other materials listed in Attachment 6 extremely difficult. Additionally, for more information on why PFAS cannot be substituted in semiconductors, please refer to information from the Semiconductor Industry Association. For example, the following information from SIA PFAS Consortium of the Semiconductor Industry Association of America: "The Impact of a Potential PFAS Restriction on the Semiconductor Sector2" https://www.semiconductors.org/wp-content/uploads/2023/04/Impact-of-a-Potential-PFAS-Restriction-on-the-Semiconductor-Sector-04_14_2023.pdf	8.Semiconductor	Semiconductor All the EEE in RoHS categories 1- 11 would use semiconductors.
		14	PFAS used for thin-film device (Micro Electro Mechanical System/MEMS, Surface Acoustic Wave/SAW device, Capacitor, etc) manufacturing process, thin-film device manufacturing equipment, and thin-film device	Construction of polymer substrates and dielectric materials, manufacturing equipment for adhesives, underfills, filter, die bond resins, valve seals, etc., heat transfer fluids surface protection	Fluorine compounds such as PFAS are the only materials that can simultaneously provide and exhibit multiple functions, such as low dielectric constant, low dielectric loss tangent, low refractive index, oil repellency, electrical insulation, water repellency, heat resistance, chemical resistance, weather resistance, mold releasability, flame resistance, separability, wear resistance, surface properties (friction coefficient), bending strength, stretching properties, non-flammability, etc. which are necessary for thin-film device(Micro Electro Mechanical Systems/MEMS, Surface Acoustic Wave/SAW, Capacitor, etc) manufacturing processes, thin-film device manufacturing equipment and thin-film device to function normally under various environments, making substitution by other materials listed in Attachment 6 extremely difficult. Additionally, for more information on why PFAS cannot be substituted in thin-film devices, please refer to information from the Semiconductor Industry Association. For example, the following information from SIA PFAS Consortium of the Semiconductor Industry Association of America: "The Impact of a Potential PFAS Restriction on the Semiconductor Sector2" https://www.semiconductors.org/wp-content/uploads/2023/04/Impact-of-a-Potential-PFAS-Restriction-on-the-Semiconductor-Sector-04_14_2023.pdf	9.Thin-film device manufacturing process	Car navigation system, Sphygmomanometer (blood pressure meters), Inkjet printer, Smartphone, PC Other products in RoHS categories 1- 11 may use thin-film devices

JP4EE Attachment 5-List of PFAS essential uses in EEE: The list explains CUU in EEE by OECD categories of PFAS as chemical materials.
The list links the functions listed in Attachment 3 and includes the reasons why these PFAS cannot be substituted.

PFAS classification	Representative Chemical Materials	Ref. No.	Currently Unavoidable Use (CUU) in electrical and electronic equipment (EEE) [Derogations for EEE should be set at this level.]	Non-exhaustive examples of uses	Reasons why PFASs are un-replaceable	Functions of EEE requiring the use of PFAS (Link to Column C of Attachment 3)	Functions of EEE requiring the use of PFAS (Link to Column G of Attachment 3)
		15	Functional material used in printing process *Please refer to the input from the related industries, such as Japan Business Machine and Information System Industries Association (JBMIA), for the concrete details.	Toner additives, Ink additives, Developer additives	Printing process need various functions such as electrical insulation, water repellency, oil repellency, chemical resistance, surface activity, low surface tension, and high negative charge. These functions are achieved by adding fluorinated materials to toner, ink, developers, organic photoconductors etc. Only fluorinated-based materials can achieve above functions simultaneously. It is impossible to achieve this with alternative materials listed in Attachment 6.	Materials such as "Printing inks/Toner" used in "printing process". These would be separately covered by stakeholders such as printing industry, therefore our current Application list (Attachment 3) does not cover them. For the details on chemicals used in printing process, please see the input from the related industries.	
Fluoroalkyl compounds with functional groups (such as -OH, -COOH, N-R, etc.) and Side-chain fluorinated polymers	PFHxA, PFBA, PFBS, Polyfluoroalkyl (meth)acrylate	16	High performance materials for mold release and protection purposes, which ensures multiple functions such as electrical insulation, heat resistance, chemical resistance or flame resistance, etc. at the same time	Resistive/Conductive Paste, Mold release agent, Antistatic agent, Solder flux, flame retardant	Fluorine compounds such as PFAS are the only materials that can simultaneously provide and exhibit multiple functions, such as electrical insulation, heat resistance, chemical resistance, flame resistance, etc. which are necessary for electrical and electronic devices as well as manufacturing equipment of components for such devices to function normally under various environments, making substitution by other materials described in Attachment 6 extremely difficult.	6.Safety and safety functions 7.Functional surface	Cable, Monitor, Medical equipment, Electric appliance, Industrial control equipment Cooking appliance, Touch panel, Smartphone All the EEE in RoHS categories 1- 11 would need this function.
		17	Semiconductor manufacturing process	Photoacid generator Photoresist	Various materials have been considered for the photoacid generators and photoresist needed for the semiconductor manufacturing process, but in the end only fluorine materials remained and are currently used. The alternative materials described in Attachment 6 have been studied in the past and when they are used, their performance is poor and they are not practical. Additionally, for more information on why PFAS cannot be substituted in thin-film devices, please refer to information from the Semiconductor Industry Association. For example, the following information from SIA PFAS Consortium of the Semiconductor Industry Association of America: "The Impact of a Potential PFAS Restriction on the Semiconductor Sector" https://www.semiconductors.org/the-impact-of-a-potential-pfas-restriction-on-the-semiconductor-sector/	8.Semiconductor	Semiconductor All the EEE in RoHS categories 1- 11 would use semiconductors.
		18	Thin-film device (Micro Electro Mechanical Systems/MEMS, Surface Acoustic Wave/SAW, Capacitor, etc) manufacturing process	Photoacid generator Photoresist	The thin-film device (MEMS(Micro Electro Mechanical Systems), SAW, Capacitor, etc.) manufacturing process, which started by making mechanical components using semiconductor manufacturing technology, uses fluorinated materials for photoacid generators and photoresist for the same reason as the semiconductor manufacturing process. The alternative materials described in Attachment 6 have been studied in the past and when they are used, their performance is poor and they are not practical. For more information on the reasons, please refer to information from the Semiconductor Industry Association. For example, the following information from SIA PFAS Consortium of the Semiconductor Industry Association of America: "The Impact of a Potential PFAS Restriction on the Semiconductor Sector" https://www.semiconductors.org/the-impact-of-a-potential-pfas-restriction-on-the-semiconductor-sector/	9.Thin-film device manufacturing process	Car navigation system, Sphygmomanometer (blood pressure meters), Inkjet printer, Smartphone, PC Other products in RoHS categories 1- 11 may use thin-film devices
		19	Functional material used in printing process *Please refer to the input from the related industries, such as Japan Business Machine and Information System Industries Association (JBMIA), for the concrete details.	Toner additives, Ink additives, Resin additives, Developer additives, Organic photoconductor additives	Printing process need various functions such as-water repellency, oil repellency, chemical resistance, releasability, surface activity, flame resistance (anti-drip function), low surface tension, and high negative charge. These functions are achieved by adding fluorinated materials to toner, ink, resin, developers, organic photoconductors etc. Only fluorinated-based materials can achieve above functions simultaneously. It is impossible to achieve this with alternative materials listed in Attachment 6.	Materials such as "Printing inks/Toner" used in "printing process". These would be separately covered by stakeholders such as printing industry, therefore our current Application list (Attachment 3) does not cover them. For the details on chemicals used in printing process, please see the input from the related industries.	
Fluoroalkanes and fluoroalkenes, and Fluoroethers and fluoro-ketones	HFC, PFC, HFO, HFE	20	Refrigerant used in various appliances such as those for Refrigeration, Air Conditioning and Heat Pump (RACHP) products *Please also see the input from the related industries, such as Japan Refrigeration and Air Conditioning Industry Association (JRAIA) about the details of the essentiality of the PFAS refrigerants.	Refrigerant is used in various refrigeration, air conditioning and heat pump products. Such RACHP products are not only used in refrigerators, freezers or air conditioners but also further incorporated into may other products for medical, measurement, manufacturing, etc.	Fluorine-based refrigerant has excellent thermodynamic properties in a wide range and is also excellent in temperature followability. Moreover, because of its low flammability and low toxicity, it does not ignite the surroundings or cause harm to the human body, even if equipment or pipes are damaged by an earthquake or storm and then the refrigerant leaks. Natural refrigerants such as ammonia (NH3), hydrocarbon (propane, isobutane, etc.) are not applicable to all the appliances as they are highly flammable or toxic. Please refer to the comments of the related industries, such as Japan Refrigeration and Air Conditioning Industry Association (JRAIA), for details on why fluorine-based coolants cannot be substituted.	11.Refrigeration, Air-conditioning and heat pump sector RACHP (Refrigerant)	Refrigerant All the EEE in RoHS categories 1- 11 may use refrigerant if needed.

JP4EE Attachment 5-List of PFAS essential uses in EEE: The list explains CUU in EEE by OECD categories of PFAS as chemical materials.
The list links the functions listed in Attachment 3 and includes the reasons why these PFAS cannot be substituted.

