The scope and scale of the project under review is not fairly represented in the EAW. Riverview Dairy is a very large food industry spread widely across the landscape in Minnesota and other states. The huge dairy operation is but a fraction of the entire corporate food enterprise that, when viewed as a whole, has tremendous potential and real impact. But current rules allow for segmenting incremental steps, whether large or small, into smaller parts.

We realize this may be allowed by current rules but nevertheless, nature responds (the environment is affected) according to natural rather than human law.

Karen Tolkkinen, a newspaper reporter put the subject project in its proper perspective, one not really allowed by environmental review because, as the EAW states below, the specific project is not presented as a phase or "stage" of any past, existing or future project, it's an expansion. And the proposer's existing facilities have already passed environmental muster so its impacts can no longer be counted.

The EAW states:

> "There are no past stages for the Project. The Existing Facility was permitted in August 2003 after undergoing environmental review and receiving a negative declaration on the need for an Environmental Impact Statement (EIS)."

In nature, serial impacts from a series of similar projects (especially large ones) in the same area add up. This by scientific definition is a "cumulative impact". But this is not definition allowed by Minnesota's environmental rules.

> "There are no planned future stages of the Project beyond what is described in this worksheet."

This statement above is also in the EAW and, for the moment it may be true. But do the public and the MPCA really believe that River View Dairy will not continue to expand and add more feedlots and even milk processing factories? EAWs are not allowed to speculate beyond what is not already in formal planning stages.

We refer to a more realistic assessment of the scope and scale of the no-less-than fourteen gigantic subcomponents of the larger project by the same owner. In Tolkkinen's recent Minnesota Star Tribune article she writes, *"the proposed expansion is the latest in a series of large dairies appearing in western Minnesota over the past two decades. Riverview's 13 dairy farms are located in Chippewa, Grant,*

Kandiyohi, Norman, Stevens, Swift, Traverse and Wilkin counties. A 14th in Traverse County, has been approved for 8,571 cows but not yet built."

The article goes on to say: "*The Existing Facility in Stevens County was permitted in August 2003 after undergoing environmental review (EAW) and receiving a negative declaration on the need for an Environmental Impact Statement (EIS). The Existing Facility operates under the NPDES General Feedlot Permit and has undergone the addition of an anaerobic digester (2008), dry manure solids storage (2010), and liquid manure storage (2014). Additionally, the Existing Facility has increased its animal unit capacity three times (2008, 2011, and 2018).*"

Our state government's tolerance (it is not the MPCA alone) for siloing a segment of what is obviously a much larger industrial enterprise, that shelters it from closer environmental scrutiny is a miscarriage of authority and a slow-moving environmental tragedy that is obvious to any student of the science.

It was one of the Izaak Walton League's early members, Aldo Leopold who aptly said:

> *"One of the penalties of an ecological education is that one lives alone in a world of wounds. Much of the damage inflicted on land is quite invisible to laymen. An ecologist must either harden his shell and make believe that the consequences of science are none of his business, or he must be the doctor who sees the marks of death in a community that believes itself well and does not want to be told otherwise."*

It is eminently and very possibly existentially regrettable that even our state agencies who accept and even produce flawed environmental assessments "do not want to be told otherwise".

These comments were prepared by Willis Mattison, professional ecologist, retired MPCA Regional Director now volunteering for the Izaak Walton League of America – Prairie Woods Chapter as chief science advisor. These comments are offered on behalf of the Prairie Woods Chapter with permission.

This concludes with our comments.

Ethan Bruer **Letter 1312**

Hello, my name is Ethan Bruer, I'm a life long resident and 5th generation farmer of Stevens county. Our family farm which started in 1884 is west of west river dairy 4 miles.

I've been reading most of these comments made and I also attended the public meeting in Morris. I'd like to point out a few things from an observation of mine. RiverView had people standing outside the Old No. 1 at 4:45pm for a meeting that was supposed to start at 6pm. Talk about stacking the deck. Lots of people in this community knew this was going to be a large meeting, yet the planned event space was exceptionally small for the masses that wanted to come and voice their views. Unfortunately many people were denied entry due to space. I'd suggest having a second meeting at a larger venue.

That being said, from what I've gathered are, if you're tied to Riverview in any way, employee, shareholder, family or any financial ties you're in favor of the expansion. Which stands to reason. But you need to look beyond on that and think what's good for the environment. Those who weren't, seemed to have genuine questions or concerns about the project. Almost each person who was in favor wrote a sermon on how great RiverView was followed by a softball lob of a question to the MPCA panel to tie it in at the end. Are we playing to emotion or are we going to look at facts, data and research? Data such as wind erosion, water, manure, nitrate runoff, all aspects that impact the environment and those around it.

With that said, I will say Riverview does a nice job keeping their facilities clean and well maintained.

I've debated writing a comment on this as I feel it puts a target on my back being a smaller farm in the area who cannot compete on such a scale as Riverview. We all know smaller farms are going away as years go by. But when that happens you don't have a community anymore. The more people and farms you have in a community the better it thrives. Not less when the "competition" is driven out. As a fifth generation farmer I want to pass this legacy and way of life down to my children. I just hope the resources, (land and water) are here for them and their kids. But with large a scale operation like Riverview it's hard to compete and be optimistic.

I'd suggest there needs to be an EIS done on this project. Something of this scale needs to have every component looked at. Whether it passes or not. There needs to be a standard or precedent for such large projects.

Thank you for you time
Ethan Bruer

Brett Boyum **Letter 1313**

The current EAW process is sufficient and thorough. There is no need for further EIS review.

Kody Livengood **Letter 1314**

I have been a resident in the Morris area for 18 years. After attending the informative and factual meeting that the MPCA hosted in Morris I am in strong support of the West River Dairy Expansion. The EAW is sufficient and there is no reason for an EIS.

Josh VanDerPol **Letter 1315**

I would request that you require an EIS. These Riverview sites are not farm scale, but industrial scale. They need to regulated at the highest possible level to protect our shared environment and water resources. The amount of water pulled from the ground is very concerning for anyone on the same aquifer. The size that they are if something goes wrong with manure application or storage it would be disastrous.

Mike Odello **Letter 1316**

I implore you to require an EIS for this project. This appears to be an unprecedented size of operation in our region. We don’t know what the impacts can be or how far-reaching they may be. Bringing jobs to the area is not a bad thing at all. My concern lays more in how our groundwater and farmland will be impacted. Our agricultural output is staggering in the area. It could be tragic if that is impacted.

Thank you for your time and your concern.

Mike Odello
Morris Area Elementary Music
UMM

Kim Larson **Letter 1317 FP**

This MPCA Animal Feedlot Permit application for an increase of Animal Units (AU's) for Riverview LLP's West River Dairy, should be approved for the follow reasons:

The West River Dairy has demonstrated exemplary history (30 yrs) through the following:

#1, Strong neighbor relations-

Prior to Riverview's initial permit for West River Dairy, they made a point to address their intentions to the neighbors that were in close proximity to the proposed permit area. This discussion was personable and often took place over the neighbor's kitchen table.

#2, Impacted economy in the proposed permit area-

As demonstrated in the initial West River Dairy permit, Riverview makes a concerted effort to incorporate area contractors/suppliers for their construction expertize/materials. Once completed, it is the neighboring farmers that are impacted economically by the opportunities of supplying West River Dairy with higher returns on the diversity of forages needed to feed the animals, as well as the option to receive the natural fertility back to their fields.

#3, West River Dairy holds a "positive file" with the Minnesota Pollution Control Agency-

Riverview maintains a long standing record of working towards positive outcomes in a collaborative effort with MPCA in maintaining our area's environmental quality. The addition of the very large amounts alfalfa acreage in the five-seven mile radius of West River Dairy is an example of the very positive impacts that West River Dairy will continue to provide to the area's environment.

Thank you for the opportunity to provide this feedback,

Kim Larson

Kandiyohi County

Eric Klindt **Letter 1318 FP**

Public Comment for Riverview LLP West River Dairy

Hello I'm Eric Klindt from Campbell MN. I'm also a County Commissioner for Wilkin County.

I'm writing in support of Riverview Dairy. They came to our county in 2018 and have been nothing but great to deal with and work with. They go above and beyond what would be expected of the most state of the art Dairy's. I have seen first hand what they have done for the public and neighbors and they always have done what's right and in my opinion, I think they have done more than they should, but they have a set of ethics that are very high.

We have been waiting for another dairy that Riverview has been planning to build in our county for many years waiting for the permit from the state, I don't think it should take this long.

I'm in support of what Riverview is planning to build, and I don't think there should be any more restrictions for them to build what they already have built across the country. Look at what they have already done, take a tour, I guarantee you will be impressed.

I look forward to them building more in our county or region.

Thank you,

Eric Klindt

Thomas Claussen **Letter 1319 FP**

Riverview should be granted the permit for expansion. Riverview LLP facilities have had a positive impact on agriculture and the community. They provide another outlet for marketing our crops and we are able to utilize the manure as a great sustainable fertilizer for our growing crops. Their employees have children in our school systems and they are involved in volunteering at community and school events.

The sites that Riverview operates are among the cleanest livestock farms that you can find in the country. Having a business in our communities that is willing to invest and grow is a great opportunity that we should not ignore. Their farms have helped increase tax receipts at the local and county level that help government budgets.

Susan Frenzel **Letter 1320 FP**

We are living with global warming which is rapidly making weather events more extreme and more frequent. There will be an increasing number of extreme storm events. We're seeing them already, year round. It is no longer possible to swim in most MN waterways due to blue-green algae caused by feces runoff from MN land. It just takes a few flooding events per year to spread feces into waterways.

How will they keep the water table around the 19,000 cow feedlot free of nitrogen from manure? How will they keep the air clean and fresh for the neighbors? How will they dispose of the manure on an ongoing daily basis that won't burden the county with fecal waste? Can they disperse it beyond the county? Right now more than 5 tons of animal waste is generated for every man, woman and child in the U.S. per Dr. Michael Greger. You don't want that concentrated in one county.

And even though the MPCA's only concern is pollution, the State has a strong health interest in avoiding another pandemic. This is a comment site for the MPCA, so you'll see it as irrelevant that epidemiologists like Dr. Michael Osterholm believe we're due within a few years for a pandemic that could originate in industrial feedlots that could kill 1/3 of mankind. Pathogens swiftly become maximally lethal where animals are packed together skin to skin, according to nutritionist (originally epidemiologist) Dr. Michael Greger. Globally, corporations have copied our megafarm model, so the next pandemic is just as likely to originate overseas as in Minnesota. Wet markets, uber feedlots, endanger mankind to save a few pennies.

And cow milk isn't even that healthy, due to the pregnancy hormones in it. A huge Swedish nutritional study of tens of thousands of people over decades found that people who drank a cup of milk per day die at a higher rate than those who don't.

I've studied comparative religion 63 years, and it turns out 2 Messengers from God arose in Iran 200 years ago, Muslims, who fulfill the prophecies/requirements of the 9 major world religions for the ones who will bring world peace at "the end of time". The prophecies about pandemics that will kill 1/3 of mankind are yet to be fulfilled, even if Christ returned in Iran as a Muslim 200 years ago. MPCA can't prevent the raging pandemics that are coming, but at least you could stop them from starting here.

We're making dairy as cheap as possible through inhumane crowding of animals. Maybe we can make the burying of our children in the next, about 7 times worse than covid, pandemic cheaper by digging mass graves and omitting coffins and just tossing people in.

Until then, and it could be within 5 years, don't let corporations destroy the sweet, fresh air, and clear, clean water for the people who live in this county, because you know there will be extreme weather events thanks to fossil fuel use, and there will be escapes from the well-intentioned lined storage structures, or you wouldn't have inserted the escape clause about extreme weather events in your statement above.

Sue Frenzel **Letter 1321 FP**

1321 FP

But what I have to say shouldn't be muzzled because it applies to the dangers to Minnesotans of animal/poultry factory farm practices. And the MPCA is the government bureau with the oversight to regulate animal and poultry factory farms. So take my comment. And act to protect Minnesotans.

I note that the head of the MPCA when the MN public was just discovering 3M's PFAs pollution came to the MPCA from 3M. So perhaps the current leadership at MPCA is from the corporate animal factory farm sector, and they're in a position to try to hide from us the dangers they actually pose to us.

NYT best-selling nutrition expert, Dr. Michael Greger, started out as an epidemiologist. One of the world's leading epidemiologists is Dr. Michael Osterholm, at the University of Minnesota.

In 2020, Dr. Michael Greger published, "How to Survive a Pandemic," about the next pandemic, possibly as soon as within 5 years, that might be a bird flu pandemic, that he predicted would probably be generated in an animal/poultry factory farm. He went in detail in the book about why viruses and bacteria become extremely lethal when generated in a system where the hosts are packed body to body, in dark, airless enclosures. Yes, dark, airless enclosures, packed body to body, causes weight to be put on fastest for poultry, cutting meat production time in half.

Greger told us calves are weaned on cow blood, which is protein nutritious, rather than on milk, which farmers can sell. Cattle (beef and dairy?) are fed chicken manure, which doesn't affect the taste of the meat of the cattle butchered for meat. Cattle are fed highly subsidized corn and soybeans which causes e coli to be produced in their stomachs, and the e coli endangers the consumer when he eats hamburger.

The reason this is relevant to MPCA, pollution control, is that you are the government bureau that can green light or limit animal and poultry factory farms.

Stink, smell and shit aren't the only things you should be paying attention to. The likelihood of animal factory farms generating pandemics is in your wheelhouse, too, within your responsibity.

Dr. Michael Osterholm published a book in December 2025 called, "The Big One," about the upcoming pandemic which might take 1/3 of mankind's lives.

I couldn't bear to finish Dr. Greger's book or to get past a few chapters of Dr. Osterholm's book.

I advise you to talk with Dr. Michael Greger and to Dr. Michael Osterholm about how animal/poultry factory farms can be modified to minimize their generation of pandemics.

As a living being, I ask you to make the factory farms you regulate act humanely toward their living products.

Thomas Probst **Letter 1322 FP**

As a consumer of dairy products, I urge the MPCA to deny this permit. The proposed size of the project is simply too large, and will have profoundly negative effects on the area's groundwater, air and neighbors, not to mention the animals themselves.

As such, approving it would make a mockery of the stated mission of the MPCA.

Thank you.

Amy Kephart **Letter 1323 FP**

This is a terrible proposal. We need more small farms, family farms, not factory farms. As a consumer of dairy products, I urge the MPCA to deny this permit. The proposed size of the project is simply too large,

and will have profoundly negative effects on the area's groundwater, air and neighbors, not to mention the animals themselves.

As such, approving it would make a mockery of the stated mission of the MPCA.

Thank you

Rita Holland **Letter 1324 FP**

I had no idea that this type of factory farm is being proposed in the Morris MN area until I read the StarTribune article in the April 2nd edition.

Having grown up on a farm in northeast South Dakota, I know the damage that these "farms" inflict on our communities. There are so many environmental, ethical, and economic downsides to this proposal. 26000 cows in a confined area is simply wrong. This is about big ag damaging the prospects for smaller farms all across Minnesota. It's wrong on so many levels.

This needs to be reviewed at the very least, with the possible damage scrutinized at every turn. Stopping it is the very best outcome, and is your responsibility as the MPCA. Please live up to your name.

Heather Rykhus **Letter 1325 FP**

I would not be in favor of granting this proposal. I think the potential for negative impact on the environment is huge with disposal of concentrated manure. I also think the cows deserve more of a real life then being held in a factory farm.

Julia Pearson **Letter 1326 FP**

I am asking that there be a full environmental impact statement for this project. The size/number of cattle will inhibit and hurt smaller, family-owned operations. The water for environment and humans would be impacted. Plus - can't we put risk to people above the profit motive?

Laura Klein

To whom it may concern;

I am writing on behalf of many neighbors, friends, and family that live in Minnesota that strongly oppose factory farming in our state, particularly the expansion of factory farming. I oppose this because it has been shown to have a negative effect on the environment, water, soil, air etc. It puts neighboring Minnesotans at risk for disease and health issues related to the environmental impact. It also is not ethical to put animals in cramped, unsanitary conditions such as those in factory farms. Theres is also a global oversupply of milk right now. Out state doesn't need more factory farm milk, we need small organic farms that care deeply about the land, relationship with the ecosystem, neighbors, animals, and role in the community.

Heidi Hardner **Letter 1328 FP**

I'm concerned about the overall scale and that it's unprecedented in the state. How can we be confident about how the consequences of failure scale with volume at these new levels?

I'm also concerned about the words "except in an extreme storm event" and how different that will look with these huge volumes compared to what might happen at a small family farm.

I see that some commenters are very confident this particular business will do everything right. The permit can say certain things are required but why should we feel confident the operators can really meet those requirements when it's so far beyond what's be done so far? Weren't we just hearing about some insane number of chickens left to starve when a large chicken outfit went out of business? They were probably fulfilling some permitting requirements right up until they weren't around to be held accountable anymore. Their business was probably an economic boon to some farmers and communities right up until it wasn't.

I see that the chickens (1.6 million!) were not actually all in one location. Well, thank goodness for that! This kind of concentration means all the local environmental consequence eggs are in one basket. I see the words "permanent stockpiles" above there too... uh, there was nothing permanent about the chicken business and presumably these will be the largest ever permanent manure stockpiles in the state?

My understanding is the decision being made currently is just about whether there should be a more detailed environmental assessment.

Yes, yes there should. What would merit such a review if not a huge increase in scale like this? If this kind of increased concentration is actually a good idea, it will pass such a review.

Thomas Kalahar **Letter 1329 FP**

This is insane. As a former feedlot inspector for Renville Co. I find this a major threat to our water supply both surface and groundwater. Our surface and groundwater in the agricultural regions of the state are already badly degraded by the Ag industry. To add yet another threat is MPCA not doing their job to protect the citizens. All the water in this region is already degraded/impaired due to lack of regulation and influence by big Ag. For once due your job and defend the citizens and not corporate agricultural.

Kevin Van Winkle **Letter 1330 FP**

I am writing this letter from the perspective of a fellow Dairyman and grain farmer.

#1. Nutrient management, River View Farms are built with some of the highest standards i have seen, covered storage ponds to help mitigate odor, when you drive onto a Riverview Farm you do not get the odor of a livestock facility the only thing I smell is fresh feed being delivered to animals. They also catch all rain water from the facilities which is stored in fresh water ponds. All nutrients are injected into the soil which is used for crop production and replaces the use of commercial fertilizers that are spread on top of the ground. Also crops grown with animal waste tend to yield more per acre than commercial fertilizer which is better for the environment. So less commercial fertilizer means less petroleum used to produce that fertilizer which is better for the environment.

#2. Creating a market for locally grown feed. The corn and soybeans that are grown on Farmland in the United States are used for feed for animals or made into ethanol to replace gasoline as far as soybeans go they are crushed and processed into vegetable oil for humans and the byproduct is soybean meal which is used for animal feed. We do not use all the corn and soybeans that are produced in the United States, about 15 percent of the corn crop is exported and around 45 percent of the soybean crop is exported. So if a livestock facility is built in any given part of the US it creates a new local market for grain. This creates competition for that grain which leads to a better price for neighbors in the area that produce the grain. Also it means less transportation of grain around the world which uses less petroleum which is better for the environment.

#3. Food security for the US. As for most Americans we do not ever think about running out of food because US farmers are great at producing it efficiently and with environmental stewardship as a high priority. We as farmers love our animals and we love our land, we have a personal connection to them and will do anything to take care of them. I know River View has the same philosophy when it comes to their animals and the environment. Dairy Farming is very hard work and requires a special set of work ethics and commitment, with that said there is fewer and fewer of us out here willing to do this. So with fewer of us willing to tackle this type of lifestyle it requires a somewhat larger scale farm to supply high quality food for our fellow Americans. So if we do not allow some new facilities to be built to replace the dairy farmers that are retiring around the US we will eventually have a problem with food security.

Bob Lefebvre **Letter 1331 FP**

I have had the fortune of working with dairy farmers across the Country. The people at Riverview from top to bottom are the best in the industry. Care, integrity and innovation are words that describe the culture. Every person is passionate about producing wholesome food by caring for the animals, environment and their fellow peers. The same care and innovation goes into the planning of their facilities. And, they have an impeccable decades long track record.

The design and planning of the expansion exceeds standards. We also know from experience that the building and operation of the facility will also exceed standards. I urge MPCA to move forward expeditiously.

Francis Casey **Letter 1332 FP**

I've toured Riverview facilities and am amazed at the strong environmental stewardship from water protection to nutrient management plans. I'm a soil scientist and know the value of manure and the organic matter it adds to soil to build nutrition and soil health. The animals are very well treated, extremely healthy and happy. There are veterinarians and highly skilled workers taking care of the animals all day. The facilities were also very clean and in the heart of the operations there was no bad odors. This business cares for the community and as industry and revenue to the state.

Darlene Aragon **Letter 1333 FP**

Confining close to 19,000 cows in one site is incomprehensible to me. Sprawling industrial facilities like this jeopardize our natural resources, animal welfare, and public health. Facilities like this keep their cows pregnant for six years and then slaughter them when they've become no longer useful. This is just another way of destroying small dairies that lovingly take care of their animals and strive to proudly produce dairy products that are healthy and unique.

Ferolyn Angell **Letter 1334 FP**

Please conduct the essential Environmental Impact Study that clearly should be done for a project of this magnitude. As a citizen of Stevens County I am deeply concerned about potential further depletion and pollution of our regional water resources. I oppose the project in general and believe that the EIS will show that this is not a sustainable or viable project.

As the wife of someone who has worked in the farm fields of this region I find it alarming to see the degradation of the land here by family corporations that put profit before environmental protection. We already know that Riverview Dairy's operations in other parts of the country have caused serious problems for people in the communities that surround their dairies. Please require Riverview to prove that they can protect the people and environment of this region.

Thank you for doing the job of protecting the residents of Minnesota!

Marv Post **Letter 1335 FP**

Dear Commissioner Kessler and MPCA Staff,

My name is Marv Post. I am a dairy farmer from Volga, South Dakota, and former chairman of the South Dakota Dairy Producers Association. I am writing to express my strong support for Riverview LLP's proposed expansion of West River Dairy near Morris, Minnesota.

I have spent my career working alongside producers, processors, and policymakers to grow South Dakota's dairy industry, and I have seen firsthand what a growing dairy herd can do for a state, for an industry, and for the rural communities that depend on both.

What a Growing Dairy Herd Has Meant for South Dakota In the early 2000s, South Dakota had fewer than 80,000 dairy cows. Today that number is more than two and a half times that. That growth happened because producers, processors, and state leaders recognized that a growing milk supply is the engine that drives the entire dairy economy.

Every time we expand processing, we expand milk production. With our ability to grow corn, alfalfa, and all the raw ingredients needed to feed a dairy cow, the Upper Midwest is simply a very efficient place to do that.

In South Dakota, it's safe to say that our dairy infrastructure has come back. We would not have the infrastructure that supports dairy farmers of all sizes without a thriving dairy industry. We would not have processors who look at our state and say, "If we build it, they will fill it." That infrastructure — processing plants, trucking routes, feed suppliers, veterinary clinics, equipment dealers — exists because there is a growing, reliable milk supply to sustain it. And when that supply grows, every dairy farmer benefits, whether they milk 100 cows or 10,000.

The benefits extend to crop farmers too. Dairy manure has proven to be a valuable source of locally sourced fertilizer, and we have seen the basis for cash grain improve in recent years because of the demand for feed crops from dairy farms. Milk processing capacity has grown dramatically up and down South Dakota's I-29 corridor. These represent real plants, real jobs, and real communities that are stronger because of a growing dairy industry.

North Dakota's Dairy Industry

Next door, North Dakota experienced the opposite outcome. As cow numbers declined and milk supply dwindled, processors lost the volume they needed to justify their operations. When processors close, remaining farmers lose their market, which accelerates the decline further. Today, North Dakota is home to just 17 dairy farms with approximately 8,000 cows. I would not wish that outcome on any state.

The Upper Midwest is positioned to be a global leader in the dairy industry, but only if we encourage and allow our farmers to grow.

Environmental Stewardship Goes Hand in Hand with Growth

This project has undergone a detailed analysis through Minnesota's EAW process. The expansion will operate under an Individual NPDES Feedlot Permit requiring zero discharge of pollutants to waters of the state. Responsible manure management is well known to improve soil health and reduce the potential for nutrient runoff from croplands. The water supply appears to be robust and more than sufficient to sustainably supply the West River Dairy expansion. It appears that the applicant and the agency have considered and addressed all of the relevant areas of environmental protection.

Furthermore, the development of the Individual Permit demonstrates real leadership on the part of both the MPCA and Riverview, and a commitment by all parties involved to pursue growth in a responsible manner.

Conclusion

We want our neighbors in Minnesota to share in the optimism and success that a growing dairy industry has brought to South Dakota. The West River Dairy expansion is exactly the kind of project that makes that possible.

I respectfully urge the MPCA to follow the facts and the science in its review of this project. The environmental review is thorough. The regulatory safeguards are robust. This project deserves to move forward so that our industry can continue to grow in the Upper Midwest — responsibly, sustainably, and in a way that benefits producers, processors, communities, and the environment alike.

Thank you for the opportunity to provide this comment.

Marv Post

Kristine Hamm **Letter 1336 FP**

This feedlot proposal is too large. I have no faith any corporate farm will abide by current regulations nor will they care for the animals. This type of gigantic farm is bad for family farms and our environment. Our history of family farms is too important to ignore and allow big business have their way.

Robert Finley **Letter 1337 FP**

A project of this nature absolutely requires an Environmental Impact Statement (EIS). Not requiring one makes a mockery of all that has been done previously to protect our land and water resources from degradation.

Jeanne Norrgard **Letter 1338 FP**

I am writing to you at the MPCA as a concerned Minnesotan, born and raised in the land of 10,000 lakes, and proud of our environmental advocacy. I love our state and I am certain that you do, too. My public comment to all of you at the MPCA is this: As the Minnesota POLLUTION CONTROL Agency, caps added by me, if you don't outright deny Riverview LLP's expansion proposal, which I truly believe is the only environmentally responsible decision to make for our state, then the only alternate and responsible environmental decision left for you to make is for you to request an Environmental Impact Statement. Please, and I know I speak for countless thousands of your fellow Minnesotans, do the job that you are all there to do. This potential dairy feedlot expansion permit request is horrific for our state in so many ways, including for our lands, our waters, our air and our public health. Requiring an EIS would require Riverview LLP to justify and to prove to you and to all Minnesotans that increasing their feedlot capacity to a maximum total of 26,397 AU, ANIMAL UNITS (read living, breathing, suffering, milk-producing cows kept in close proximity in total confinement barns) while inconceivable to me, is environmentally sound; that spreading an unimaginable volume of manure onto our lands isn't a dire contamination threat to our lands, our waters, our wildlife, our air quality, our public health; that there is no risk of inadvertent manure spills onto our lands and into our groundwater, streams and lakes; that closely confining many thousands of animals for the entirety of their lives presents no risks of illness and disease to be spread amongst them or to their caregivers; that a mass casualty event such as mass illness requiring euthanasia has been contemplated, planned for and mitigated; that the environmental disaster implied by the ominous words "except in an extreme storm event" has also been planned for and mitigated;

...and I wish I knew the other environmental risks there are that I would cite today if I knew them. Instead, I must trust that you at MPCA know what these additional environmental risks are and that, with an EIS, you will hold Riverview LLP accountable to the highest standards of environmental protection that our state and we Minnesotans expect and deserve. We Minnesotans and our beautiful state are worth protecting. Thank you.

Shannon Nieland **Letter 1339 FP**

I hope that the MPCA recognizes Riverview's long history of doing right by the communities it's established in. Not only do they invest into communities through their support of agriculture education, community events, sports and employment, they also build operations that are sustainable. When it comes to pollution and manure seepage, I have seen no evidence of any case of water contamination at previous sites, and I would encourage the MPCA to examine their track record.

Many of the towns in West Central Minnesota are dead or dying, with little to no growth in businesses or recreation. In contrast, our community in Morris is growing and thriving—in large part due to companies like Riverview investing into it and supporting communities and families like mine.

Patricia Cole **Letter 1340 FP**

To Whom it May Concern,

I am writing to formally express my strong opposition to the proposed expansion of the Riverview dairy operation in Morris, Minnesota. As a concerned citizen who worked for over 40 years as a Registered Professional Engineer, I believe this project—which would become the largest livestock farm in state history—poses unacceptable risks to our local environment, our groundwater and the health of our community.

My primary concerns include:

Water Depletion: The facility is permitted to pump up to 226 million gallons of water per year. This massive appropriation rivals the consumption of the entire City of Morris (permitted for 300 million gallons) and threatens to deplete local groundwater and impact the Pomme de Terre River.

Nitrate Pollution: The collection and application of manure from such a massive number of animals significantly increases the risk of nitrates leaking into groundwater. Given Riverview's history of manure spills in western Minnesota, I am deeply concerned about the long-term safety of our drinking water, and the impact that will have on the cancer rates of those living in the area.

Inadequate Environmental Review: I join organizations like the Land Stewardship Project in calling for a full Environmental Impact Statement (EIS). The current Environmental Assessment Worksheet (EAW) is insufficient to address the unprecedented scale of this facility and its cumulative impacts on the region's land and water.

I urge the MPCA to deny the current permit and require a more rigorous environmental review to protect the health and resources of Stevens County residents. The impact of these large scale corporate farms and livestock enclosures on the health of our groundwater aquifers needs to be of concern to ALL Minnesotans.

Sincerely,

Patricia Cole

Jacqueline Colby **Letter 1341 FP**

Because of the environmental harm and increased animal suffering these large factory farms cause, I am adamantly against allowing these permits.

TJ Hennen **Letter 1342 FP**

I have lived with in 5 miles of the proposed expansion for most of my life. I am not concerned about Riverview as a company itself. I think that they a great asset to our community. However, I am concerned about is the true environmental impact of the proposed expansion. I believe that a full Environmental Impact Statement should be done prior to the expansion. Also, I have noticed that our water quality has gone down in past 15 years. What happens when our well goes dry? Who will pay for that?

Audrey Arner **Letter 1343 FP**

I am writing to formally request that the MPCA mandate a full Environmental Impact Statement (EIS) for the proposed West River Dairy expansion. As the largest livestock operation in Minnesota's history, the cumulative environmental risks—specifically regarding Contaminants of Emerging Concern (CECs)—far exceed the scope of the current Environmental Assessment Worksheet (EAW).

The Minnesota Department of Health (MDH) and the MPCA classify hormones as CECs. MDH data indicates that these substances already affect 90% of tested Minnesota lakes, and a U.S. Geological Survey study found the Mississippi River in Minnesota has the highest rate of "feminized" fish--male fish that develop female characteristics, such as eggs in their testes. The cause is attributed to endocrine-disrupting chemicals (EDCs) that act as estrogens, causing sexual disruption.

The scale of the West River Dairy expansion poses the following significant risks:

- Hormone Output: Pregnant and lactating cows produce large amounts of estrogen and related hormones. An 18,000-cow herd produces approximately 15 pounds of estrogen daily. Hormones are potent in very small concentrations. In addition, large dairies routinely use synthetic hormones to maximize lactation and control the cows' reproductive cycles, which further increases this biological load.

- Environmental Persistence: Estrogens in dairy wastewater are notably persistent and often fail to biodegrade under the anaerobic conditions found in manure storage lagoons.

- Public Health Implications: These hormones bioaccumulate in the food chain. Human exposure through contaminated drinking water is linked to impaired fertility, developmental malformations, and hormone-sensitive cancers.

- Private Wells: Rural residents relying on private wells are particularly vulnerable. No one monitors our wells for safety, so the full financial and health burden of testing and harm falls directly on us. Most municipal systems are incapable of filtering out these contaminants, so well owners are particularly disadvantaged by lack of regulatory oversight to keep our water safe. We deserve better. Our state prides itself on its water, pure water at that. If our water is no longer drinkable because others have profited from making it so, regulation and justice must prevail.

Having grown up along Shakopee Creek in the adjacent watershed to the proposed expansion, I have witnessed the degradation of local watersheds firsthand; the Shakopee is now a designated critical nutrient hotspot. Nearby is Dublin Dairy, one of Riverview LLP's 8000 cow dairies. Do we have CEC data for Shakopee Creek? A blueprint for protecting our water and preventing contamination may become apparent if we choose to look. Perhaps we have hardly begun to accurately assess the environmental

impact of dairies of this size, placing them ahead of CEC data collection and the safety of our drinking water.

If this expansion is green-lighted, hormones and endocrine disruptors will enter our water system at an unprecedented scale, affecting us all. Along with raising already elevated levels of nitrogen, phosphorus, and E. coli, the West River Dairy expansion represents a permanent threat to regional water security. I urge the MPCA to require a comprehensive EIS to study these cumulative impacts.

Rose and Dan Murphy — Letter 1344 FP

We have the following concerns regarding Riverview's proposed expansion

-an Environmental Impact review of industrial measures must be done

-impact of local water supply—future water supply, safety of water available, especially long term (we are aware of the issues created by Riverview in AZ)

-expansion will likely be a boost to the local economy, but consider how many small dairy farms have been/will be forced to sell out having a negative impact on the local economy

Kim Larson — Letter 1345 FP

ATTN: Charles Peterson

My name is Kim Larson and I am a farmer in Kandiyohi County, MN. My full background is not only an agricultural producer but the experience as an agricultural regulator, as well. In the early 2000's I was selected to develop, and carry out the duties as the initial Delegated Feedlot Officer for Kandiyohi County. Over the three years that I devoted to the position, I developed a unique perspective of both sides of the process, and I believe that experience benefits my assessments in this discussion.