PFAS classification	Representative Chemical Materials	Ref. No.	Currently Unavoidable Use (CUU) in electrical and electronic equipment (EEE) [Derogations for EEE should be set at this level.]	Non-exhaustive examples of uses	Reasons why PFASs are un-replaceable	Functions of EEE requiring the use of PFAS (Link to Column C of Attachment 3)	Functions of EEE requiring the use of PFAS (Link to Column G of Attachment 3)
		21	Refrigerant, coolant, cleaning agent and solvent used for semiconductor process	Cooling of manufacturing equipment	Fluorinated compounds such as PFAS are the only media that can be used over a wide range of operating temperatures for safe and efficient heat transfer, while simultaneously possessing excellent properties such as electrical insulation, inertness, and extremely low surface tension, along with excellent thermodynamic properties, making substitution by other materials extremely difficult. For more details on why fluorinated coolants cannot be substituted in semiconductor processes other than etching, please refer to the comments of the relevant industry associations.	8.Semiconductor	Semiconductor All the EEE in RoHS categories 1- 11 would use semiconductors.
		22	Refrigerant, coolant, cleaning agent and solvent used for thin-film device (Micro Electro Mechanical Systems/MEMS, Surface Acoustic Wave/SAW etc) process	Cooling of manufacturing equipment	Fluorinated compounds such as PFAS are the only media that can be used over a wide range of operating temperatures for safe and efficient heat transfer, while simultaneously possessing excellent properties such as electrical insulation, inertness, and extremely low surface tension, along with excellent thermodynamic properties, making substitution by other materials extremely difficult. For more details on why fluorinated coolants cannot be substituted in thin-film device processes other than etching, please refer to the comments of the relevant industry associations. A similar exemption to that for semiconductor process is needed for the thin-film device manufacturing process, since the thin-film device manufacturing process uses the same materials and technologies as the semiconductor manufacturing process.	9.Thin-film device manufacturing process	Car navigation system, Sphygmomanometer (blood pressure meters), Inkjet printer, Smartphone Other products in RoHS categories 1- 11 may use thin-film devices
		23	Chemicals for ultra-fine processing applications, as typified by semiconductor and MEMS manufacturing processes *HFC-23 (CHF 3), HFC-32 (CH 2 F 2), HFC-152 a (CHF 2-CH 3) , HCFC-141 b (CCl 2 F-CH 3), HFO-1132 a (CH 2=CF 2) , are outside the scope definition of this regulation. Minor uses; In the electronics and semiconductor industries, fluorinated gases are used in etching and chamber cleaning processes to form nano-level fine semiconductor integrated circuits, etc., including CHF 3, CF 4, perfluoroethane, perfluoroalkane, and perfluorocycloalkane	Etching gas for semiconductor and glass substrates Equipment such as etching equipment/CVD equipment Substrate cleaning gas	In the semiconductor industry, perfluorogas and polyfluorogas are used in etching and chamber cleaning processes to form nano-level fine semiconductor integrated circuits etc.. Although the amount used is small, today's electronics products require extremely complicated and delicate processing to realize various functions such as high performance, multi-function, and low power consumption. To achieve this, we combine various gases to perform processing with advanced and delicate control. There is no substitute for the gas currently in use in the semiconductor manufacturing process, which is highly and finely assembled. If its use is prohibited, all semiconductor manufacturing will be stopped. The semiconductor industry controls the chemical substances used at all stages of the manufacturing process. Most of the chemical substances used are decomposed during the manufacturing process, and equipment is installed to decompose and recover unreacted residual gases in order to reduce emissions. The continued use of PFAS in the semiconductor manufacturing process is an essential component of the supply of electronics products that support wide range of current and future daily necessities and social infrastructure and is a fundamental prerequisite for semiconductor production. For this reason, it is considered essential to exempt semiconductor manufacturing, the semiconductor itself, and related equipment from the scope of regulation as CUU. PFAS gases are always stable, easy to handle, and very reactive with the material to be etched (such as semiconductor or glass substrates) in reactive ion etching (RIE). Moreover, only fluorinated compounds such as PFAS gases can etch Si, and other materials gases have high volatility (high vapor pressure) of reaction products (such as SiF4), making it difficult to substitute them.	8.Semiconductor 9.Thin-film device manufacturing process	Semiconductor Car navigation system, Sphygmomanometer (blood pressure meters), Inkjet printer, Smartphone All the EEE in RoHS categories 1- 11 would use semiconductors. Other products in RoHS categories 1- 11 may use thin-film device.
		24	Fluids for immersion processes (testing, measuring or adding function) in production processes and laboratories	Test solvent for gross leak test, etc., high-precision temperature characteristic measurement, and voltage application medium for polarization of piezoelectric ceramic elements	Fluorinated compounds are the only media that can maintain the quality of an object without leaving stress or contamination on the object in the process due to their extremely low surface tension and high volatility. Furthermore, fluorinated compounds simultaneously possess excellent functions such as excellent thermodynamic properties, electrical insulation, and inactivity, which ensure the stability and accuracy required in the process. The MIL standard (MIL-STD-883/750) specifies the use of hollow packages in airtight testing, which is essential to ensure their airtight performance. Therefore, it is difficult to substitute other substances.	This application is described not in current Application List (Attachment 3)	Car navigation system, Sphygmomanometer (blood pressure meters), Inkjet printer, Smartphone. Other products in RoHS categories 1- 11.
Others (PFAS other than ones mentioned above)	Fluorinated engineering plastic materials such as fluorinated polyimide and Liquid crystal materials. Other fluorinated compounds	25	Transparent electronic circuit board and circuit	Transparent printed circuit board for touch panels	Fluorinated polyimide has transparency, heat resistance, and low water absorption required for touch panels used in smartphones and tablets. The high water absorbency of transparent heat-resistant plastic (polyether sulfone) reduces low dimensional stability and impairs the linearity of touch panels, so it cannot be used.	1.Optical function	Camera, Lighting, Monitor/Panel, Optical cable, Smartphone Other products in RoHS categories 1- 11 would need this function if they use optical function in control panels for example.
		26	Liquid crystal display (LCD) elements	Liquid crystal substances (small molecules), Vertical alignment liquid crystal display device, Interlayer spacer to control the cell gap of LCD panels.	"Fluorinatad Liquid Crystal substances (PFAS LC)" have low driving voltage, high response speed, and low temperature dependence of driving voltage, which are required for low power consumption video displays that require multiple functions simultaneously. Cyano-based crystal substances cannot meet these requirements simultaneously. So it was replaced by "PFAS LC" as a technological breakthrough. The power consumptions of other displays (e.g. OLED) are higher than LCDs using PFAS LC. Fluorinated polyimides with long-chain fluorinated alkyl groups in the side chains have high heat resistance and stable. For other LCD elements, fluorinated polyimides with long-chain fluorinated alkyl groups in the side chains have high heat resistance and stable vertical orientation over a wide temperature range. These properties cannot be replaced by polyimides with hydrocarbon side chains. The structural materials for maintaining uniform cell gap of a large-sized liquid crystal panels are required to have high precision thickness uniformity, no contamination in the manufacturing process, chemical resistance, no influence to optical system and heat resistance at the same time. These are not able to be replaced by silicone or acrylic resin.	5. Display function(Liquid crystal display / LCD) 7. Functional surface	Liquid crystal display panel (TV, Monitor for various device) Other products in RoHS categories 1- 11 would need this function if they use control panels or monitors for example.
		27	Optical elements	Additives for polyamideimides, polyimides, and polyester tapes	By introducing a trifluoromethyl group or the like into the polyimide, low refractive index, low dielectric constant, separation, light transmission, and flexibility can be imparted. In this way, the fluorinated material introduced with fluorine as a substituent in the engineer plastic material has excellent electrical properties, water and oil-repellency, surfactant resistance, flame retardancy (anti-drip function), low surface tension. It can simultaneously impart and express multiple functions, and if the Non-PFAS alternatives listed in Attachment 6 are used singly or in combination, the worst performance is exhibited. Therefore, it is impossible to substitute to those alternatives.	1.Optical function	Camera, Lighting, Monitor/Panel, Optical cable, Smartphone Other products in RoHS categories 1- 11 would need this function if they use optical function in control panels for example.

JP4EE Attachment 5-List of PFAS essential uses in EEE: The list explains CUU in EEE by OECD categories of PFAS as chemical materials.
The list links the functions listed in Attachment 3 and includes the reasons why these PFAS cannot be substituted.

PFAS classification	Representative Chemical Materials	Ref. No.	Currently Unavoidable Use (CUU) in electrical and electronic equipment (EEE) [Derogations for EEE should be set at this level.]	Non-exhaustive examples of uses	Reasons why PFASs are un-replaceable	Functions of EEE requiring the use of PFAS (Link to Column C of Attachment 3)	Functions of EEE requiring the use of PFAS (Link to Column G of Attachment 3)
		28	Functional materials used in printing process *Please refer to the input from the related industries, such as Japan Business Machine and Information System Industries Association (JBMIA), for the concrete details.	Toner additives, Ink additives, Developer additives, Organic photoconductor additives	Printing process need various functions such as water repellency, oil repellency, chemical resistance, releasability, surface activity, low surface tension, and high negative charge. These functions are achieved by adding fluorinated materials to toner, ink, developers, organic photoconductors etc. Only fluorinated-based materials can achieve above functions simultaneously. It is impossible to achieve this with alternative materials listed in Attachmemt 6.	Materials such as "Printing inks/Toner" used in "printing process". These would be separately covered by stakeholders such as printing industry, therefore our current Application list (Attachment 3) does not cover them. For the details on chemicals used in printing process, please see the input from the related industries.	
All the PFAS (fluoropolymers and others)	PTFE, PFA, FEP, ETFE, PVDF,PFHxA Polyfluoroalkyl (meth)acrylate	29	Functional coatings* (* "Functional coating" is a coating applied to an article in order to give it the required functions, such as low dielectric properties, low dielectric loss tangent, electrical insulation, heat resistance, UV resistance, chemical resistance, corrosion resistance, weather resistance, water repellency, oil repellency, slipperiness, low refractive index and so on. "Functional coating" includes, but not limited to, "conformal coating" used to protect electronic materials. In our input, we use the term "functional coating" because the required functions are not only to protect the objects.)	Electronic circuit boards, semiconductors, small electronic components (e.g. capacitors, resistors, coils, diodes, transistors, switches, connectors and their electrical junction points), casing, motors, voice coils, parts to protect optical features (e.g. liquid crystal panels, touch panels, optical sensors, LED, Toslink, optical fibers, lenses for electronic cameras, projection lenses, polarizers), printing process (Toner/ink adhesion prevention, toner/developing carrier themselves), oil barrier, fan, razor blade, and so on.	Fluorine compounds are the only coating materials that can simultaneously provide and express multiple functions required for the proper functioning of electrical and electronic equipment in various environments, such as low refractive index, low dielectric constant and low dielectric loss tangent, electrical insulation, oil repellency, water repellency, heat resistance, UV resistance, chemical resistance, weather resistance, mold release and optical protection (i.e. for optical sensors, lenses and so on). In addition to the above, toner/development carriers are also required to be fluidity, charging characteristics, and durability.	1.Optical function 2.High speed communication and transmission function 4.Sliding function in mechanical section 6.Safety and safety functions 7.Functional surface 10.Energy supply (Battery,Fuel cells, Solar cells) 12.Passive electronic components and manufacturing process	Camera, Lighting, Monitor/Panel, Optical cable, Smartphone, PC, Antenna, Base stations Motor, Printer, Industrial equipment, Cable, Medical equipment, Electric appliance, Industrial control equipment, Cooking appliance, Touch panel, All the EEE in RoHS categories 1- 11 would need this function.
	PTFE, PFPE, PFHxA, PFBS	30	Lubricants where the use takes place under harsh conditions or the use is needed for safe and intended functioning and/or safety of equipment	Electronic cameras, lens systems for electronic cameras, moving parts of the helicoid of projection lenses and moving ball frames, driving parts of ultrasonic testing equipment, drives for optical discs, torque limiters for scanners and other moving parts of precision equipment in electrical and electronic equipment.	To protect the mechanical properties of the moving parts of precision components in electrical and electronic equipment, the lubricant (e.g. grease) is given an autophobic property to prevent wetting and spreading. If the lubricating components applied to the operating parts of precision components become wetted and diffuse, the durability and performance of the product will be significantly reduced. To prevent this, fluorine compounds are added which have good dispersibility in lubricants (e.g. grease) and can provide oil repellency due to their self-hydrophobic properties. Only fluorine compounds with low surface free energy can provide oil repellency and are difficult to replace. In addition, due to the recent miniaturisation and high integration of components, it is difficult to avoid them due to the structure of the components.	4.Sliding function in mechanical section 6.Safety and safety functions	Motor, Printer, Industrial equipment, Camera, Cable, Monitor, Medical equipment, Electric appliance, Industrial control equipment All the EEE in RoHS categories 1- 11 would need this function.

List of abbreviations

Acronym	Explanation
PTFE	Polytetrafluoroethylene
PFA	Perfluoroalkoxyl polymer
FEP	Fluorinated ethylene propylene
ETFE	Ethylene tetrafluoroethylene
PVDF	Polyvinylidene fluoride
PCTFE	Polychlorotrifluoroethylene
FKM	Family of fluorocarbon-based fluoroelastomer materials
FFKM	Perfluorelastomers
FEPM	Tetrafluoroethylene propylene
FFKO	Perfluoropolyether elastomer
PFPE	Perfluoropolyether
PFHxA	Perfluorohexanoic acid
PFBA	Perfluorobutanoic acid
PFBS	Perfluorobutane sulfonic acid
HFC	Hydrofluorocarbon
PFC	Perfluorinated compound
HFO	Hydrofluoroolefin
HFE	Hydrofluoroether

JP4EE Attachment 6- Unfeasibility of “possible substitutes” in actual EEE

As far as we know, the most comprehensive available information on alternatives to PFAS would be "A guide to PFAS in electronics" by ChemSEC. However, from the point of view of the actual manufacturers of EEE, the listed "possible substitutes" seem to be (still) infeasible to achieve the EEE performance needed in today's IT society. Therefore, we prepare this attachment to explain why alternatives are not feasible. Please refer to Column G (Comments on ChemSec-Electronics-Guide).

ChemSEC: “A guide to PFAS in electronics”:
https://chemsec.org/reports/check-your-tech-a-guide-to-pfas-in-electronics/

Category of use	Function performed	Product(s)	PFAS identified	Contained in the product?	Actively used?	Alternatives available?	Alternatives Identified	Additional Comments	References	Comments on ChemSec-Electronics-Guide
Electrical Devices	Structure/low dielectric constant/insulation	Printed Circuit Boards (PCB)/ Printed Wiring Board (PWB)	6:2 FTSA (27619-97-2) Perfluorooctane sulfonamid (754-91-6) PFOS (1763-23-1) PFBA (375-22-4) PTFE (9002-84-0) ethene,1,1,2,2-tetrafluoro-, polymer with 1,1'oxybis[ethene] (102646-47-9)	Yes[1,2]	Confirmed[3]	Yes	FR-4 epoxy, Polyimide laminates, liquid crystal polymer, polyester, polyethylene naphthalate (PEN), bismaleimide triazine (BT), ~~cyantate~~ cyanate ester, ceramics [4]	PFOS and PFOA are banned so considered unlikely to be still be used for this function. The alternative FR4 contains brominated flame retardants, which might lead to a case of regrettable substitution [62] Noted by industry [62] that for existing designs, PTFE cannot be easily substituted in PCB/PWB without a complete redesign of the equipment (including the mechanical dimensions of the product) and not feasible for spare parts.	1,2,3,4, 62	All of the materials listed as alternatives have a high relative permittivity (square root proportional to transmission loss), and especially the dissipation factor (proportional to transmission loss) is very large, so it is not a substitute for high-frequency printed circuit boards. This difference in properties will have a significant impact on the social demand for reduced power consumption in the carbon-neutral era, as well as on the dramatic reduction of power consumption for the transmission of millimeter wave band mobile communications (5G/6G) and digital data communications in high-speed servers (224/448 Gbps) that are expected in the future.
Electrical Devices	Final Coating/protection/waterproofing	Printed Circuit Boards (PCB)/ Printed Wiring Board (PWB)	6:2 FTSA (27619-97-2) Perfluorooctane sulfonamid (754-91-6) PFOS (1763-23-1) PFBA (375-22-4) PTFE (9002-84-0) ethene,1,1,2,2-tetrafluoro-, polymer with 1,1'oxybis[ethene] (102646-47-9)	Yes[5]	Confirmed[6]	Yes	Acrylic Resin, Epoxy, Urethane resin, silicone resin [7]		5,6,7	The substances listed in the alternatives identified cannot be substituted for all applications. For example, epoxy resin is hard and cannot be used for flexible substrates. In addition, even if it can be used, urethane resin and acrylic resin are inferior to PFAS in moisture-proof, so it is necessary to increase the film thickness to obtain the necessary moisture-proof properties. Silicone resin cannot be used in the vicinity of relays, mechanical switches or membrane switches, where the silicone resin has a risk that siloxanes that deteriorate and release the silicone accumulate on the conduction part and cause conduction failure and may cause malfunction due to contact failure. For details, please refer to the high-speed communication section of Attachment 4, Smartphone and Protective Coat.
Electrical Devices	Liquid impregnates	Capacitors	Aliphatic perfluoroalkane (355-42-0) Perfluoromethylcycloalkane (1805-22-7, 255-02-2) Perfluoro-1,3-dimethylcycloalkane (355-27-3) Perfluorotrialkyl amine (311-89-7) Perfluorinated cyclic ethers (?)	Yes[1]	Unconfirmed	Yes	Mineral oils, vegetable oils, silicone oils, and biodegradable synthetic oils.[8]		1,8	We have no information.
Electrical Devices	Dielectric films	Capacitors	PTFE (9002-84-0) PVDF (24937-79-9)	Yes[8]	Unconfirmed	Yes	Various other polymers such as polypropylene (PP), polyethylene (PE), polystyrene (PS), polycarbonate (PC), PEN, polyphenyl sulfide (PPS), polyester imides (PEI), polyethyleneterephthalate (PET), polybutyleneterephthalate (PBT), polyetheretherketone (PEEK), polyvinylchoride (PVC), polyimides (PI), polyamides (PA), and polymethylmethacrylate (PMMA)		1	We have no information.
Electrical Devices	Electrical signal; Piezoelectrical material	Acoustical Equipment	PVDF (24937-79-9) Copolymers with trifluoroethylene	Yes[1]	Confirmed[9]	Yes	Piezoelectric films seem to all be made of PVDF, but there are other piezoelectric materials that can be used depending on the application, such as ceramic piezoelectric materials or piezoelectric crystals[10]		1,9,10	Ceramics have been proposed as alternatives to piezoelectric elements, but they are fragile and limited in shape, making it difficult to form large areas.
Electrical Devices	Acoustic vent membranes	Acoustical Equipment	Not specified	Yes	Unconfirmed	No	No alternatives identified	Alternatives for moist protection do not seem to be available.	*REF for this one?*	We cannot comment on PFAS or alternatives because there are no examples.
Electrical Devices	Dipole moment	LCDs(Liquid Crystal Displays)	Fluoropolymers	Yes[1,11]	Unconfirmed	Yes	Can use other screen technologies instead of LCD		1,11	OLEDs (organic light-emitting diode) cannot replace all LCDs. Compared to LCDs, OLEDs have some challenges to solve such as higher power consumption (contrary to energy saving), shorter life, and inability to repair (high cost). Therefore, it is impossible to replace the LCDs during the proposed five-year grace period. It took 20 years for OELDs to reach their current status, so we think that it will take a similar number of years to solve such challenges and replace LCDs.

Category of use	Function performed	Product(s)	PFAS identified	Contained in the product?	Actively used?	Alternatives available?	Alternatives Identified	Additional Comments	References	Comments on ChemSec-Electronics-Guide
Electrical Devices	Protective coating	LCDs(Liquid Crystal Displays)	PCTFE (9002-83-9)	Yes[1]	Unconfirmed	Yes	Can use other screen technologies instead of LCD		1	We have no information.
Electrical Devices	Electrical Insulation/dust repellent	Flat panel display	Tetrabutylphosphonium perfluorobutane sulfonate (220689-12-3) Tetrabutylphosphonium perfluoromethane sulfonate Tetrabutylphosphonium perfluorohexane sulfonate Tetrabutylphosphonium perfluorooctane sulfonate	Yes[1]	Unconfirmed (patent)	Yes	Various other polymers such as polyester and polycarbonate		1, 12, 13	In flat panel display materials, the required performance (optical properties) of the product can be satisfied by introducing fluorine atoms to the functional molecules in the material. Alternative substances must have the characteristics of "low surface tension", "high wettability to the base material", and "hydrophobicity" equivalent to fluorine, but no substitute substance has been found that satisfies these sufficiently. In addition, general-purpose polymers are listed as alternatives, but as described above, polymers alone cannot meet the required performance (optical properties) and some alternatives have fluorine introduced, so they are considered inappropriate as non-PFAS alternatives.
Electrical Devices	Not specified	Razors	PTFE (9002-84-0)	Yes[1]	Unconfirmed	Uncertain	Unconfirmed		1,14	PFAS are used for lubricity, durability, and antifouling requirements.
Electrical Devices	Not specified	Various (Switches, Vacuum cleaners, Coffee makers, Keyboards, Screens, TVs	Not specified	Yes[1]	Unconfirmed	Uncertain	Unconfirmed		1,14	We have no information.
Electrical Devices	Coating	Electroluminescent lamps in commercial/safety signs	PCTFE (9002-83-9)	Yes[1]	Unconfirmed	Uncertain	Unconfirmed		1	We have no information.
Electrical Devices	Insulation/Fire prevention	Wiring and cable insulation	PVDF-HFP copolymer (9011-17-0) FEP (25067-11-2) ETFE (68258-85-5) ECTFE (25101-45-5) PCTFE (9002-83-9) PTFE (9002-84-0)	Yes[1]	Confirmed[15]	Yes	Plastics (PVC, PE, PP, etc.) Rubbers (neoprene, silicone, etc) [16,17,18]	Industry note that, in practice PVC is favoured for this use, so in fact PFAS could be used if PVC is not possible. Other materials mentioned as alternatives have some drawbacks [62].	1,15,16,17,18	Flame retardant cables used in harsh conditions must have very good fire resistance. PVC as a flame-retardant material is not satisfactory, and safety cannot be guaranteed at all with other PFAS alternatives.
Electrical Devices	Insultation / heat resistant	Wiring and cable insulation	PTFE (9002-84-0)	Yes[62]	Confirmed [62]	Yes[62]	Rubbers (neoprene, silicone, etc)	Industry association [62] note that rubbers have less mechanical strength and less abrasion resistance. Thicker insulation might be needed or additional mechanical support. Might lead to partial redesign to accomodate for the additional space required.	62	Flame retardant cables used in harsh conditions must have very good fire resistance. PVC as a flame-retardant material is not satisfactory, and safety cannot be guaranteed at all with other PFAS alternatives.
Electrical Devices	Insultation / heat resistant in combination with specific sensors	Wiring and cable insulation	PTFE (9002-84-0)	Yes[62]	Confirmed [62]	Yes[62]	Rubbers (neoprene, silicone, etc)	Industry association [62] note that silicone insulation will lead to chemical deposition on the sensors, making them malfunction.	62	Special sensors used in harsh conditions are required to be heat-resistant, chemical-resistant, and durable. Neoprene rubber has lower characteristics than PFAS. In addition, silicone rubber deteriorates and separates siloxanes, which may cause conduction failure of the contacts.
Electrical Devices	Insulation / chemical resistant	Wiring and cable insulation	PTFE (9002-84-0)	Yes[62]	Confirmed [62]	No[62]	No alternatives identified	Industry association [62] note that no alternative available when chemical resistance is required.	62	Insulated cables used in acidic or alkaline atmospheres and environments where chemicals come into contact are required to have excellent chemical resistance, and no material other than PFAS has been identified that can ensure safety.
Electrical Devices	High frequency electrical insulation	Wiring and cable insulation	PTFE (9002-84-0)	Yes[62]	Confirmed [62]	Uncertain[62]	Unconfirmed	Industry association [62] note thatPTFE has a very low dielectric constant. There is no comparable alternative.	62	No alternatives for high frequency electronic insulating materials have been identified.
Electrical Devices	Insulating spacers locate conductive components	(Coaxial) cable	PTFE (9002-84-0)	Yes[62]	Confirmed [62]	Uncertain[62]	Unconfirmed		62	In the insulated spacers in coaxial cables, PFAS alternatives cannot be identified.
Electrical Devices	High voltage insulator	Connectors and other parts in submarine long distance telecommunication cable applications	PTFE (9002-84-0)	Yes[62]	Confirmed [62]	Uncertain[62]	Unconfirmed		62	No alternative to PFAS has been identified in high-voltage insulators used in connectors and other components for submarine long-distance communication cable applications.
Electrical Devices	Additive in plastic resins (e.g. PC/ABS)	Plastic Enclosures	PTFE (9002-84-0)	Yes[62]	Confirmed [62]	Uncertain[62]	Unconfirmed		62	We have no information.