In preparation, I committed myself to reviewing the entire Environmental Assessment Worksheet (EAW). Beyond the 72 pages posted online, are the 26 categories of Attachments totaling hundreds of pages.

Associated Agency Reviews Confirm No Significant Concerns

The State Historic Preservation Office found no properties listed on the National or State Registers and no known archaeological resources that would be affected by this project. The DNR Natural Heritage Review found no ecologically significant areas along with no State-listed endangered or threatened species on the project site. The review within the route of the water pipeline returned with *"No Further Review Required"* across all categories. In response to Agency comments from MPCA and the State Archaeologist, Riverview voluntarily removed certain manure application fields from the manure plan, demonstrating responsiveness.

Water Utilization

The EAW is explicit in backgrounding the fact that the well that will supply the West River expansion originally received permitting for 452 million gal/yr. Riverview is reducing that initially granted appropriation to 226 million gal/yr. It would be hard to ignore the extraordinary effort that Riverview put forth in being creative enough through this expansion to significantly reduce the total permitted water appropriation capacity in this aquifer. If a 452 million gal/yr appropriation was initially found to be sustainable in this location, an appropriation of half that amount cannot logically constitute a significant environmental impact, especially considering the on-going regulatory measures incorporated into the DNR's permit.

DNR Comment Letter (March 17, 2026) Inaccuracies

It is puzzling to understand the DNR's statements that the EAW had not considered any impacts on the Pomme de Terre River. EAW Section 12.B.3 (pg 34-37) specifically discusses impacts to the Pomme de Terre, including detailed pumping restrictions based on stream flows (Tables 16 & 17). Included under Section 12.B.g.4 includes multiple points addressing pumping restrictions applied to avoid indirect impacts. The letter further indicates that groundwater is *"limited"* in the project area. However, this would be in conflict with their previously detailed review of the aquifer in this location where the DNR found water usage, twice the currently proposed appropriation, to be fully sustainable.

EAW is Comprehensive and Complete

This EAW is far beyond a typical livestock EAW review. As I pointed out initially, there are literally several hundred pages of technical analysis covering ground water, surface water, air quality, natural resources, and cumulative effects. Under Minnesota law, an EAW is intended to be a *"brief document"* designed to set out *"basic facts"* about a project. I believe that it is self-evident that this EAW published by MPCA, greatly exceeds that standard in advance, as it appears that the MPCA has already produced an EIS level of information with respect to this project.

Furthermore, under Minnesota law (Minn. R. 4410), an EIS is required only when there is potential for *"significant environmental effects".* It does not reference any prerequisite for an EIS determined on the basis of an animal unit (A.U.) threshold. As Minnesota AgriGrowth noted in their comments, the purpose of an EIS is to assess environmental impacts, not create public policy on the appropriate size of dairy farms in Minnesota, as that should obviously remain with the representation of elected legislators.

Finally, under Minnesota Rules, an RGU must consider *"the extent to which the environmental effects are subject to mitigation by the ongoing public regulatory authority."* Within this EAW, multiple layers of ongoing regulatory …. DNR water appropriation permitting, MPCA individual feedlot permitting, and NPDES zero-discharge requirements …. all serve as specific, targeted mitigation measures that Minnesota courts have recognized as sufficient enough to validate the findings for potential environmental effects.

Consideration of an Individual Permit

The development of an individual permit for this project further shows that the Agency has all of the protections and tools in place to ensure this project is fully protective of the environment, and that no potential for significant environmental effects could be found. As a former County Feedlot Officer, I recall the numerous times in our County's permitting process that when a specific item of concern was identified, we did our best to prevent *"regulation overreach"* by targeting those items with *focused mitigating conditions* that would provide the *specific protection* that is sought.

Conclusion

Upon thorough review, I would encourage a decision by the agencies involved to approve the West River Dairy expansion. With the rigorous safeguards for environmental security well documented in this EAW, the request for an EIS would be considered overreach. And finally, it would be regrettably unfortunate if the process of environmental review for livestock proposals morphed into …. *an act of prohibition.*

Respectfully,
Kim Larson

Diane Baum

I am against this for reasons including concern about groundwater contamination, as well as sustainability of the Pomme de Terre aquifer to provide watwer to not only this endeavor, but to continue to have water available for other businesses, residents and farmers in our community. Based on the performance of the Sulphur Valley, AZ operation, I have serious doubts about the trustworthiness of this project here in Morris.

Kevin Meixel

We here at Meixel Farms, and Meixel Truck sales support the west river dairy expansion. They always have practical logistics planning, and clear milestones to help scale production smoothly. We enjoy doing business with them because of their commitment to quality, transparency, and collaboration—the kind of partnership that values open communication and mutual success. Their expansion creates many local jobs, from farming and harvesting to processing, packaging, and distribution, which strengthens the local economy and builds a more resilient community. By investing in local talent and infrastructure, they not only boost employment but also foster entrepreneurial spirit, support small businesses, and contribute to steady, inclusive growth that benefits families and neighborhoods alike.

It's important for those who oppose the dairy expansion to consider the broader implications of their stance. By resisting this growth, they may be overlooking the significant benefits it can bring to the local community and economy. The expansion is not just about increased production; it represents a vision for the future, one that fosters job creation and stimulates local businesses. Without embracing such opportunities, there is a risk of stagnation, both economically and socially. It's essential to look beyond immediate concerns and recognize that progress often requires bold steps forward. Engaging with the expansion can provide a pathway to innovation, sustainability, and a thriving community that benefits everyone in the long run.

Nancy Thorson **Letter 1348 FP**

I think allowing Riverview LLP to expand their operations in Morris would be a big mistake, knowing of their previous manure spills in the state.

Blake Criswell **Letter 1349 FP**

ATTN: Charles Peterson

My name is Blake L. Criswell, CFS, and I am the owner and consultant of GotWhey, LLC, a Minnesota registered LLC, consulting to dairy manufacturing plants across the United State and in Minnesota like Riverview. I am writing in full support of their proposed West River Dairy expansion in Stevens County.

Through my work in the dairy manufacturing industry, responsible, strong, and stable milk production is key to maintaining a high-quality supply of milk in the region.

The proposed expansion represents a meaningful economic benefit to the region. It will generate demand for local vendors, support both construction and long-term employment, and contribute to the vitality of rural communities that rely on agriculture.

From my direct experience, Riverview is a professional and reliable partner that contributes positively to the communities where it operates. Their presence strengthens the local economy and supports a broad network of agricultural and service-related businesses.

Projects like this are essential to maintaining a competitive and sustainable rural economy in Minnesota. Continued investment in agriculture ensures that local businesses can continue to provide jobs, services, and economic stability close to home.

No EIS is needed as the state environmental review process is rigorous and very sufficient. I respectfully encourage your support and approval of this important project.

Sincerely,
Blake L. Criswell, CFS
Shorewood, MN

Lynnette Kayser **Letter 1350 FP**

The environmental impact to the community will be devastating. Air and water quality will be affected in a very bad way!

Mitchell DeBuhr **Letter 1351 FP**

Living close to the dairy, I am concerned about the water input this dairy will require. I am also concerned with water quality. I have a family and livestock living off well water. Loosing that resource would be catastrophic. I have concern regarding local traffic and wildlife impact. Many times trucks running to the dairy disregard traffic laws and don't share road space safely when we are working in ditches. Lastly with the need for land and the ability for them to pay large prices, it affects local families being able to afford land as prices are driven up.

Tracey Eliason **Letter 1352 FP**

I can't believe this is being considered. The increase to this facility will cause well water contamination that down the road could in put local water tables and personal wells at stake. The other side of this debate is manure storage. This may sound good but it all has to be disposed of and that much manure will have to impact the water supply in the future. What will be the options then? I grew up in Hancock 9 miles from Morris and some days the smell was bad, I can only imagine by increasing the dairy to this extremely large size will make living in the surrounding area unbearable.

Brady Koehl **Letter 1353 FP**

Dear Community Members,

First off, I wanted to introduce myself. My name is Brady Koehl, & I have now lived in Stevens County for 32 years & counting (with a brief hiatus to attend college in Marshall, MN). I am a resident of Hancock, MN – I am a father, husband, farmer, accountant, city council member, & community volunteer. This isn’t really my cup of tea to make a public comment, but the more I thought about it, the more I thought there were some things I needed to say on this matter.

I do want to start off by saying, I understand & acknowledge the environmental concerns. As farmers in greater MN, this is something that we are conscious of every day. As everything scales, & the size of the equipment, livestock herds, & everything in between grows larger – this can seem very intimidating & can be perceived in a negative way by many. I am here to tell you we are hyper aware of this. However, I take comfort in knowing that an operation like Riverview has already done more than their share of due diligence on a project of this nature, including the necessary research in the background, permitting, etc. to make sure that this is done in the correct way. This type of operation already operates under strict regulatory oversight, & the systems are in place to meet MPCA requirements.

Further, I wanted to dig a little bit into some of the specific concerns. I have heard comments about the size of the dairy, & the emissions from the animals., etc. Keep in mind – this dairy will be large, but half of the dairy is already in existence! Yes, the dairy that will be operating after the expansion will be the largest in MN. But it is not all new construction – half is already operating smoothly today. On top of this, I would encourage you to explore some of the positive things that Riverview is already doing to offset many of these concerns. From ensuring the operation is energy efficient as possible – this is something that is done in the name of cost – to capturing the methane gas & re-purposing this in an environmentally friendly way, the operation is only helped by reducing these things.

I have also heard concerns with the manure that will be a biproduct of this increased herd. As a farmer that has used this bi-product, the misconceptions of this being a negative for the land & water are often mis-cast. Regardless of the form, farmers need fertilizer as part of their crop plan. The larger percentage that comes from organic matter sources, the more positive of an impact there is the potential for on the land. Also – as a farmer that is in the business of organic production, this manure becomes a necessity & helps drive the growth in that area of our business.

Finally, the water. This is a concern, & I know this is something that has been seen around the nation. However, in a highly rural area like Stevens County, the water issues that are often tied to overuse or strain on local water systems in more densely populated or drought-prone areas have not come to light. As we become more efficient with our water use, more intentional with our practices, & are conscious of the numerous issues with water around the nation, & around the world – this is being considered, measured, studied, & remedied wherever possible. On top of this – Riverview has a plan in place to re-use much of the water that is in the end-product that is a key cog of this expansion plan. I would encourage you to ask their representatives about this, as it is a very cool concept.

Finally, to anyone reading this that is not familiar with Stevens County, I would encourage you to come & pay us a visit. This area is special & is uniquely positioned to pursue this kind of opportunity. We tend to join as one in support of projects of this nature, & we recognize the many benefits that Riverview has brought to our community, our families, & to the many individuals that are involved with the economics of the area. On top of that, on the drive west past the existing west-river dairy, I am reminded of the beauty of the countryside that we are lucky enough to live in. When you drive past, yes, you will note the operation. But I would encourage you to reach out & ask for a tour & explore more before you develop an opinion. If you would like to talk about this – feel free to reach out to me – I am happy to discuss both sides of the arguments for & against this expansion. I am always open to more information.

Sincerely,
Brady Koehl

Steve Olinger **Letter 1354 FP**

This expansion is very troubling. concerns with the amount of manure, amount of water. Very concerning what this expansion will have on the sites dairy farmers who already have been under extreme pressure. Why cn be done with the manure, can it really be used for fertilizer without increasing Athene risk of nitrate pollution?

Douglas Lande **Letter 1355 FP**

Requiring a full environmental impact assessment in this case should be required. A large CFO that degrades soil and water and air should not be allowed in a State that says it stands for a healthy environment.

Francisco Guadarrama Capitaine **Letter 1356 FP**

I support West River Dairy Expansion and Feedlot Permit

No EIS required. Have a great day

Thank you!

Rebeca Ramos **Letter 1357 FP**

I support West river expansión, no EIS required

Diane Baum **Letter 1358 FP**

This is a revised comment from my previous one. I attended the MPCA meeting April 28. After seeing so many in the crowd who are a part of Riverview dairy, I have come to the conclusion that the dairy itself stacked the meeting and dominated the discussion, to the detriment of those who also wanted to participate- space was limited and many were turned away. I still have very valid concerns regarding the proximity of this operation to the Pomme de Terre River, which is already stressed out due to farm fertilizer runoff. I am concerned about the contaminants already in that river that, although they meet EPA guidelines, as was mentioned last night, those guidelines are out of date in regards to the current health concerns this river poses. The potential for an accidental leak at Riverview makes this a very tenous situation. To make a leap from 8,000 to 20,000 animals without regard for potential hazards is foolish at best. Riverview has already experienced a manure leak at its Murdock facility, why is this risk being allowed here in Morris? I urge you all to fully consider the repercussions of this and make a decision that will benefit ALL residents of Stevens County and Morris, not JUST those who will benfit financially. Thank you.

Todd Charnetzki **Letter 1359 FP**

Having worked with Riverview LLC for many years, I would support this project. The are wonderful stewards of the land, cows, and environment they control. They actually help their neighbors do better through example and open communication.

Samantha Kramer **Letter 1360 FP**

I fully support the project and appreciate the work Riverview has done to ensure the safety of the community and stewardship of the animals.

Jerry Seibel **Letter 1361 FP**

I attended the recent public hearing on the West River expansion permit and would like to submit the following public comment. At the outset, I should note that many of the comments at the hearing, although perhaps scripted, seem to accurately reflect the fact that Riverview is very generous and appears to be a good neighbor. While these are laudable attributes, it appears that they may not be very relevant to the environmental review that your permitting process contemplates.

It is my understanding that the proposed expansion would result in an approximate 200% increase in animal units at this one location. I may not be reading it correctly but it appears that there might be an allowable increase of up to 26000 animal units, which would be over a 300% increase. In either case, it would result in the largest feedlot in one location in Minnesota if not the country. It appears as if the proposal, from an environmental standpoint, is going where no man has gone before.

The thrust of my comment is that there needs to be a focus on the cumulative environmental effect of this proposal upon the entire geographic area. Although the proposed expansion is the largest feedlot in the geographic area, it is not the only feedlot in the area. Whether these are dairy, pig or cattle feedlots, they all have a potential environmental effect upon the air, soil and water. Additionally, these feedlots are not the only users of these resources. Area farms not associated with West River also apply either manure or fertilizer to virtually every field that is farmed in the area. Although this is anecdotal and not necessarily accurate, it appears that irrigation of cropland in the area has increased, placing a further strain on water resources. It seems incongruous that the cumulative effect of the largest feedlot expansion in the state, if not the nation, should not be more fully explored through utilization of an EIS or conditions on the permit approval mandating graduated expansion with follow up mandatory environmental assessment of the whole area.

I am fully aware that additional delay could have some economic impact upon Riverview. So would an environmental disaster. From the presentation at the public meeting, I am aware that the proposed application includes certain provisions designed to mitigate negative environmental impacts of the feedlot. I am not knowledgeable as to whether the mitigation efforts are state of the art, but I am assuming they probably are. However, state of the art does not equate to absolute certainty. Mistakes or failures still happen. Once a negative impact happens, you cannot put the toothpaste back in the tube or the poop back in the cows. I can't believe that the policy of the state of Minnesota is going to permit the largest feedlot expansion in a single geographic area without more fully exploring the already existing environmental condition of the area. I am not sufficiently knowledgeable whether it is more environmentally friendly to concentrate large feedlots in a single geographic area or to spread them out through the state, but I assume that MPCA staff has such requisite knowledge.

Thank you for the opportunity to comment and for your thoughtful approach to this issue.

Dick Cheney **Letter 1362 FP**

I fully support the expansion of this facility. I believe in a free market, and it is my belief that this riverview expansion satisfies the requirements of the State pursuant to the clean water act. I believe what river view has done and is doing to advance industry within the State is advantageous to the citizens of the State. I have toured river view facilities in the past. I have never observed anything that would have struck me as deprecative to the resources of the State. I believe in a robust economy, and one of the land uses that fuels that economy in the state of Minnesota is production of commodities like livestock and grains. Minnesota is very protective of its resources via its regulatory environment, any entity that can navigate those regulations is in it for the long haul. I believe river view has and will continue to stand the test of time. I also believe the agents of the state have provided and will continue to provide the most accurate information regarding expansions like river view. The public is stupid and reacts on emotions. I don't believe a company willing to put up funding will jeopardize that by overlooking issues the agents of the state have. I love you.

Lilia Mendoza Acosta **Letter 1363 FP**

I think it is an opportunity for more jobs.

It has given my family and me hope; thanks to the employment it provides, we are able to give our children a better future. Like any job, it is demanding and time-consuming, but it is our duty as parents to build a good future for our children.

Michael Smith **Letter 1364 FP**

The proposed Riverview expansion in Stevens County poses significant environmental and economic harm to the county, it's water supply, it's environment, it's economy and it's citizens. The water sources and related ecosystems are fragile already, and this unprecedented expansion threatens the short and long term sustainability of these systems. In addition, small family farms and county residents face economic threats from mega corporate farm operations, negative impacts on water, land and other environmental and economic resources critical to remaining in business and loss of future viability. At the very least, we urge MPCA to require an extensive Environmental Impact Study prior to any consideration of an expansion request of this magnitude.

Hunter Bohn **Letter 1365 FP**

As a resident of Morris and a person who loves to utilize outdoor public spaces for recreation activities, I am concerned by the amount of waste this change would produce. The nutrient load from manure on the lands surrounding the facility will likely be disproportionate, with closer locations receiving more inputs than locations farther away, as a function of transport cost and equipment abilities. I am concerned that public water bodies will be impacted, affecting fishing, boating, and wildlife observation opportunities in the vicinity. Many of the lakes in the area are already known to be relatively shallow, and green algae (cyanobacteria) blooms are often encountered in the summer months. These blooms are detrimental to fish health and to the health of birds that use these lakes for breeding and migration sites. The health of humans and pets can also be affected by these blooms, if severe enough. Adding more nutrients to the landscape with increased manure supplies under this proposal will negatively affect the surrounding waterways and the wildlife and people that utilize them for survival and leisure.

Federico Cano Nepauseno **Letter 1366 FP**

Thank you for this opportunity to share my opinion, I support completely this project, I think it's a great time to start a new job for different people.

David Hauge **Letter 1367 FP**

The dairy x beef calf has exploded. They will be big enuf to supply blackshirt feed yards with significant numbers of these calves. Commercial market that they are taking advantage of and ultimately hurts the rancher and beef producers.

David Israels-Swenson **Letter 1368 FP**

I would really like to see a full environmental impact assessment on this plan. I appreciate the growth and diversity Riverview has brought to the Morris community but am concerned that an operation of this size may negatively impact our local water quality and believe that caution is merited.

Gary Dukes **Letter 1369 FP**

Subject: Formal Opposition to the West River Dairy Expansion (Riverview LLP) and Petition for a Full Environmental Impact Statement (EIS)

I am writing to formally express my strong opposition to the proposed expansion of the West River Dairy facility near Morris, MN. This project, which seeks to increase capacity from 7,855 cows to 18,855 (totaling over 26,000 animal units), is unprecedented in the state of Minnesota. Given the massive scale and the history of this specific site, I urge the MPCA to deny the permit or, at minimum, require a comprehensive Environmental Impact Statement (EIS) before further consideration.

1. Water Quality and Watershed Impairment

The facility is located within the Pomme de Terre River watershed, a system already listed as impaired for bacteria and nutrients.

• Waste Volume: The expansion would result in approximately 250 million gallons of liquid manure storage. The risk of catastrophic failure or "allowable" seepage from clay-lined basins poses a permanent threat to local groundwater and the Pomme de Terre River, which flows into the Minnesota River.

• Application Risks: In a region prone to heavy spring rains, the saturation of phosphorus and nitrogen in the soil leads to inevitable runoff, worsening toxic algal blooms downstream.

2. Massive Groundwater Depletion

Riverview LLP has requested to pump 226 million gallons of water annually. Concentrated pumping of this magnitude threatens the domestic wells of neighbors and the long-term viability of the aquifer for the broader community.

3. Public Health

The emission of hydrogen sulfide, ammonia, and nitrous oxide (N2O) from a facility of nearly 19,000 cows is a significant public health hazard.

• Respiratory Impact: Neighbors are subjected to particulate matter and noxious gases that are linked to asthma, bronchitis, and other chronic respiratory conditions.

• Climate Change: N2O is a greenhouse gas roughly 300 times more potent than CO2. Permitting a single facility to emit such a concentrated volume contradicts Minnesota's stated climate goals.

4. Social Justice and Economic Disparity

The expansion of "Mega-Dairies" is not a neutral economic development; it is a driver of rural inequity.

• Consolidation vs. Community: By flooding the market with industrial-scale milk production, Riverview systematically pushes small- and mid-sized family farms out of business. This destroys the fabric of rural Stevens County, replacing independent business owners with a transient, low-wage labor model.

• Environmental Justice: Industrial CAFOs are consistently sited in rural areas where residents have fewer resources to fight protracted legal battles. This places the "negative externalities" of corporate profit—pollution, road damage, and smell directly onto the shoulders of local citizens while the profits are exported.

• Lack of Oversight: In 2014, the MPCA Citizens' Board ordered an EIS for a much smaller version of this project. Since that board was abolished, the lack of a mandatory EIS for a project three times larger represents a failure of democratic oversight and a victory for corporate lobbying over public interest.

Conclusion

The MPCA must recognize that the "West River Dairy Expansion" is not a standard agricultural project; it is an industrial experiment at a scale Minnesota has never seen. I urge that a full EIS be conducted to study the cumulative impacts on our water, our climate, and our rural social structure.

Sincerely,
Gary Dukes

David Jungst **Letter 1370 FP**

"This permit requires the facility to be designed, operated, and maintained to prevent discharge to waters, EXCEPT IN AN EXTREME STORM EVENT."

I have lived in this part of Minnesota for over 50 years. I know West central Minnesota gets extreme weather.

This facility, the Riverview LLP West River Dairy, will see extreme storm events and it will cause damages to the surrounding area. Just last summer in two days, July 27 and 28, the City of Morris got over seven inches of rainfall. When the storage ponds at this site over top, the storm water and manure will flow downstream to the east where just across the road is a large county tile drain pipe and draw that flows to the Pomme de Terre River less than four miles away.

Conversely, I have seen drought when the Pomme de Terre River completely stopped flowing and was reduced to puddles in its channel just downstream from this facility where the well is to be located to supply it.

An EAW (Environmental Assessment Worksheet) is insufficient for this site. The magnitude of this animal confinement operation, which will be the largest in the state of Minnesota, warrants that an Environmental Impact Statement should be required before a permit for this feedlot expansion can be issued.

Dave Vipond, H2 Land Stewards **Letter 1371 FP**

Dear MPCA Decision Makers,

On behalf of H2 Land Stewards, we respectfully submit this letter in support of the Riverview Farms West River Dairy Expansion.

H2 Land Stewards is a grassroots, nonprofit organization representing several hundred Minnesota residents, primarily landowners and agricultural producers. Our organization was established to educate members about their landowner rights and to protect those rights from erosion through unnecessary, inconsistent, or disproportionate government action. We strongly support regulatory processes that are fair, predictable, and grounded in sound science.

Riverview Farms has demonstrated a longstanding commitment to responsible land stewardship and proactive conservation practices. Environmental safeguards are already built into their existing systems and operational plans. These are established, proven practices that function as intended to protect soil and water resources. Riverview Farms has shown initiative by planning ahead and investing in systems that reduce risk and improve environmental protection, rather than relying on reactive measures.

While the proposed West River Dairy will be larger in scale than some other operations, it is not different in kind. The expansion does not introduce new practices, new risks, or fundamentally different impacts. The same conservation measures, best management practices, and regulatory oversight that apply to comparable dairy operations are already incorporated here. Size alone does not warrant treating this project differently from others that operate under the same established framework.

For these reasons, H2 Land Stewards does not believe a full Environmental Impact Statement (EIS) is justified. Existing environmental safeguards are already embedded in the system, and additional environmental review requirements would not meaningfully increase environmental protection. Instead, requiring an EIS based solely on scale risks creating regulatory inconsistency and setting a precedent that discourages responsible growth by landowners who are already operating within compliance.

Riverview Farms has approached this expansion transparently and in good faith, engaging with the permitting process and demonstrating a cooperative posture toward regulatory oversight. This proactive approach should be recognized and encouraged. Regulatory decisions should remain proportional to demonstrated environmental risk and based on actual operational differences—not assumptions tied to size alone.

H2 Land Stewards urges the MPCA to give the West River Dairy Expansion full and fair consideration and to recognize that responsible agricultural growth, supported by existing conservation systems, does not warrant unnecessary regulatory escalation. Thank you for your time and consideration.

Respectfully,
H2 Land Stewards

Gary Wertish, Minnesota Farmers Union — Letter 1372 FP

Dear Commissioner Kessler:

On behalf of Minnesota Famers Union (MFU) and responding to a vote from our Full Board, I write to request that you require an Economic Impact Statement (EIS) for Riverview LLP's permit to expand their West River Dairy in Stevens County. This scale of expansion is unprecedented in our state and we believe strongly that Minnesotans deserve a fuller examination of its environmental, economic, and social consequences.

MFU is a grassroots organization that has represented Minnesota's family farmers, ranchers and rural communities since 1918. Our membership and our Full Board include family dairies, including many who are struggling to stay in business while they shoulder prices below their cost of production. This challenge is not new with the number of Minnesota dairies declining by nearly half in the last decade, dropping from 3,470 in 2016[1] to just 1,600 farms today.[2] And while farms are declining, cows are

[1] Minnesota Dairy Industry Profile. Minnesota Department of Agriculture, 2016. https://www.mda.state.mn.us/sites/default/files/inline-files/dairyindprofile.pdf.
[2] Dairy Industry Consolidates. Dairy Star, 2026. https://dairystar.com/stories/dairy-industry-consolidates,30685?.

consolidating into fewer operations. This one company is permitted for nearly a third of Minnesota's dairy herd.[3]

This consolidation has consequences not just for those families, but also for rural schools, small businesses, veterinary practices, churches, and other institutions that make life possible in rural Minnesota. According to an analysis from 2020, the average Minnesota dairy generates $1.6 million in economic activity.[4] A more complete analysis of the economic and social consequences of this project is needed.

Beyond that, we believe there are important environmental concerns that an EIS would more fully address. Our members understand that livestock projects draw water year-round and we want to ensure that we are stewarding this shared resource and safeguarding sufficient supply for neighboring farms. We also understand that consolidating livestock increases the potential consequences of a natural disaster, zoonotic disease, or human disease affecting workers.

To close, this project is different than those that are approved through our existing processes. From my memory of that time, when we established our current regulatory framework for feedlots in the late 1990s no-one contemplated a nearly 19,000 cow dairy operation. That is more than 60 times the average size herd in our state.

This project is different and deserves distinct consideration and the full public comment afforded by an EIS. If you have any questions, please contact our Government Relations Director, Stu Lourey, at stu@mfu.org or (320) 232-2047. Thank you for considering the needs and perspectives of Minnesota's farm families.

Sincerely,
Gary Wertish
President, Minnesota Farmers Union

Eric Lindberg, Minnesota Center for Environmental Advocacy — Letter 1373 FP

Minnesota Center for Environmental Advocacy's

Comments on the Draft NPDES Permit for the West River Dairy Expansion

May 7, 2026

INTRODUCTION

Minnesota Center for Environmental Advocacy (MCEA) respectfully submits the following comments on the draft National Pollutant Discharge Elimination System (NPDES) permit for Riverview, LLP's (Riverview) proposed expansion of the West River Dairy in Stevens County. MCEA is a nonprofit with expertise in environmental law and policy. For more than 50 years, MCEA has worked in courts, at the legislature, and with public agencies to enact, strengthen, and enforce smart environmental laws.

Riverview is proposing a feedlot expansion that would accommodate an additional 11,000 cows, together with a new 1,304-foot by 692-foot cross-ventilated freestall barn, a new milking parlor, three new liquid manure storage areas, a temporary manure tank, and a solid manure storage building sized for up to a year of storage. Riverview reports that its proposed expansion would produce more than

[3] Proposed dairy in Morris would become Minnesota's largest feedlot. Star Tribune, March 16, 2026. https://www.startribune.com/proposed-dairy-in-morris-would-become-minnesotas-largest-feedlot/601596774.
[4] The Role of Dairy Farmers In Minnesota's Rural Economy. University of Minnesota Extension, June 9, 2020. https://conservancy.umn.edu/server/api/core/bitstreams/8b58793b-073e-4c43-81fd-96e0ffe1d172/content.

72,000 tons of carbon dioxide equivalent emissions (CO_2e) per year, as estimated in the corresponding Environmental Assessment Worksheet (EAW).[1]

As drafted, the Minnesota Pollution Control Agency (MPCA) cannot issue the permit for this expansion, because the permit does not comply with Minnesota law. Subpart 4 of Minnesota Rule 7020.0505 requires Riverview to submit an Air Emission Plan describing "methods and practices that will be used to minimize air emissions resulting from animal feedlot or manure storage area operations." Methane, nitrous oxide, and carbon dioxide are "air emissions resulting from animal feedlot or manure storage area operations." Yet Riverview's Air Emission Plan contains no greenhouse gas (GHG) emission controls, no monitoring or reporting obligation directed at GHG emissions, and no incorporation of GHG emissions mitigation proposals discussed in the project's EAW. The application and draft permit fail to address GHG emissions at all.

Because the draft permit incorporates Riverview's application materials—including the deficient Air Emission Plan—as enforceable terms, the noticed permit itself fails to comply with the plain language of Minnesota Rule 7020.0505, subpart 4(B)(1). Before issuing a permit, Riverview must submit an Air Emission Plan that satisfies the requirements of the rule by describing methods and practices that will be used to minimize GHG emissions, and MPCA must re-notice the draft permit for public comment.[2]

I. PROPOSED PROJECT AND REGULATORY BACKGROUND

A. Riverview's Project

Riverview, the fifth largest dairy farming company in the world and the second largest in the United States,[3] has operated the West River Dairy in Stevens County since 2004. West River Dairy houses over 7,800 head of dairy cows and is one of the largest feedlot projects in the state of Minnesota.[4] Riverview now seeks an 11,000-head expansion. The Expansion Project would house thousands of additional cows in a crossventilated, total-confinement, free-stall barn. Clay-lined basins with impermeable covers would be used to collect and store manure and wastewater. The resulting 18,855-head feedlot would be the largest in state history.[5]

The expansion would significantly increase West River Dairy's GHG emissions. New GHG emission sources include direct emissions from livestock digestion and manure management, alongside indirect emissions from feed production, energy use, and other life-cycle emissions associated with animal agriculture. The EAW reports that Riverview's Expansion Project would add at least 72,000 tons of CO_2e

per year to the existing West River Dairy facility.[6] That estimate excludes GHG emissions associated with upstream feed production, downstream processing, and other life-cycle sources.[7] Even at this lower bound, 72,000 tons of CO_2e represents one-sixth of the entire statewide emission reductions achieved by Minnesota's Priority Climate Action Plan cost-share and grants program.[8] Offsetting the reported lifetime GHG emissions from Riverview's Expansion Project would require a decade's worth of carbon sequestration by 32 million trees.[9] [10]

B. Regulatory Background

Minnesota's largest feedlots are subject to state and federal laws that require feedlot owners to obtain permits designed to protect human health and the environment from feedlots' adverse effects. NPDES permits are required for any concentrated animal feeding operation that discharges to waters of the United States.[11] Alongside federal NPDES permits, MPCA issues State Disposal System (SDS) permits that "address program issues which the federal regulations do not cover under an NPDES permit program."[12] If a project would house 1,000 or more animal units, a feedlot applicant may apply for an independent SDS permit, or it may apply for a federal NPDES permit that incorporates Minnesota's SDS permit requirements.

Riverview's Expansion Project would add 15,400 animal units to the existing West River Dairy, far exceeding the state SDS permit threshold, and the company has elected to apply for a federal NPDES permit that includes Minnesota's SDS permit restrictions.[13]

C. Air Emission Plans

Many conditions and restrictions in Riverview's draft NPDES permit are required by Chapter 7020 of the Minnesota Rules (the "Feedlot Rules"). MPCA established the Feedlot Rules in 1971 under the agency's authority to "adopt, amend, and rescind rules and standards having the force of law . . . [for] the prevention, abatement, or control of water, air, and land pollution."[14] The Feedlot Rules address a wide range of environmental impacts. When MPCA proposed changes to the Feedlot Rules in 1999, the agency noted in its Statement of Need and Reasonableness (SONAR) for the rule changes that it "intends to use the SDS permit as it has under the current program to address program issues which the federal

[14] Minn. Stat. § 116.07, subds. 2(a), 4.

regulations do not cover under an NPDES permit."[15] MPCA went on to specify that such issues include feedlot emissions: "The Agency has included provisions for addressing air quality issues in SDS and interim permits under the current program. In addition, the proposed rule requires owners having 1,000 animal units or more to develop and implement an Air Emission Plan (part 7020.0505, subp. 4, item B, subitem 1.)"[16]

The Feedlot Rules contain specific provisions dealing with odor complaints and reference a specific standard for the toxic pollutant hydrogen sulfide. In addition, Minnesota Rule 7020.0505, subpart 4, requires a more general plan to address "air emissions." It states, in relevant part:

> B. In addition to the requirements of item A, a permit application for an animal feedlot capable of holding 1,000 animal units or more or a manure storage area capable of holding the manure produced by 1,000 animal units or more must contain:
>
> (1) an air emission plan that includes:
>
> (a) methods and practices that will be used to minimize air emissions resulting from animal feedlot or manure storage area operations including manure storage area start-up practices, loading, and manure removal; . . .