Category of use	Function performed	Product(s)	PFAS identified	Contained in the product?	Actively used?	Alternatives available?	Alternatives Identified	Additional Comments	References	Comments on ChemSec-Electronics-Guide
Electrical Devices	V0 flame retardancy plastics	Adapters, PSUs, wiring	PTFE (9002-84-0)	Yes[62]	Confirmed [62]	Yes[62]	(Unspecified) BFRs, CFRs [62]	PTFE as an additive (3000-5000 ppm) in PC [62]; Industry noted that in order for plastics to meet the V0 flame retardancy grade, it is required that there is suppression of dripping of any melted plastic as the plastic is heated. Only alternatives would be brominated or chlorinated flame retardants which are also restricted.	62	Resins used in the housings of devices such as TVs and personal computers, and resins used around power supplies and heating elements in electrical parts may be required to be certified as flame retardant according to UL94 standards by law. In order to satisfy these standards, the addition of flame retardants is unavoidable, but especially for advanced resins of V-0 grade or higher, it is necessary to prevent the generation of burning particles that can ignite, and drip prevention is essential. When halogen flame retardants are regulated by law, and inorganic flame retardants and phosphate ester flame retardants may be used, inorganic flame retardants need to be added in large quantities to obtain a sufficient flame-retardant effect, resulting in impaired physical properties of the resin. On the other hand, phosphate ester flame retardants are limited to resins that are easy to exert effects (resins that are easily carbonized including oxygen) due to the flame-retardant expression mechanism (carbonization layer formation during combustion). Flame retardant resins using phosphate ester flame retardants in polycarbonate and styrene resin alloys (PC/ABS) are widely used in home appliances and OA equipment, but because they are easy to drip due to the plasticizing effect of phosphate ester flame retardants. In order to achieve V-0, it is essential to add PTFE, which is an anti-drip agent (fibrillated fluoropolymer increases the melt tension of low-viscosity resins and has an anti-drip effect) as a flame retardant auxiliary. In addition, the addition of an anti-drip agent makes it possible to reduce flame retardants.
Electrical Devices	Protective coatings (dirt, scratch, smudge resistance)	Radiation Curable Coatings on Smartphones & other screens	PTFE (9002-84-0) PVDF (24937-79-9) Perfluoropoly-ether and polyurethane blend	Yes[19]	Unconfirmed	Yes	Silica-based coatings, Polymethylmethacrylate powder coating[19]		19	PFAS alternatives for antifouling coatings that satisfy solvent resistance have not been identified.
Electrical Devices	Protective coatings (dirt, water, UV)	Solar Panels	FEP (25067-11-2) ETFE (68258-85-5) FEVE (146915-43-7)	Yes[19]	Unconfirmed	Yes	PET、PC、Polyamides、PS Titanium Dioxide nanoparticles[19]		19	Durability, weather resistance, light resistance (especially UV resistance), and antifouling are important for the protective film of photovoltaic panels, but PET, PC, Polyamide, and PS are easily degraded by the ultraviolet light contained in sunlight, which shortens the life of the panel. TiO2 is added to improve hydrophilicity, not an alternative.
Electrical Devices	Coating	ICT equipment with imaging senors	Not specified	Yes[62]	Confirmed [62]	No[62]	No alternatives identified	Industry association notes that use in coating to fill main ingress path to oleic acid and thus prevent glue failure at imaging sensor. Coating must be able to fill the gap by capillary action after jet dispensing. Only potential alternative is Silicone but Silicone absorbs oil, is sticky, causes cross contamination and leads to adhesion loss of other components. [62]	62	We have no information.
Electrical Devices	Lubricant	ICT equipment	Not specified	Yes[62]	Confirmed [62]	No[62]	No alternatives identified	Lubrication/coating e.g. for Silicone O ring installation – e.g. to provide good corrosion resistance, low Coefficient of Friction <0.15, good adhesion to substrate, low surface roughness Ra < 0.6 um, harder than Polycarbonate to withstand 30K cycles of REL testing. Coating to fill main ingress path to oleic acid and thus prevent glue failure at imaging sensor. Coating must be able to fill the gap by capillary action after jet dispensing. Industry association noted that all alternative dry coatings have been tested and failed for either corrosion or cosmetics. Alternative lubricants have been tested and do not meet performance requirements [62].	62	In ICT equipments, PFAS alternatives for dry coat cannot be used due to corrosion and appearance problems. Also, PFAS alternatives for lubricants do not meet the required properties.
Electrical Devices	Coating	Touchscreen displays, camera glass, mousepads, backglass	Not specified	Yes[62]	Confirmed [62]	Yes [62]	Silicone-based coatings	Low surface energy anti-finger printing and haptics enabling coatings Industry association[62] note that silicone alternatives absorb oil, are sticky, and cross contamination leads to adhesion loss of other components. Silicone alternatives would create dysfunction in haptics - blocking transmission to sensors in touchscreens.	62	When a touch display or camera lens is coated with a silicone base alternatives it is not suitable for high-performance products because silicone base alternatives absorb oil, increase stickiness, which causes dysfunction of haptics (blocking transmission to touchscreen sensors) .

Category of use	Function performed	Product(s)	PFAS identified	Contained in the product?	Actively used?	Alternatives available?	Alternatives Identified	Additional Comments	References	Comments on ChemSec-Electronics-Guide
Electrical Devices	Proton exchange membrane	Fuel Cell	Ethanesulfonic acid, 2-[1-[difluoro[(trifluoroethenyl)oxy]methyl]-1,2,2,2,-tetrafluoroethyoxy-1,1,2,2-tetrafluoro-, polymer with tetrafluoroethene (31175-20-9) PTFE (9002-84-0) Other proprietary polymers	Yes[20]	Confirmed	Uncertain	Hydrocarbon multi-block copolymer electrolyte membranes [multiblock copolymer poly(sulphonate phenylene)-b-poly(arylene ether ketone)] - under development. [20] Car industry argues that no replacements are available, since for example only PFSA ionomers have reached technological maturity for use in proton exchange membranes for these functions in the harsh environment of a fuel cell. [21]		20, 21	PTFE is the only material that can withstand redox environments. For details, please refer to the comments of the organizations that handle the equipments.
Electrical Devices	Binder	Lithium Ion Batteries	PVDF (24937-79-9)	Yes[22,23]	Confirmed[24]	Maybe	PI, PAA, CMC, SBR Many suggest that PVDF will soon be replaced with better performing and more environmentally friendly alternatives, but this appears to be largely at research stage.[22,23]		22.23.24	Please refer to the input from the battery industries, such as those from Battery Association of Japan (BAJ) for the concrete details.
Electrical Devices	Electrolyte	Lithium Ion Batteries	LiTFSI (90076-65-6) LiBETI (132843-44-8) LiFAP、LiTFAB LiFSI (171611-11-3) LiTA	Yes[25]	Confirmed[26]	Yes	$LiPF_6$ is the standard electrolyte for lithium ion batteries, but more efficient PFAS compounds are being developed/implemented.		25, 26	Please refer to the input from the battery industries, such as those from Battery Association of Japan (BAJ) for the concrete details.
Electrical Devices	Cathode electrode binder material	Lithium Batteries	PVDF and copolymers	Yes[62]	Confirmed [62]	No	No alternatives identified	Industry association [62] consider that there is no alternative to PVDF for cathode electrode binder material. It is noted [62] that over the years many polymers have been tried and PVDF has consistently been found to be the best option to meet the performance and process requirements for binder material. Originally PVDF was used as the binder material for both anode and cathodes. More recently styrene-butadiene copolymer (SBR) was found to be a good alternative for the anode binder material. CMC is used together with SBR as a thickener to control slurry viscosity. CMC/SBR is now the most popular anode binder material due to its low cost and good cell performance. But SBR is not a good option for the cathode binder material as its double bound structure can be oxidized under cathode potential. Replacing PVDF with other polymers will likely cause cell performance and manufacturability issues.	62	Please refer to the input from the battery industries, such as those from Battery Association of Japan (BAJ) for the concrete details.
Electrical Devices	Battery separator material	Lithium Batteries	PVDF and copolymers	Yes[62]	Confirmed [62]	No[62]	No alternatives identified	Industry association [62] consider that no alternative would result in similar performance of battery.	62	Please refer to the input from the battery industries, such as those from Battery Association of Japan (BAJ) for the concrete details.
Electrical Devices	Creation of important microporous structures	Speaker modules	Expanded PTFE	Yes[62]	Confirmed [62]	No[62]	No alternatives identified	Expanded PTFE for speaker membrane. Industry association[62] notes that PTFE has a unique ability to create important microporous structures that allow for proper air permeability and good water and dust-proofing. Industry association [62] consider that using an alternative would result in loss of sound transmission quality and durability,	62	We have no information.
Electrical Devices	Gaskets	Electronic circuits	PTFE	Yes[62]	Unconfirmed	No[62]	No alternatives identified	Industry association [62] notes that PTFE has unique quality to allow vapor and gas to pass through while preventing liquds from doing so which is required for applications in which venting is very important. This is important in many elecronic circuits that require venting without water entering an enclosure and building up around circuits. Industry association [62] consider that using an alternative would not allow for water proofing simultaneous with gas permeability.	62	There is no gasket material that is both solvent resistant and heat resistant other than PFAS.