In its 1999 SONAR, MPCA explained this new planning requirement by noting that "the need clearly exists to establish standards for the design, construction, and operations of animal feedlots and manure storage areas such that the negative impacts of gases generated at these facilities are minimized, particularly past the property line of a facility."[17] The agency supported that conclusion by highlighting "a very comprehensive and recent review of the effects of animal agriculture on air quality" from the University of Minnesota, together with a 1999 report from the Office of the Legislative Auditor.[18]

Both reports described feedlots' contribution to global warming. The Generic EIS explained that:

> [E]missions from animal production systems include an extensive list (168) of gaseous compounds. The three most researched gases are hydrogen sulfide, ammonia, and methane. Hydrogen sulfide poses the largest safety risk in confined spaces (indoor) and is of concern in the ambient air (outdoor) mainly because of the Minnesota state ambient air standard for this gas. It seems that swine facilities and manure storage units produce the largest concentrations and emissions of hydrogen sulfide. Ammonia is also produced by animal production systems, especially poultry facilities. Indoor concentrations of ammonia pose some health concerns inside buildings but emissions may contribute to ecological damage to the environment. **Finally, methane emissions, which are more of a problem with cattle than other animal species, contribute to global warming concerns**.[19]

---

QUALITY BD., Generic Environmental Impact Statement on Animal Agriculture: A Summary of the Literature Related to Air Quality and Odor (H) (Sept. 1999), https://www.lrl.mn.gov/docs/pre2003/other/990616/vol2.pdf [Exhibit 133] [hereinafter Generic EIS Volume 2]; OFFICE OF THE LEGIS. AUDITOR, Animal Feedlot Regulation: A Program Evaluation Report (Jan. 1999), https://www.auditor.leg.state.mn.us/ped/1999/fedlt99.htm [Exhibit 134] [hereinafter *Office of the Legis.Auditor*].

[19] *Generic EIS Volume 2, supra* note 18, at H-41 (emphasis added).

Regarding GHGs in particular, the Generic EIS highlighted it "is well known that methane emissions from animal agriculture, or any other source, contribute to global warming."[20] The report discussed scholarship identifying "global emission rates of methane at 540 x 109 kilograms per year with 5% of the emissions resulting from the anaerobic decomposition of animal manure and another 15% coming from the gut of ruminant animals."[21] Based on its survey of the literature, the Generic EIS stressed that "methane and other greenhouse gas emissions from animal agriculture have an impact far beyond the immediate location of their source."[22]

The Office of the Legislative Auditor released its own 1999 report that, among other concerns, flagged environmental risks posed by GHG emissions:

> The main purpose of feedlot regulation is to protect Minnesota citizens from pollution caused by animal manure. Manure is a valuable resource that can provide beneficial nutrients to the soil and thus help in the production of crops. However—if improperly stored, transported, or disposed—manure may pollute lakes and streams or drinking water sources. Manure can also produce unpleasant and annoying odors and emissions, possibly affecting the health of nearby residents. In addition, **emissions from manure may contribute to acid rain and greenhouse gas effects** . . .
>
> In addition to concerns about water pollution, feedlots with high concentrations of manure may produce unpleasant odors and emit gases such as hydrogen sulfide, ammonia, and various volatile organic compounds that may affect air quality. With the trend to larger feedlots and bigger manure storage facilities, complaints about feedlot odors and concerns about air quality have increased in recent years. Other environmental concerns raised include the health and nuisance impacts of flies, the effects of endotoxins in the air at certain facilities, **and the contribution of manure emissions to greenhouse gas effects and acid rain.**[23]

II. RIVERVIEW'S AIR EMISSION PLAN OMITS GHG EMISSIONS

Riverview's NPDES permit application included an Air Emission Plan describing steps Riverview could take to mitigate odors from the Expansion Project.[24] The Plan lists two sources at the industrial dairy that are "likely to generate significant odors": animal holding areas and manure storage areas. Riverview identifies several steps for mitigating odors from these sources. For animal holding areas, the Air Emission Plan includes proposals to "disperse/mix air with tree plantings," "promptly clean up any spilled feed," and eight other odor mitigation proposals. For manure storage areas, the Plan includes an additional fourteen odor mitigation measures, including proposals to "cover the solid manure stockpile" and to "notify neighbors of manure application and avoid holidays."[25] After listing twenty-four odor mitigation proposals, the plan states that if "continued odor complaints are validated, at least one of the practices identified . . . will be implemented pursuant to MPCA request/approval."[26] The Air Emission Plan does not commit the company to employing any of the identified odor mitigation measures.

[24] *Riverview's EAW for West River Dairy*, *supra* note 1, at 446, 455–56 (Attachment 22, Minnesota NPDES Individual Feedlot Permit Application at 1, 9).
[25] *Id.* at 455–56.
[26] *Id.* at 456.

In addition to strategies for odor control, the Air Emission Plan contains measures targeting hydrogen sulfide. The plan notes that MPCA may "request a report" from Riverview in the event that ambient air quality monitoring "indicates an exceedance of the Hydrogen Sulfide Standard."[27] In this report, Riverview would demonstrate that it is deploying at least one of ten hydrogen sulfide emissions controls, including, for example, "chemical additions," "straw cover," or "composting," to manage hydrogen sulfide emissions.[28]

Despite the Feedlot Rules' broadly-worded directive to describe "methods and practices that will be used to minimize air emissions," Riverview's Air Emission Plan fails to identify any other pollutants that will be emitted from its operation or methods to minimize them. In particular, Riverview's Air Emission Plan contains no analysis of GHG emissions. The plan offers no quantitative or qualitative limit on GHG emissions, no measures specifically targeting GHG mitigation, and no monitoring, recordkeeping, or reporting obligation directed at GHG emissions. The Air Emission Plan does not incorporate, attach, or reference the GHG mitigation measures identified in this project's EAW. As a result, neither Riverview's permit application, nor the resulting draft permit, contains any discussion of "methods and practices that will be used to minimize air emissions" associated with the facility's projected 72,210 tons of annual CO2e emissions.[29]

III. THE PERMIT CANNOT BE ISSUED BECAUSE IT FAILS TO ADDRESS GHG EMISSIONS AS REQUIRED BY MINNESOTA LAW

Subpart 4 of Minnesota Rule 7020.0505 requires Riverview to submit an Air Emission Plan setting out "methods and practices that *will be used* to minimize air emissions" from its operations as part of its permit application. (Emphasis added.) The plain meaning of "air emissions" includes GHGs. Riverview's Air Emission Plan nevertheless omits GHG emissions entirely. Without a plan addressing methods and practices Riverview will use to minimize its GHG emissions, MPCA cannot issue Riverview's NPDES permit.

A. The Feedlot Rules Plainly Require Feedlot Applicants To Describe Methods And Practices For Minimizing GHG Emissions

An applicant for a feedlot or manure storage area capable of holding 1,000 animal units or more must submit an Air Emission Plan. That Plan must include "methods and practices that will be used to minimize air emissions resulting from animal feedlot or manure storage area operations including manure storage area start-up practices, loading, and manure removal."[30]

GHGs are air emissions that must be discussed in Riverview's Air Emission Plan. State law defines GHGs as "emissions."[31] Methane, nitrous oxide, and other GHG emissions are emissions "resulting from animal feedlot or manure storage area operations."[32] Regulatory language is construed according to words' "common and approved usage," and when "clear and free from all ambiguity, the letter of the law shall not be disregarded under the pretext of pursuing the spirit."[33] The rule's plain meaning includes GHG

[27] *Id*.

emissions produced by Riverview's feedlot project. Despite this broad and unqualified language, Riverview's Air Emission Plan fails to address GHG emissions at all.[34]

B. Several GHG Mitigation Measures Are Available For MPCA To Require In Riverview's Air Emission Plan

Riverview itself, along with commenters weighing in on the NPDES permit or the EAW, have identified several GHG mitigation measures that MPCA can make enforceable through Riverview's Air Emission Plan as required by the applicable rule. For instance, the EAW reports that Riverview will "utilize crossbred dairy cows selected for improved production efficiency relative to conventional dairy breeds," producing lower GHG emissions on a per-animal basis.[35] The EAW asserts that Riverview will minimize greenhouse gas emissions by adopting "efficient feed practices, including sourcing the majority of ingredients locally, adjusting rations to maximize production and minimize spoilage, and reducing emissions through implementation of feed additives like Rumensin," and states that manure "will be incorporated into the soil during land application by [Commercial Animal Waste Technicians], thereby reducing emissions."[36] In total, Riverview lists more than a dozen strategies in the EAW for minimizing this project's greenhouse gas emissions. These measures can easily be translated into terms in Riverview's Air Emission Plan and incorporated into the permit.

Alongside mitigation measures listed in Riverview's Draft EAW, public commenters have advocated that several important measures be added to the Final EAW. The Comments of MCEA et al. on the EAW describe additional ways for Riverview to "minimize air emissions" from its proposal, including practices related to manure management, livestock management, and even energy use and procurement. For details on these measures, please see the attached Comments of MCEA et al. at pages 18–27 and supporting exhibits. Ample GHG management strategies exist to include in a revised permit application and revised public notice.

To ensure Riverview's EAW mitigation measures translate to real-world reductions, MPCA must adhere to the Feedlot Rules by including an Air Emission Plan in the *permit* that specifies enforceable measures Riverview will take to minimize its air emissions, including GHG emissions. Because the draft permit incorporates Riverview's application materials as enforceable permit terms,[37] the omission of any GHG mitigations from the Air Emission Plan means the draft permit itself fails to comply with the plain language of Minnesota Rule 7020.0505, subp. 4(B)(1). As noticed, the permit cannot be issued.[38]

---

[34] MPCA has undisputed authority to regulate greenhouse gas emissions from facilities within the state of Minnesota. *See* Minn. Stat. § 116.07, subd. 2(a)–(b) (authorizing rulemaking for "the prevention, abatement, or control of air pollution"); *Minn. Auto. Dealers Ass'n v. Minn. Pollution Control Agency*, No. A22-0796 (Minn. Ct. App. Jan. 30, 2023) (upholding MPCA's Clean Cars Minnesota rule and confirming that the agency's air-pollution authority encompasses greenhouse gases); *In re Denial of Contested Case Hearing Request & Modification of a Notice of Coverage Under Individual NPDES Feedlot Permit No. MN0067652*, No. A19-0207, 2019 WL 5106666 (Minn. Ct. App. Oct. 14, 2019) (holding that MPCA's refusal to analyze greenhouse gas emissions in a feedlot EAW was arbitrary and capricious); *In re Proposed Rules of the Minn. Pollution Control Agency Governing Permits for Greenhouse Gas Emissions*, OAH Docket No. 8-2200-22910-1, 2012 WL 6645129 (Minn. Off. Admin. Hearings Nov. 9, 2012) (concluding that MPCA possesses statutory authority under Minn. Stat. § 116.07 to regulate greenhouse gases as air contaminants).

[36] *Id.*

[37] Draft NPDES Permit, *supra* note 13, § 6.4 ("[T]he Permittee is authorized to construct and operate the facility according to the submitted and MPCA-approved permit application materials . . . The application materials are an enforceable part of this Permit.") (citing Minn. R. 7001.0150).

[38] In addition to being required by the feedlot rule, an Air Emission Plan that sets out mandatory GHG mitigation measures helps to satisfy the requirements of the Minnesota Environmental Policy Act. *See Comments of MCEA et al., supra note 10*; *Citizens Advocating Responsible Dev. v. Kandiyohi Cnty. Bd. of Comm'rs*, 713 N.W.2d 817, 835 (Minn. 2006) (explaining that

C. Exempting Riverview From Addressing GHG Emissions Based On MPCA's Air Emission Plan Template Would Reflect Unlawful And Unpromulgated Rulemaking

Riverview's Air Emission Plan appears to be generated from an online form made available to applicants through MPCA's website. If MPCA allows feedlot applicants to comply with Minnesota Rule 7020.0505, subp. 4(B)(1) by simply checking the "affirmed" box on the template form, the agency would be enforcing an invalid and unpromulgated rule.

Administrative rules include any "agency statement of general applicability and future effect" adopted to implement or make specific the law the agency administers.[39] If a state agency wishes to create an administrative rule, it must engage in a rulemaking process that includes notice published in the State Register, a statement of need and reasonableness, opportunity for written and oral public comment, and frequently independent review by an administrative law judge.[40] State agencies are prohibited from enforcing a "policy, guideline, bulletin, criterion, manual, standard, or similar pronouncement" as though it were a duly adopted rule.[41] To separate lawful guidance documents from unpromulgated rules, Minnesota courts examine whether agency documents offer an "interpretation of a rule [that] corresponds with its plain meaning."[42]

If MPCA's template form is used to demonstrate compliance with Minnesota Rule 7020.0505, subp. 4(B)(1), the agency would be enforcing an unpromulgated rule. First, the form contradicts the Feedlot Rules' plain meaning by wrongly restricting the Rules' scope. Subpart 4 of Minnesota Rule 7020.0505 requires an Air Emission Plan that addresses "emissions resulting from animal feedlot or manure storage area operations." Those emissions include GHGs. By interpreting the rule to omit GHG emissions, contrary to the rule's plain text, MPCA's form falls outside the bounds of lawful interpretation.

Second, MPCA's form fails to describe "methods and practices that *will be used* to minimize air emissions." (emphasis added). Despite the rule's mandatory language, MPCA's form rests on hypotheticals. *If* continued odor complaints are validated, then the template states "at least one of the practices identified above will be implemented," and *if* ambient air quality monitoring "indicates an exceedance of the Hydrogen Sulfide Standard," the owner may be required to submit a second, separate air emissions report offering "documentation that one of the following [strategies] will control the emissions."[43] Absent complaints or exceedances, the template form does not require feedlot applicants to commit to *any* air emission reduction strategies. This approach is inconsistent with the Feedlot Rules' directive to describe emission reduction measures that "will be used."

D. Including GHG Emissions In Feedlot Air Emission Plans Is Consistent With Minnesota's Climate Commitments And The Minnesota Environmental Rights Act

Failing to address GHG emissions in a feedlot permit proposed by one of the largest industrial dairy producers in the world, for what would become the largest dairy operation in the State, is inconsistent with Minnesota's ambitious climate commitments. The Minnesota Legislature has set climate targets to reduce GHG emissions across every sector of the economy. Beginning with the Next Generation Energy Act in 2007, and continuing through the Next Generation Climate Act of 2023, the Legislature has targeted a fifty-percent reduction relative to 2005 by 2030 and net zero by 2050, and it has directed

---

mitigation measures must be "specific, targeted, and . . . certain"). Unless made enforceable requirements of the permit, the measures identified in Riverview's EAW are merely vague promises of good intent. *See id.*

[39] Minn. Stat. § 14.02, subd. 4.

[40] *See* Minn. Stat. §§ 14.05, 14.131, 14.14, 14.22, 14.50.

[41] Minn. Stat. § 14.381, subd. 1.

[42] *Cable Commc'ns Bd. v. Nor-W. Cable Commc'ns P'ship*, 356 N.W.2d 658, 667 (Minn. 1984).

[43] *Riverview's EAW for West River Dairy, supra* note 1, at 455–56.

every state agency, including MPCA, to contribute to achieving these targets.[44] The Legislature confirmed that the goal is "to reduce statewide greenhouse gas emissions across *all sectors* producing greenhouse gas emissions."[45] Animal agriculture is not exempt.

Despite these requirements, methane emissions from the agricultural sector have *increased* approximately fifteen percent since 2005, emissions from livestock digestion have *increased* approximately three percent over the same period, and total GHG emissions from the agricultural sector are rising even as statewide GHG emissions have fallen.[46] Agriculture now accounts for roughly a quarter of Minnesota's net GHG emissions, and animal agriculture is the single largest source of methane in Minnesota.[47] To align with Minnesota's climate targets, MPCA must enforce the Feedlot Rules by requiring feedlot owners to plan for GHG emission reductions from their agribusiness projects, including Riverview's unprecedentedly large expansion proposal.

Enforcing the Air Emission Plan requirement would also align with the Minnesota Environmental Rights Act (MERA). MERA, one of Minnesota's bedrock environmental laws, was passed in 1971 "to create and maintain within the state conditions under which human beings and nature can exist in productive harmony in order that present and future generations may enjoy clean air and water, productive land, and other natural resources with which this state has been endowed."[48] MERA allows Minnesota residents to bring civil actions "against any person, for the protection of the air, water, land, or other natural resources located within the state, whether publicly or privately owned, from pollution, impairment, or destruction."[49] Minnesota residents may also challenge "any environmental quality standard, limitation, rule, order, license, stipulation agreement, or permit [as] inadequate to protect the air, water, land, or other natural resources located within the state from pollution, impairment, or destruction."[50]

Given the scale of the climate crisis, and the need to reduce GHG emissions from the agricultural sector, requiring emission reduction efforts from one of the country's largest dairy operators is fully consistent with MERA's protective purpose. Unmitigated GHG emissions from the state's largest industrial feedlot would adversely affect the environment.[51] The Feedlot Rules contain no other GHG regulatory mechanism beyond Minnesota Rule 7020.0505's planning requirement. Allowing Riverview to submit an Air Emission Plan that omits GHGs, a crucial source of "air emissions resulting from animal feedlot or manure storage area operation," would risk the pollution, impairment, or destruction of Minnesota's natural resources.

CONCLUSION

For the above reasons, MPCA cannot issue the draft NPDES permit as noticed. MPCA should require Riverview to submit a revised Air Emission Plan that identifies enforceable methods and practices to minimize greenhouse gas emissions resulting from the West River Dairy Expansion Project, incorporate those measures into a revised draft permit, and re-notice the revised permit for public comment.

Travis Moser **Letter 1374 FP**

Dear Commissioner Kessler and Commissioner Petersen:

We are residents of western Minnesota, eastern North Dakota, and eastern South Dakota, representing generations of farmers, business owners, and communities writing to share our strong support for Riverview's proposed West River Dairy expansion and to offer our perspective as you consider the project's path forward.

Many of us have spent our lives working this land, growing crops, raising livestock and building our livelihood here. We understand firsthand the importance of protecting our natural resources while also sustaining the farms, families, and local economies that depend on them. That balance matters deeply to us, and it is why we support this project.

Riverview is not new to our communities. They have a long track record of operating with care for the land, respect for animals, and a genuine commitment to the people and rural communities where they live and work. We have seen their approach up close: investing in environmental stewardship, partnering with local farmers, and contributing to the long-term vitality of the region.

The proposed West River Dairy expansion has undergone extensive and rigorous review. The Environmental Assessment Worksheet (EAW) and feedlot permit application together include nearly 900 pages of detailed technical analysis, developed over more than three years in coordination with state agencies. The project is subject to oversight from multiple agencies, including the MPCA, DNR, and MDH, ensuring a comprehensive evaluation of groundwater, surface water, air quality, and natural resources.

In addition, the farm will operate under an individual NPDES feedlot permit – one of the most stringent and site-specific permits in Minnesota – and includes enhanced environmental protections that go beyond baseline requirements. Riverview has also taken proactive steps to reduce impacts, including voluntarily cutting permitted groundwater use in half and incorporating stormwater capture and reuse into the project design.

Based on what we know and what has been studied, we believe the current environmental review process is thorough, science-based, and appropriate for this project. An Environmental Impact Statement (EIS) should be reserved for situations where the evidence clearly demonstrates it is necessary. In this case, we are confident the existing process provides a full and careful evaluation.

For our communities, this project is also about the future, supporting family farms, creating economic opportunities, and strengthening our rural areas for generations to come. Riverview's model of working with neighboring farmers and investing locally reflects the kind of agriculture we want to see continue and grow.

We appreciate the seriousness of your roles and the responsibility you carry in reviewing projects like this. We respectfully encourage you to rely on the extensive environmental review already underway and the strong record of stewardship demonstrated by Riverview.

Thank you for your time and consideration.

Sincerely,

Ronald Visser **Letter 1375 FP**

Ronald Visser

Go on a tour! Riverview does them on every dairy. This is the best way to fully understand the dairy operation.

What you will see is:

A great cow environment-the barns are designed with cow comfort as top priority. The cows are calm when milking. They have access to feed, water, and a bed all day.

A great employee culture-the team is professional, hardworking and loves the cows.

A clean site-the farm is well organized, kept clean and well maintained.

A great manure plan-the manure lagoons are covered to control odor and to keep precipitation and manure separate; the lagoons have plenty of storage capacity-14 months. You might see manure injected into the soil after harvesting in the fall.

No rodents-the clean facility along with a pest control program keeps rodents in check.

Very few flies-the clean facility, constant air flow in the barn and a fly control program limit the flies.

My parents built a new 60 cow tie-stall barn in 1973 when I was 3 years old. I've been told that our county had 175 dairy farms at the time. 7 milk processors competed for our milk. Today, none of those farms have dairy cows. The entire dairy infrastructure (processing, veterinarians, nutritionists, consultants, ag lenders-dairy, equipment dealers/repairs, etc.) is gone. I have watched a similar transition in the far north of Minnesota, all of North Dakota and Black Hill area in South Dakota. Very few dairy farms remain in these areas, and the infrastructure is far away or gone. Milk processing left drove most of this.

I have spent my entire life in the dairy industry. I have witnessed the transition from tie-stall barns to larger free-stall barns in the Midwest. Most of the traditional cow regions in the Midwest and Northeast are now a blend of both. This trend will continue as small tie-stall barns get replaced with larger free-stall barns. The dairy infrastructure here is good.

The dairy industry has had regions in Idaho, Texas, Indiana, South Dakota and Kansas where the dairy infrastructure took off or is taking off. The harsh reality is that these new pockets of dairy rarely include the addition of small dairy farms. What we have currently in the United States dairy industry (and Global) are traditional cow regions, areas that are losing and areas that are gaining.

Riverview plays a huge role in maintaining a healthy dairy infrastructure in Minnesota. The dairy industry in Minnesota is stronger because of Riverview. Making it more difficult, or impossible, for Riverview, or any other dairy operation, to obtain permits to operate in Minnesota will result in the movement of dairy infrastructure and the dairy industry somewhere else. Making it less difficult for Riverview, or any other dairy operation, to obtain permits to operate in Minnesota will result in the movement of dairy infrastructure and the dairy industry into Minnesota.

The dairy industry is no different than any other industry as it relates to the environment. We have become better stewards of the land through knowledge and regulations. You can still find people or businesses that have complete disregard for the environment. The next level for me is those that are willing to follow the rules. Most farmers that I know are above these levels as they do their best to be efficient and follow practices that are positive for the environment. The next level for me is doing things to improve the environment that add cost to their business. The ultimate level is where you can find Riverview. The environmental impact is considered in every decision that they make, often resulting in additional costs and reduced efficiency.

I would like to see the dairy industry grow in my home state of Minnesota. I live a mile from a Riverview site. I breathe the air and drink the water from my well. Yes, I appreciate the protections in place for our environment. The rules need to be in place and verified for the first two levels mentioned in the previous paragraph. We don't need additional regulations for those like Riverview at the ultimate level. We do need to explore ways to make it easier (or an option) to grow for those "good farmers" at level 3

or 4 above. I don't see that right now in Minnesota. I do see our neighboring states provide this opportunity.

Riverview plays a huge role in supporting other agriculture infrastructure and other agricultural industries in Minnesota as well. The farmers next to the dairy benefit in many ways: manure as fertilizer for improved soil health, additional cropping options with corn silage and alfalfa haylage, and use of machinery and labor during forage harvest and manure application. This reaches further with the use of by-products from corn and soybean processing as food sources for dairy cows.

The additional cows proposed as part of this expansion are not introducing anything new or untested. Riverview has extensive experience managing operations of this size safely and responsibly. The current Environmental Assessment Worksheet (EAW) process is doing exactly what it is intended to do—evaluating potential impacts and ensuring environmental protections are in place. Based on the proven track record of Riverview and the safeguards provided through the EAW process; this expansion does not warrant a full Environmental Impact Statement (EIS). The existing environmental review process already provides adequate protection for Minnesota's natural resources while allowing responsible agricultural operations to move forward. Riverview Farms has shown that agricultural growth and strong environmental stewardship can go hand in hand. I respectfully encourage the MPCA to consider their outstanding environmental record and support the proposed West River Dairy expansion. Thank you for your time and consideration, and for the important work you do to protect Minnesota's environment.

Josh VanDerPol **Letter 1376 FP**

I would request that you require an EIS. These Riverview sites are not farm scale, but industrial scale. They need to regulated at the highest possible level to protect our shared environment and water resources. The amount of water pulled from the ground is very concerning for anyone on the same aquifer. The size that they are if something goes wrong with manure application or storage it would be disastrous.

Impacts of Waste from Concentrated Animal Feeding Operations on Water Quality

JoAnn Burkholder,[1] Bob Libra,[2] Peter Weyer,[3] Susan Heathcote,[4] Dana Kolpin,[5] Peter S. Thorne,[3] and Michael Wichman[6]

[1]North Carolina State University, Raleigh, North Carolina, USA; [2]Iowa Geological Survey, Iowa City, Iowa, USA; [3]The University of Iowa, Iowa City, Iowa, USA; [4]Iowa Environmental Council, Des Moines, Iowa, USA; [5]Toxic Substances Hydrology Program, U.S. Geological Survey, Iowa City, Iowa, USA; [6]University Hygienic Laboratory, Iowa City, Iowa, USA

Waste from agricultural livestock operations has been a long-standing concern with respect to contamination of water resources, particularly in terms of nutrient pollution. However, the recent growth of concentrated animal feeding operations (CAFOs) presents a greater risk to water quality because of both the increased volume of waste and to contaminants that may be present (e.g., antibiotics and other veterinary drugs) that may have both environmental and public health importance. Based on available data, generally accepted livestock waste management practices do not adequately or effectively protect water resources from contamination with excessive nutrients, microbial pathogens, and pharmaceuticals present in the waste. Impacts on surface water sources and wildlife have been documented in many agricultural areas in the United States. Potential impacts on human and environmental health from long-term inadvertent exposure to water contaminated with pharmaceuticals and other compounds are a growing public concern. This workgroup, which is part of the Conference on Environmental Health Impacts of Concentrated Animal Feeding Operations: Anticipating Hazards—Searching for Solutions, identified needs for rigorous ecosystem monitoring in the vicinity of CAFOs and for improved characterization of major toxicants affecting the environment and human health. Last, there is a need to promote and enforce best practices to minimize inputs of nutrients and toxicants from CAFOs into freshwater and marine ecosystems. *Key words:* **ecology, human health, poultry, swine, water contaminants, wildlife.** *Environ Health Perspect* **115:308–312 (2007). doi:10.1289/ehp.8839 available via** *http://dx.doi.org/* **[Online 14 November 2006]**

Background and Recent Developments

Concentrated animal feed operations and water quality. Animal cultivation in the United States produces 133 million tons of manure per year (on a dry weight basis) representing 13-fold more solid waste than human sanitary waste production [U.S. Environmental Protection Agency (U.S. EPA) 1998]. Since the 1950s (poultry) and the 1970s–1980s (cattle, swine), most animals are now produced for human consumption in concentrated animal feeding operations (CAFOs). In these industrialized operations, the animals are held throughout their lives at high densities in indoor stalls until they are transported to processing plants for slaughter. There is substantial documentation of major, ongoing impacts on aquatic resources from CAFOs, but many gaps in understanding remain.

Contaminants detected in waste and risk of water contamination. Contaminants from animal wastes can enter the environment through pathways such as through leakage from poorly constructed manure lagoons, or during major precipitation events resulting in either overflow of lagoons and runoff from recent applications of waste to farm fields, or atmospheric deposition followed by dry or wet fallout (Aneja 2003). The magnitude and direction of transport depend on factors such as soil properties, contaminant properties, hydraulic loading characteristics, and crop management practices (Huddleston 1996). Many contaminants are present in livestock wastes, including nutrients (Jongbloed and Lenis 1998), pathogens (Gerba and Smith 2005; Schets et al. 2005), veterinary pharmaceuticals (Boxall et al. 2003; Campagnolo et al. 2002; Meyer 2004), heavy metals [especially zinc and copper; e.g., Barker and Zublena (1995); University of Iowa and Iowa State Study Group (2002)], and naturally excreted hormones (Hanselman et al. 2003; Raman et al. 2004). Antibiotics are used extensively not only to treat or prevent microbial infection in animals (Kummerer 2004), but are also commonly used to promote more rapid growth in livestock (Cromwell 2002; Gaskins et al. 2002; Liu et al. 2005). In addition, pesticides such as dithiocarbamates are applied to sprayfields (Extension Toxicology Network 2003). Although anaerobic digestion of wastes in surface storage lagoons can effectively reduce or destroy many pathogens, substantial remaining densities of microbial pathogens in waste spills and seepage can contaminate receiving surface- and groundwaters (e.g., Burkholder et al. 1997; Mallin 2000). Pharmaceuticals can remain present as parent compounds or degradates in manure and leachates even during prolonged storage. Improper disposal of animal carcasses and abandoned livestock facilities can also contribute to water quality problems. Siting of livestock operations in areas prone to flooding or where there is a shallow water table increases the potential for environmental contamination.

The nutrient content of the wastes can be a desirable factor for land application as fertilizer for row crops, but overapplication of livestock wastes can overload soils with both macronutrients such as nitrogen (N) and phosphorous (P), and heavy metals added to feed as micronutrients (e.g., Barker and Zublena 1995). Overapplication of animal wastes or application of animal wastes to saturated soils can also cause contaminants to move into receiving waters through runoff and to leach through permeable soils to vulnerable aquifers. Importantly, this may happen even at recommended application rates. As examples, Westerman et al. (1995) found 3–6 mg nitrate (NO_3)/L in surface runoff from sprayfields that received swine effluent at recommended rates; Stone et al. (1995) measured 6–8 mg total inorganic N/L and 0.7–1.3 mg P/L in a stream adjacent to swine effluent sprayfields. Evans et al. (1984) reported 7–30 mg NO_3/L in subsurface flow draining a sprayfield for swine wastes, applied at recommended rates. Ham and DeSutter (2000) described export rates of up to 0.52 kg ammonium m^{-2} $year^{-1}$ from lagoon seepage; Huffman and Westerman (1995) reported that groundwater near swine waste lagoons averaged 143 mg inorganic N/L, and estimated export rates at 4.5 kg inorganic N/day. Thus, nutrient losses into receiving waters can be excessive relative to levels (~ 100–200 μg inorganic N or P/L)

known to support noxious algal blooms (Mallin 2000). In addition to contaminant chemical properties, soil properties and climatic conditions can affect transport of contaminants. For example, sandy, well-drained soils are most vulnerable to transport of nutrients to underlying groundwater (Mueller et al. 1995). Nutrients can also readily move through soils under wet conditions (McGechan et al. 2005).

Presence of contaminants in water sources. The presence of many contaminants from livestock waste has been documented in both surface water and groundwater supplies in agricultural areas within the United States (e.g., Campagnolo et al. 2002; Kolpin et al. 2002; Meyer 2004). Urban wastewater streams also contain these contaminants, and efforts to accurately determine sources of contamination are under way (Barnes et al. 2004; Cordy et al. 2004; Kolpin DW, unpublished data). The U.S. Geological Survey (USGS) began pilot surveillance programs for organic wastewater contaminants in 1999 and expanded that effort to a national scale over the past 5 years (Kolpin et al. 2002). Recent USGS efforts have focused specifically on water quality in agricultural locations (Kolpin DW, unpublished data). Nutrient levels have been detected in high parts per million (milligrams per liter) levels; pharmaceuticals and other compounds are generally measured in low levels (ppb [micrograms per liter]). In Europe, surveillance efforts conducted in Germany documented the presence of veterinary pharmaceuticals in water resources (Hirsch et al. 1999).

Animal wastes are also rich in organics and high in biochemical oxygen-demanding materials (BOD); for example, treated human sewage contains 20–60 mg BOD/L, raw sewage contains 300–400 mg BOD/L, and swine waste slurry contains 20,000–30,000 mg BOD/L (Webb and Archer 1994). Animal wastes also carry parasites, viruses, and bacteria as high as 1 billion/g (U.S. EPA 1998). Swine wastes contain > 100 microbial pathogens that can cause human illness and disease [see review in Burkholder et al. (1997)]. About one-third of the antibiotics used in the United States each year is routinely added to animal feed to increase growth (Mellon et al. 2001). This practice is promoting increased antibiotic resistance among the microbial populations present and, potentially, increased resistance of naturally occurring pathogens in surface waters that receive a portion of the wastes.

Contaminant impacts. Some contaminants pose risks for adverse health impacts in wildlife or humans. The effects of numerous waterborne pathogens on humans are well known, although little is known about potential impacts of such microorganisms on aquatic life. With respect to nutrients, excessive phosphorus levels can contribute to algal blooms and cyanobacterial growth in surface waters used for recreation and as sources of drinking water. Research is beginning to investigate the environmental effects, including endocrine disruption and antibiotic resistance issues (Burnison et al. 2003; Delepee et al. 2004; Fernandez et al. 2004; Halling-Sorensen et al. 2003; Sengelov et al. 2003; Soto et al. 2004; Wollenberger et al. 2000). However, knowledge is limited in several crucial areas. These areas include information on metabolites or environmental degradates of some parent compounds; the environmental persistence, fate, and transport and toxicity of metabolites or degradates (Boxall et al. 2004); the potential synergistic effects of various mixtures of contaminants on target organisms (Sumpter and Johnson 2005); and the potential transport and effects from natural and synthetic hormones (Hanselman et al. 2003; Soto et al. 2004). Further, limited monitoring has been conducted of ecosystem health in proximity to CAFOs, including monitoring the effects on habitats from lagoon spills during catastrophic flooding (Burkholder et al. 1997; Mallin et al. 1997; Mallin et al. 2000).