Category of use	Function performed	Product(s)	PFAS identified	Contained in the product?	Actively used?	Alternatives available?	Alternatives Identified	Additional Comments	References	Comments on ChemSec-Electronics-Guide
Electrical Devices	Low friction	Moving parts, paper handling in printers	PTFE	Yes[62]	Confirmed [62]	Yes [62]	Several other materials, depending on the specific use case.	Industry association [62] notes that alternatives have to be investigated on case by case basis and there is no drop-in replacement. Often a more comprehensive redesign is required.	62	The low-friction properties of PTFE include not only a low coefficient of dynamic friction but also a low coefficient of static friction, as well as heat resistance, electrical insulation, flame retardancy, and chemical resistance. Replacing it with a substitute product causes an increase in power consumption due to an increase in sliding resistance, a deterioration in quietness, and a shortening of service life due to deterioration in durability. *Please refer to the input from the related industries, such as Japan Business Machine and Information System Industries Association (JBMIA), for the concrete details.
Electrical Devices	Low friction - non-stick (e.g. prevent toner sticking)	Moving parts e.g. in printers	PTFE	Yes[62]	Confirmed [62]	No[62]	No alternatives identified		62	*Please refer to the input from the related industries, such as Japan Business Machine and Information System Industries Association (JBMIA), for the concrete details.
Electrical Devices	Chemical resistance	Printers: ink tubing, sealing, parts in contact with ink	Fluoropolymers and fluoroelastomers	Yes[62]	Confirmed [62]	No[62]	No alternatives identified	Industry association [62] consider that for chemcial resistance, there is no alternative	62	Containers and tubes that can maintain the performance of the things contained inside must have multiple functions such as abrasion resistance, heat resistance, chemical resistance, and cleanliness, and such materials have not been confirmed except for PFAS. *Please refer to the input from the related industries, such as Japan Business Machine and Information System Industries Association (JBMIA), for the concrete details.
Electrical Devices	Lubrication	Lubricant	PTFE, PFHxA related substances	Yes[62]	Confirmed [62]	Yes [62]	Silicone lubricants	Industry association [62] consider that product redesign could be required due to chemical interactions between the alternative and the product. PFAS are very inert and alternatives might have unwanted interactions with the product	62	Silicone may be substituted in some applications, but in applications that are overused in harsh environments, silicone lubricants deteriorate and produce volatile low-molecular siloxanes, resulting in poor electrical contacts and unsafe use.
Manufacture	Chemical resistance, flexibility, sealing	Tubing, valves, sealing	PTFE, PVDF, fluoroelastomers	No (only used in factory, not in electronic product)	Confirmed [62]	No[62]	No alternatives identified	Industry association [62] consider that for chemcial resistance, there is no alternative	62	
Manufacture	Separation of high voltage components	Dielectric Fluids (3M™ Novec™ 7100 Engineered Fluid 3M™ Fluorinert™ Electronic Liquids)	1,1,1,2,2,3,4,5,5,5-decafluoropentane (138495-42-8) PTFE	Yes[1]	Confirmed[27]	Yes	Natural and synthetic esters[28,29,30]		27,28,29,30	-Alternatives tend to have a flash point, and the lower the viscosity, the lower the flash point. Therefore, when designated as a hazardous material, more caution is required in storage, transportation, and handling than before. In addition, the use of these products requires explosion-proof equipment, which entails a huge investment. - Ester-based products deteriorate due to hydrolysis and require caution.
Manufacture	Liquid burn-in testing		Perfluoroperhydrofluorene (307-08-4) PFPEs	Yes[1]	Unconfirmed	Uncertain	N/A		1	
Manufacture	Reliability testing		Perfluoroalkyl methyl ether (375-03-1)	Yes[1]	Unconfirmed	Uncertain	N/A		1	
Manufacture	Dielectric test media	Galden® PFPE Hermetic Seal Testing[36], 3M™ Fluorinert™ Electronic Liquids[40]	Methyl perfluoroalkyl ether (163702-07-6) Methyl perfluoroisoalkyl ether (163702-08-7)	Yes[1]	Confirmed[31]	Uncertain, see reference [32] for a list of compounds and their respective dielectric strengths that may meet manufacturing requirements	Use would need high dielectric breakdown strength, be non-flammable[1]		1,31,32	PFAS is used because it is a low-dielectric and nonflammable material at the same time, but no alternative has been found.
Manufacture	Thermal shock testing	Galden® PFPE Hermetic Seal Testing[36], 3M™ Fluorinert™ Electronic Liquids[40]	Perfluoroisohexane (355-04-4) Perfluoro-1,3-dimethylcycloalkane (355-27-3) Perfluoromethyldecalin (306-92-3) Perfluoroperhydrofluorene (307-08-4) Perfluorotetradecahydrophenanthrene (306-91-2) PFPEs	Yes[1]	Confirmed[33]	Uncertain	Use would need to be non-reactive[1]		1,32,33	PFAS is used because it is a material with low dielectric constant and stability at the same time, but no alternative to it has been found.
Manufacture	Gross and fine leak testing	Galden® PFPE Hermetic Seal Testing[36], 3M™ Fluorinert™ Electronic Liquids[40]	PFPEs	Yes[1]	Confirmed[33]	Uncertain	Use would need to be non-reactive[1]		1,31,33,34	There is no alternative that is non-flammable, insulating, low-viscosity, inert, low erosive and moderately volatile.
Manufacture	Electrical environmental testing	3M™ Fluorinert™ Electronic Liquids [40]	Perfluorinated fluids	Yes[1]	Confirmed[31]	Uncertain	Use would need to be non-reactive[1]		1,31	It is required to be non-flammable and must contain a certain amount of fluorine. Since alternative products are not nonflammable, using them requires investment in explosion-proof equipment.
Manufacture	Use for testing in general		Perfluoromethylcycloalkane (355-02-2) Perfluoro-1,2-dimethylcycloalkane (306-98-9) Perfluoroperhydrofluoranthene (662-28-2)	Yes[1]	Unconfirmed	Uncertain	N/A		1	Solvents for thermostatic chambers that measure the temperature characteristics of electronic components with ultra-high accuracy must be non-flammable, insulating, low-viscosity, inert, low-erosive, and highly thermally conductive, and have moderate volatility, and there is no alternative.

Category of use	Function performed	Product(s)	PFAS identified	Contained in the product?	Actively used?	Alternatives available?	Alternatives Identified	Additional Comments	References	Comments on ChemSec-Electronics-Guide
Manufacture	Heat transfer fluids	General heat transfer	1H-Perfluoroalkane (354-33-6) 1,1,2,2,-Tetrafluoroethane (359-35-3) 1,1,2,2-tetrafluoro-ethene, oxidized, polymd., reduced, decaroxylated (161075-02-1)	Yes[1]	Confirmed[35]	Yes	Various proprietary blends on the market that claim to be environmentally friendly; based on "ester chemistry" and others, and generally said to be biodegradable and often halogen free[36,37,38,39]		1,35,36,37,38,39	It must have high volume resistivity, low viscosity, and prevent moisture content from increasing during use. In addition, it must be nonflammable unless it is used in an explosion-proof facility, which requires a huge investment. Ester-based products require attention because of degradation due to hydrolysis.
Manufacture	Heat transfer fluids	Total Immersion cooling	Methyl perfluoroalkyl ether (375-03-1) Ethyl perfluoroisoalkyl ether (297730-93-9)	Yes[1]	Confirmed	Yes	See row for "General Heat Transfer"		See row for "General Heat Transfer"	See row for "General Heat Transfer"
Manufacture	Heat transfer fluids	Evaporative Cooling	Aliphatic perfluoroalkane (76-19-7) 1,1,1,2,2,3,4,5,5,5-decafluoropentane (138495-42-8)	Yes[1]	Confirmed	Yes	See row for "General Heat Transfer"		See row for "General Heat Transfer"	See row for "General Heat Transfer"
Manufacture	Heat transfer fluids	Brine Cooling	1,1,1,2,2,3,4,5,5,5-decafluoropentane (138495-42-8) Methyl perfluoroalkyl ether (163702-07-6) Methylperfluoroisoalkyl ether (163702-08-7) Ethyl perfluoroalkyl ether (163702-05-4) Perfluoroindane (374-80-1)	Yes[1]	Confirmed	Yes	See row for "General Heat Transfer"		See row for "General Heat Transfer"	See row for "General Heat Transfer"
Manufacture	Heat transfer fluids	Direct contact cooling	Aliphatic perfluoroalkane (335-57-9) 1H-perfluoroalkane (354-33-6) 1,1,2,2,-tetrafluoroethane (359-35-3) Perfluoroisohexane (355-04-4) Perfluoro-2-methyl-3-ethylpentane (354-97-2) Perfluoro-2,4-dimethyl-3-ethylpentane (50285-18-2) Perfluoromethylcycloalkane (1805-22-7) (355-02-2) Perfluoro-1,2-dimethylcycloalkane (306-98-9) Perfluoro-1,3-dimethylcycloalkane (335-27-3) Perfluorodecalin (306-94-5) Perfluoromethyldecalin (306-92-3) Perfluoroperhydrofluorene (307-08-4) Perfluorotetradecahydrophenanthrene (306-91-2) Perfluoroperhydrofluoranthene (662-28-2) Perfluoroperhydrobenzyltetralin (116265-66-8)	Yes[1]	Confirmed	Yes	See row for "General Heat Transfer"		See row for "General Heat Transfer"	See row for "General Heat Transfer"
Manufacture	Cleaning	Solvent Systems and Cleaning Products	3,3,4,4,5,5,6,6,-octafluoro-1-Hexene (159148-08-0) 3,3,4,5,5,5-hexafluoro-1-Pentene (2375-68-0) 1,1,1,2,3,4,5,5,5-nonafluoro-2-(trifluoromethyl)-Pentane (85720-78-1) 1,1,1,2,2,3,4,5,5,5,-decafluoro-Pentane (138495-42-8) Methyl perfluoroalkyl ether (22410-44-2), (375-03-1), (163702-07-6) Methyl perfluoroisoalkyl ether (22052-84-2) Methyl perfluoroisobutyl ether (163702-08-7) Ethyl perfluoroalkyl ether (163702-05-4) Ethyl perfluoroisobutyl ether (163702-06-5) 1,1,2,2-tetrafluoro-1-(2,2,2-trifluoroethoxy)-ethane (406-78-0) Aliphatic non-branched perfluoroalkanes (76-19-7)	Yes[1]	Confirmed[40]	Yes	IPA, Other alcohol cleaners without PFAS added Products listed on Green-Screen website[41]		1,40,41	When cleaning, low surface tension is required, as well as nonflammability unless the equipment is explosion-proof, which entails a huge investment.
Manufacture	Carrier fluid/lubricant deposition	Carrier fluid/lubricant deposition	Perfluoroisohexane (355-04-4) 1,1,1,2,2,3,4,5,5,5-decafluoro-Pentane (138495-42-8)	Yes[1]	Confirmed[42]	Yes	Honeywell fluorinated (but not perfluorinated) Solstice® solvents[43]		1,42,43	It is required to be nonflammable and must contain a certain amount of fluorine. Since the alternatives are not non-flammable, using them requires explosion-proof equipment, which entails a huge investment.
Manufacture	Etching	Piezoelectric ceramic filters	PFOS (1763-23-1)	No[1]	Unconfirmed[44]	Yes	Fluoroboric acid[45]	Industry association [62] note that PFOS and PFOA are banned. Unlikely to be still in use	1,44,45, 62	
Manufacture	Pulsed plasma nano-coating	Smartphones and Tablets	PFOA (335-67-1)	Yes[1,46]	Confirmed[47]	Yes	Epoxy, urethane, acrylic, silicone, paralyne[47] PFAS-free nanocoatings[48]	Industry association [62] note that PFOS and PFOA are banned. Unlikely to be still in use There are other types of coatings used in the industry for the same purpose: evaporative curing, moisture curing and heat curing. Examples of non-fluorinated radiation curable coatings are silica-based coatings and polymethylmethacrylate powder.	1,46,47,48, 62	
Manufacture	Haptics enabling coating	Smartphones and Tablets	-	Yes	Unconfirmed	Uncertain	For touchscreens, which needs haptics enabling coatings, good alternatives are currently lacking.			
Manufacture	Air/moisture resistance	General electronic equipment packaging	PCTFE (9002-83-9)	Yes[1]	Confirmed[49]	Yes	Other moisture and vapor-barrier packaging, such as mylar and a mixture of aluminium foil and various non-fluorine-containing polymers[50]		1,49,50	Since aluminum foil does not allow the user to see the parts in the package, fluorine film can only be used where moisture-proofing and transparency are required at the same time.