Ecologic and wildlife impacts. Anoxic conditions and extremely high concentrations of ammonium, total phosphorus, suspended solids, and fecal coliform bacteria throughout the water column for approximately 30 km downstream from the point of entry have been documented as impacts of waste effluent spills from CAFOs (Burkholder et al. 1997; Mallin et al. 2000). Pathogenic microorganisms such as *Clostridium perfringens* have been documented at high densities in receiving surface waters following CAFO waste spills (Burkholder et al. 1997). These degraded conditions, especially the associated hypoxia/anoxia and high ammonia, have caused major kills of freshwater fish of all species in the affected areas, from minnows and gar to largemouth bass, and estuarine fish, including striped bass and flounder (Burkholder et al. 1997). Waste effluent spills also stimulated blooms of toxic and noxious algae. In freshwaters, these blooms include toxic and noxious cyanobacteria while in estuaries, harmful haptophytes and toxic dinoflagellates arise. Most states monitor only water-column fecal coliform densities to assess whether waterways are safe for human contact. World Health Organization (WHO) guidelines for cyanobacteria in recreational water are 20,000 cyanobacterial cells/mL, which indicates low probability of adverse health effects, and 100,000 cyanobacterial cells/mL, which indicates moderate probability of adverse health effects (WHO 2003). Yet fecal bacteria and other pathogenic microorganisms typically settle out to the sediments where they can thrive at high densities for weeks to months following CAFO waste effluent spills (Burkholder et al. 1997).

The impacts from CAFO pollutant loadings to direct runoff are more substantial after such major effluent spills or when CAFOs are flooded and in direct contact with surface waters (Wing et al. 2002). Although the acute impacts are often clearly visible—dead fish floating on the water surface, or algal overgrowth and rotting biomass—the chronic, insidious, long-term impacts of commonly accepted practices of CAFO waste management on receiving aquatic ecosystems are also significant (U.S. EPA 1998). One purpose of manure storage basins is to reduce the N content of the manure through volatilization of ammonia and other N-containing molecules. Many studies have shown, for example, that high nutrient concentrations (e.g., ammonia from swine CAFOs, or ammonia oxidized to NO_3, or phosphorus from poultry CAFOs) commonly move off-site to contaminate the overlying air and/or adjacent surface and subsurface waters (Aneja et al. 2003; Evans et al. 1984; Sharpe and Harper 1997; Sharpley and Moyer 2000; Stone et al. 1995; U.S. EPA 1998; Webb and Archer 1994; Westerman et al. 1995; Zahn et al. 1997). Inorganic N forms are added to the atmosphere during spray practices, and both ammonia and phosphate can also adsorb to fine particles (dust) that can be airborne. The atmospheric depositions are noteworthy, considering that a significant proportion of the total ammonium from uncovered swine effluent lagoons and effluent spraying (an accepted practice in some states) reenters surface waters as local precipitation or through dry fallout (Aneja et al. 2003; U.S. EPA 1998, 2000). The contributed nutrient concentrations from the effluent greatly exceed the minimal levels that have been shown to promote noxious algal blooms (Mallin 2000) and depress the growth of desirable aquatic habitat species (Burkholder et al. 1992). The resulting chronically degraded conditions of nutrient overenrichment, while not as extreme as during a major waste spill, stimulate algal blooms and long-term shifts in phytoplankton community structure from desirable species (e.g., diatoms) to noxious species.

A summary of the findings from a national workshop on environmental impacts of CAFOs a decade ago stated that there was "a surprising lack of information about environmental impacts of CAFOs to adjacent lands and receiving waters" (Thu K, Donham K, unpublished data). Although the knowledge base has expanded since that time, especially regarding adverse effects of inorganic N and P overenrichment and anoxia, impacts of many CAFO pollutants on receiving aquatic ecosystems remain poorly understood. As examples, there is poor understanding of the impacts of fecal bacteria and other microbial pathogens from CAFO waste effluent contamination on

aquatic communities; impacts of antibiotic-resistant bacteria created from CAFO wastes on aquatic life; impacts of organic nutrient forms preferred by certain noxious plankton; impacts from the contributed pesticides and heavy metals; and impacts from these pollutants acting in concert, additively or synergistically. This lack of information represents a critical gap in our present ability to assess the full extent of CAFO impacts on aquatic natural resources.

Despite their widespread use, antibiotics have only recently received attention as environmental contaminants. Most antibiotics are designed to be quickly excreted from the treated organism. Thus, it is not surprising that antibiotics are commonly found in human and animal waste (Christian et al. 2003; Dietze et al. 2005; Glassmeyer et al. 2005; Meyer 2004) and in water resources affected by sources of waste (Glassmeyer et al. 2005; Kolpin et al. 2002). Although some research has been conducted on the environmental effects from antibiotics (e.g., Brain et al. 2005; Jensen et al. 2003), much is yet to be understood pertaining to long-term exposures to low levels of antibiotics (both individually and as part of complex mixtures of organic contaminants in the environment). The greatest risks appear to be related to antibiotic resistance (Khachatourians 1998; Kummerer 2004) and natural ecosystem functions such as soil microbial activity and bacterial denitrification (Costanzo et al. 2005; Thiele-Bruhn and Beck 2005).

Human health impacts. Exposure to waterborne contaminants can result from both recreational use of affected surface water and from ingestion of drinking water derived from either contaminated surface water or groundwater. High-risk populations are generally the very young, the elderly, pregnant women, and immunocompromised individuals. Recreational exposures and illnesses include accidental ingestion of contaminated water that may result in diarrhea or other gastrointestinal tract distress from waterborne pathogens, and dermal contact during swimming that may cause skin, eye, or ear infections. Drinking water exposures to pathogens could occur in vulnerable private wells; under normal circumstances community water utilities disinfect water sufficiently before distribution to customers. Cyanobacteria (blue–green algae) in surface water can produce toxins (e.g., microcystins) that are known neurotoxins and hepatotoxins. Acute and chronic health impacts from these toxins can occur from exposures to both raw water and treated water (Carmichael et al. 2001; Rao et al. 2002). Removal of cyanotoxins during drinking water treatment is a high priority for the drinking water industry (Hitzfield et al. 2000; Rapala et al. 2002). The WHO has set a provisional drinking water guideline of 1 μg microcystin-LR/L (Chorus and Bartram 1999). While there are no drinking water standards in the United States for cyanobacteria, they are on the U.S. EPA Unregulated Contaminant Monitoring Rule List 3 (U.S. EPA 2006).

Exposure to chemical contaminants can occur in both private wells and community water supplies, and may present health risks. High nitrate levels in water used in mixing infant formula have been associated with risk for methemoglobinemia (blue-baby syndrome) in infants under 6 months of age, although other health factors such as diarrhea and respiratory disease have also been implicated (Ward et al. 2005). The U.S. EPA drinking water standard of 10 mg/L NO_3–N and the WHO guideline of 11 mg/L NO_3–N were set because of concerns about methemoglobinemia. (Note: "nitrate" refers to nitrate–nitrogen). Epidemiologic studies of noncancer health outcomes and high nitrate levels in drinking water have reported an increased risk of hyperthyroidism (Seffner 1995) from long-term exposure to levels between 11–61 mg/L (Tajtakova et al. 2006). Drinking water nitrate at levels < 10 mg/L has been associated with insulin-dependent diabetes (IDDM; Kostraba et al. 1992), whereas other studies have shown an association with IDDM at nitrate levels > 15 mg/L (Parslow et al. 1997) and > 25 mg/L (van Maanen et al. 2000). Increased risks for adverse reproductive outcomes, including central nervous system malformations (Arbuckle et al. 1988) and neural tube defects (Brender et al. 2004; Croen et al. 2001), have been reported for drinking water nitrate levels < 10 mg/L.

Anecdotal reports of reproductive effects of nitrate in drinking water include a case study of spontaneous abortions in women consuming high nitrate water (19–26 mg/L) from private wells (Morbidity and Mortality Weekly Report 1996).

While amassing experimental data suggest a role for nitrate in the formation of carcinogenic *N*-nitroso compounds, clear epidemiologic findings are lacking on the possible association of nitrate in drinking water with cancer risk. Ecologic studies have reported mixed results for cancers of the stomach, bladder, and esophagus (Barrett et al. 1998; Cantor 1997; Eicholzer and Gutzwiller 1990; Morales-Suarez-Varela et al. 1993, 1995) and non-Hodgkin lymphoma (Jensen 1982; Weisenburger 1993), positive findings for cancers of the nasopharynx (Cantor 1997), prostate (Cantor 1997), uterus (Jensen 1982; Thouez et al. 1981), and brain (Barrett et al. 1998), and negative findings for ovarian cancer (Jensen 1982; Thouez et al. 1981). Positive findings have generally been for long-term exposures at > 10 mg/L nitrate. Case–control studies have reported mixed results for stomach cancer (Cuello et al. 1976; Rademacher et al. 1992; Yang et al. 1998); positive results for non-Hodgkin lymphoma at > 4 mg/L nitrate (Ward et al. 1996) and colon cancer at > 5 mg/L (De Roos et al. 2003); and negative results for cancers of the brain (Mueller et al. 2001; Steindorf et al. 1994), bladder (Ward et al. 2003), and rectum (De Roos et al. 2003), all at < 10 mg/L. Cohort studies have reported no association between nitrate in drinking water and stomach cancer (Van Loon et al. 1998); positive associations with cancers of the bladder and ovary at long-term exposures > 2.5 mg/L (Weyer et al. 2001); and inverse associations with cancers of the rectum and uterus, again at > 2.5 mg/L (Weyer et al. 2001).

Exposure to low levels of antibiotics and other pharmaceuticals in drinking water (generally at micrograms per liter or nanograms per liter) represent unintentional doses of substances generally used for medical purposes to treat active disease or prevent disease. The concern is more related to possible cumulative effects of long-term low-dose exposures than on acute health effects (Daughton and Ternes 1999). A recent study conducted in Germany found that the margin between indirect daily exposure via drinking water and daily therapeutic dose was at least three orders of magnitude, concluding that exposure to pharmaceuticals via drinking water is not a major health concern (Webb et al. 2003). It should be noted that when prescribing medications, providers ensure patients are not taking incompatible drugs, but exposure via drinking water is beyond their control.

Endocrine-disrupting compounds are chemicals that exhibit biological hormonal activity, either by mimicking natural estrogens, by canceling or blocking hormonal actions, or by altering how natural hormones and their protein receptors are made (McLachlan and Korach 1995). Although very low levels of estrogenic compounds can stimulate cell activity, the potential for human health effects, such as breast and prostate cancers, and reproductive effects from exposure to endocrine disruptors, is in debate (Weyer and Riley 2001).

Workshop Recommendations

Priority research needs.

- Ecosystems monitoring: Systematic sustained studies of ecosystem health in proximity to large CAFOs are needed, including effects of input spikes during spills or flooding events.
- Toxicologic assessment of contaminants: Identification and prioritization of contaminants are needed to identify those that are most significant to environmental and public health. Toxicity studies need to be conducted to identify and quantify contaminants

(including metabolites), and to investigate interactions (synergistic, additive, and antagonistic effects).

- Fate and transport: Studies of parent compounds and metabolites in soil and water must be conducted, and the role of sediment as a carrier and reservoir of contaminants must be evaluated.
- Surveillance programs: Programs should be instituted to assess private well water quality in high-risk areas. Biomonitoring programs should be designed and implemented to assess actual dose from environmental exposures.

Translation of science to policy.

- Wastewater and drinking water treatment: Processes for water treatment must be monitored to ensure adequate removal or inactivation of emerging contaminants.
- Pollution prevention: Best management practices should be implemented to prevent or minimize release of contaminants into the environment.
- Education: Educational materials should be continued to be developed and distributed to agricultural producers.

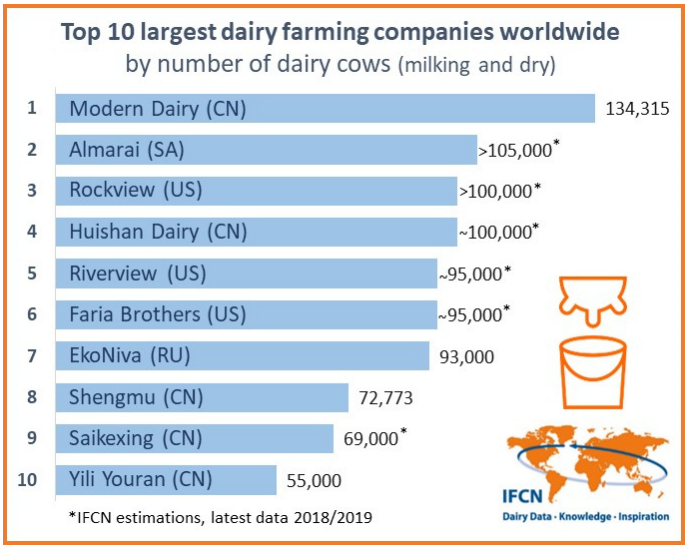
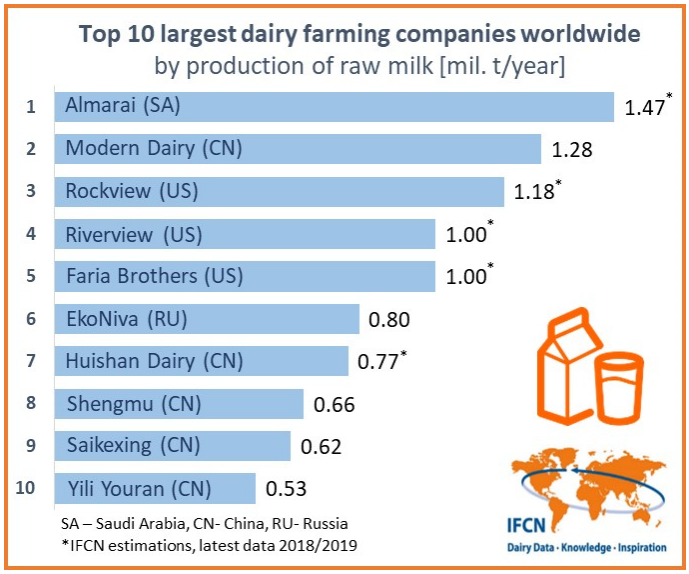
IFCN Top-10 List: Dairy Farming Companies Worldwide 2020

IFCN Dairy Research Network, Kiel, Germany
Milica Kocic, Torsten Hemme
milica.kocic@ifcndairy.org; torsten.hemme@ifcndairy.org



29th January 2020



Summary: According to IFCN's latest research, Saudi Arabia and China have the largest dairy farming enterprises in the world. China holds half of the top 10 list, while the rest of the companies are located in Saudi Arabia, Russia and the USA. These top 10 companies, with multiple dairy farms, together produced 1.1% of world's milk output in 2018.

Almarai the largest "dairy farm" by milk volume
Almarai from Saudi Arabia has the largest milk production with 1.47 million metric tons per year. This volume is similar to the milk production of Indonesia or Norway. Almarai has over 100,000 dairy cows.

***Modern Dairy* the largest "dairy farm" by cow number**
Modern Dairy from China has the largest dairy herd in the world with 134,315 dairy cows. They recorded 1.28 million metric tons of milk in 2018. This company manages its herd in 26 locations located across seven different provinces.

Almarai, Mengnui and Yili the top 3 farming companies
The Chinese farms are often subsidiaries of large milk processors (e.g. *Mengniu, Yili*, etc.) or have long-term strategic partnerships with them in order to secure upstream supply chain and synergize the best of both producers and processors of milk. Based on this IFCN classifies the top 3 dairy farming companies Almarai, Mengnui and Yili.

US dairy farms driven by family ownership models

The three US farms have developed over generations out of single dairy farms. Currently they have a large number of dairy farms in different states. These farms are in many cases run by different family members.

***EkoNiva* the fastest growing dairy farm in the world**
Ekoniva is the largest milk producer in Europe and is the fastest growing farming company in this list. They expect to exceed 1,0 million tons of milk in 2020.

The myth of large vs small dairy farms: IFCN research of farming systems in over 50 countries shows that larger farms usually outperform smaller farms in various aspects of sustainability (environmental, social and economic). Source: IFCN Dairy Report 2019

Method: The research was conducted by the IFCN Dairy Research Network aiming to create a better understanding of the dairy world. The data is based on annual reports, publicly available information and experts' estimations. IFCN welcomes any feedback to improve this analysis.

IFCN is a global network for dairy economic research and consultancy in the supply chain. In 2020 dairy researchers from over 100 countries and over 140 dairy related companies are a member. For details: www.ifcndairy.org

Global dairy production: Top 10 largest dairy farms in the world

Ana Sofia Santos (Head of Research and Innovation at Feedinox CoLAB)

Updated: 2 Jun 2025 | 12 min read

Introduction

Global **dairy production** is increasingly driven by large-scale farms capable of producing hundreds of thousands of tonnes of raw milk annually. This article ranks the world's top 10 largest dairy farms based on annual milk output, highlighting how scale, technology, and productivity shape modern dairy production.

- Introduction
- Why is scale becoming the dominant factor in global dairy production?
- How were the world's largest dairy farms ranked?
- Where is large-scale dairy production geographically concentrated?
- Which farms lead global dairy production by scale and output?
- Which technologies drive efficiency in large-scale dairy production?
- Why are European dairy farms absent from the global top 10 ranking?
- Key Takeaways
- References

Why is scale becoming the dominant factor in global dairy production?

Global **dairy production** is no longer defined by herd expansion alone. Instead, scale, productivity per cow, capital intensity and technology adoption are now the primary drivers of competitiveness.

According to the OECD–FAO Agricultural Outlook, global milk production is **projected to grow at 1.5–2% annually through 2031–2034**, with the majority of growth coming from higher yields, improved management, and technological innovation, rather than increases in animal numbers.

- Only farms or farm groups that own and directly manage dairy herds are included
- Dairy cooperatives, processors, and farmer networks are excluded
- The goal is structural consistency at the farm level, not market share or processing capacity

Where is large-scale dairy production geographically concentrated?

Mega-scale dairy farms are primarily concentrated in China, Saudi Arabia, Russia, the United States, and Southeast Asia. These regions combine access to capital, land, and regulatory frameworks that allow dairy operations to scale rapidly.

Rank	Farm / Farm Group	Country	Raw milk production (t/year)
1	Mudanjiang Mega Dairy Farm	China	+2,000,000
2	Almarai	Saudi Arabia	+1,470,000
3	Modern Dairy	China	+1,200,000
4	Ekolnica	Russia	+1,200,000
5	Riverview LLP	USA	+800,000–1,000,000
6	Rockview Family Farms	USA	+1,000,000
7	Huishan Dairy	China	+800,000
8	Al Safi Dairy Farm	Saudi Arabia	+350,000
9	Greenfields Dairy Farm	Indonesia	+400,000–450,000
10	Fair Oaks Farms	USA	+350,000–400,000

Which farms lead global dairy production by scale and output?

1. Mudanjiang Mega Dairy Farm (China)

At the top of the ranking stands Mudanjiang Mega Dairy Farm, producing an estimated **2 million tonnes of raw milk annually**. With a herd exceeding 135,000 **dairy cows**, it currently represents the most concentrated industrial dairy operation. With yields approaching 15,000 kg per cow per year reflect intensive genetic selection, precision nutrition, and fully controlled housing systems.

2. Almarai (Saudi Arabia)

Saudi Arabia features prominently, led by Almarai, whose dairy farms collectively produce close to **1.5 million tonnes of milk per year** under desert conditions. This output is enabled by heavy investment in cooling infrastructure, imported feed, and vertical integration. While highly resource-intensive, these systems demonstrate that climatic constraints can be overcome through capital and technology, achieving productivity levels comparable to temperate-zone mega farms.

3. Modern Dairy (China)

Modern Dairy ranks among the world's largest dairy producers, with an estimated annual production of around **1.20 million tonnes of raw milk**. The company operates multiple very large farms under centralized ownership, allowing them to capture economies of scale while spreading geographic and climatic risk.

4. Ekolnica (Russia)

Ekolnica is Russia's largest farm group, with annual milk production estimated at approximately **1.2 million tonnes**. The group's size and presence across multiple farming sites help balance production conditions across regions, limiting the impact of weather or regional disruptions on overall milk output.

5. Riverview LLP (United States)

In the United States, Riverview LLP has emerged as one of the largest dairy operators, with annual milk production estimated between **800,000 and 1 million tonnes**. Operating across multiple states, the company relies heavily on automation, genetic progress, feed efficiency, and data-driven management to remain competitive in a mature market characterized by rising labor, regulatory, and environmental costs.

6. Rockview Family Farms (United States)

Rockview Family Farms ranks among the world's largest dairy operations, with annual milk production close to **1 million tonnes**. It is recognized as the largest documented family-owned dairy farm group, highlighting the scale that can be reached under single-family ownership.

7. Huishan Dairy (China)

Huishan Dairy represents a centrally managed, multi-farm group in China, with total production of approximately **800,000 tonnes per year**. Its model emphasizes geographic dispersion, standardized management, and integration with domestic processing and retail markets.

8. Al Safi Dairy Farm (Saudi Arabia)

Al Safi Dairy Farm is one of the world's largest single-site, fully integrated dairy operations, with annual milk production of around **550,000 tonnes**. Located in Saudi Arabia, its performance is driven by extreme capital intensity and advanced cooling systems, enabling consistently high productivity despite harsh climatic conditions.

9. Greenfields Dairy Farm (Indonesia)

Greenfields Dairy Farm generates an estimated **400,000 to 450,000 tonnes of milk per year**, making it one of Southeast Asia's largest dairy operations.

Source: Greenfields

10. Fair Oaks Farms (United States)

Fair Oaks Farms, the largest documented single-site dairy farm in the U.S., rounds out the top 10 with **350,000 to 400,000 tonnes of annual milk production**.

Which technologies drive efficiency in large-scale dairy production?

Across all Top 10 farms, innovation is the common denominator. High-output dairy systems consistently deploy:

- Precision feeding and ration optimization
- Digital herd monitoring and health analytics
- Advanced reproductive and genetic programs
- Automation and standardized operating protocols

These technologies underpin the OECD–FAO projection that future milk supply growth will be driven primarily by productivity gains per animal, not by expanding herd sizes.

Why are European dairy farms absent from the global top 10 ranking?

One outcome of this ranking is the absence of European Union dairy farms from the global Top 10. This is not due to missing data, but to structural differences in production models.

European dairy farming is dominated by family-owned farms, operating under strict environmental, animal welfare, and land-use regulations. Scale is achieved primarily through cooperative aggregation, rather than through ultra-large, centrally owned farms. As a result, even Europe's largest individual farms fall well below the production thresholds required to be included in a global Top 10 ranking based on raw milk output per farm. Nonetheless, the EU's dairy sector is highly efficient and will be addressed in future articles.

Key Takeaways

- The world's largest dairy farms highlight a sector increasingly driven by scale, capital, and technology.
- Productivity gains—not herd expansion—will define future milk supply growth.
- Cooperative-based models are dominant in Europe and India, while mega-farms dominate in China and Saudi Arabia.
- Understanding these structural differences is essential for informed discussions on sustainability, competitiveness, and global food security.

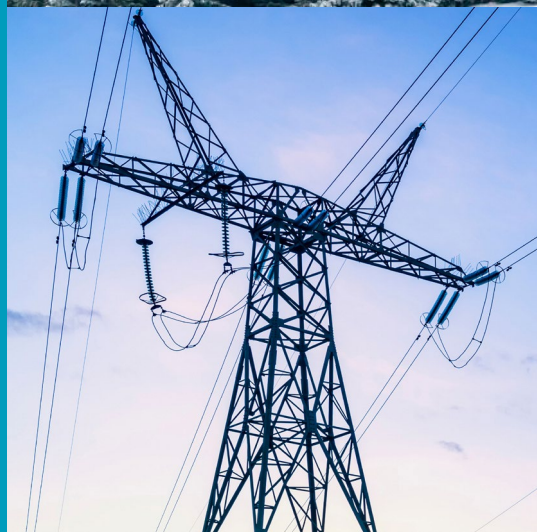
REPORT TO THE LEGISLATURE



JANUARY 2025

Greenhouse gas emissions in Minnesota 2005-2022

Biennial inventory report tracking the state's greenhouse gas emissions contributing to climate change.

MINNESOTA

Pollution Control Agency
Department of Commerce

Greenhouse gas emissions in Minnesota 2005-2022:

Biennial inventory report tracking the state's greenhouse gas emissions contributing to climate change.

Report to Legislature, January 2025. Jointly submitted by the Pollution Control Agency and the Department of Commerce

Legislative charge

Minn. Stat. § 216H.02 Greenhouse gas emissions control.

Subd. 1. Greenhouse gas emissions-reduction goal. It is the goal of the state to reduce statewide greenhouse gas emissions across all sectors producing those emissions to a level at least 15% below 2005 levels by 2015, to a level at least 30% below 2005 levels by 2025, and to a level at least 80% below 2005 levels by 2050. The levels shall be reviewed based on the climate change action plan study.

Minn. Stat. § 216H.07 Emissions-reduction attainment; policy development process.

Subd. 3. Biennial report. (a) By January 15 of each odd-numbered year, the commissioners of commerce and the Pollution Control Agency shall jointly report to the chairs and ranking minority members of the legislative committees with primary policy jurisdiction over energy and environmental issues the most recent and best available evidence identifying the level of reductions already achieved and the level necessary to achieve the reductions timetable in section 216H.02. (b) The report must be in easily understood nontechnical terms.

Introduction

The reality of climate change continues to have a profound impact on the lives of Minnesotans. The extreme conditions Minnesota experienced in 2023 and 2024, including an exceptionally warm winter and major spring rains, were consistent with ongoing climate change trends. The changes in our climate are being felt across Minnesota's communities, economy, cultures, and ecosystems.

More information about climate trends and the impacts of climate change is available from the **Department of Natural Resources** www.dnr.state.mn.us/climate

Heavy rains are now more common in Minnesota and more intense than at any time on record. Long-term observation sites have seen dramatic increases in 1-inch rains, 3-inch rains, and the size of the heaviest rainfall of the year. Frequent and intense storms are damaging homes, businesses, infrastructure, farms, and ecosystems.

Minnesota's winters are also becoming shorter and milder. This climate trend is called "cold weather warming," and it means that the average temperature of winter months is increasing faster than the average temperature of summer months. Over the last 50 years, Minnesota's winter has warmed an incredible 13 times faster than summer. Warmer winters allow some pests like ticks and certain invasive species to survive and multiply. Over those 50 years, Minnesota lakes have also lost an average of 10 to 14 days of ice, affecting lake and fish health, outdoor recreation opportunities, and business owners.

Simply put, Minnesota is getting warmer and wetter. Changes to our climate, such as heavier and more frequent rainfall events and warmer winters, are caused by human activities that release greenhouse gases (GHGs). Our changing climate has economic and environmental impacts for Minnesotans. Over the past decade, for instance, our state has been experiencing a much higher rate of natural disasters, with a higher number of individual storms that cause more than $1 billion in damage.

This report summarizes what we know about GHG emissions in Minnesota, including the major sources and trends over time. Tracking GHG emissions and identifying their sources are two important ways that state government can help Minnesotans understand how our actions contribute to our changing climate and how we can curb our climate pollution.

To guide our response to climate change, the State of Minnesota has developed a Climate Action Framework (mn.gov/framework). The Framework identifies immediate, near-term actions to reduce climate pollution and prepare Minnesota communities for the impacts of climate change. The Framework is currently being updated to include a comprehensive set of actions that help us achieve those goals. Analyzing Minnesota's emissions through this inventory allows us to track progress on the Framework goals and focus on actions with maximum impact to address climate change.

This inventory documents Minnesota's GHG emissions from 2005 through 2022 and shows the impact of actions taken by individuals, organizations, and governments across Minnesota to reduce climate pollution. The COVID-19 pandemic changed how Minnesotans lived and worked in 2020. As Minnesotans returned to regular activities, emissions that dropped steeply in 2020 rebounded, reflecting a similar trend nationally. Despite the rebound, emissions from sectors like transportation, electricity generation, industrial, agriculture, and waste remain below 2019 levels, indicating lasting changes toward increased energy efficiency and a low-carbon economy.

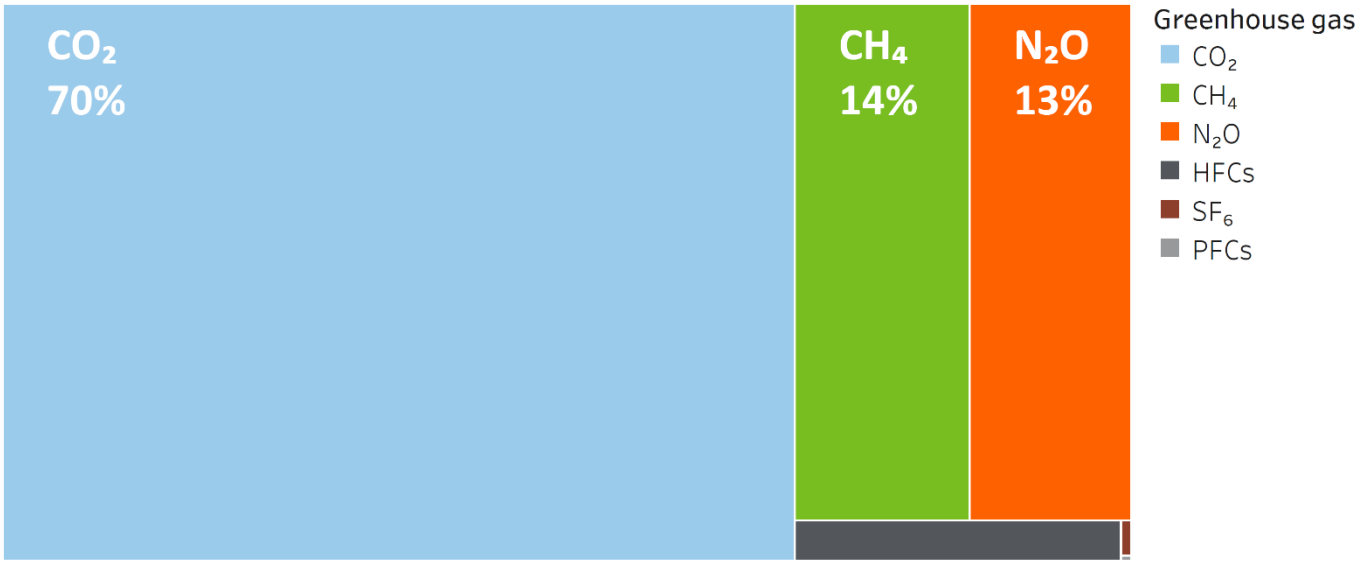
Billions of dollars in state and federal climate investments made between 2022 and 2024 will reduce GHG emissions in Minnesota. The impacts of these investments cannot yet be seen in the data of this report, and the

momentum of those investments will be felt for decades to come. While there is much work ahead to meet our climate goals, this inventory demonstrates that collaborative action and smart policy-making work.

Evaluating greenhouse gas emissions

Greenhouse gases (GHGs) warm the planet's atmosphere and surface. Human activity increases the amount of GHGs in the atmosphere, leading to changes in Earth's climate. The Minnesota Greenhouse Gas Emissions Inventory accounts for the six GHGs originally covered by the Kyoto Protocol of the United Nations Framework Convention on Climate Change: carbon dioxide (CO_2), nitrous oxide (N_2O), methane (CH_4), sulfur hexafluoride (SF_6), and two types of compounds called hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs).

GHGs come from a variety of sources in our state:



- Fossil fuel combustion is responsible for most carbon dioxide emissions in Minnesota and the United States. The majority of fossil fuels used today are burned to generate electricity, fuel vehicles, and provide heat for homes and industrial processes, all of which are significant sources of emissions.
- Animal agriculture is responsible for most methane emissions in Minnesota. Materials decomposing in landfills and in bodies of water also emit methane.
- Agricultural nutrient management practices, including fertilizer application and subsequent mineralization, cause over 50% of nitrous oxide emissions.
- Most hydrofluorocarbon emissions are from refrigerants used in vehicle and building air conditioners.
- Perfluorocarbons and sulfur hexafluoride account for a small portion of GHG emissions and are released from technical applications like semiconductor manufacturing and electricity transmission.

Carbon dioxide is the primary GHG emitted by human activities, followed by methane and nitrous oxide. Other GHGs are emitted in smaller amounts, but trap heat more effectively than carbon dioxide, and some stay in our atmosphere for a very long time, contributing more to climate change.

Global warming potential (GWP) is a relative measure of how much heat a GHG traps in the atmosphere. To compare different emissions and pollutants, we use the effect of carbon dioxide on our climate as a standard reference. In this report, emissions are reported as metric tons of carbon dioxide-equivalent (CO_2-e), meaning emissions are stated in relative terms that reflect their impact on global temperatures.

Minnesota's net GHG emissions in 2022 by gas

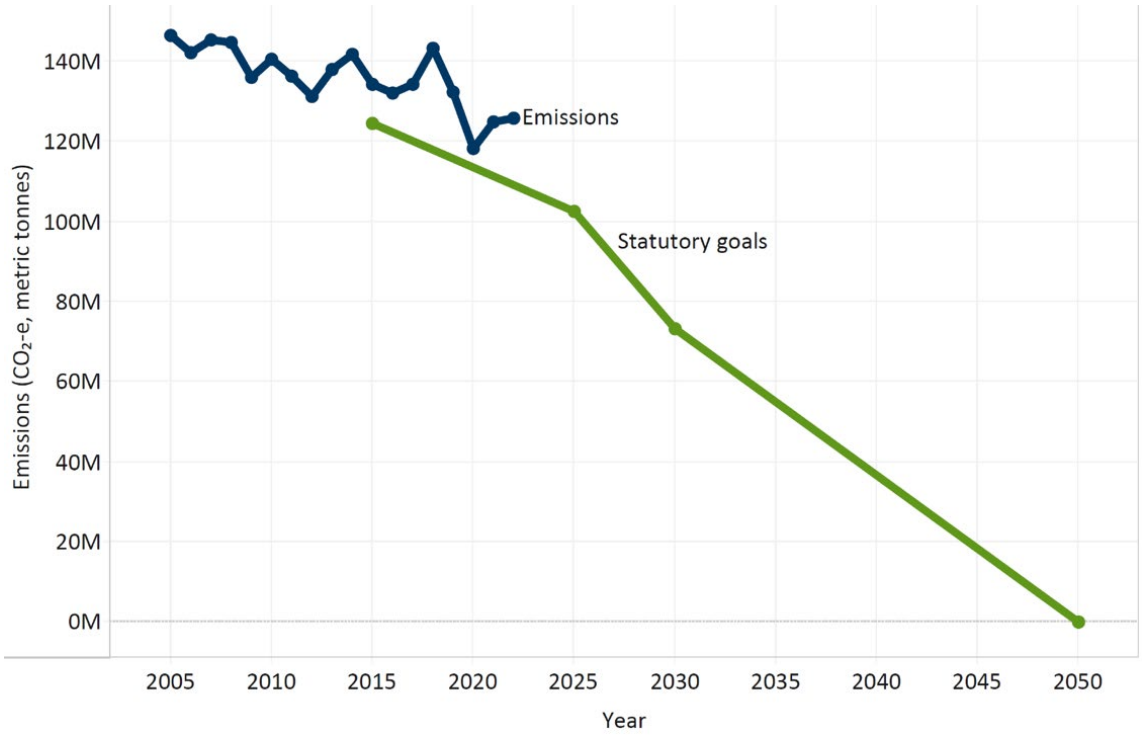
Emissions are expressed as percent of total CO_2-equivalent and includes carbon sequestration.

Greenhouse gases, their 100-year global warming potentials, and their persistence in Earth's atmosphere.

Greenhouse gas	Global warming potential (GWP)	Persistence in Earth's atmosphere
Carbon dioxide (CO_2)	1	Variable, up to thousands of years
Nitrous oxide (N_2O)	265	121 years
Methane (CH_4)	28	12 years
Sulfur hexafluoride (SF_6)	23,500	3,200 years
Hydrofluorocarbons (HFCs)	Up to 12,400	Up to 242 years
Perfluorocarbons (PFCs)	Up to 11,100	2,600 to 50,000 years

Source: IPCC Fifth Assessment Report, Working Group 1 Chapter 8

Tracking statewide emission reduction progress



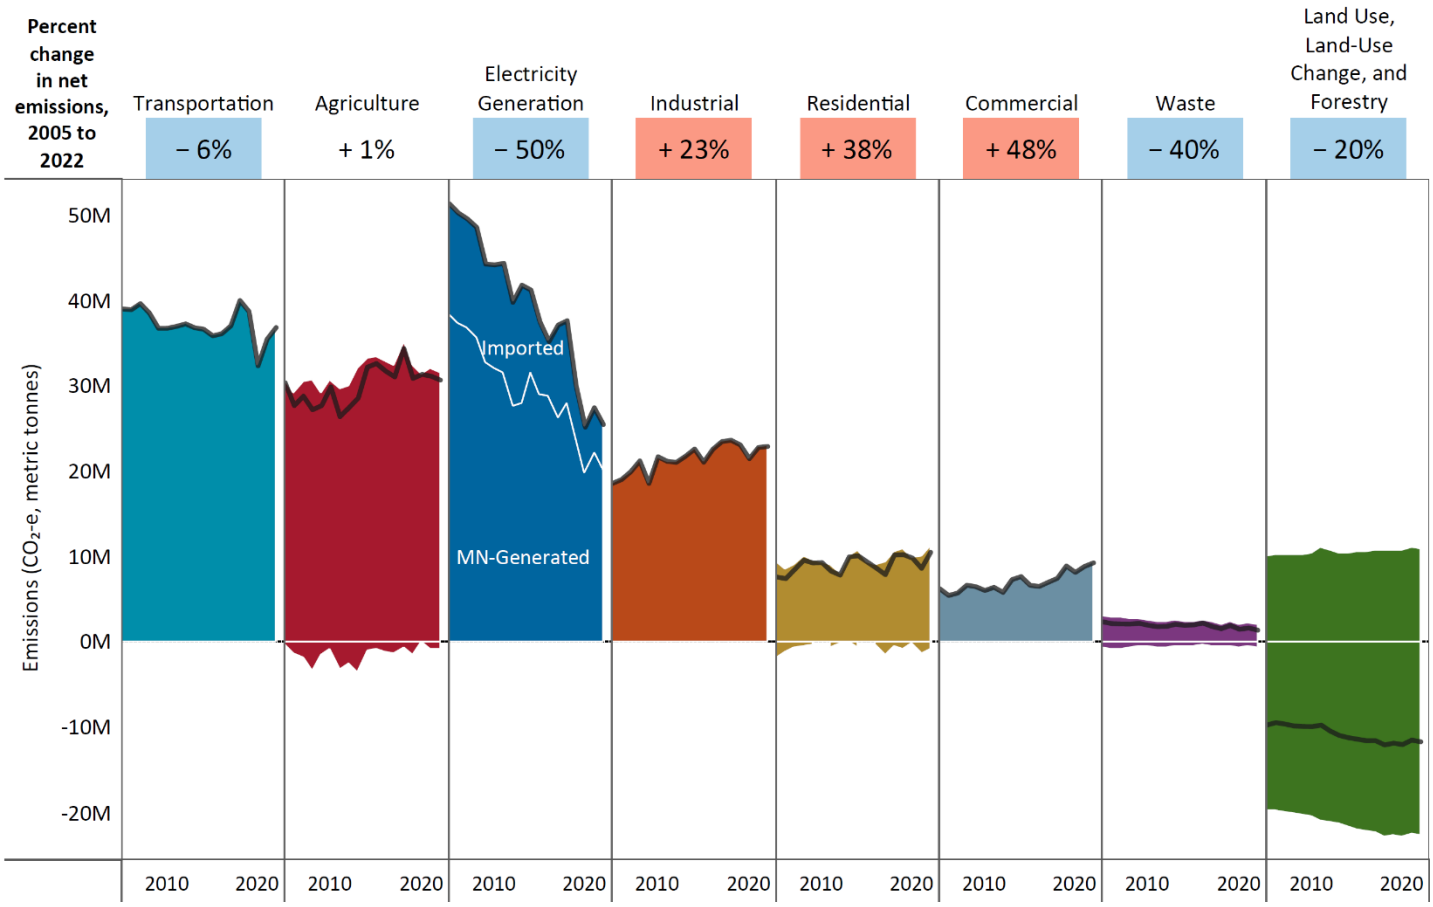
In 2007, the Minnesota Legislature passed the Next Generation Energy Act, setting our state's first science-based goals to reduce our GHG emissions in the state compared to our emissions in 2005.[1] Since then, Minnesota has reassessed and updated our state's GHG emissions goals in the Climate Action Framework, and subsequently in statute, based on current scientific evidence. Now, Minnesota's GHG emissions reduction goals are to reduce emissions by 15% by 2015, 30% by 2025, 50% by 2030 (from a 2005 baseline), and to reach net-zero by 2050.

Minnesota did not reach the statutory goal of reducing emissions by 15% by 2015. Between 2005 and 2022, Minnesota's GHG emissions fell by 14%, making it difficult to achieve our goals if we maintain current trends. Changes in fuels used for electricity generation have resulted in significant emission reductions from the electricity generation sector and are the most significant contributor to statewide emission reductions between 2005 and 2022.

Between 2020 and 2022, emissions rose due to economic activity resuming after the height of the COVID-19 pandemic, reflecting increased energy use and transportation demands. The emission increases in 2021 and 2022 are consistent with nationwide emission increases calculated by the US EPA. The good news is that 2022 emissions reflect a continuation of pre-pandemic long-term downward trends.

Recent emission reductions show that action can get us on track to achieve our statutory goals and reach net-zero emissions by 2050. The rate of reduction since 2005 shows that much work remains to achieve these ambitious and necessary goals.

Minnesota's greenhouse gas emissions and statutory goals

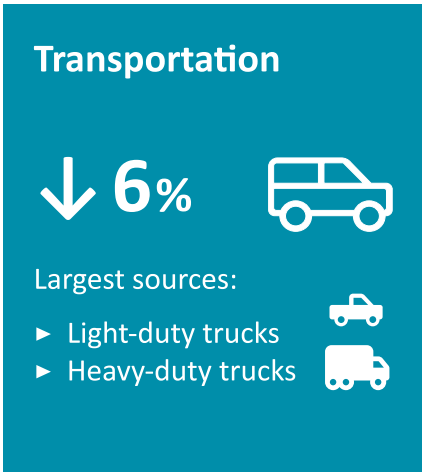


[1] Data revisions and changes in methodology can cause the baseline to change, but continuity is provided when making relative year-to-year emissions comparisons.

Sectoral greenhouse gas emissions

This section reports annual GHG emissions and terrestrial sequestration of carbon from 2005 through 2022 for the eight economic sectors in Minnesota: transportation; agriculture; electricity generation; industrial; residential; commercial; waste; and land use, land-use change, and forestry. The “agriculture” and “land use, land-use change, and forestry”sectors have replaced the “agriculture, forestry, and other land use” sector from previous inventories to allow for better alignment with the EPA's national GHG quantification approach and to provide greater detail than in previous reports. Interactive data visualizations are available at https://www.pca.state.mn.us/air-water-land-climate/climate-change-trends-and-data.

Minnesota’s GHG emissions across economic sectors from 2005 to 2022, ranked by net 2022 emissions.



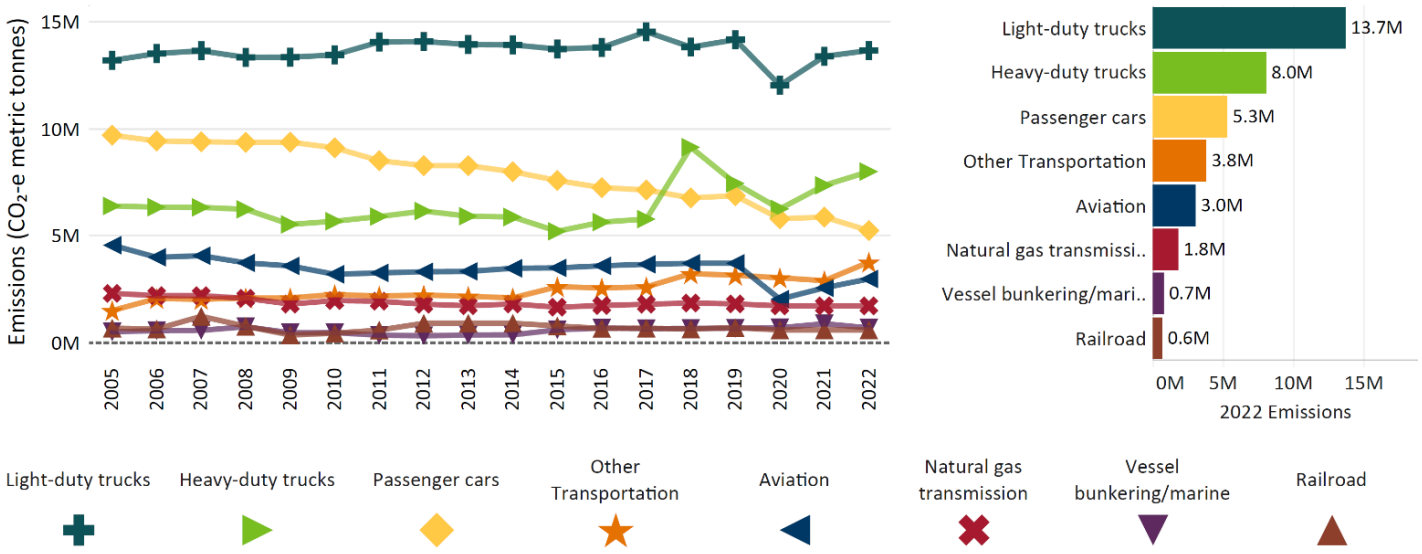
Dark lines represent the net emissions for each sector (gross emissions minus sequestration). Carbon sequestration is shown as negative emissions, present in the agriculture; residential; waste; and land use, land use change, and forestry sectors. The electricity generation sector differentiates emissions from electricity generated in Minnesota versus those from imported electricity. The percent change from 2005 to 2022 is shown above the chart by sector. Blue and red indicate reductions and increases in emissions, respectively.

Transportation

Minnesota's largest source of GHG emissions is the transportation sector, accounting for about 29% of the state's total emissions. Since the baseline year of 2005, total GHG emissions from transportation have decreased by about 6%. While emissions from aviation and light-duty trucks rebounded after the height of the pandemic in 2020, they remain below pre-pandemic levels. In contrast, emissions from heavy-duty trucks are now higher than pre-pandemic levels.

GHG emissions 2005-2022

Emissions sources in the transportation sector include:



- on-road vehicles, including passenger vehicles, light-duty trucks, medium- to heavy-duty trucks, RVs, buses, and motorcycles
- airplanes and other aviation equipment
- trains
- marine vehicles
- off-highway gasoline vehicles and equipment, including military vehicles, ATVs, and snowmobiles
- vehicle air conditioning units
- natural gas transmission pipelines

Our personal choices have a significant impact on emissions, especially when it comes to how we move around. Passenger vehicles account for about 14% of emissions in this sector, while light-duty trucks (including pickup trucks, minivans, and SUVs) make up about 37%. Medium- to heavy-duty trucks (including delivery vans, large commercial vehicles, and tractor-trailers) produce about 22% of emissions in this sector.

While stronger federal vehicle emissions standards have helped reduce GHG emissions overall, long-term trends in consumer preferences for larger vehicles and the increasing number of miles driven (except during the pandemic) have slowed potential progress in reducing emissions. Although the adoption of electric vehicles is growing, the trend toward larger, higher-emitting vehicles challenges the pace at which electric vehicles and vehicle emissions standards can reduce emissions.

Continued investment in cleaner vehicles and expanding transportation options, such as public transit, biking, walking, and rolling, is essential to achieve further emission reductions in this sector. Also important to the reduction of transportation sector emissions are changes in land use development patterns that promote denser development and housing near amenities and transportation options. This type of development makes the use of transportation options other than cars more convenient and encourages shorter trips.

Transportation sector GHG emissions

Emissions by subsector from 2005 to 2022 (left) and only 2022 (right). “Other Transportation” includes bus, motorcycle, RV, mobile air conditioning, and miliary/other off-highway emissions.

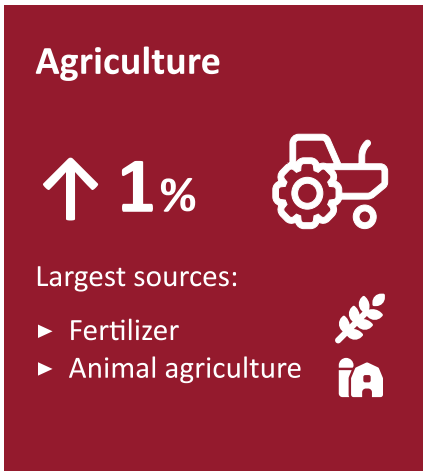
Agriculture

Minnesota's second-largest source of GHG emissions is the agriculture sector, accounting for about 25% of the state's net emissions. Since 2005, net GHG emissions from agriculture are essentially unchanged.

In previous versions of this report, agriculture, forests, and other land uses were grouped into a single sector. Separating agriculture into its own sector results in better alignment with the US Environmental Protection Agency's (EPA) national approach to GHG quantification, allows more detail, and clarifies that sequestration in natural landscapes offsets emissions from all sectors, not only agriculture.

Emission sources and sequestration in the agriculture sector include:

- livestock digestion
- manure storage and land application
- fertilizer use
- methane emissions avoided due to the anaerobic digestion of manure (a process that captures methane that would otherwise be emitted to the atmosphere)
- emissions and sequestration of carbon within cropland soils*



*Due to the difficulty of differentiating grazed from ungrazed grasslands, carbon stock changes within all grasslands are included in the land use, land-use change, and forestry sector

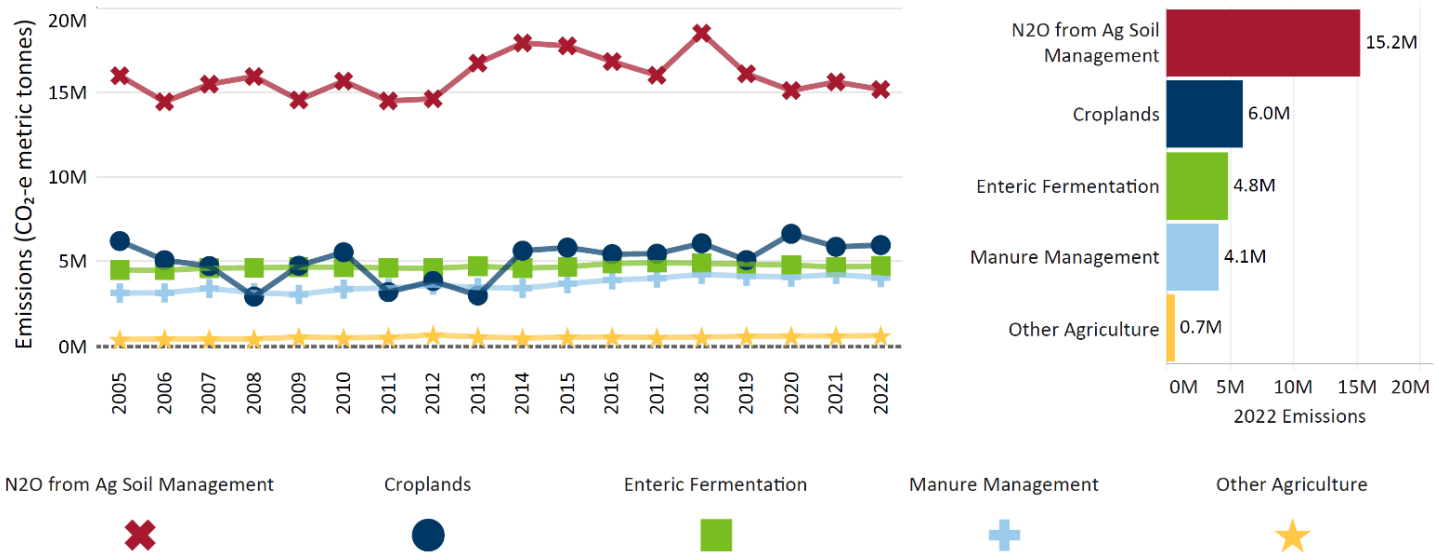
Within agriculture, GHG fluxes (i.e., emissions and sequestration) are largely driven by plants and the microbes in soils, manure storage areas, and cattle digestive systems. It is not possible to directly measure these fluxes across the state, so we use scientific models to estimate them. Models of GHG fluxes within agricultural systems continue to become more sophisticated, useful, and accurate. While coarse data on management decisions (e.g., aerial imagery, grower surveys, and product sales records) are sources of uncertainty in these estimates, models provide helpful estimates of the impacts of crop and livestock management practices, environmental conditions, and other variables on GHG emissions and sequestration.

Agricultural practices in Minnesota are responsible for 96% of the state's nitrous oxide emissions and 44% of the state's methane emissions. The largest sources of nitrous oxide are the land application of synthetic fertilizers and manure, and the subsequent mineralization and runoff of that nitrogen. Methane emissions are caused by cattle digestion and manure storage practices.

The largest source of carbon dioxide from the agricultural sector is the use of drained organic soils for crop production. Compared to other states, Minnesota is uniquely rich in organic soils, which form within peatlands (a class of wetlands that includes bogs) over thousands of years and have high soil carbon content. When left untouched, peatlands are massive stores of carbon. However, during the 20th century in Minnesota, there was significant drainage and tillage of peatlands for crop production. Lowering the water table exposes these large carbon stocks to the air,

GHG emissions 2005-2022

Minnesota agriculture summary



- Minnesota has over 65,000 farms operating on 21.5 million acres of cropland, 3% of which are irrigated.
- Minnesota has 650 organic farms on 164,000 acres.
- Minnesota ranks in the top 10 for over 20 agricultural products, including #1 in turkeys and sugar beets, #2 in hogs, #3 in soybeans, and #4 in corn.
- Minnesota has approximately 25,000 farms with animals, including 8.9 million hogs, 2.1 million cattle and calves, 14.9 million turkeys, 14.5 million laying hens, and 7.8 million broiler chickens.

Sources: US Department of Agriculture, Minnesota Department of Agriculture

which which allows them to decompose and release carbon dioxide for several decades unless they are rewetted. Regardless of the soil health practices employed, drained organic soils lose more carbon than they can gain. In contrast, there are approximately 20 million acres of croplands on mineral soils (i.e., non-peat soils) in Minnesota, which, on average, are sequestering soil carbon. The carbon sequestered by Minnesota's approximately 20 million acres of croplands on mineral soils is outweighed by the carbon dioxide emissions from the roughly 405,000 acres of croplands on drained organic soils. This area, approximately equivalent to the size of Hennepin County, represents a significant source of greenhouse gas emissions. The most effective way to reduce these emissions is to restore drained organic soils where practicable to their natural state as peatlands. In addition to curbing emissions, restored peatlands provide critical habitat for unique native species and help protect downstream water quality. Efforts to rewet peatlands are already underway on private, public, and tribal lands, with additional public funding for this work becoming available soon.

While net emissions from Minnesota agriculture have not changed significantly since 2005, improved efficiency and more sustainable agricultural management practices have resulted in our farms producing more food, biofuel, and fiber than ever before. Agriculture is the second-highest emitting sector in the state, as emissions from electricity generation have declined substantially since 2005. Significant opportunities remain for emission reductions and additional carbon sequestration while maintaining agricultural productivity. Investments are being made at the state and federal levels to support sustainable agricultural practices and on-farm energy and efficiency projects, such as the recent EPA-awarded $200 million grant to cut climate pollution from our state's food systems through the federal Climate Pollution Reduction Grants program.

Agriculture sector GHG emissions

Emissions by subsector from 2005 to 2022 (left) and only 2022 (right). "Other Agriculture" includes field burning of agricultural residues, CO_2 from carbon containing fertilizers, and rice cultivation.

Reducing emissions and sequestering carbon through crop agriculture

Within crop agriculture, nitrous oxide emissions can be reduced through the efficient use of nitrogen fertilizers. Successful nitrogen use results from applying the right source of nitrogen at the right rate, time, and place to maximize plant uptake and minimize losses to the environment. To enhance nitrogen efficiency, timing strategies can be complemented with the use of nitrification inhibitors, urease inhibitors, and other controlled-release fertilizers. These products extend the duration of nitrogen availability to growing crops, reducing nitrogen losses and GHG emissions by about 21 metric tons of CO_2-equivalent per 100 acres per year. If applied to 10 million acres per year, these products could reduce agricultural soil emissions by about 2 million metric tons of CO_2-equivalent annually, equivalent to removing about 500,000 gasoline-powered passenger vehicles from the road for one year.

Actions aimed at improving soil health and water quality can also boost carbon sequestration in plants, soil, and aquatic ecosystems. Examples include planting perennial field borders; incorporating trees and shrubs; retiring marginal lands into conservation easements; and the long-term adoption of reduced tillage, perennials in crop rotations, and cover crops. Cover cropping has been shown to prevent soil erosion, reduce nutrient losses, suppress weeds, and accumulate organic carbon in soil. According to United States Department of Agriculture surveys, from 2012 to 2022, the number of acres in Minnesota with cover crops increased from about 408,000 to 760,000. Although results vary, a typical implementation of cover crops in Minnesota results in a net reduction of about 15 metric tons of CO_2-equivalent per 100 acres per year. Therefore, in 2022, cover crops likely reduced net emissions by over 113,000 metric tons of CO2-equivalent, comparable to removing about 26,000 gasoline-powered passenger vehicles from the road for one year. There is potential to significantly increase cover cropping in Minnesota. If cover cropping was implemented and maintained on about 13 million of the 20 million acres of crop agriculture in Minnesota, this could also reduce net GHG emissions from agriculture by up to 2 million metric tons of CO_2-equivalent per year, comparable to removing about 500,000 gasoline-powered passenger vehicles from the road for one year.

Reducing emissions from animal agriculture

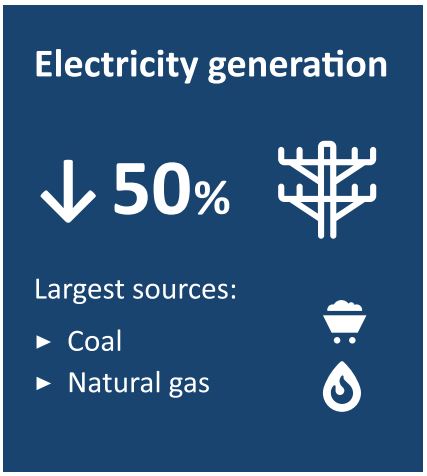
Within animal agriculture, methane is the dominant GHG and is produced through cattle digestion and manure storage. An important long-term action to limit methane from cattle digestion (or "enteric fermentation") is to incorporate relevant genetics into herds to increase feed conversion efficiency, reduce cull rates, and influence other aspects of digestion, including the rumen microbial community. Increasing feed digestibility also helps, though Minnesota cattle already feed on high-quality forage compared to much of the globe. A variety of feed additives can also reduce enteric methane production by up to 30% during certain life stages, but research is ongoing and cost is currently a barrier to adoption.

Another source of avoidable methane emissions is manure stored as a liquid under anaerobic conditions, such as in open lagoons. Where manure is stored as a liquid, managed anaerobic digestion systems can capture the resulting methane and sell or use it as a replacement for fossil fuels. Anaerobic digestion systems work better for some species and types of manure infrastructure than others. They are most economical at large farms or in cooperative models (with manure from multiple farms combined in a single system), where market incentives promote renewable fuels (e.g., via low carbon fuel standards), and where other materials can be co-digested. Alternatively, managing manure as a solid and grazing livestock in pastures generates little methane because the manure is broken down by aerobic microbes. Other methane-reducing manure management interventions include composting and avoiding land application during wet field conditions.

Electricity generation

Electricity generation is the third-largest source of GHG emissions in Minnesota, accounting for about 20% of the state's net emissions. Burning fossil fuels, especially coal, to generate electricity for Minnesotans, whether produced in-state or out-of-state, is this sector's primary source of GHG emissions. Other smaller sources include:

- methane from coal storage
- carbon dioxide from scrubbing other air pollutants from facility emissions
- sulfur hexafluoride from electricity transmission and distribution



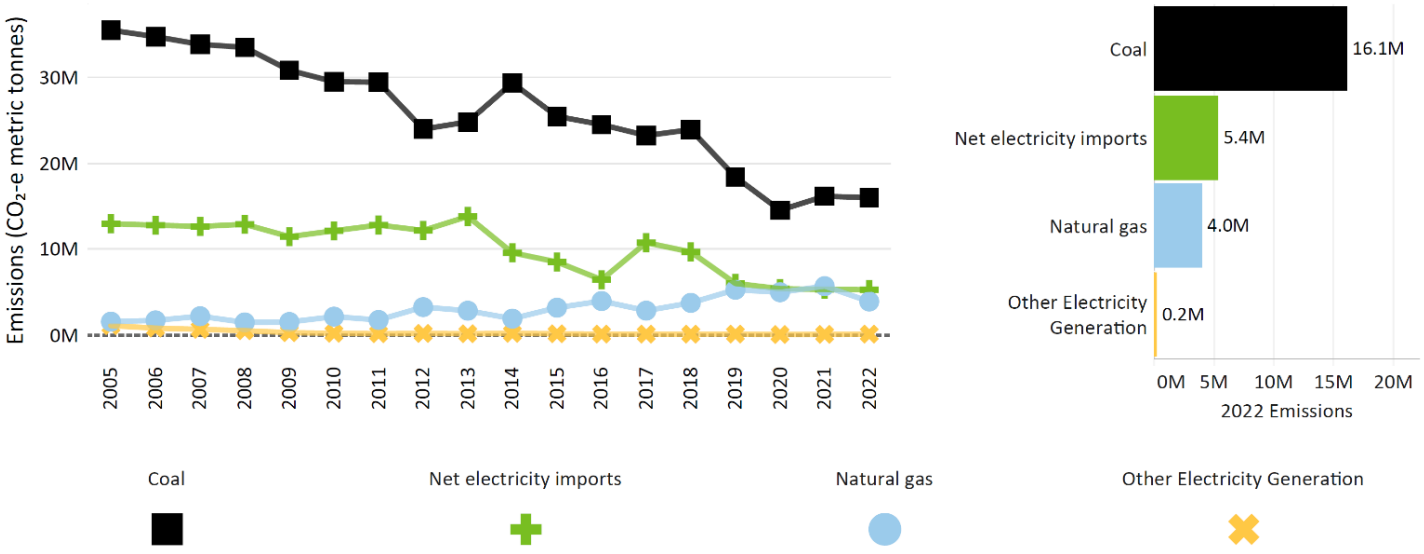
Since 2005, emissions from the electricity generation sector have declined by 50%. The significant decrease is mainly a result of the transition away from coal toward renewable energy sources to generate electricity. Renewable sources produced 32% of Minnesota-generated electricity in 2022.

Previously, Minnesota's electricity generation sector was the largest source of GHG emissions, and the greatest emissions reductions have been made here.

In Minnesota, we use more electricity than we generate inside our borders. As required by the statute, this report measures total GHG emissions from electricity generation, including emissions from electricity generated at facilities within the state, and provides an estimate of the electricity used here in Minnesota that is generated outside of our state borders (imported). Emissions from both Minnesota-generated and imported electricity generation have decreased since 2005.

Emissions per kilowatt-hour from electricity imported from the regional electrical grid are higher than in-state generation because some neighboring states haven't reduced their emissions as much as Minnesota. The amount of electricity imported into Minnesota continues to decrease as in-state generation increases, reducing the amount of estimated imported electricity and associated GHG emissions.

GHG emissions 2005-2022



Percentage of Minnesota electricity utility generation (resource mix), 2022

Coal	27.4%
Wind	25.6%
Nuclear	24.9%
Gas	14.8%
Solar	3.2%
Biomass	2.0%
Hydroelectric	1.6%
Other fossil	0.4%

Source: eGRID

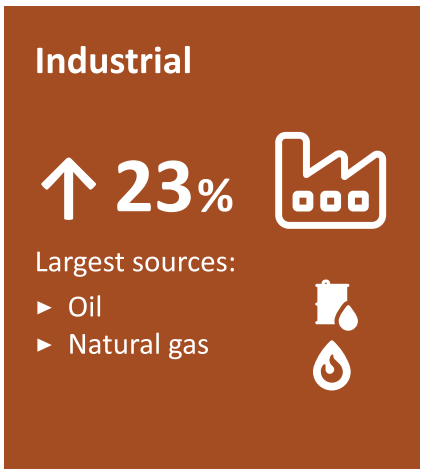
GHG emission reductions will continue in the electricity generation sector as a result of planned closures of coal-fired power plants in Minnesota, as indicated in the table below. In addition, in 2023, the Minnesota Legislature adopted a new Clean Electricity Standard that requires electric utilities to provide net-zero, or 100% carbon-free, electricity by 2040. Carbon-free electricity is important to help the state reduce emissions through electrification of other uses of fossil fuel combustion, such as vehicles and building heating. Continued focus on thoughtful transition to support an electric grid that is reliable, safe, affordable, and increasingly clean is vital to achieving economy-wide GHG emission reduction goals.

Electricity generation sector GHG emissions

Emissions by subsector from 2005 to 2022 (left) and only 2022 (right). "Other Electricity Generation" includes oil, SF6 emissions related to transmission, non-CO2 emissions from biofuels, coal storage, and flue-gas desulfurization.

Utility-owned coal-fired electricity generating units in Minnesota (as of December 2024)

Facility	Size (MW)	Status
Hibbing Public Utilities Commission		
Hibbing 3	10	Standby/backup: available for service but not normally used
Hibbing 5	20	Standby/backup: available for service but not normally used
Hibbing 6	6	Standby/backup: available for service but not normally used
Minnesota Power		
Boswell Unit 3	365	Operating: Cease coal-fired operations by year-end 2029
Boswell Unit 4	558	Operating: Proposed to cease coal-fired operations by 2035
Hibbard Energy Center Unit 3	30	Operating
Hibbard Energy Center Unit 4	32	Operating
Xcel Energy		
Sherburne County 1	680	Operating: full retirement by 2026
Sherburne County 3	876	Operating: full retirement by 2030
Allen S King	511	Operating: full retirement by 2028

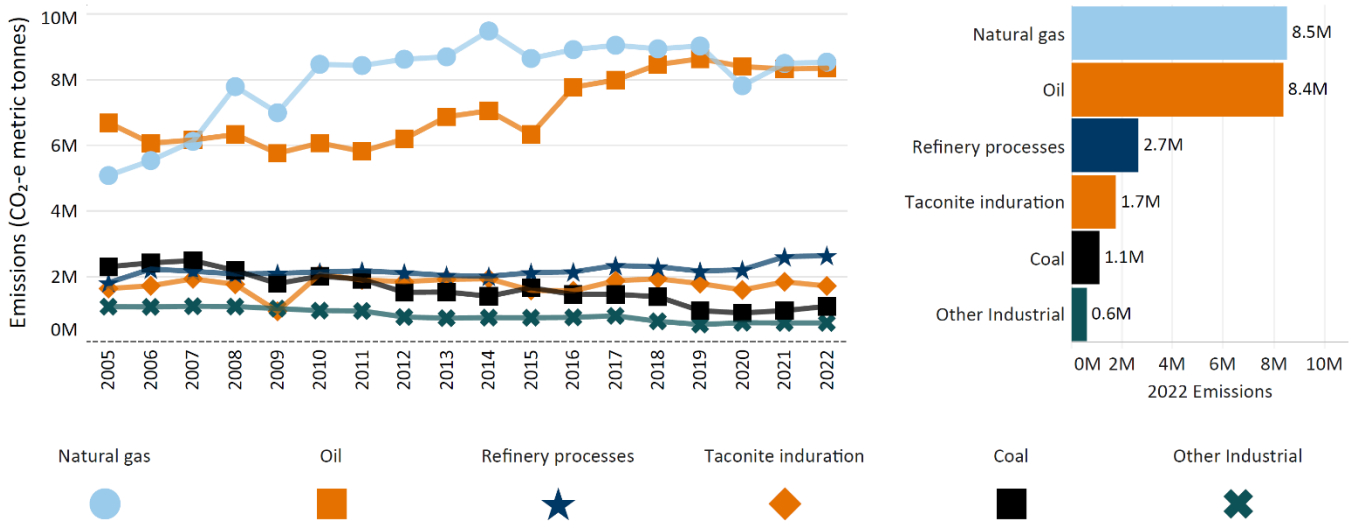


Industrial

The industrial sector is the fourth-largest source of GHG emissions in Minnesota, accounting for about 18% of the state's net emissions. The industrial sector includes direct emissions from industrial facility processes and fossil fuel combustions. Emissions from electricity use in the industrial sector are accounted for under the electricity generation sector. Since 2005, emissions have increased in this sector by 23%.