Category of use	Function performed	Product(s)	PFAS identified	Contained in the product?	Actively used?	Alternatives available?	Alternatives Identified	Additional Comments	References	Comments on ChemSec-Electronics-Guide
Semiconductors	Photolithography		PFOA (335-67-1) PFOS (1763-23-1) Perfluoropolymers	Yes	Unconfirmed [51]	Potentially	hydrocarbon-based greases, Molybdenum disulfide, graphite (for photolithography) [52]	PFOA and PFOS have been largely phased out	51, 52	PFOS and PFOA have already been eliminated in Japan, and PFOS and PFOA are not used as identified PFAS (we agree with Additional Comments), but they are used as PFAS. Also, 'Contained in the product? (Column E)' is Yes. As with antireflection films, the resist used in the front-end process does not remain in the final semiconductor product. In other applications, current semiconductor technology uses photoresist in many applications to provide properties by leaving a variety of products in the final semiconductor product. In this case, the PFAS remains in the final semiconductor product. The authorities should review the materials of "Semiconductor PFAS Consortium https://www.semiconductors.org/pfas/" in detail. Hydrocarbon greases, molybdenum disulfide, and graphite (for photolithography) already use carbon films as mask materials, but lithography is essential for patterning mask materials, and resist materials are still needed.
Semiconductors	Photoresist matrix, changes solubility when exposed to light	Photoresist	PFOA (335-67-1) PFOS (1763-23-1) PFHxS (alternative to PFOS/PFOA) [28,29,30]	Yes	Confirmed	Yes	KrF (248nm) (active ingredient not disclosed) [53] DOW™ photo-resists (non-PFOS) composed of solvents, acrylic, other polymer resins, cross-linking agents, stabilizers and/or surfactants Alternatives should containt fluorine	PFOS has been largely phased out	53,54,55,56	KrF resists and DOWTM photo-resists (non-PFOS), which are listed as alternative resists, are of limited use and do not cover all resists with different exposure wavelengths. If non-PFOS is used, PFOS is excluded under the Stockholm Convention, and the resists currently used in Japan are already PFOS-free but not PFAS-free. Photoresist requires several actions such as photoacid generation as well as surface activity, and the authorities only mention some of them, so the difficulty of replacing non-PFAS is clearly underestimated. The authorities should review the materials of "Semiconductor PFAS Consortium https://www.semiconductors.org/pfas/" in detail. It is stated that the replacement of photo-oxidants will take more than 25 years.
Semiconductors	Increase the photosensitivity of the photoresist	Photoresist (photosensitizer)	PFOA (335-67-1) PFOS (1763-23-1)	Yes	Unconfirmed	No	N/A	PFOS has been largely phased out	-	
Semiconductors	Generate strong acids by light irradiation	Photoresist (Photo-acid generator, PAG)	PFOA (335-67-1) PFOS (1763-23-1) Shorter-chain PFAS (PFBS) functionalized fluoroethanesulfonates	Yes	Confirmed	None currently (patents filed/fluorine free alternatives have been proposed)	Aromatic PAGs identified in patents (WO2009091704) Heteroaromatic PAGs identifed in patents (WO2009091702, US20110183259).Triphenylsulfoniumbenzo[b]thiophene-2-sulfonic acid, 4(or7)-nitro-,ion(1-) (TPS TBNO) is identified Glodde et al. have proposed a Fluorine free PAG in their 2010 publication. Functionally need to generate strong acids	PFOS has been largely phased out	57,58	From "SIA PFAS Consortium"page38 https://www.semiconductors.org/pfas/ The authorities need to consider all the material at this URL. "non-PFAS PAGs (CN5 and thiophene sulphonate), which has highlighted the difficulty of developing formulations that meet all performance criteria simultaneously, as shown in Table 4-4. As such, non-PFAS PAGs are for a narrow range of use applications only, as no known non-PFAS PAG/photoacid exhibits the same level of performance for all criteria. While a candidate chemistry might show good acid strength, it will have lower photospeed because of lower acid diffusivity, and at the same time the acid anion might be transparent for a single wavelength only. PFAS PAGs, on the other hand, present simultaneously good to excellent performance for all listed performance criteria with the notable exception of environmental persistence."
Semiconductors	Controlling the diffusion of the acid to unexposed region	Photoresist (Quencher)	PFOA (335-67-1) PFOS (1763-23-1)	Yes	Unconfirmed	Uncertain	N/A	PFOS has been largely phased out	-	
Semiconductors	Provide low reflectivity	Antireflective coating	PFOA (335-67-1) PFOS (1763-23-1) PFHxS (alternative to PFOS/PFOA, 355-46-4)	It is noted the FP coating is not present in the final chip and is spun out and goes to waste/destroyed in the etching process	Confirmed	Yes	-AZ Aquatar 8 (Fluoroalkyl acid ester, homopolymer, hydrolyzed, 67829000004-6092P)[2] -DOW™ anti-reflect (non-PFOS), composed of solvents, acrylic, other polymer resins, cross-linking agents, stabilizers and/or surfactants -FP with a short fluoroalkyl side chain less than C4 -Alternatives should containt fluorine; functionally require low refractive index		19,59	The materials listed in column D has already been published in the Stockholm Convention. Column G is substituted for "present" and column H is substituted for "FP with a short fluoroalkyl side chain less than C4." This indicates that there is no substitute for all applications of semiconductors. The applications are diverse, and it is very dangerous to understand that there is one substitute for all alternatives. The authorities themselves describe FPs whose substitutions eventually have short fluoroalkyl side chains less than C4.
Semiconductors	Facilitate the control of the development process	Developer	PFOA (335-67-1) PFOS (1763-23-1) Shorter-chain PFAS used as alternatives to PFOA/PFOS	Yes	Confirmed	Uncertain	Patent US20080299487 for unfluorinated surfactant, vaguely described.	PFOS has been largely phased out	57	Contained in the product? is Yes,but like an antireflection film, no developer remains in the final semiconductor. But, the opinion that "photoresist used in semiconductor manufacturing does not remain in the product" is decades old, and current semiconductor technology uses photoresist in many applications to provide properties by leaving a variety of products in the final product. In this case, the PFAS remains in the final semiconductor product. In some applications, it should be emphasized that the PFAS remains in the final semiconductor product. Authorities should review the materials of the Semiconductor PFAS Consortium https://www.semiconductors.org/pfas/ in detail.
Semiconductors	Rinsing the photoresist to remove the developer	Rinsing Solution	Unknown	Uncertain	Unconfirmed	Uncertain	Use would require low surface tension		57	