Emissions sources in the industrial sector include:

- fossil-fuel combustion
- petroleum refining
- taconite processing
- lead recycling
- industrial wastewater treatment
- solvent use
- manufacturing of steel, glass, and semiconductors

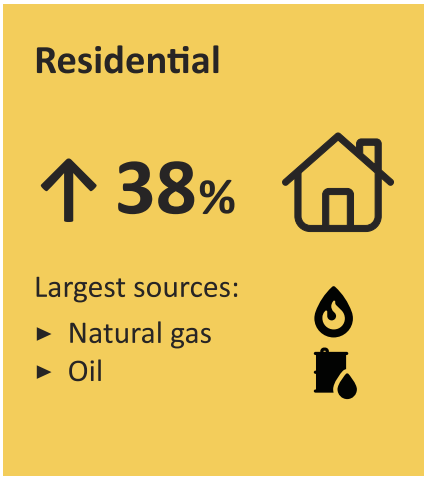


GHG emissions 2005-2022

While total GHG emissions from the industrial sector have declined since a peak in 2018, they are still higher than the 2005 baseline. The trends in emissions from specific fuels used are more varied. Industrial emissions from coal have declined since the 2005 baseline, while emissions from natural gas and oil (e.g. fuel oil, waste oils, propane, etc.) have increased relative to the 2005 baseline.

Changes are needed in industrial activities to meet statutory goals. Emissions from the industrial sector are closely tied to economic activity, but reductions in emissions do not require that our growth and productivity slow or decline. The Climate Action Framework includes a focus on transforming Minnesota's economy through innovation. With federal funding and technical assistance, industrial businesses can be national leaders in changing operations to increase efficiency and reduce fossil fuel use through electrification or the use of other greener fuels. The state is embarking on a study of the specific types of industrial and manufacturing processes that generate GHG emissions in the state. This study and the facility GHG emission data the MPCA receives will inform the development of a strategy to reduce emissions in the industrial sector and Minnesota's Climate Action Framework.

Industrial sector GHG emissions



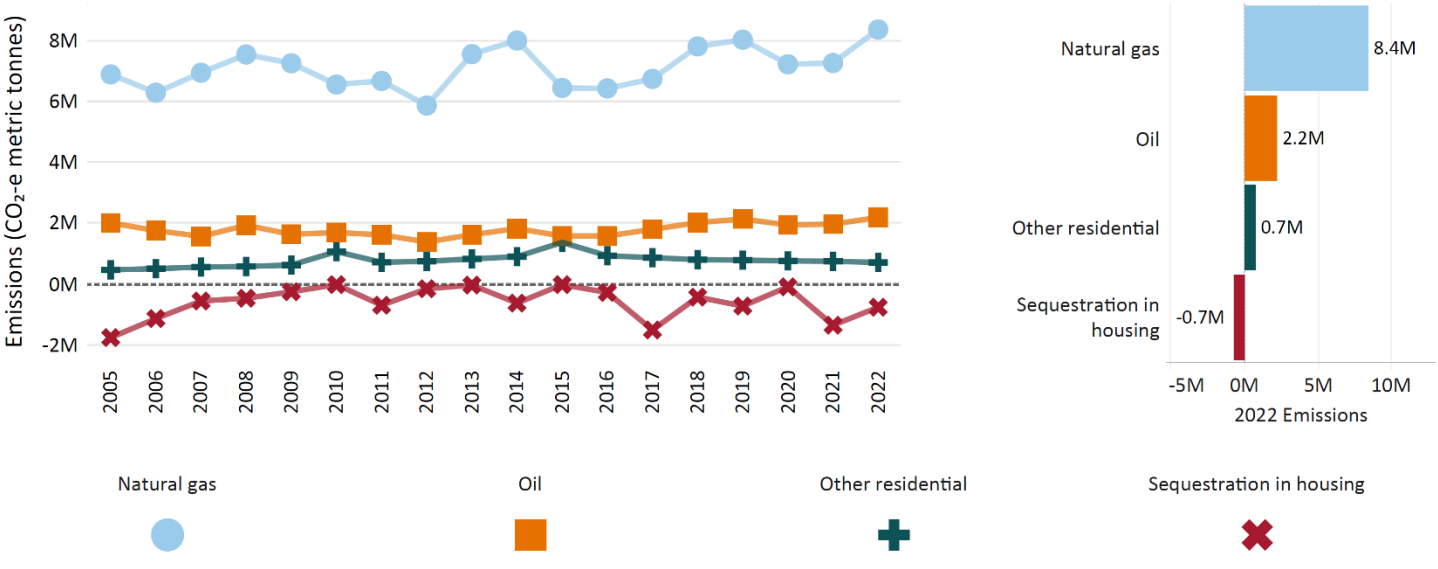
Emissions by subsector from 2005 to 2022 (left) and only 2022 (right). “Other Industrial” includes VOCs and toxics release, industrial wastewater treatment, semiconductor manufacturing, non-CO_2 emissions from biofuels, industrial solvent release, oil refining, and several sources related to specific manufacturing processes.

Residential

The residential sector is the fifth-largest source of GHG emissions in Minnesota, accounting for about 8% of the state's net emissions. The residential sector includes direct combustion of fossil fuels for heating and appliances, emissions from consumer products, and carbon stored in structural materials.

Since 2005, net emissions from the residential sector have increased by 38%. The largest residential emissions source is natural gas used for home heating and appliances. Emissions from residential natural gas and oil (e.g. propane and fuel oil) use have exceeded pre-pandemic levels. Annual variation in weather influences heating demand, affecting the GHG emissions in this sector. Improving home energy efficiency through weatherization and switching to electric technologies like heat pumps and appliances can significantly reduce residential emissions.

GHG emissions 2005-2022



It's important to note that emissions from electricity use in residences are not included in the residential sector; they are accounted for under the electricity generation sector.

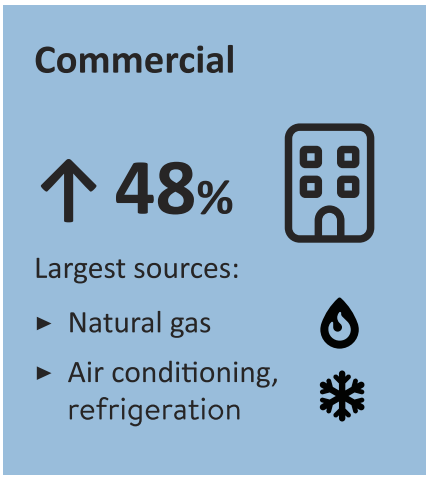
Emissions sources in the residential sector include:

- fossil-fuel combustion for heating and in-home appliances, such as furnaces, water heaters and clothes dryers
- home-product use
- food additives
- refrigerant leakage from air conditioners and refrigerators

This category includes carbon sequestered in wood construction materials. Over the lifetime of a house, carbon is stored and effectively removed from the atmosphere for decades, which offsets some emissions.

Residential sector GHG emissions

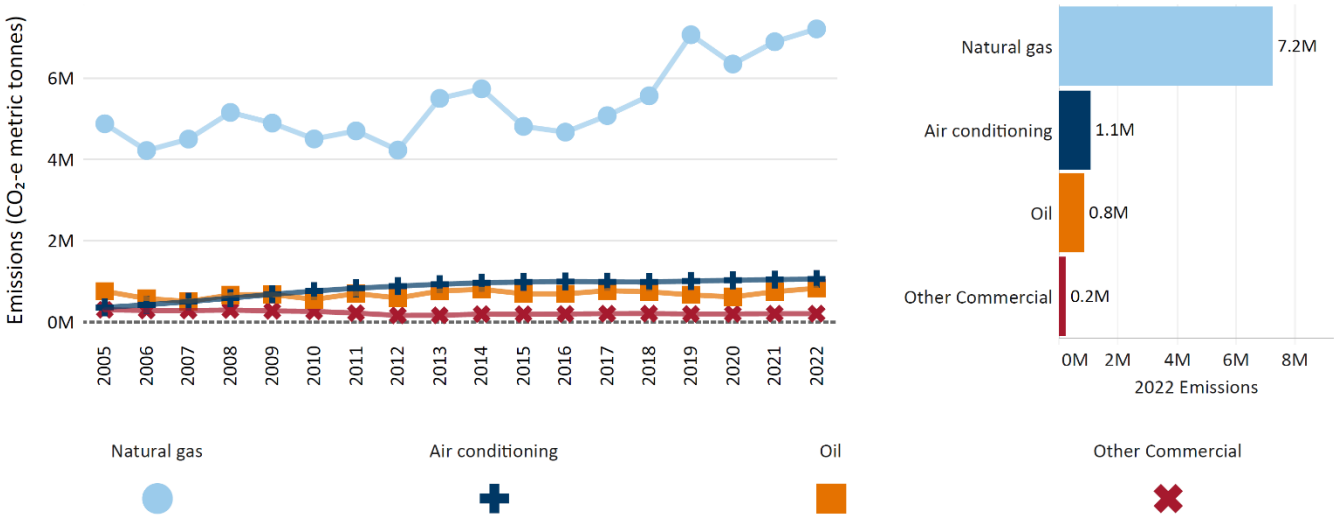
Emissions by subsector from 2005 to 2022 (left) and only 2022 (right). "Other Residential" includes non-CO_2 emissions from wood burning, aerosols, soaps/detergents, HFC emissions from air conditioning and refrigeration, carbon loss from wood in housing, and food additives.



Commercial

The commercial sector is the sixth-largest source of greenhouse gas emissions in Minnesota, accounting for about 7% of the state's net emissions. Emissions from the commercial sector are predominantly derived from fuel combustion to provide buildings with heating, in addition to refrigerant leakage from air conditioning and refrigeration equipment. This sector includes buildings that house businesses, institutions, and government facilities. Business buildings include retail stores, offices, and food service establishments. Institutional buildings include schools, corrections facilities, and hospitals. As with the residential sector, emissions from electricity use in the commercial sector are not included in this inventory sector; they are accounted for under the electricity generation sector. Since 2005, emissions from the commercial sector increased by 48%.

Emissions sources in this sector include:



- fossil-fuel combustion
- air conditioning
- solvent use
- medical N_2O emissions

GHG emissions 2005-2022

The increase in emissions from the commercial sector is predominantly driven by the increase in combustion of natural gas. Natural gas emissions in this sector have increased by nearly 50% since 2005, with 2022 being the highest year on record. Emissions from air conditioning and refrigeration chemical leakage have continued to increase, though their growth has slowed since 2015. Investments in energy efficiency, electrification, and building efficiency will help commercial and institutional sources reduce fossil fuel use and energy consumption. The scheduled phase-down of high global warming potential hydrofluorocarbons refrigerants will also reduce the total GHG emissions from this sector.

Commercial sector GHG emissions

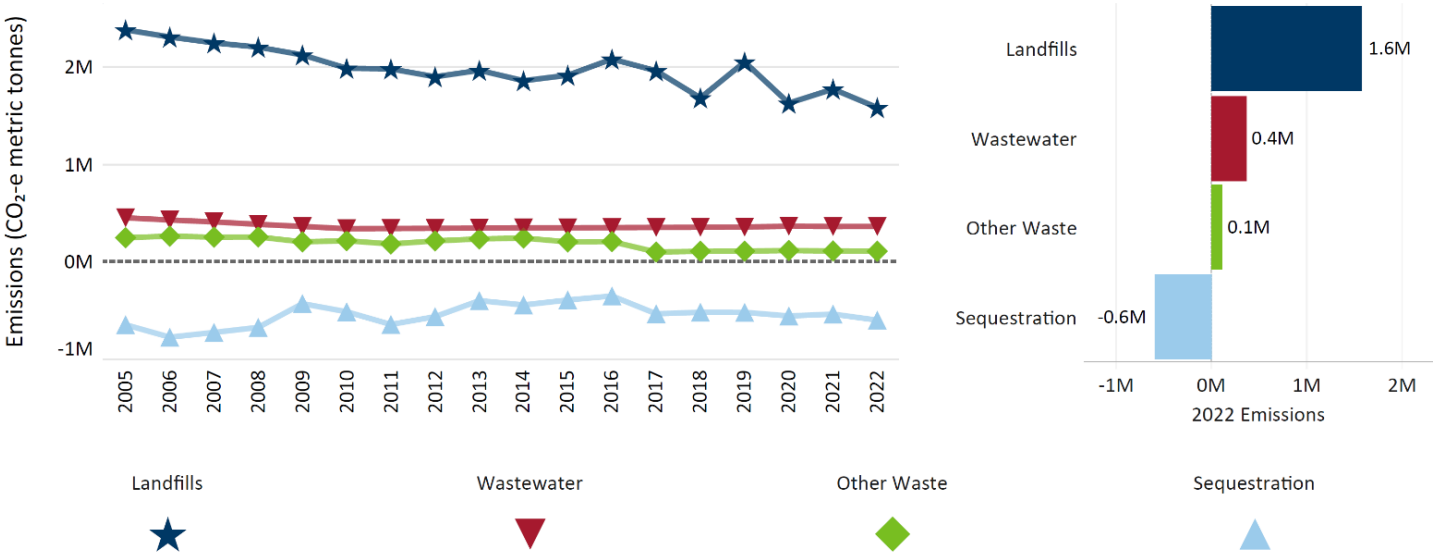
Emissions by subsector from 2005 to 2022 (left) and only 2022 (right). "Other Commercial" includes coal, solvent use, medical uses of nitrous oxide, non-CO2 emissions from biofuels, and limestone use.

Waste

The waste sector produces about 1% of GHG emissions annually in Minnesota. Compared to the 2005 baseline, GHG emissions from the waste sector have decreased by about 40%.

Emissions sources in the waste sector include:

- fossil fuel combustion in waste processing
- incinerator fuels
- waste incineration
- methane from landfill gas and wastewater treatment



GHG emissions 2005-2022

The waste sector includes one emissions sink, which is the landfilling of wood construction materials. Although reuse and recycling of lumber and wood products is preferable, construction waste disposed of within construction and demolition landfills stores carbon for many years. In Minnesota, more construction waste is landfilled than the amount that decays within landfills each year, resulting in carbon sequestration that partially offsets other waste emissions.

Gradually decreasing methane emissions from landfills drives this sector's overall GHG reduction trend. This decline in methane emissions is due to a combination of factors. Aging waste in operating landfills results in lower emissions because older waste emits less methane as the organic fraction decomposes and becomes more stable. Also, gas capture technologies used at landfills reduce methane emissions by combusting it in a flare or using it to produce usable energy. As the closed landfill program administrator, the Minnesota Pollution Control Agency (MPCA) is working to address methane emissions from these facilities.

Waste sector GHG emissions

Emissions by subsector from 2005 to 2022 (left) and only 2022 (right). "Other Waste" includes processing-related emissions from waste-related facilities and incineration-related emissions from waste facilities and rural open burning

Land use, land-use change, and forestry

Minnesota's land use, land-use change, and forestry (LULUCF) sector sequesters more GHGs than it emits, resulting in net negative emissions of 11.6 million metric tons of CO_2-e in 2022, offsetting 8.4% of all other emissions in the state. The rate of net sequestration has increased by about 20% since 2005, a trend that has largely been driven by growth within and expansion of Minnesota's forests.

The LULUCF sector consists of non-agricultural lands and waters. In the context of GHG accounting, "land use" refers to categories of land surfaces based on vegetation, hydrology, and human activities; it does not refer to land use planning and zoning in urban and suburban contexts, which is another common use of this term. International GHG reporting standards recommend quantifying land-use-related GHG emissions and sequestration if they occur on managed lands or are associated with human activity. In practice, all lands and waters in Minnesota are managed or influenced by humans to some extent, so we aim to include all land use types for which robust accounting methodology exists.

The "land-use change" component of this sector accounts for emissions and sequestration caused by conversions between forest lands, grasslands, surface waters, and settlements. Lands converted from croplands to any of these uses are included. However, lands remaining in, or converted to, croplands are included in the agriculture sector. We use the same land use definitions as the US Environmental Protection Agency[2] (EPA) and lands are considered remaining within a given use type if in continuous use for more than 20 years.

Rates of plant growth and decay, weather, and management decisions influence the exchanges of GHGs between lands, waters, and the atmosphere. While the science of land-use-related GHG accounting has developed rapidly, some land-use types do not yet have quantification methods or require input data that are not readily available. Wetlands have particularly complex GHG exchanges, so the only wetland-associated estimates currently included are emissions caused by peat harvesting. Trees outside of forests and developed areas (e.g., between crops or along rivers and streams) and carbon stored in harvested wood products are also not yet included due to limitations in data and methods.

GHG emissions 2005-2022

Land use, land-use change, and forestry

↓ **20%** **8.4% offset**

Largest carbon sinks:

- Existing forests
- Land converted to forest

Minnesota land use summary

Minnesota's total surface area is approximately 54 million acres and more than 70% of the land is privately-owned.

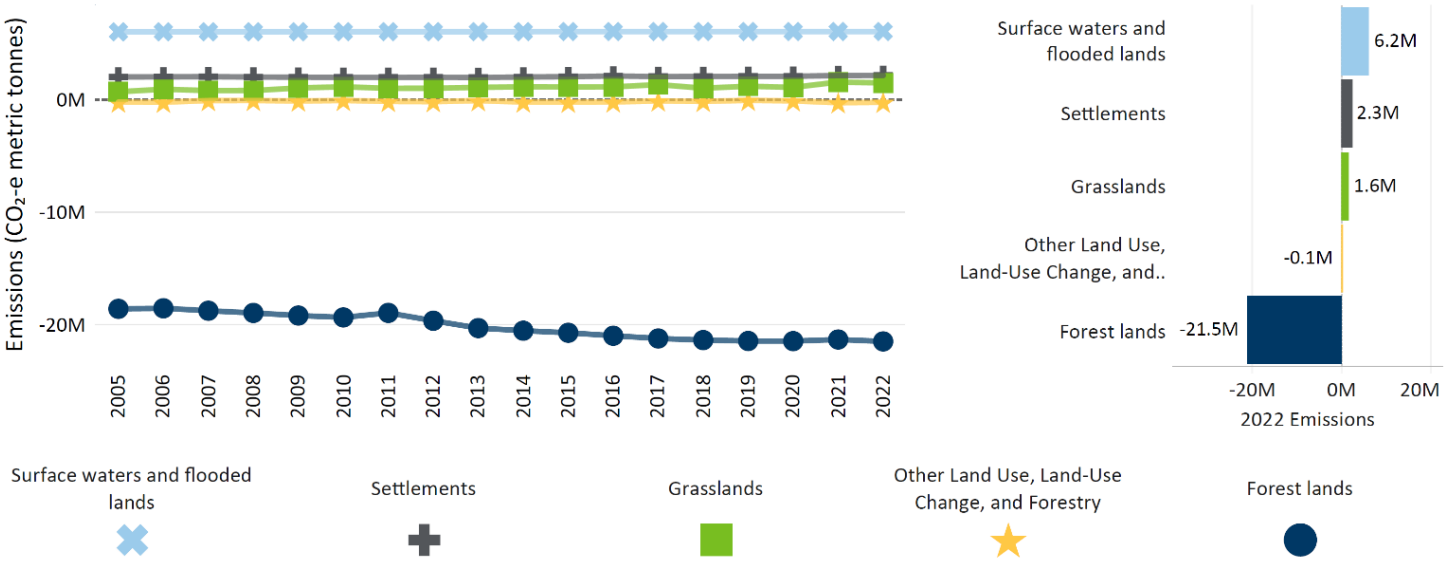
Percent of Minnesota's surface area by land use:

- Croplands: 39%
- Forests: 34%
- Grasslands: 8%
- Wetlands: 8%
- Open water: 6%
- Settlements: 5%
- Barren/other: <1%

Sources: US Geological Survey, MN DNR

Different land-use types store carbon and exchange greenhouse gases with the atmosphere at different rates. Conversion from carbon-rich natural systems, like forests, grasslands, and wetlands, to intensively managed croplands or developed lands, results in carbon emissions. Conversely, restoration of natural lands typically results in carbon sequestration. For lands remaining in a given land use, rates of sequestration and emissions depend on factors such as time since establishment, soil type, hydrology, and local management (e.g., timber harvest, grazing, fire, and fertilizer use).

[2] https://www.epa.gov/ghgemissions/methodology-report-inventory-us-greenhouse-gas-emissions-and-sinks-state-1990-2022



Forests in Minnesota sequester significant amounts of carbon dioxide each year (about 15% of total statewide emissions in 2022). The strength of Minnesota's forest carbon sink is attributable to multiple factors, including continued regrowth following the decades of widespread forest clearing for agriculture and unsustainable forest management practices throughout the 19th century. In addition, adopting sustainable timber harvesting practices in the 20th century played an important role in enhancing Minnesota's forest carbon sink.

Surface waters are the largest source of emissions in this sector. Reservoirs, canals, and ditches are significant human-caused sources of methane emissions. While lakes and rivers are natural water bodies, human contributions of nutrients to these waters increase their methane emissions above natural levels.

Settlements (which include cities, roads, and other developed lands and both categories of converted and remaining settlements) are the second largest net source of GHGs in this sector in 2022. The conversion of natural and working lands to settlements results in emissions, especially when organic soils are drained to allow for development. Many urban, suburban, and ex-urban communities in Minnesota also have robust tree canopies, however, which offset about a third of settlements' gross annual emissions.

Minnesota's grasslands are the third largest net source of emissions in 2022. Grasslands contain large stores of soil carbon, but the characteristics of the soils beneath these grasslands largely determine whether a given site emits or sequesters carbon. Ungrazed or moderately grazed grasslands on mineral soils typically sequester carbon, but a relatively small acreage of grasslands on drained organic soils (i.e., former peatlands) releases more carbon each year than is stored by grasslands on mineral soil. See the agriculture sector for further explanation of emissions from drained organic soils.

Land use, land-use change, and forestry sector GHG emissions

Emissions by land use type from 2005 to 2022 (left) and only 2022 (right). Several types of surface waters have been combined into "Surface waters and flooded lands." Lands remaining in and converted to a given land use (i.e. settlements, grasslands, and forest lands) have also been combined for this figure. See the interactive online data vizualizations for more details.

Harvested wood products

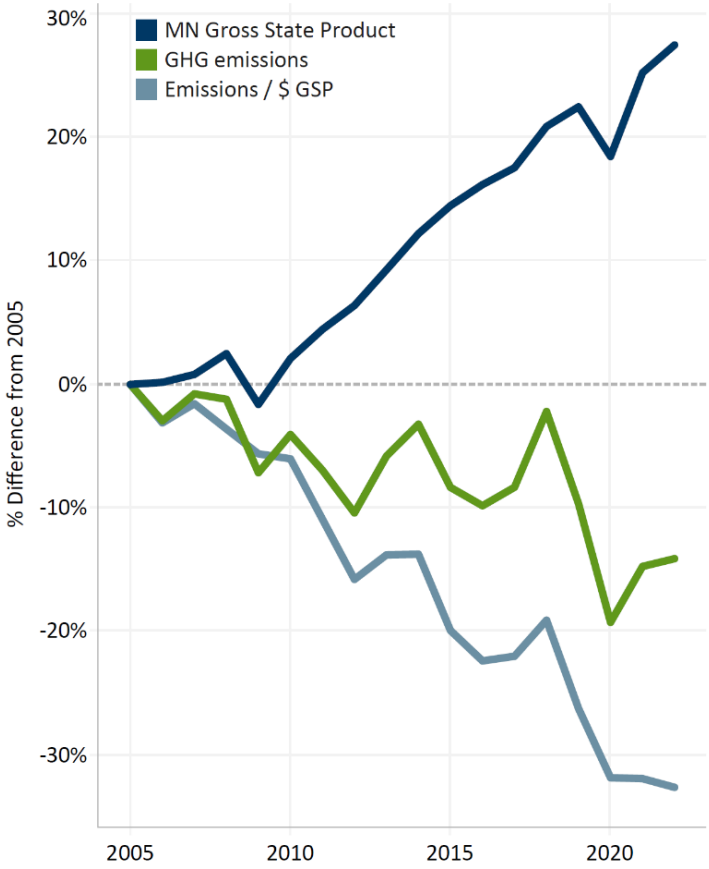
Harvested wood products store carbon—sometimes for long periods of time—and can also substitute for fossil-fuel-intensive products such as concrete and steel. The statewide GHG inventory currently does not include the net emissions associated with carbon stored in and emitted from wood products harvested from Minnesota's forests, except as estimates of wood used in residential construction and stored in construction and demolition landfills (see Residential and Waste sectors). A more complete accounting of the exchange of GHGs between Minnesota's forests and the atmosphere would include comprehensive annual estimates of carbon stored in and emitted from all harvested wood products, such as lumber, plywood and particleboard, and pulp and paper products.

When forests are managed with timber harvest, a large portion of the wood absorbed and stored in trees is transferred into wood products where it is stored for variable amounts of time. Long-lived wood products such as engineered wood and lumber are typically disposed of in landfills, where decomposition proceeds slowly.

Nationally, harvested wood products, both in use and in solid waste disposal sites, represent a consistent carbon sink that is roughly 12% of the magnitude of the national forest carbon sink. If this nationwide proportion is roughly true for Minnesota, harvested wood products might represent an additional 2.5 million metric tons of CO_2-e of sequestration and increase Minnesota forests' net sink from -21.5 million to -24 million metric tons of CO_2-e. We are developing a methodology for accounting for harvested wood products in Minnesota's GHG inventory and plan to include harvested wood products in the next iteration of this report.

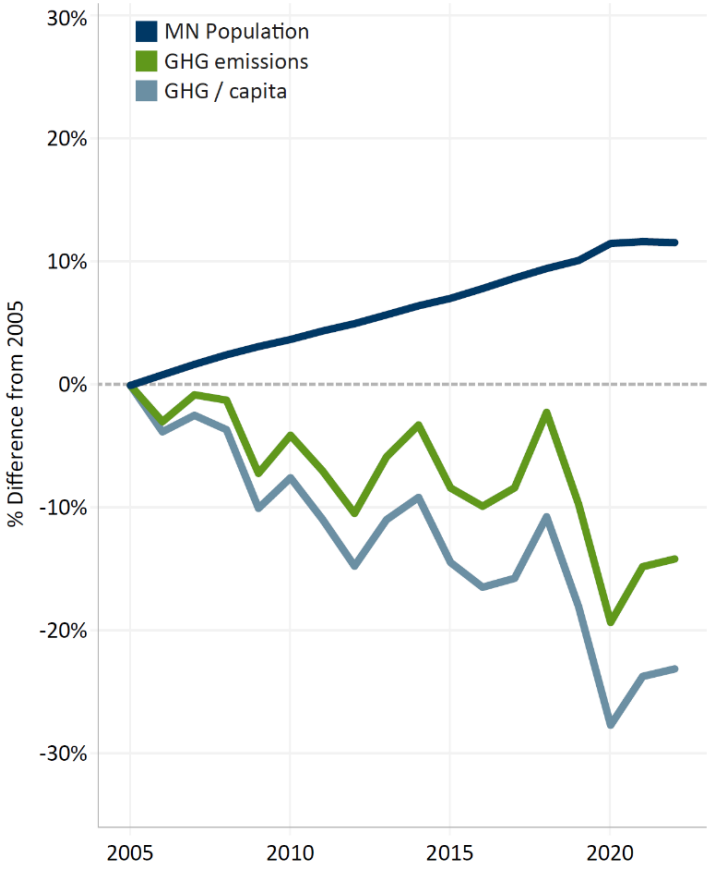
Increasing carbon sequestration and storage through land management

As the only sector that currently sequesters more GHGs than it emits, Minnesota's Land Use, Land Use Change, and Forestry sector will be critical to achieving the state's net-zero emissions goal. Fortunately, when our lands and waters are managed well, they not only release lower amounts of GHGs and absorb and store more carbon, they can also enhance climate resilience, support healthy plant and animal populations, and sustain our quality of life.



Examples of actions that support healthy landscapes and mitigate climate change:

- Forest managers can follow site-level guidelines and best practices to manage forests for wildlife habitat, recreation, clean water, timber, and climate resilience benefits over the long term.
- Grassland and prairie managers can establish a diverse mix of plant species – which has been demonstrated to enhance carbon storage – and adopt grazing practices that protect and enhance diversity and continuous cover.
- State, local, federal, and tribal governments can restore degraded lands, wetlands, and waterbodies to provide habitat, water quality, climate, economic, and recreational benefits.
- Residents, landowners, and communities can plant and care for native trees, wildflowers, and grasses.



Greenhouse gas emissions and our economy

Measuring the amount of GHG emissions compared to other economic indicators is one way to understand how GHG emissions relate to the state's economy. Trends show that Minnesota has begun disconnecting economic growth from GHG emissions. Minnesota's gross state product has grown since 2005, while GHG emissions have generally decreased, demonstrating that the state economy can grow without increasing GHG emissions. Similarly, Minnesota's generally decreasing GHG emissions show that population growth can occur while reducing GHG emissions. Though the population in Minnesota is increasing, there is a growing decrease in emissions per person. The Climate Action Framework outlines initiatives to advance Minnesota's transition to a clean economy, helping to ensure greenhouse gas emissions reductions align with the goals in state law.

GHG emissions per dollar gross state product
2005 to 2022

GHG emissions per capita
2005 to 2022

Our path forward: Minnesota's Climate Action Framework

In September of 2022, Minnesota's Climate Action Framework was released. The Framework, developed with input from 3,000+ Minnesotans, sets a vision for how the state will address and prepare for climate change. It identifies near-term actions we must take to achieve the long-term vision of **a carbon-neutral, resilient, and equitable future for Minnesota**.

The Framework is organized around six climate action goals with specific steps and progress measures to guide and evaluate our work.

- **Clean transportation**
  Transportation represents the greatest opportunity to reduce climate pollution. The Framework aims to connect and serve all people through a safe, equitable, and sustainable transportation system.
- **Climate-smart natural and working lands**
  Minnesota can manage natural and working lands to address climate change by absorbing and storing carbon, reducing emissions, and sustaining local economies.
- **Resilient communities**
  Communities experience the impacts of climate change differently, and solutions must be tailored to local needs. The state can prepare communities with the resources they need to plan and build a more resilient future for themselves.
- **Clean energy and efficient buildings**
  Minnesotans can benefit from investments in clean energy and energy efficiency that will create jobs, lower energy costs, and contribute to a more stable climate.
- **Healthy lives and communities**
  Changes in Minnesota's climate threaten the health of every community, but not everyone experiences these impacts equally. The Framework's goal is to protect the health and well-being of all Minnesotans in the face of climate change.
- **Clean economy**
  Transitioning to a cleaner economy must include solutions that benefit everyone. Minnesota will build an economy that addresses climate change and equitably provides family-sustaining job opportunities.

The Framework will guide the state of Minnesota's priorities for addressing climate change in the coming years. Actions identified in the document will be developed into new policies, programs, and grants to reduce our greenhouse gas emissions. The Framework is currently being updated to include a more comprehensive set of actions that help us achieve those goals. Analyzing Minnesota's emissions through this inventory allows us to track progress on the Framework goals and focus actions for maximum impact to address climate change.

Learn more about our next steps to tackle climate change and how you fit into this work by visiting **mn.gov/framework.**

Conclusion

Since launching our Climate Action Framework in 2022, Minnesota has made significant progress on climate action, including historic climate funding and policies adopted in 2023. These state funds combined with billions of dollars federal funding have advanced dozens of programs to cut climate pollution and prepare our state for a warmer, wetter Minnesota.

Minnesota has successfully reduced emissions by approximately 14% since 2005, but we have significant work to do to meet our goal of being carbon-neutral by 2050. While emissions bounced back after the most disruptive period of the COVID-19 pandemic, our overall emissions have not returned to 2019 levels, indicating we are still on a downward trend.

This inventory report doesn't capture the impacts of historic climate action funding at the state and federal level since 2022, which will result emission reductions in the coming years and decade. To achieve our goals, we must continue Minnesota's commitment to climate action by government, businesses, institutions, and individuals that reduces climate pollution while fostering economic growth and jobs across Minnesota.