Category of use	Function performed	Product(s)	PFAS identified	Contained in the product?	Actively used?	Alternatives available?	Alternatives Identified	Additional Comments	References	Comments on ChemSec-Electronics-Guide
Semiconductors	Etching	3M™ Fluorinert™ Electronic Liquids	PFOA (335-67-1) PFOS (1763-23-1) short-chain perfluoroalkyl sulfonates are alternatives in use today	No (at least there shouldn't be, its reported that PFAS is captured in the waste/it's a closed system)	Confirmed	Yes	Amyl acetate (628-63-7)、Anisole (100-66-3) n-Butyl acetate (123-86-4)、Ethyl lactate (97-64-3) Propylene glycol methyl ether acetate (108-65-6) Methyl-3-methoxypropionate (3852-09-3) non PFOS-based surfactants are in use for etching application for etching agents with ceramic filters (WSC 2011),		60	It seems that the description of equipment coolant is urged from row C, but since PFOS and PFOA are neither etchant nor coolant, it is strange in a double sense. The authorities do not understand the dry etching process of semiconductors. The authorities should review the materials of "Semiconductor PFAS Consortium https://www.semiconductors.org/pfas/" in detail.
Semiconductors	Etching Wetting agent	See General etching	See General etching	See General etching	See General etching	See General etching	Use would require low surface tension		See row for "General etching"	
Semiconductors	Etching Reduce the reflection of the etching solution	See General etching	See General etching	See General etching	See General etching	See General etching	Use would require low refractive index		See row for "General etching"	
Semiconductors	Etching agent in dry etching	See General etching	See General etching	See General etching	See General etching	See General etching	Use would require Strong acids		See row for "General etching"	The main dry etch is PFC, and those indicated by "PFAS identified" are not used. "Alternatives Identified" are also completely wrong.
Semiconductors	Etch Cleaning of Silicon Wafers	General etching	PFOA (335-67-1) PFOS (1763-23-1) PFBS (375-73-5) PFNA (375-95-1) PFHxA(307-24-4)	No	Unconfirmed (patented) [1]	Uncertain	Patent EP 3 588 535 A1 details several surfactants including PFAS and non-fluorosurfactants which may be alternatives[1] Use would require Strong acids [35]		1, 61	Perfluoroalkyl acids such as PFOA and PFOS (which are already substances subject to the Stockholm Convention) are not used for "etch cleaning of silicon wafer". This usage information for PFOA and PFOS is incorrect. Therefore, the description of line H is completely wrong. It can be guessed from the document of the authority that the description is about photo-oxidizer, but it seems that the answer is not about wafer etching but about photoresist. In addition, the description of the patent is found on the whole, but for this technology to be established as a substitute, many tests and quality assurance are required for mass production. In the end, there are many patents that are not used because the test and quality assurance cannot be satisfied and cannot be applied to mass production. By listing the patent number, authorities that provide alternative cases underestimate the difficulty of substitution. Authorities should review the Semiconductor PFAS Consortium https://www.semiconductors.org/pfas/ document in detail.
Semiconductors	Remove cured epoxy resins/Cleaning of integrated circuit modules		Unknown	Uncertain	Unconfirmed	Uncertain	N/A			
Semiconductors	Remove dielectric film build up	Cleaning vapour deposition chamber	Unknown	Uncertain	Unconfirmed	Uncertain	Use would require reactive oxygen species (ROS) generation[1]		1	
Semiconductors	Non-stick coating composition on carrier wafer	Wafer thinning	PFOA (335-67-1), PFOS (1763-23-1) likely if used, but unconfirmed	Uncertain	Unconfirmed (patented) [1]	Uncertain	Use would require low surface tension[1]		1	PFOA and PFOS subject to the Stockholm Convention are described in Wafer thinning, but the meaning of this description is not understood.
Semiconductors	working fluid	Vacuum pumps	Perfluoroalkoxy alkanes (PFA) fluoropolymers	Uncertain	Unconfirmed	Uncertain	Use would require alternative be stable, non-reactive[1]		1	
Semiconductors	polymeric PFAS used in inert moulds, pipes, elastomers	Technical equipment in contact with process chemical or reactive plasma	Polymeric PFAS	Uncertain	Unconfirmed	Uncertain	Use would require alternative be stable, non-reactive[1]		1	
Semiconductors	Bonding ply composition	Multilayer circuit board	PFOA (335-67-1), PFOS (1763-23-1) likely if used, but unconfirmed	Uncertain	Unconfirmed (patented) [1]	Uncertain	Use would require low dielectric constant, low dissipation factor[1]		1	PFOA and PFOS subject to the Stockholm Convention are described, but the meaning of this description is not understood. "Authorities should review the Semiconductor PFAS Consortium https://www.semiconductors.org/pfas/ document in detail.
Semiconductors	Vapor Phase Soldering	Galden® LS and HS grades (LS/HS) [36]	PFPEs	Yes	Confirmed	Uncertain			33	Alternative materials that do not affect the substrate by soldering with high temperature reflow need to be developed. Authorities should review the Semiconductor PFAS Consortium https://www.semiconductors.org/pfas/ document in detail.

List of abbreviations

Acronym	Explanation
6:2 FTSA	6:2 Fluorotelomer sulfonic acid
PFOS	Perfluorooctane sulfonic acid
PFBA	Perfluorobutanoic acid
PTFE	Polytetrafluoroethylene
PVDF	Polyvinylidene fluoride
PCTFE	Polychlorotrifluoroethylene
HFP	Hexafluoropropylene
FEP	Fluorinated ethylene propylene
ETFE	Ethylene tetrafluoroethylene
ECTFE	Ethylenechlorotrifluoroethylene
FEVE	Fluoroethylene Vinyl Ether Resin
LiTFSI	Lithium bis(trifluoromethanesulfonyl)imide
LiBETI	Lithium bis(pentafluoroethanesulfonyl)imide
LiFSI	Lithium Bis(fluorosulfonyl)imide
PFHxA	Perfluorohexanoic acid
PFPE	Perfluoropolyether
PFHxS	Perfluorohexane sulfonic acid
PFBS	Perfluorobutane sulfonic acid
PFNA	Perfluorononanoic acid

Lobe Pumps	10008350	Fluoroelastomer/polymer seals Bearing components Flame resistant plastics used in Wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Piston Pumps	10008351	Fluoroelastomer/polymer seals Bearing components Flame resistant plastics used in Wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Plunger Pumps	10008352	Fluoroelastomer/polymer seals Bearing components Flame resistant plastics used in Wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Diaphragm Pumps	10008353	Fluoroelastomer/polymer seals, valve seats, check valves, diaphragms, pump head components, tubing, valving, pistons, Flame resistant plastics used in cables, wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Pneumatics Pumps	10008354	Fluoroelastomer/polymer seals Bearing components Flame resistant plastics used in Wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Industrial Pumps - Electric Engines	10008355	Fluoroelastomer/polymer seals Bearing components Flame resistant plastics used in Wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Industrial Pumps -Combustion Engines	10008356	Fluoroelastomer/polymer seals Bearing components Flame resistant plastics used in Wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Industrial Pumps – Replacement Parts / Accessories	10008364	Replacement parts would use various PFAS for repair of pumps (seals, components, etc)	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Fire Fighting Equipment	10008382	Fluoroelastomer/polymer seals Bearing components Flame resistant plastics used in Wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Industrial Pumps - Engines	11030100	Fluoroelastomer/polymer seals Bearing components Flame resistant plastics used in Wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Industrial Pumps – Replacement Parts / Accessories	11050100	Replacement parts would use various PFAS for repair of pumps (seals, components, etc)	Alternate materials do not exist that meet the MDEP definition for "Alternative".

Product Description	GPC/HTS Code	Use of PFAS	Alternatives
Pumps	10004055	Fluoroelastomer/polymer seals, bearing components, molded plastic components, Tribologic components, coatings Flame resistant plastics used in cables, wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Valves/Fittings - Water and Gas	10004024	Fluoroelastomer/polymer seals, valve liners	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Valves/Fittings Accessories/Replacement Parts - Water and Gas	10008011	Includes multiple PFAS materials for replacement/repair. (e.g. bearings, gaskets, compression packings, seals, seats, linings)	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Underfloor Heating	10004003	Fluoroelastomer/polymer seals Flame resistant plastics used in cables, wiring, Motors and Controllers required to meet UL safety standards.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Relays/Contactors	10005570	PFAS critical for meeting UL and NEC flammability safety standards	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Switches	10005586	PFAS critical for meeting UL and NEC flammability safety standards	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Inverters	10008390	PFAS critical for meeting UL and NEC flammability safety standards	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Distribution Boards/Boxes	10005583	PFAS critical for meeting UL and NEC flammability safety standards	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Circuit Assemblies/Integrated Circuits	10005661	PFAS critical for meeting UL and NEC flammability safety standards. Used in coatings for water resistance	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Thread Sealant (Paste)	3403.19.00.00	Fluoropolymer friction reducer and thread sealant critical to NPC piping systems and system sealing. Chemical resistance, Gas permeability, coefficient of friction, non-hardening properties.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Thread Sealant (Tape)	3403.19.00.00	Fluoropolymer friction reducer & thread sealant critical to piping systems and system sealing. Chemical resistance, Gas permeability, coefficient of friction, non-hardening properties.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Lined Hoses	3917.39.00.10 3917.21.00.00 4009.42.00.50 3917.33.00.00 3917.29.00.90 3917.39.00.50	Temperature and chemical resistance	Alternate materials do not exist that meet the MDEP definition for "Alternative".

Product Description	GPC/HTS Code	Use of PFAS	Alternatives
Lined Pipes Valves and Fittings	7306.19.10.10 8481.30.20.90 8481.80.30.65 8481.80.30.20 7307.19.90.80 8481.80.90.50 7307.99.10.00 7306.19.10.50 8481.80.10.90 8481.80.30.30 8481.80.30.75	Temperature and chemical resistance	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Sealants	10003204	Chemical resistance, Gas permeability, Diffusion coefficient	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Adhesives		Chemical resistance, Gas permeability, Diffusion coefficient	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Lubricating Greases	10005268	Long period operation, High temperatures, Low friction/low wear, Good gliding properties, Resistant to aggressive chemicals and reagents	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Lubricating Oils/Fluids	10005267	Long period operation, High temperatures, Low friction/low wear, Good gliding properties, Resistant to aggressive chemicals and reagents	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Lubricating Products Variety Packs	10005270	Long period operation, High temperatures, Low friction/low wear, Good gliding properties, Resistant to aggressive chemicals and reagents	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Lubricating Waxes	10005269	Long period operation, High temperatures, Low friction/low wear, Good gliding properties, Resistant to aggressive chemicals and reagents	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Grinder/Macerator	10002611	Fluoroelastomer/polymer seals, bearing components	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Mechanical Seals	10008364	Fluoroelastomer/ polymer seals	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Compression Packing	6815.19.00.00 3901.10.50.30 5911.90.00.40 6815.13.00.00 6815.19.00.00	Fluoropolymer yarns and yarn coatings. Chemical resistance, Gas permeability, temperature capability and coefficient of friction.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Reciprocating Seals	3926.90.45.00	Fluoropolymer/ Fluoroelastomer base material for molded/machined seals. Chemical resistance, Gas permeability, temperature capability and coefficient of friction.	Alternate materials do not exist that meet the MDEP definition for "Alternative".

Product Description	GPC/HTS Code	Use of PFAS	Alternatives
Rotary Seals	3926.90.45.00 4016.93.00.00	Fluoropolymer/Fluoroelastomer base material for molded/machined seals. Chemical resistance, Gas permeability, temperature capability and coefficient of friction.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Gasketing	3920.99.10.00 3920.99.50.00 3921.90.40.90 4002.59.00 3904.61.00.90 3926.90.45 3920.10.00.00	Fluoropolymer and fluoroelastomer base material for sheets, tapes, fabricated parts. Chemical resistance, Gas permeability, temperature capability, compressibility and coefficient of friction.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Flange Guards (Fabric)	5407.71.00.60	Fluoropolymer fibers/yarns/ fabrics. Chemical resistance, Gas permeability, temperature capability and coefficient of friction.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Expansion Joints	4016.93 3926.90.90 7307.99.00 4016.99 3926.90.90 3926.90.99	Fluoropolymer and fluoroelastomer base material, coating, liner or cover. Chemical resistance, Gas permeability, temperature capability and coefficient of friction, flexural toughness	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Diaphragms	8413.91 3926.90.45	Fluoropolymer and fluoroelastomer base material. Chemical resistance, Gas permeability, temperature capability and coefficient of friction, flexural toughness	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Industrial Valves & parts	9032 8481	Includes multiple PFAS materials based on the specific application need; multiple performance characteristics depending on application.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Actuators	8412 8471	Includes multiple PFAS materials based on the specific application need; multiple performance characteristics depending on application.	Alternate materials do not exist that meet the MDEP definition for "Alternative".
O-Rings	4016.93.0000	Includes multiple PFAS materials based on the specific application need; multiple performance characteristics depending on application, to include chemical and temperature resistance; reduce friction	Alternate materials do not exist that meet the MDEP definition for "Alternative".
Spring energized seals	8481	Specialty seals used in extreme temperatures to restrict emissions to atmosphere in cryogenic applications	Alternate materials do not exist that meet the MDEP definition for "Alternative".