Minnesota is updating our Climate Action Framework in 2025 to include a more comprehensive set of actions with a stronger focus on collaboration, community benefits, and workforce needs. Though we have made progress, we must accelerate the pace and scale of our climate actions to achieve our long-term vision of a carbon-neutral, resilient, and equitable future.

Appendix: Methodology

Greenhouse gas emission inventory

The GHG inventory reports progress toward statutory goals and transparently provides information with high confidence in our results. The long record of emissions and high level of data disaggregation using the best available data and methods based on EPA and Intergovernmental Panel on Climate Change (IPCC) recommendations helps ensure the inventory is complete, consistent, transparent, accurate, and relevant. The EPA produces a national GHG inventory and a downscaled state-level GHG inventory. Both national and state EPA inventory versions are useful and incorporated in many parts of this inventory. However, there are differences between the MPCA inventory and others, such as the focus on activities like energy use or process emissions rather than on economic sectors, the division of electricity sector emissions, and the inclusion of imported electricity emissions. Inventories may present different details but are helpful as comparisons despite their differences.

Minnesota's state-level emission reduction goals are expressed as percentage reductions from estimated emissions in a historical baseline year (2005). Like most GHG inventories, the Minnesota GHG inventory has undergone substantial revisions since it was first built. It is continuously revised as methods and data improve and new emission sources are incorporated. When possible, these changes are applied to all inventory years to ensure consistency, including the 2005 baseline year. Developing a consistent time series of emissions estimates is essential to measure progress.

Not all emissions are included in statewide emission totals. Only those sources which can be included in the baseline year are evaluated. While it would be ideal to inventory and track all sources of GHG emissions from activities within Minnesota, in practice, the inventory consists of only those sources for which a well-developed scientific understanding of the physical and biological processes involved in the production and emission of GHGs exists. To include an emission source in the inventory, generally accepted protocols or methods must exist, and continuous data or reasonable quality must be available to support estimation.

Only emissions that occur within the geographical borders of the state are estimated, with two exceptions. Our estimate includes net electricity imports to meet Minnesota's electricity demand, which exceeds in-state electricity production. Emissions from the combustion of aviation fuel purchased in Minnesota but not necessarily combusted within Minnesota air space are also included.

GHG inventory protocols require accounting for photosynthetically-removed carbon dioxide stored in biomass in forests, landfills, and structures. Long-term storage of wood-carbon in residential structures and demolition and construction landfills is included in statewide GHG emission totals as sequestration because the materials will remain as carbon stores for a long time. Forest carbon fluxes are included from forest land that remains forest land and land converted to forest land following the EPA state methodology report (2022).

Within the agriculture and LULUCF sectors, some specific inclusions and exclusions are worthy of mention: Croplands enrolled in contract-based conservation programs (e.g., Conservation Reserve Program) are included in this sector because they are relatively likely to return to crop production, while former croplands that have been converted to wetlands, grasslands, forests, or settlements are instead included in the land use sector. Because grasslands are not exclusively used for agricultural purposes, grassland biomass and soil carbon fluxes are included in the land use sector, but any emissions from grazing livestock and manure are accounted for within the agriculture sector. Trees within croplands (e.g., windbreaks, agroforestry) are not included in the agriculture sector because quantification methods are not yet available. Finally, upstream emissions associated with the production of inputs such as fertilizers and equipment are out of scope for the agriculture sector; if these activities occur within Minnesota, their emissions are accounted for in the industrial sector.

Emissions are estimated from 1990 to 2020, though presented here in an abbreviated timeline. With a few exceptions, the methods used to develop these estimates are derived from the following sources:

- US Environmental Protection Agency (2022) Inventory of US greenhouse gas emissions and sinks: 1990-2020.
- US Environmental Protection Agency (2022) Methodology Report: Inventory of US greenhouse gas emissions and sinks by state: 1990-2020.
- US Environmental Protection Agency Motor Vehicle Emissions Simulator (MOVES) Models (versions 2014b and 3.1)

Changes in methods and data sources

The methods used to develop the emission estimates are generally consistent from year to year, and changes made since the last report are discussed here.

Data collection methods implemented by the Minnesota Department of Transportation improved our accounting of vehicle miles traveled and the breakdown of miles traveled by vehicle type. However, these improved data are only available for recent years. Comparisons to 2005 details are therefore less accurate, but the overall trend in emissions is similar to the information reported in EPA's Inventory of US Greenhouse Gas Emissions and Sinks report and is still useful for tracking overall progress.

Since the last report, significant changes have been made to estimate GHG fluxes within the agriculture and land use, land-use change, and forestry sectors. In a shift from previous inventories, we now primarily use estimates provided by the EPA [3] for both of these sectors and have replaced historical estimates for consistency. The EPA inventory uses more sophisticated modeling with more complete coverage of both sectors than previously provided in this report.

Within the agriculture sector, this shift allows the inclusion of soil carbon fluxes in mineral soils (previous versions only included fluxes from organic soils). Other methods differ slightly from our previous approach, but estimates for each flux are generally similar to those derived using our previous methods.

Within the LULUCF sector, this shift to using EPA estimates allows us to include grasslands, settlements, and canals/ditches for the first time. EPA's estimates for lands converted to reservoirs were corrected for a known area overestimate. Lawn-applied nitrogen fertilizer emissions were previously accounted for within the residential sector but are now accounted for within settlements in the LULUCF sector. Estimates for emissions from lakes/ponds and rivers/streams are not included in the EPA inventory and are calculated using emission factors derived from peer-reviewed literature. For detailed definitions and methods of land use, see the

[3] US EPA's Inventory of US GHG Emissions and Sinks by State 1990-2022. https://www.epa.gov/ghgemissions/methodology-report-inventory-us-greenhouse-gas-emissions-and-sinks-state-1990-2022

associated Technical Supporting Document, which will be published shortly following this report and available on the same website: https://www.pca.state.mn.us/air-water-land-climate/climate-change-trends-and-data. We are committed to continuing to adopt the best available methods across all land use types and aim to include all GHG fluxes associated with wetlands, trees outside of forests and settlements, and harvested wood products in the future.

We strive to use the best available data and methods and are currently developing analyses using the US Department of Agriculture's Carbon Management & Emissions Tool (COMET) farm tool for potential future use to estimate fluxes from all of agriculture, as well as grasslands within LULUCF.

The Energy Information Administration (EIA) Fuel Oil and Kerosene Sales Report had previously been used to disaggregate fuel types and uses within economic sectors; however, that dataset has been discontinued. Now, the best available data is from the EIA State Energy Data System (SEDS), which is not as disaggregated with regard to fuel type or sector. As a result, we are no longer able to report agricultural diesel use nor distinguish biodiesel blends from total distillate fuel oil. This results in a small overestimate of CO_2 emissions from biodiesel in non-transportation uses. In addition, data derived from SEDS includes agriculture-related fuel combustion within industrial fuel combustion; therefore, these emissions are now included in the industrial sector totals.

In previous versions of this report, emissions related to peat harvesting were reported in the industrial sector. Those emissions are now reported in the land use, land-use change, and forestry sector, in alignment with the EPA's sectoral arrangement.

In previous versions of this report, methane emissions from hydroelectric reservoirs were duplicated in the electricity generation and the former agriculture, land use, and forestry sectors. These hydroelectricity-related emissions are now included only in land use, land-use change, and the forestry sector, which aligns with the EPA's sectoral arrangement.

Ozone-depleting substances (ODS) historically used as common refrigerants were replaced by other compounds, namely hydrofluorocarbons (HFCs) and perfluorocarbons (PFCs), collectively known as ODS substitutes. These ODS substitutes are high global warming potential GHGs whose emissions are included in this inventory. In previous reports, the procedure for estimating emissions from ODS substitutes in the commercial sector included scaling down national emissions to the population of Minnesota and subtracting emissions from state-level residential and transportation sectors. In this report, the estimation has been changed to leverage the state-level EPA GHG inventory, which estimates sector-specific emissions from ODS substitutes for Minnesota.

In the previous report, residual fuel oil was overestimated in the off-highway category of the transportation sector due to duplication in the railroad, marine, and military and other off-highway categories. It is now accounted for only in the marine category. An additional clerical error in the military and other off-highway category was corrected.

Finally, in the last report, commercial sector emissions associated with fuel oil combustion were overestimated. This error has been corrected in calculations for the current report.

The overall impact of these methodological changes is an improved understanding of Minnesota's progress toward statutory emissions reduction goals. Ongoing improvement in methodologies will continue to improve our understanding of Minnesota's historic emissions in future versions of this report.

Uncertainty of estimates and opportunities for improvements

It is difficult to calculate the precise amounts of GHG emissions; however, getting a reasonable estimate is still critical in understanding the general scope of emissions.

Several methods and data sources are used to estimate emissions from each activity within a sector to get a comprehensive view. Some of the methods for generating the estimates are very detailed and result from site-

specific measurements for both activity and emissions. In contrast, others use a model with only general data to characterize the source of emissions.

The accuracy of data for different economic sectors can vary:

- Fossil fuel combustion in each sector, such as electricity generation and industrial uses, has low uncertainty, especially when aggregated to state totals because the activity is regulated and tracked.
- Emissions from on-road transportation are estimated using the MOVES model, which depends on vehicle population and vehicle miles traveled data. Methods to measure vehicle miles traveled and types of vehicles on our roads have changed over time. This means that we understand current transportation activity much better than we did in the past, and it also means that there is more uncertainty in estimates for past years. However, our emissions trend is similar to other published estimates, such as the EPA state inventory.
- Methane generated from municipal solid waste in landfills is modeled. There is some uncertainty from data inputs and the model's underlying equations and assumptions.
- Emissions and sequestration from agriculture, forestry, and land use have a higher degree of uncertainty due to the multitude of factors influencing biological processes and the difficulty of obtaining accurate, relevant, detailed information.

STATE OF MINNESOTA
Executive Department

Governor Tim Walz

Executive Order 19-37

Establishing the Climate Change Subcabinet and the Governor's Advisory Council on Climate Change to Promote Coordinated Climate Change Mitigation and Resilience Strategies in the State of Minnesota

I, Tim Walz, Governor of the State of Minnesota, by the authority vested in me by the Constitution and applicable statutes, issue the following Executive Order:

Climate change is an existential threat that impacts all Minnesotans and our ability to thrive. Communities, farms, and industry face more frequent extreme weather events that threaten the infrastructure that we rely on to connect all parts of our state, cause undue economic stress, and place our communities and environment at risk. By increasing risks from vector-borne diseases and extreme weather, especially for vulnerable populations and individuals with pre-existing conditions, climate change threatens Minnesotans' health and wellbeing.

Climate change is a complex problem, and Minnesota recognizes that the impacts of climate change are disproportionally borne by disadvantaged communities. Disparities exist in Minnesota, including those based on race, gender, geography, and economic status, and they prevent us from reaching our full potential as a state. These disparities can be exacerbated by policies that do not reflect considerations of equity.

By working collaboratively, we can build resilient communities, promote community prosperity, mitigate risk to our farms and businesses, and create a homegrown clean economy. Currently, job growth in the clean energy sector is outpacing job growth in the overall economy. Continued leadership on climate change will position Minnesota for long-term economic success.

Minnesota's 2007 Next Generation Energy Act set statutory goals to reduce greenhouse gas emissions in the state by 30% of 2005 levels by 2025 and 80% by 2050. Minnesota fell short of its 2015 goal of 15% and is not on track to meet the 2025 goal. We must redouble our efforts to meet our future goals.

To fulfill Minnesota's statutory goals, avoid the severe economic, health, and ecological impacts associated with a changing climate, and fully realize the benefits of a healthy, sustainable, and resilient state, our state government must work across the enterprise in a coordinated approach to develop equitable strategies that will mitigate climate change and achieve greater resilience.

For these reasons, I order that:

1. A Climate Change Subcabinet ("Subcabinet") is established.

2. The purpose of the Subcabinet is to:

    a. Identify policies and strategies that will put Minnesota back on track to meet or exceed our goals, established under Minnesota Statutes 2019, section 216H.02, to reduce statewide greenhouse gas emissions across all sectors to a level at least 30% below 2005 levels by 2025, and to a level at least 80% below 2005 levels by 2050.

    b. Identify policies and strategies that will enhance the climate resiliency of Minnesota's natural resources, working lands, and communities.

3. The members of the Subcabinet are the Commissioner, Executive Director, or Chair of the following agencies and boards:

    a. Pollution Control Agency ("MPCA")

    b. Department of Commerce

    c. Department of Labor and Industry

    d. Department of Management and Budget

    e. Department of Employment and Economic Development

    f. Department of Agriculture

    g. Department of Public Safety

    h. Department of Natural Resources

    i. Department of Health

    j. Department of Transportation

    k. Board of Water and Soil Resources

    l. Department of Administration

    m. Metropolitan Council

    n. Environmental Quality Board

    o. Minnesota Housing Finance Agency

4. The Commissioner of the MPCA will serve as Chair of the Subcabinet.

5. The duties of the Subcabinet are as follows:

    a. **Climate Mitigation and Resilience Policy and Strategy Development.**

        i. Identify policies and strategies that the State may adopt to meet or exceed the economy-wide greenhouse gas emissions goals of the 2007 Next Generation Energy Act and achieve 100% clean energy by 2050.

        ii. Identify challenges and opportunities to mitigate climate change and consider how climate change mitigation policies intersect with the work of the Subcabinet members' agencies or boards.

        iii. Identify policies and strategies that will enhance the climate resiliency of Minnesota's natural resources, working lands, and communities and assist the state enterprise, families, businesses, and local communities to prepare for climate change impacts that cannot be avoided or mitigated.

        iv. Consider how climate change mitigation and resilience policies and strategies can reduce greenhouse gas emissions and energy waste; promote economic development, innovation, and job creation; ensure equitable distribution of benefits; and address disparities in current impacts related to climate change.

        v. Submit a written update to the Governor on December 1 of each year, with a first update due by December 1, 2020.

    b. **Public Engagement.** Successful policy and strategy development requires that those impacted, including frontline communities, indigenous peoples, industry, and workers, among others, have a voice and the opportunity to participate in the process. The Subcabinet will develop and implement a public engagement framework to ensure meaningful public engagement is conducted by the Subcabinet's agencies and boards. The purpose of the engagement framework is to:

        i. Build partnerships and shared understanding across Tribal Nations; local communities; and sectors including, but not limited to, agriculture, transportation, business, and conservation and environmental interests.

        ii. Provide a platform for dialogue about the strengths and challenges of climate change mitigation and resilience solutions, including policies and voluntary actions, and how these solutions will impact the lives of Minnesotans, including those who have been traditionally underrepresented in policy discussions, are disproportionately impacted by climate change, and are impacted by the transition to a clean energy economy.

iii. Highlight regional differences across Minnesota regarding the effects of climate change and locally relevant solutions.

iv. Share and gather ideas for how Minnesotans can get involved with, and stay informed about, climate change issues that matter to them.

6. The Governor's Advisory Council on Climate Change ("Advisory Council") is established to advise the Subcabinet in its duties.

7. The Advisory Council will be comprised of up to 15 members appointed by the Governor. The Governor will seek representation from community leaders, individuals with experience in the business sector, agriculture, conservation and environmental protection, and other relevant stakeholders.

8. The duties of the Advisory Council are as follows:

   a. Meet up to four times per year to identify opportunities for, and barriers to, the development and effective implementation of policies and strategies to reduce greenhouse gas emissions and promote climate change resiliency.

   b. Promote equity by examining how climate change impacts communities across the state and how potential solutions can address current disparities, incorporating the perspectives of people of color, indigenous people, rural Minnesotans, and other populations who experience disproportionate impacts from climate change.

   c. Promote a just transition for impacted workers and communities by examining the trade-offs that may accompany policies.

9. The MPCA, in coordination with other state agencies and boards, will provide staffing and administrative support to the Subcabinet and the Advisory Council.

This Executive Order is effective fifteen days after publication in the State Register and filing with the Secretary of State. It will remain in effect until rescinded by proper authority or until it expires in accordance with Minnesota Statutes 2019, section 4.035, subdivision 3.

Signed on December 2, 2019.

Tim Walz
Governor

Minnesota Greenhouse Gas Inventory

MINNESOTA POLLUTION CONTROL AGENCY

Main sources of GHG emissions and sequestration by sector in 2023

This figure shows the main sources of greenhouse gas emissions in each sector for 2023, the most recent year of available data. Mouse over each bar to see emissions by subsector for 2023. Negative emissions represent carbon sequestration.

Each sector includes the following emissions sources and sinks:

Transportation: Fuel combustion in gasoline and diesel vehicles, aviation, rail, air conditioning leakage, and natural gas pipelines

Minnesota Greenhouse Gas Inventory

MINNESOTA POLLUTION CONTROL AGENCY

Sector-level details

Subsector-specific GHG emissions from 2005 to 2023 are shown. Hover over the figures to view for details. Filter options to change plot type, sector, or the GHGs included. Line plots display trends for individual subsectors over time as separate lines and are paired with a legend differentiating the subsectors. The legend lists subsectors from largest to smallest emission sources in 2023.

Figure 3. Industrial Agriculture Contributes to Climate Change

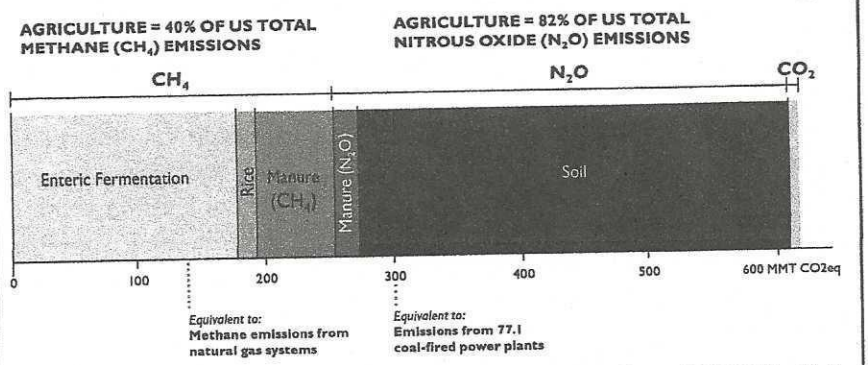
Source: U.S. EPA, INVENTORY OF U.S. GREENHOUSE GAS EMISSIONS AND SINKS: 1990-2018 (Feb. 2020), https://www.epa.gov/sites/production/files/2020-02/documents/us-ghg-inventory-2020-main-text.pdf (tables 2-1 & 2-2, trends in U.S. greenhouse gas emissions; 2-4, energy; 2-5, combustion; 2-10, industrial; 5-1, agriculture; 6-1, land use and land use change; and 7-1, 7-3 & 7-6, waste & landfills); coal-fired power plants equivalencies from U.S. EPA, *Greenhouse Gas Equivalencies Calculator*, https://www.epa.gov/energy/greenhouse-gas-equivalencies-calculator. Percentages are of total gross U.S. anthropogenic GHG emissions.

countries are already investing significant sums into agroforestry research and production, yet the United States has lagged, despite robust research demonstrating its significant potential to sequester carbon while producing ample food. Moreover, food production needs will increase as the global population continues to grow. Thus, perhaps even more than agriculture's current contribution, its long-term determinative factor in climate stability demands careful policy attention.

2. U.S. Agricultural Greenhouse Gas Emissions

The U.S. Environmental Protection Agency (EPA) estimates that 2019 emissions from agricultural activities—growing crops and raising livestock and poultry—totaled about 629 million metric tons of carbon dioxide equiva-

lent (MMT CO_2 eq.), accounting for more than 10% of total U.S. greenhouse gas emissions.[12]



These agricultural emissions are at a minimum roughly equivalent to that produced by 136 million automobiles in a typical year.[13] However, unlike the greenhouse gas emissions of most other sectors of the economy, which consist of CO_2 released from the burning of fossil fuels, agriculture greenhouse gas emissions consist largely of nitrous oxide (N_2O) from soils and manure and methane (CH_4) from livestock and manure (as shown in Figure 3 on page 40). Agriculture also produces CO_2 from fossil fuel combustion (both on farms and off-site for on-farm electricity) and CO_2 from land conversion, neither of which are included in the EPA sector total. Agriculture is responsible for approximately 80% of U.S. N_2O emissions and 40% of U.S. CH_4 emissions—the same as the entire oil and gas sector's production emissions.[14]

The largest source of U.S. agricultural greenhouse gas emissions according to EPA is agricultural soil management. Activities by microorganisms in soil naturally result in emissions of N_2O, while agricultural practices, management, and land use can stimulate and accelerate these emissions by increasing the availability of nitrogen. Agricultural greenhouse gas emissions are dominated by emissions resulting from application of fertilizer as well as emissions associated with the breakdown of soil organic matter.[15] Soil management generates approximately half of all U.S. agricultural emissions and 93% of all U.S. N_2O emissions from agriculture.[16] Seventy-three percent of N_2O emissions from agricultural soil management come from cropland and 27% come from grazed grasslands.[17]

The next largest source of agricultural emissions is enteric fermentation, which results from the digestive process of ruminants (largely cows and sheep in the United States) (see Figure 4, page 42). Enteric fermentation creates CH_4, which animals subsequently release into the atmosphere through

12. U.S. EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2019, at 5-1 (2021), https://www.epa.gov/sites/production/files/2020-02/documents/us-ghg-inventory-2020-main-text.pdf. The 2019 emissions are more than 1% higher than those from just the prior year, 2018.
13. *Compare id., with* U.S. EPA, Greenhouse Gas Emissions From a Typical Passenger Vehicle (2018) (a typical passenger vehicle emits 4.6 metric tons of CO_2 annually).
14. *See* U.S. EPA, *Overview of Greenhouse Gases*, https://www.epa.gov/ghgemissions/overview-greenhouse-gases (last updated Sept. 8, 2020).
15. U.S. EPA, Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2018, Box 5-3 at 5-36 (2020) (EPA 430-R-20-002), https://www.epa.gov/sites/production/files/2020-04/documents/us-ghg-inventory-2020-main-text.pdf). In the methodology used by EPA to calculate nitrous oxide emissions, microorganisms in soil produce nitrous oxide at rates dependent on the availability of nitrogen, land use and management, weather, soil types, and other environmental conditions.

17. *See id.* at 5-25 tbl.5-15.

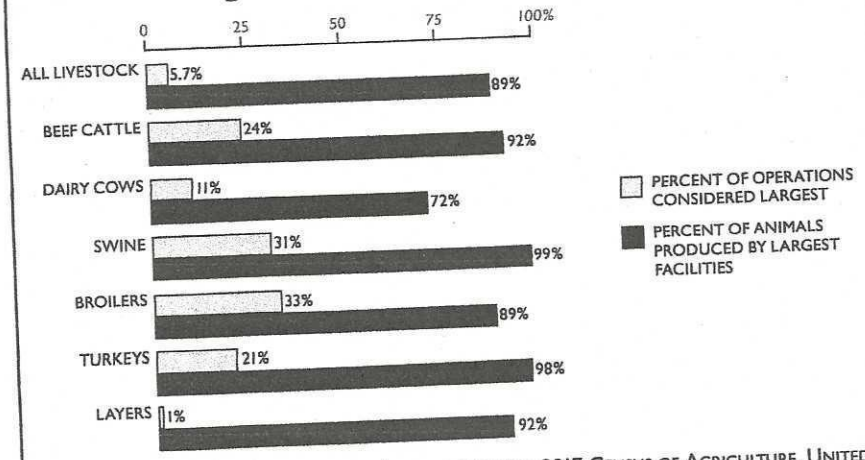
Figure 4. Major Sources of Agricultural Greenhouse Gas Emissions in the United States

Source: U.S. EPA, INVENTORY OF U.S. GREENHOUSE GAS EMISSIONS AND SINKS: 1990-2018, at 5-2 tbl.5-1 (Feb. 2020), https://www.epa.gov/sites/production/files/2020-02/documents/us-ghg-inventory-2020-main-text.pdf.

belching and exhalation.[18] Enteric fermentation is responsible for 32% of all agricultural emissions and 27% of CH_4 emissions in the United States.[19] (As discussed below, the relative impact of bovine exhalation would be much greater using more appropriate approaches for calculating CH_4 emissions.)

Manure management activities are the third major category of U.S. agricultural emissions, releasing N_2O and CH_4 in quantities that total 13% of total U.S. agricultural emissions.[20] The largest animal facilities—those with over 1,000 cattle on feed, 1,000 dairy cows, 2,000 finishing hogs, 100,000 turkeys sold, 300,000 broilers sold, or over 50,000 laying hens —generate the substantial majority of these emissions. Greenhouse gas emissions from enteric fermentation and manure are largely dependent on the number of animals raised in these facilities, which are heavily concentrated in a small proportion of the largest operations: over 50% of dairy cows in the United States are in the 4% of operations that stock 1,000 or more dairy cows.[21]

18. Andy Thorpe, *Enteric Fermentation and Ruminant Eructation: The Role (and Control?) of Methane in the Climate Change Debate*, 93 CLIMATE CHANGE 407, 411 (2009).
19. *See* U.S. EPA, *supra* note 15, at ES-7 tbl.ES-2, 5-2 tbl.5-1.
20. *See id.* at 5-2 tbl.5-1.
21. *See* NATIONAL AGRICULTURAL STATISTICS SERVICE, USDA, 2017 CENSUS OF AGRICULTURE, U.S. NATIONAL LEVEL DATA tbl.12 (2019). NASS uses different class sizes than does EPA in its definition of a "concentrated animal feeding operation" under the Clean Water Act. Pursuant to EPA rules, a large concentrated animal feeding operation (CAFO) is one with more than 1,000 animal units. An animal unit is defined as an animal equivalent of 1,000 pounds live weight and equates to 1,000 head of beef cattle, 700 dairy cows, 2,500 swine weighing more than 55 pounds, 125,000 broiler chickens, or 82,000 laying hens or pullets. *See* 40 C.F.R. §122.23(b)(4).



More than 90% of hogs in the United States are in the 12% of facilities that stock 2,000 or more hogs,[22] and more than three-quarters of all cattle on feed in the United States are in the 5% of facilities that stock 1,000 or more cattle.[23] As shown in Figures 5 and 6 (see page 44), the climate footprint of animal agriculture is directly correlated to this concentration of inventory, with a few large facilities responsible for the majority of greenhouse gas emissions.

Methane emissions released from soils flooded for rice cultivation and the field burning of crop residues make up more than 2% of total U.S. greenhouse gas emissions from agriculture.[24] In addition, CO_2 emissions from urea fertilization and liming—included by EPA in its estimate of agricultural emissions for the first time in 2015[25]—account for just under 2% of agricultural emissions.[26] We compare emissions of various agricultural activities in Figure 4.

The vast majority of agricultural emissions are from animal production, particularly beef and dairy. In the United States, meat and dairy production—including emissions related to production of their feed (which is about half of U.S. crop production), grazing, enteric fermentation, and manure—accounts for almost 80% of agriculture's greenhouse gas emissions.[27] If the global cattle population were a country, it would constitute the second largest greenhouse gas emitter after China.[28] Both the grazing stage for cows and the feedlot stage for beef, dairy, swine, and poultry production, as practiced now, produce substantial greenhouse gas emissions.[29] Because cows produce only one calf at a time, which nurse for months and then must graze until their bodies can take a grain diet in a feedlot, there are about five cows grazing for each of the close to 30 million cows in feedlots.[30] This requires vast amounts of land—almost 800 million acres or about 40% of the contiguous United States is devoted to grazing.[31]

Figure 7. Annual Greenhouse Gas Emissions From Largest Animal Facilities

Source: CLAIRE HUANG, EARTHJUSTICE, AIR AND GHG EMISSIONS CAFOS: QUANTIFYING A NATIONAL ESTIMATE 25 (Aug. 19, 2020).

In addition, approximately half of all harvested cropland is devoted to animal feed crop production, adding to animal agriculture's already capacious footprint.[32] This cropland is often cultivated more intensely than cropland growing human food and often emits more nitrous oxide per acre than the production of crops for human consumption.[33] However, only a fraction of those crop calories is delivered to humans because the feed-to-meat ratio is so inefficient. For example, the production of one pound of beef from feedlot

32. There were approximately 310 million acres of harvested cropland in 2007 according to the Census of Agriculture. NATIONAL AGRICULTURAL STATISTICS SERVICE, U.S. DEPARTMENT OF AGRICULTURE, 2007 CENSUS OF AGRICULTURE: U.S. NATIONAL LEVEL DATA 16 tbl.8 (2009). The U.S. Department of Agriculture (USDA) estimates that approximately 165 million of those acres were devoted to feed crops; however, up to 10% of the feed was diverted to biofuels. CYNTHIA NICKERSON ET AL., USDA, MAJOR USES OF LAND IN THE UNITED STATES, 2007, at 20 (2011) (EIB-89). This total does not include soybeans, which USDA considers a "food crop," despite the fact that soybean meal is typically used as animal feed. TANI LEE ET AL., USDA, MAJOR FACTORS AFFECTING GLOBAL SOYBEAN AND PRODUCTS TRADE PROJECTIONS (2016).

33. Conventionally grown feed crops, such as corn, soybean, and hay, generally result in high N_2O emissions. *See* EPA, *supra* note 15, at 5-23.

cattle requires 15 pounds of grain.[34] As a result, grazing and feed crop production contribute almost two-thirds of N_2O emissions from agricultural soils.[35]

Not only does animal agriculture overall have an outsized impact on climate change, but this impact is—under current production methods—particularly influenced by beef, dairy, and to a lesser extent, swine production. This impact is all the more striking given that Americans receive only 30% of their calories from animal products.[36]

3. State-Level Agricultural Greenhouse Gas Emissions

While virtually all U.S. states have important agricultural sectors, their agricultural emission rates vary significantly due to climate differences and the type and intensity of agriculture within the state. A major factor is the amount of livestock. The top 10 highest overall greenhouse gas emitters (including fossil fuel emissions) account for nearly 50% of national emissions, with Texas and California in the lead. (See total emissions listed below state names in Figures 8 and 9 on pages 47 and 48.) However, the states with the largest total agricultural greenhouse gas emissions are Iowa (63 MMT CO_2 eq./yr.) with more than 10% of all U.S. agricultural greenhouse gas emissions, Texas (38 MMT CO_2 eq./yr.), Nebraska (33 MMT CO_2 eq./yr.), and California (29 MMT CO_2 eq./yr.). All of these states have both very high numbers of livestock and extensive cropland.

States also vary in the significance of agricultural emissions, accounting for more than 50% of total state emissions in South Dakota, and more than 30% of state emissions in Idaho, Nebraska, and Iowa. Finally, agricultural greenhouse gas emissions also vary when scaled by total cropland acres, indicating the relative intensity of the agricultural practices and the portion of

34. The feed conversion ratio expresses the number of pounds of grain necessary to increase the "live weight" of a head of cattle by one pound. At industrial feedlots, a feed conversion ratio of 6:1 is common. Dan W. Shike, Beef Cattle Feed Efficiency 3 (2013). About 40% of the live weight of a head of cattle is sold as beef, which means that 15 pounds of grain is necessary to yield one pound of beef. *See* Rob Holland et al., University of Tennessee Institute of Agriculture, How Much Meat to Expect From a Beef Carcass 9 (2016) (PB-1822).

35. This includes grassland emissions, which account for 73.3 MMT CO_2 eq., as well as 48% of cropland emissions—the approximate percentage of harvested cropland devoted to feed crop production in 2007—which adds an additional 92.7 MMT CO_2 eq. *Compare* U.S. EPA, *supra* note 15, at 5-2 tbl.5-1, 5-25 tbl.5-15 (showing annual emissions from agriculture by source), *with supra* note 32(explaining how the percentage of harvested cropland devoted to feed crop production was calculated). Together, they were responsible for 166 MMT CO_2 eq. or 62% of all emissions from agricultural soils in 2016. This total does not include the approximately 16.5 million acres devoted to the production of biofuel feedstock. *See supra* note 32.

Environmental Assessment Worksheet

This most recent Environmental Assessment Worksheet (EAW) form and guidance documents are available at the Environmental Quality Board's website at**:** https://www.eqb.state.mn.us/ .The EAW form provides information about a Project that may have the potential for significant environmental effects. Guidance documents provide additional detail and links to resources for completing the EAW form.

Cumulative potential effects can either be addressed under each applicable EAW Item or can be addressed collectively under EAW Item 21.

Note to reviewers: Comments must be submitted to the RGU during the 30-day comment period following notice of the EAW in the *EQB Monitor*. Comments should address the accuracy and completeness of information, potential impacts that warrant further investigation and the need for an EIS.

1. Project Title

Niron Magnetics Manufacturing Plant

2. Proposer

Proposer:	Niron Magnetics
Contact person:	Dave Bance
Title:	Principal Environmental Engineer
Address:	650 Taft Street NE
City, State, ZIP:	Minneapolis, MN 55413
Phone:	612-327-9488
Email:	dave.bance@nironmagnetics.com

3. Responsible Governmental Unit (RGU)

RGU Agency:	City of Sartell
Contact person:	Kari Haakonson
Title:	Director of Community and Economic Development
Address:	125 Pinecone Road N
City, State, ZIP:	Sartell, MN 56377
Phone:	320-258-7312
Email:	kari.haakonson@sartellmn.com

4. Reason for EAW Preparation

Required:	Discretionary:
☐ EIS Scoping	☐ Citizen petition
X Mandatory EAW	☐ RGU discretion
	☐ Proposer initiated

If EAW or EIS is mandatory give EQB rule category subpart number(s) and name(s):

4410.4300 Subp. 14 (B)(2):

B. For construction of a new or expansion of an existing industrial, commercial, or institutional facility, other than a warehousing or light industrial facility, equal to or in excess of the following thresholds, expressed as gross floor space, the local governmental unit is the RGU:

(1) unincorporated area, 100,000 square feet;
(2) third or fourth class city, 200,000 square feet;
(3) second class city, 300,000 square feet; and
(4) first class city, 400,000 square feet.