Baker Hughes PFAS UUD

Product	Product Uses	Baker Hughes Brand	Product GPC Brick Codes https://gpc-browser.gs1.org/	Applicable HTS US Code-(import)	Components in Product Containing PFAS Substances	Type of PFAS Used in Components	Intended use of the product and explain how it is essential for health, safety or the functioning of society	Describe how the specific use of PFAS in the product is essential to the function of the product	Available Alternative Technologies	Additional Comments
Condition Monitoring and Industrial Inspection Equipment, Pressure and Flow Measurement Devices and Sensing Equipment	Power Generation (e.g., power plants gas/steam turbines, wind, hydro, nuclear) Chemicals Mining and Metals Industrial applications Municipal applications Transportation applications (highways, roads, bridges, railway lines, aircraft)	Bently Nevada Waygate Technologies Panametrics Druck Reuter-Stokes		9031.80.8085 8537.10.9170 8543.90.8885 8543.70.4500 9031.49.9000 9002.19.0000 9031.90.9195 9022.12.0000 9022.90.2500 9022.90.4000 9026.10.2100 9026.80.2000 9026.20.4000 9026.90.6000 9032.89.6050 9026.90.2000 9026.20.8000 9026.90.0000 9026.20.8000 9030.10.0000 9027.50.4060	PFAS is in the value chain of condition monitoring/inspection/sensing equipment and has been identified in electronic components and sensors, including: • Semiconductors • Printed Wiring Boards • Cables • O Ring seals, Gaskets	• Polytetrafluoroethylene (PTFE) • Fluorocarbon Rubber (FKM) • Perfluoroelastomer (FFKM) • Trifluoroethylene-propylene copolymer (FEPM) • CAS Number: 9002-84-0 Teflon • CAS Number: 9011-17-0 Viton • CAS Number: 25067-11-2 Hexafluoropropylene / tetrafluoroethylene copolymer • CAS Number: 29420-49-3 Potassium 1,1,2,2,3,3,4,4,4-nonafluorobutane-1-sulphonate • CAS Number: 65545-80-4 2-(Perfluoroalkyl) Ethanol	Monitoring of the performance of various types of equipment and infrastructure to ensure integrity and safety. Equipment monitoring includes air compressors, compressors, gear boxes, gas and steam turbines, marine propulsion, motors, pumps, cooling tower fans, centrifuges, ball mills, blowers, agitators. Infrastructure monitoring includes bridges, railroad tracks, aircraft and industrial infrastructure. Industrial sensors applications include precise radiation measurement, nuclear reactor monitoring, UV flame detection, and downhole sensing for directional drilling. Druck's piezo-resistive pressure sensors, pressure transducers, pressure test and calibration instruments are used in toughest environment across wide range of industries including Aerospace, Transportations, and other Industrial applications. Panametrics' solutions for measuring and analyzing moisture, oxygen, liquid, steam, and gas flow are widely deployed across many industries, including oil and gas. Industrial inspection products	These products use components containing Teflon, Viton, and PTFE which have the following properties: Chemical resistance, Low volatility/high stability, Thermal resistance, Cleanliness, UV resistance, and Flame resistance. Teflon can withstand temperatures from -200 to 260 degrees Celsius, which makes it a good choice for cables and wires that will be exposed to high temperatures like in the case of turbines or compressors where our sensors will be installed.	We are not aware of any available alternative at this time. Similar products include: • Polyurethane: It is a type of potting compound that is often used as an insulator in for PWA assemblies. This cannot be used at higher temperatures such as up to 260 degrees. • Ethylene-propylene diene monomer (EPDM): It is a type of rubber that is also often used as O-rings. This material is not resilient to petroleum products and has low resistance. It cannot be used in high temperatures. • Silicone: is a material often used as a coating for cables and wires. At prolonged high temperatures, aging silicone rubber will result in gradual hardening, shrinkage, and embrittlement. This means that frequent maintenance will be required. Silicone does not meet the temperature, chemical resistance, and lifespan requirements.	
Compressors	Hydrogen Mining Energy Injection of CO2 Gas pipelines Industrial facilities Petrochemical Plants Power Generation Municipal facilities	Nuovo Pignone		8414.80.2015 8537.10.9170	PFAS can be found in compressors in gaskets, seals, washers, abradable seals, anti-friction and/or anti-corrosion coatings. Also, in a compressor system, PFAS are used in most of subcomponents like control and safety valves, lube oil system, flexible hoses, filtering systems, heat exchangers, and cables. Compressors also have a set of auxiliary equipment (e.g., sensors and their cabling) that contain PFAS. Compressors are incomplete without the auxiliaries and cannot function.	• Polytetrafluoroethylene (PTFE) • Fluoroelastomers (FKM) • Fluorosint 500 • Halar • Teflon • FFKM - Perfluoro elastomer • Aflas • VITON • Xylan • FVMQ • Fluorosilicone • Sermalon • PFA • ETFE • Modified polyolefin	Compressors are used for a wide variety of industrial, manufacturing and municipal applications: • Hydrogen (reciprocating compressor) • CCUS (high pressure compressors working with CO2) • Liquefied Natural Gas (centrifugal compressors) • Industrial (refining, chemicals – usually centrifugal compressor) • Pipeline (centrifugal compressors) • Air compression	Given the extreme working conditions that are typical for compressors (high pressure, cryogenic or high temperature, corrosive and toxic environment with H2S, CO2, NH3), PFAS are instrumental to ensure safe operations, high efficiency, and extended maintenance intervals. PFAS are critical for use in gaskets, seals and coatings. Gasket and seals are essential to avoid leaks or sudden release of high pressure and toxic gas. Coatings are necessary to withstand harsh gas mixtures. The design of compressors, including use of components with PFAS, is dictated by specific industrial standards (e.g., API 617, API 692, API 684, API 6A) or customer's technical specifications.	The use of metallic seals in gaskets could be studied for the face seal on the head flange, while a complete redesign is required for radial gaskets. The redesign would require 200 hours per compressor model (we have 10 different compressor models), a complete test campaign, a review of the assembly cycle of all models and consequent investments would require significant amount of money for cycle variations. The use of metallic seals in gaskets could be studied for the face seal on the head flange, while a complete redesign would be required for radial gaskets. Such redesign effort for the entire compressor product line would require thousands of engineering hours and dedicated component and full-scale validation and verification tests. Also, a review of manufacturing and assembly cycles with relative investments would be needed. Overall, the impact is estimated in the order of several millions of euros. We tested valves with a graphite packing and a metal seal, but they increased energy use or did not meet standards due to higher leakage. For coating in Xylan, an alternative solution is still not available. Once available, product redesign will be	Feasibility of complete replacement of PFAS gaskets and seals with PFAS free alternatives is uncertain. The efforts to transition to a PFAS-free operation of compressors will be challenging as alternatives that will guarantee the same level of safety and efficiency of machines do not exist. It is also notable that non-PFAS seals are not compliant with some customer specifications, resulting in the loss of competitiveness by US manufacturers/importers. Known alternatives to PFAS for seals (e.g., graphite) provide significantly worse sealing performance and add additional friction to the valve motion. This friction increases the entire energy consumption of the industrial plants leading to even more emissions to provide that power. Even if an alternative component is identified, our compressors would need to be redesigned, retested, new manufacturing processes established, new sub-supplier qualifications,
Gas and Steam Turbines	Power Generation Chemical Industrial applications Gas transportation pipelines Navy (marine)	Nuovo Pignone		8411.82.8010 8406.81.1020 8406.82.1010 8406.82.1020	PFAS components are used in gaskets, O-rings, seals and washers. Other elements include valves and filtering systems, which are needed to ensure the proper operation. Turbines also have a set of auxiliary equipment (e.g., sensors and their cabling) that contain PFAS. Turbines are incomplete without the auxiliaries and cannot function.	• Chemloy • Polytetrafluoroethylene (PTFE) • Fluoroelastomer (FKM) • Perfluoroelastomer (FFKM) • CAS Number: 9002-84-0 Teflon • CAS Number 9011-17-0 – Viton	Turbines are used as a mechanical drive for compressors and pumps (e.g., LNG liquefaction plants, CO2 injection sites), pipelines and power generation and for heat and power systems (notably cogeneration).	Both gas and steam turbines are operated with high pressure and high temperature fluids to achieve the highest levels of efficiency, and due to this both technologies require durable components to ensure reliable and safe operations. PFAS substances are critical elements in turbines - they can be found in gaskets, seals and washers. All these pieces of equipment ensure the expected performance in terms of power and efficiency. Gas and steam turbines, which are used for the oil and gas industry, are specifically designed according to several industrial standards (e.g., API 612, API 616) and customers' specifications may be even more stringent. In general, PFAS substances are instrumental to guarantee safe operations and extended intervals without failure.	At this stage, we do not have any information on potential alternatives as we have not tested them during the period of consultation. Mineral fibers have been assessed in a theoretical setting but are less flexible. Spiro-metal gaskets are less flexible and must be studied further for radial applications. Metallic gaskets (which are non-flexible) are an option for a limited number of seals. Studying and applying alternatives would require: - Approximately 500 engineering hours for feasibility studies; • If feasible, product redesign would require 1,000 hours per engine model; and • a complete test campaign, a review of the assembly cycles of all models and consequent high investments would be required. PFAS oil seals allow for reduced clearances and consequent reduced safety and environmental risks. Metallic seals are already in use, but normally are associated with higher leakages thus resulting in lower efficiency and performance versus non-metallic seals. They have lower resistance to harsh conditions	Feasibility of complete replacement of PFAS gaskets and O-ring with PFAS free alternatives is not yet confirmed. The efforts to transition to a PFAS free operation for turbines will be challenging as finding alternatives that will guarantee the same level of safety and efficiency of machines does not exist at this stage. It is also notable that non-PFAS seals are not compliant with some customer specifications, resulting in the loss of competitiveness by US manufacturers/importers. Even if an alternative component would be found, which is uncertain at this stage, our turbines would need to be redesigned, retested, new manufacturing processes established, new sub-supplier qualifications, sources established. Furthermore, new certifications would be necessary, which requires human resources and takes time.