5. Project Location

County: Stearns

City/Township: City of Sartell

PLS Location (¼, ¼, Section, Township, Range): NW1/4 S28 T125 R28

Watershed (81 major watershed scale): Mississippi River – Sartell (070120201)

GPS Coordinates (centroid): 94.2046514°W 45.6096918°N

Tax Parcel Number:
92.56577.0809 (Niron-owned. Facility site.)
92.56577.0808 (Niron-owned. Outlot.)
92.56577.0802 (City-owned. Temporary construction staging)
92.56577.0803 (City-owned. Temporary construction staging).

At a minimum attach each of the following to the EAW:

- U.S. Geological Survey 7.5 minute, 1:24,000 scale map indicating Project boundaries (photocopy acceptable); and
  See Figure 1, Appendix A
- County map showing the general location of the Project;
  See Figure 2, Appendix A
- Site plans showing all significant Project and natural features. Pre-construction site plan and post-construction site plan.
  Draft civil design drawings in Appendix B.
- List of data sources, models, and other resources (from the Item-by-Item Guidance: *Climate Adaptation and Resilience* or other) used for information about current Minnesota climate trends and how climate change is anticipated to affect the general location of the Project during the life of the Project (as detailed below in item 7. Climate Adaptation and Resilience).

6. Project Description

a. Provide the brief Project summary to be published in the EQB Monitor, (approximately 50 words).

Niron Magnetics proposes to develop a portion of an approximately 63-acre site in Sartell, MN to construct a manufacturing facility in two phases with a finished square footage of approximately 287,000 square feet. The facility will produce rare earth-free permanent magnets using Niron's novel process and material.

b. Give a complete description of the proposed Project and related new construction, including infrastructure needs. If the Project is an expansion include a description of the existing facility. Emphasize: 1) construction, operation methods and features that will cause physical manipulation of the environment or will produce wastes, 2) modifications to existing equipment or industrial processes, 3) significant demolition, removal or remodeling of existing structures, and 4) timing and duration of construction activities

Proposed Project

Niron Magnetics (Niron) proposes to construct a manufacturing facility on an undeveloped site located on 4th Avenue South between Heritage Drive and 3rd Street South in Sartell, MN (PID 92.56577.0809). See Figure 1 and Figure 2, Appendix A).

The Project area is a 63.02-acre undeveloped set of parcels within Sartell's city limits, located near the City of Sartell's Public Works facility and a landfill currently operated by the City of Sartell. The Project area contains a mixture of brushy grassland, recently fallowed cropland, two wetlands, and a historic constructed stormwater feature. Niron intends to permanently develop 25.8 acres of the site.

The proposed facility would produce Niron's patented rare earth-free high-performance permanent magnets. Pressed magnets will be cut to size and shape, then coated either in an enclosed spray booth or in a plating line. Finished magnets are then packaged and sent to customers. At full build-out, the facility would consist of six staffed buildings and three unoccupied structures. See the draft civil design drawings in Appendix B.

Production would occur in the Oxide building, Milling building, and Finishing/Warehouse building, as well as the Nitriding structure. All production activity to create the iron nitride magnet material or material transfer would be located inside sealed, inerted equipment or closed piping. Automated processes would be monitored inside the Control Room building. The facility would be accessed through a gate controlled from the Guard House building. An Electrical building would securely house electrical distribution to the facility. A Methanol Column structure would collect and purify solvents for reuse within plant processes. A Flare structure would serve to mitigate any emergency releases from relief devices. The Flare equipment would be contained within a structure that blocks light emitted from the flare. A Hot Oil Heater would be located onsite for process heating. The burner would be configured to combust multiple types of gases and would contain a stack with ports for performance testing. A Cooling Tower would be located onsite for process cooling. See Table 1 below for select details.

Permits for land disturbance, construction stormwater management, and air emissions were previously obtained, and site preparation work was initiated in October 2025. A design change was implemented in January 2026 that increased the gross square footage above 200,000 square feet, triggering the need for an EAW per MN 4410.4300 Subp. 14 (B)(2). The increase in proposed gross square footage was the result of adding a second floor to some buildings and did not expand the originally proposed and permitted ground disturbance footprint. Already completed disturbance activities include limited preliminary grading and stockpiling of imported fill soil. All site work has been paused until completion of the EAW process.

Initial site preparation and grading would create a level construction site using clean fill from an offsite local source. Minimal excavation or grading within native soil would be needed. Construction activities would re-commence upon completion of the environmental review process. Facility construction would commence upon issuance of remaining Project permits (see EAW Section 9). Construction is anticipated to take up to four years and would be completed in two phases.

The Project would result in 25.8 acres of permanent disturbance from grading and construction of the facility structures, two access drives, a parking lot, stormwater management features, utilities, and landscaped lawn space. Permanent disturbance would occur within parcel 92.56577.0809 and the 4th Avenue right-of-way. See Figure 3, Appendix A and draft civil design drawings in Appendix B.

The Project would also result in 8.5 acres of temporary disturbance. Temporary construction easements would be obtained for two City of Sartell parcels (92.56577.0802 and 92.56577.0803) to use them for construction trailers, contractor parking, materials staging, and construction stormwater management. To minimize topsoil compaction or other damage, approximately eight inches of existing topsoil would be stripped from the temporary disturbance area, then stockpiled and stabilized. Gravel fill would replace the removed topsoil to serve as a base pad for trailers, parking, and equipment staging. After construction, the gravel would be removed and replaced with the stockpiled topsoil. The disturbed area would be revegetated using an approved native seed mix.

c. **Project magnitude**

Table 1 summarizes the Project magnitude.

Table 1. Project Magnitude

Description	Value
Total Project Area Acreage	63.02
Temporary Ground Disturbance Acreage	8.5
Permanent Ground Disturbance Acreage	25.8
Number and type of residential units	0
Residential building area (in square feet)	0
Commercial building area (in square feet)	0
Industrial building area (in square feet)	286,971 (Phase 1: 135,871. Phase 2: 151,100)
Institutional building area (in square feet)	0
Roads/Parking Lots (acres)	5.2
Structure height(s)	
Oxide Building	43 ft
Nitriding Structure	105 ft
Milling Building	41 ft
Finishing/Warehouse Building	48 ft
Electrical Building	20 ft
Control Room Building	18 ft
Guard House Building	12 ft
Methanol Column Structure	64 ft
Hot Oil Heating Unit	40 ft
Cooling Tower	34 ft
Flare Structure	82 ft

d. Explain the Project purpose; if the Project will be carried out by a governmental unit, explain the need for the Project and identify its beneficiaries.

The purpose of this project is to establish a first-of-its-kind, full-scale U.S. manufacturing facility for rare-earth-free high-performance permanent magnets, supporting both local economic development and national supply chain resilience. Through a public–private partnership between Niron Magnetics and the City of Sartell, the project would meet a critical need: rebuilding the city's industrial tax base, restoring high-quality manufacturing jobs after the 2012 closure of the Verso paper mill, and positioning Minnesota as a leader in advanced materials innovation.

Niron Magnetics' technology represents the first major breakthrough in permanent magnet materials in decades. Developed at the University of Minnesota and refined in Minneapolis, Niron's Iron Nitride magnets are produced without any rare earth elements—using abundant, domestically sourced materials such as iron and nitrogen. This rare-earth-free magnet platform not only eliminates exposure to environmentally damaging mining practices abroad but also reduces U.S. dependence on foreign supply chains that have historically constrained production of electric vehicles, electronics, renewable energy systems, and defense technologies.

The Sartell project would be one of Minnesota's largest construction and manufacturing projects, with a planned investment of over $550 million. The project would be built in two phases. Phase 1 would support construction of a projected 136,000-square-foot manufacturing facility. Phase 2 is estimated to add an additional 151,000 square feet, bringing the total facility to approximately 287,000 square feet. Upon completion, the facility is anticipated to create 175 full-time jobs.

A local benefit of the project to the city is creating new jobs, broadening the tax base, and investing in workforce development and educational initiatives designed in partnership with local institutions. Nationally, the facility would address an urgent and growing need for domestically produced permanent magnets. Global demand is projected to exceed supply by 55,000 tons by 2040, threatening production timelines for EVs, wind turbines, and essential defense systems. By producing up to 1,500 tons of Iron Nitride magnets annually, the Sartell facility will help close that gap while establishing Minnesota as the epicenter of next-generation magnet manufacturing.

This project represents a long-term investment in economic vitality, technological leadership, and supply chain security, benefiting the City of Sartell, the State of Minnesota, and industries across the United States.

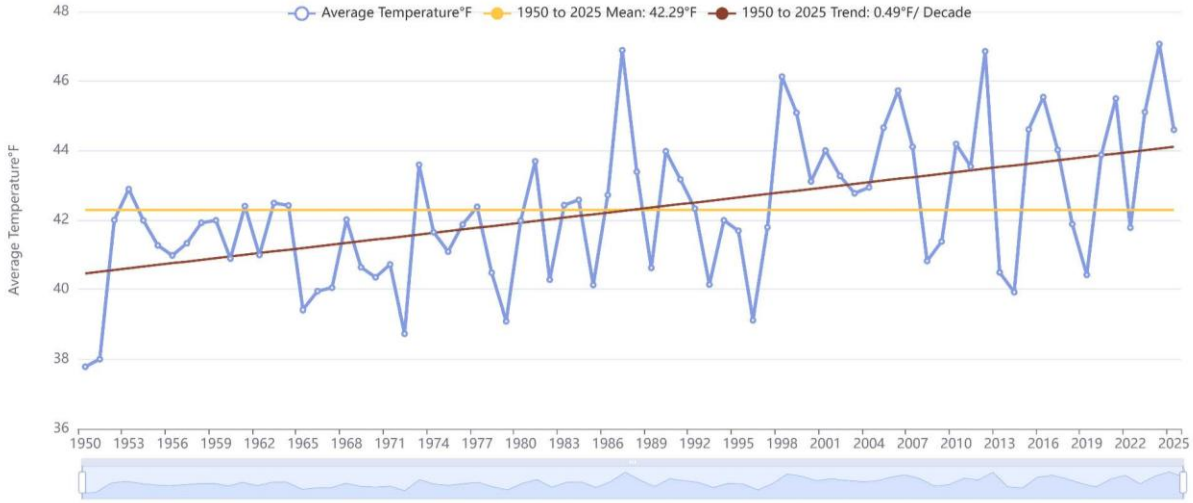
e. Are future stages of this development including development on any other property planned or likely to happen? ☐ **Yes** **X No**

If yes, briefly describe future stages, relationship to present Project, timeline and plans for environmental review.

f. Is this Project a subsequent stage of an earlier Project? ☐ **Yes** **X No**

If yes, briefly describe the past development, timeline and any past environmental review.

7. Climate Adaptation and Resilience



a. *Describe the climate trends in the general location of the Project (see guidance: Climate Adaptation and Resilience) and how climate change is anticipated to affect that location during the life of the Project.*

In general, Minnesota is anticipated to experience an increase in temperature, precipitation, and more frequent extreme precipitation events resulting from climate change. Between 1895 and 2020, annual average temperatures have risen three degrees Fahrenheit and precipitation has increased by an average of 3.4 inches in Minnesota.[1] The highest average temperature increases have occurred during the winter. Since 1895, temperatures during the winter have increased at a rate two to three times higher than during the summer. [2] In particular, winter warming rates have risen more sharply in recent decades. Current climate warming trends, most notably during the winter, are anticipated to continue.

Heavy rain events have become more frequent in Minnesota and more intense. From 1973 to 2021, Minnesota experienced 16 mega-rain events[3] with a notable increase since 2000. Of these 16 events, three occurred in the 1970s, one in the 1980s, one in the 1990s, six mega-rain events occurred in the 2000s, four in the 2010s, and one in 2020. Between 2000 to 2021, more than twice as many mega rain events occurred compared to the prior 27 years (1973 to 1999).[4]

Climate trends in Stearns County parallel the overall statewide trends, indicating Minnesota's climate is becoming warmer and wetter. Exhibit 1 and Exhibit 2 illustrate historical average annual temperature and precipitation trends from 1950 to 2025, respectively. During this time period, the County experienced an average annual temperature increase of 0.49 degrees Fahrenheit (°F) per decade and an annual precipitation increase of 0.45 inches per decade.

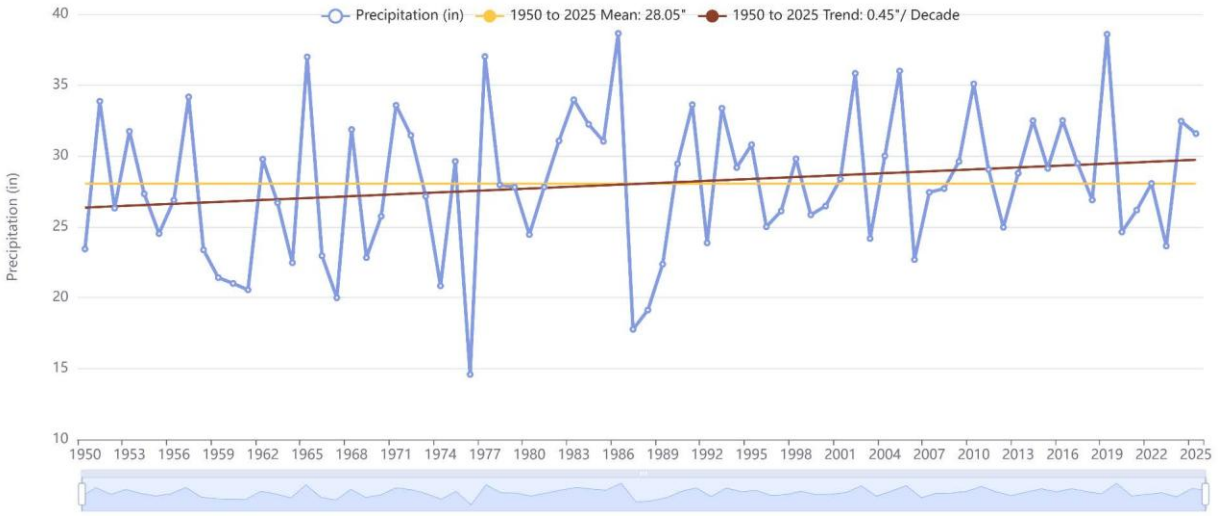


Exhibit 1. Historical Annual Average Temperature in Stearns County (1950 – 2025)

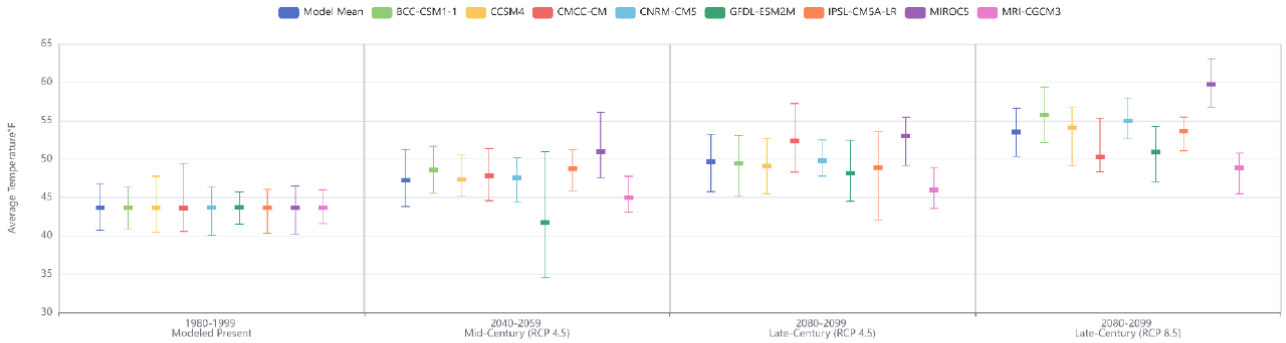
Source: DNR Climate Explorer available at https://climate-explorer.dnr.state.mn.us/main/historical

[1] DNR, undated(a). Climate Trends. Available at: https://www.dnr.state.mn.us/climate/climate_change_info/climate-trends.html. Accessed November 2025.
[2] Ibid.
[3] Mega-rain events are defined as events in which six inches of rain covers more than 1,000 square miles and the core of the event tops eight inches.
[4] MnDNR, 2024(a). Historic Mega-Rain Events in Minnesota. Available at: https://www.dnr.state.mn.us/climate/summaries_and_publications/mega_rain_events.html.

Exhibit 2. Historical Annual Average Precipitation in Stearns County (1950 – 2025)



Source: DNR Climate Explorer available at https://climate-explorer.dnr.state.mn.us/main/historical

Projected climate trends indicate that temperatures within the County would continue to increase. Exhibit 3 illustrates Projected temperatures for the County. Several climate models are shown in the projected temperature analysis. The model mean, shown in blue on the first boxplot to the left in each model category, illustrates the average of all models included in the analysis. Exhibit 3 shows the modeled present condition, mid-century (2040-2059) at Representative Concentration Pathway (RCP) 4.5, late-century (2080-2099) at RCP 4.5, and late-century (2080-2099) at RCP 8.5. RCP is a greenhouse gas concentration scenario used by the Intergovernmental Panel on Climate Change in the fifth assessment report. RCP 4.5 is an intermediate scenario in which emissions decline after peaking around 2040 and RCP 8.5 represents a worst-case scenario in which emissions continue rising through the 21st century.

Under the RCP 4.5 scenario, the annual temperature is anticipated to increase within the County from a modeled present mean of 43.7°F (1980-1999) to a mid-century (2040-2059) model mean of 47.2°F and a late-century (2080-2099) model mean of 49.6°F. Under the RCP 8.5 worst-case scenario, the County would experience a late-century (2080-2099) model mean temperature of 53.5°F. In comparison to the modeled present mean (1980-1999), the late-century (2080-2099) modeled mean annual temperature would increase by approximately 12.6 percent under the RCP 4.5 scenario and increase by approximately 20.2 percent under the RCP 8.5 scenario.

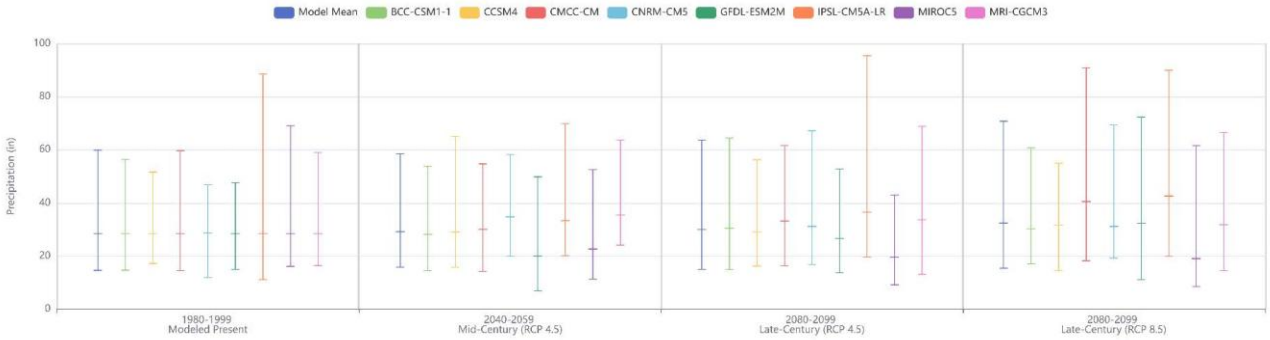


Exhibit 3. Projected Temperatures in Stearns County

Source: DNR Climate Explorer available at https://climate-explorer.dnr.state.mn.us/main/historical

Exhibit 4 presents Projected average annual precipitation for Stearns County. Under the RCP 4.5 scenario, the annual precipitation is anticipated to increase within the County from a modeled present mean of 28.5 inches (1980-1999) to a mid-century (2040-2059) model mean of 29.2 inches and a late-century (2080-2099) model mean of 30.1 inches. Under the RCP 8.5 worst-case scenario, the County would experience a late-century (2080-2099) model mean precipitation of 32.5 inches. In comparison to the modeled present mean (1980-1999), the late-century (2080-2099) modeled mean annual precipitation would increase by approximately 5.5 percent under the RCP 4.5 scenario and increase by approximately 13.1 percent under the RCP 8.5 scenario.

Exhibit 4. Projected Precipitation in Stearns County

Source: DNR Climate Explorer available at https://climate-explorer.dnr.state.mn.us/main/historical

b. For each Resource Category in the table below: Describe how the Project's proposed activities and how the Project's design will interact with those climate trends. Describe proposed adaptations to address the Project effects identified.

Table 2 summarizes climate considerations related to the Project and adaptation considerations.

Table 2. Climate Considerations and Adaptations

Resource Category	Climate Considerations	Project Information	Adaptations
Project Design	Projected climate trends include increasing temperatures, precipitation, and frequency of heavy rainfall events. Minnesota is trending towards warmer temperatures. Urban heat islands occur when impervious surfaces, such as roofs and paved surfaces, absorb heat during the day and release it at night, amplifying the warming trend.	Conversion from undeveloped land to developed land including construction of buildings, roadways, and parking areas would increase impervious surface area. Increased impervious surfaces would increase volume of stormwater runoff and potential flooding risk during heavy rain events. Impervious surfaces may create local heat island effects by absorbing heat during daytimes hours and radiating it at night leading to an increase in surface temperatures.	The Project would follow proposed and recommended actions for impervious surface coverage outlined by the City of Sartell in their Zoning Regulations. Additional measures to minimize heat island effects can include strategically planting trees to increase shading near buildings to reduce energy use. The Project area contains coarse, well-drained soils that significantly limit the potential for localized flooding.

Resource Category	Climate Considerations	Project Information	Adaptations
Land Use	Heavier rainfall is expected to bring a higher risk of localized flooding. Increased temperatures may create public health crises primarily for vulnerable communities such as children and the elderly.	The Project area currently consists of fallow cropland, brush/grassland, deciduous tree canopy and some wetlands. Conversion from undeveloped land to industrial development would increase impervious surfaces and may contribute to local heat island effects.	The Project does not propose critical facilities such as hospitals, daycare centers, public utilities, or schools within the Project area that would have heightened sensitivity to the climate considerations identified. Wetlands would be preserved within the Project area, and avoidance and minimization of impacts to tree canopy within the Project area would occur where feasible. Local heat island effects from adding impervious surface to the Project area may be mitigated by avoiding removal of existing tree canopy where feasible and the planting of new trees to increase shade in developed areas.
Water Resources	Addressed in Item 12.		
Contamination/ Hazardous Materials/Wastes	The Project area is projected to experience an increase in precipitation and heavy rainfall events.	The Project is anticipated to involve the use of chemical/ hazardous materials in their manufacturing process. The Project would include the use of Aboveground Storage Tanks. All hazardous materials would be stored indoors or inside Aboveground Storage Tanks and not exposed to storm events.	Facilities for storing and using hazardous materials would be constructed to building codes, fire codes, and industry best practices. Chemical inventories are expected to exceed EPA's Risk Management Program thresholds, and a Risk Management Program and Plan would be developed and submitted to the EPA. Aboveground Storage Tanks would be designed and registered in accordance with MPCA requirements. A Spill Prevention, Control, and Countermeasures (SPCC) plan would be developed for oil storage.

Resource Category	Climate Considerations	Project Information	Adaptations
			Waste generated during construction and operations would be properly managed and disposed of in accordance with Minnesota Pollution Control Agency (MPCA) requirements. The facility would operate under an MPCA Large Quantity Generator License and would develop a Contingency Plan to manage risks.
Fish, wildlife, plant communities, and sensitive ecological resources (rare features)	Addressed in Item 14.		

8. Cover Types

Estimate the acreage of the site with each of the following cover types before and after development.

The following tables and Figure 4, Appendix A summarize cover types within the Project area.

Table 3. Cover Types

Cover Types	Before(acres)[1]	After (acres)
Wetlands and shallow lakes (<2 meters deep)	7.88	7.88
Deep lakes (>2 meters deep)	0.0	0.0
Wooded/forest	11.51	9.51
Brush/grassland/fallowed cropland	43.50	12.0
Lawn/landscaping	0.0	5.70
Green infrastructure total (from table below*)	0.0	0.0
Impervious surface	0.0	23.60
Stormwater Basins	0.13	4.33
Total	**63.02**	**63.02**

[1] *Before" Acreages are approximate and based on geospatial observation of Stearns County 2024 aerial imagery (see Figure 4, Appendix A) and 2023 wetland delineation data.*

Table 4. Green Infrastructure

Green Infrastructure*	Before (acreage)	After (acreage)
Constructed infiltration systems	0	0
Constructed tree trenches and tree boxes	0	0
Constructed wetlands	0	0
Constructed green roofs	0	0
Constructed permeable pavements	0	0
Other (describe) Landfill-based geothermal system	0	0
Total	**0**	0

Table 5. Tree Canopy

Trees	Percent	Number
Percent tree canopy removed, or number of mature trees removed during development	18%	261
Number of new trees planted	TBD*	TBD*

*City of Sartell's tree preservation rules state that developers must plant at least 1 tree per 1,000 square feet of building floor square footage or per 100 feet of lot perimeter, whichever is greater. The number of new required trees can be reduced based on the number of existing mature trees not removed by the Project. Niron must submit a Landscaping Plan to the City for approval.

9. Permits and Approvals Required

List all known local, state and federal permits, approvals, certifications and financial assistance for the Project. Include modifications of any existing permits, governmental review of plans and all direct and indirect forms of public financial assistance including bond guarantees, Tax Increment Financing and infrastructure. All of these final decisions are prohibited until all appropriate environmental review has been completed. See Minnesota Rules, Chapter 4410.3100.

Table 6. Permits and Approvals

Unit of Government	Type of Application	Status
Federal		
U.S. Environmental Protection Agency	Risk Management Plan submittal	Pending
U.S. Internal Revenue Service	Qualified Advanced Energy Project Tax Credit (48C)	Complete
State		
Minnesota Pollution Control Agency	Air Emission Registration Permit, Option D	Complete (#14500196-101)
Minnesota Pollution Control Agency	Construction Stormwater Permit	Complete (#C00073325)
Minnesota Pollution Control Agency	Industrial Stormwater Permit	Pending
Minnesota Pollution Control Agency	Aboveground Storage Tank Registrations	Pending
Minnesota Pollution Control Agency	Large Quantity Generator License	Pending
Minnesota Department of Natural Resources	Water Appropriation Permit (new well)	Pending
Minnesota Department of Natural Resources	Water Appropriation Permit (construction dewatering)	To be applied for, if needed
Minnesota Department of Employment and Economic Development	Minnesota Forward Fund financial assistance	Received
Local		
City of Sartell	Environmental Assessment Worksheet	Pending
City of Sartell	Wetland Conservation Act wetland delineation approval	Complete
City of Sartell	Land Disturbance Permit	Complete (#25-LD00004)
City of Sartell	Construction Permits (Site Plan, Building, Plumbing, Electrical)	Pending
City of Sartell	Certificate of Occupancy	Pending
City of Sartell	Tank Permit	Pending
City of Sartell	Industrial Wastewater Permit	Pending
City of Sartell	Tax Increment Financing Development Agreement	Complete

10. Land use

a. Describe:

i. Existing land use of the site as well as areas adjacent to and near the site, including parks and open space, cemeteries, trails, prime or unique farmlands.

The Project area currently consists of vacant grassland and brushland, recently fallowed crop land, a large wetland, and scattered groves of mixed trees. Adjacent land uses include residential areas to the north and east, light industrial and vacant land to the west, and a closed landfill to the south. The Mississippi River is approximately 350 feet to the east of the Project area.

There are several public parks within ½-mile of the Project area, including Rotary Regional Park, Natures Edge Park, Sabre Park, Watab Regional Park, Veteran's Regional Park, and Val Smith Regional Park. A City of Sartell public trail runs north-south along 4th Avenue South. See Figure 5, Appendix A.

There are mapped Prime Farmland soils within the Project area. The property was converted to non-farming use prior to this proposed Project and the Project requires no federal funding or federal permitting, thus the federal Farmland Protection Policy Act (FPPA) does not apply.

ii. Plans. Describe planned land use as identified in comprehensive plan (if available) and any other applicable plan for land use, water, or resources management by a local, regional, state, or federal agency.

The 2016 City of Sartell Comprehensive Plan (Comp Plan) Future Land Use map indicates the Project area was anticipated to be utilized for a mix of Medium Density Residential and Office/Warehouse uses.[5] See Figure 6, Appendix A.

iii. Zoning, including special districts or overlays such as shoreland, floodplain, wild and scenic rivers, critical area, agricultural preserves, etc.

The Project area is currently zoned for Light Industrial by the City of Sartell.[6] See Figure 7, Appendix A. The Project area is not within a Shoreland, Wild and Scenic River, or Floodplain overlay district.

iv. If any critical facilities (i.e. facilities necessary for public health and safety, those storing hazardous materials, or those with housing occupants who may be insufficiently mobile) are proposed in floodplain areas and other areas identified as at risk for localized flooding, describe the risk potential considering changing precipitation and event intensity.

The proposed facility would not be within a floodplain area or an area otherwise at risk for flooding.

b. Discuss the Project's compatibility with nearby land uses, zoning, and plans listed in Item 9a above, concentrating on implications for environmental effects.

The proposed Project is compatible with City of Sartell zoning and current land use planning.

c. Identify measures incorporated into the proposed Project to mitigate any potential incompatibility as discussed in Item 10b above and any risk potential.

Not applicable.

[5] City of Sartell. 2016. "2026 Comprehensive Plan". Available at https://www.sartellmn.com/services/community_development___planning2/comprehensive_plan.php.

[6] City of Sartell. 2026. "Sartell Zoning Map". Available at https://sartellmn.com/services/community_development___planning2/maps.php.

11. Geology, Soils and Topography/Land Forms

a. Geology - Describe the geology underlying the Project area and identify and map any susceptible geologic features such as sinkholes, shallow limestone formations, unconfined/shallow aquifers, or karst conditions. Discuss any limitations of these features for the Project and any effects the Project could have on these features. Identify any Project designs or mitigation measures to address effects to geologic features.

The surficial geology in the Project area has been mapped by the Minnesota Geological Survey's (MGS) Geologic Atlas of Stearns County as being sediments consisting of glacial till, specifically deposits associated with the Superior Lobe (Figure 9, Appendix A). These deposits consist of predominantly sandy loam soil, unsorted sediment, with pebbles, cobbles, and boulders. The till in this area is mapped as being water-washed, and may be mantled by silt, sand, or gravel in some places. [7] The relief in the Project area is generally subdued, forming a gently undulating surface around 1,050 feet above mean sea level (AMSL) with minor rises to about 1,060 feet AMSL in the northwest and 1,070 feet AMSL in the northeast.

The bedrock geology in the Project area has been mapped by the MGS Geologic Atlas of Stearns County as being Reformatory granodiorite from the Early Proterozoic Period. The unit is characterized by grey to pinkish-gray, medium grained, weakly porphyritic and trachytic hornblende-biotite granodiorite.[8] The bedrock topography[9] within the Project area is mapped to be approximately 960 to 1,020 feet AMSL and the depth to bedrock[10] is estimated to be approximately 50 to 100 feet. According to the Minnesota Department of Health (MDH) Minnesota Well Index (MWI), no wells were identified within the Project area and six wells were identified within one quarter mile of the Project area.[11] These wells were drilled to depths between 14 and 76 feet and do not record the presence of bedrock. The well log reports and stratigraphic records are available in Appendix B.

According to the MNDNR, Karst Feature Inventory, there are no known karst or sinkhole features within the Project area or within the vicinity of the Project area.[12] Further, the US Geological Survey (USGS) does not identify the Project area as being within a known or potential karst area.[13] The nearest known feature is a sinkhole located approximately 50 miles southeast of the Project area in Ramsey, Minnesota. The first encountered bedrock in the Project area is the Reformatory granodiorite, which is an insoluble crystalline igneous rock not known for karst development. Due to the lack of soluble carbonate bedrock, the formation of karst within the Project area is unlikely.

b. Soils and topography - Describe the soils on the site, giving NRCS (SCS) classifications and descriptions, including limitations of soils. Describe topography, any special site conditions relating to erosion potential, soil stability or other soils limitations, such as steep slopes, highly permeable soils. Provide estimated volume and acreage of soil excavation and/or grading. Discuss impacts from Project activities (distinguish between construction and operational activities) related to soils and topography. Identify measures during and after Project construction to address soil limitations including stabilization, soil corrections or other measures. Erosion/ sedimentation control related to stormwater runoff should be addressed in response to Item 12.b.ii.

The Project area features gently undulating topography with minor rises in the northwest and northeast.

Elevation ranges from approximately 1,050 feet AMSL to 1,060 feet AMSL in the northwest and 1,070 feet AMSL in the northeast. The Project area was used for agricultural purposes from the 1930's until the late 2010s. The Project area also contains a large wetland in the center-east, a small wetland in a small grove of trees in the southwest corner, a human-made drainage ditch in the southwest corner, and two small stormwater ponds along 4th Avenue.

According to the U.S. Department of Agriculture (USDA) Natural Resource Conservation Services (NRCS) soil survey data, there are five soil map units within the Project area. The upland soil units predominantly consist of fine and loamy sands with mucky soil in surface depressions associated with wetland areas. The mapped soils range from moderately well drained to very poorly drained. The upland soil units are expected to feature relatively high susceptibility to wind erosion, while wetland soils are expected to feature very low susceptibility to wind erosion. The mapped soil units are expected to feature low to moderate susceptibility to water erosion and mixed permeability. See Figure 9, Appendix A for USDA-NRCS soil mapping and Table 7 below for a summary of select attributes for each of the mapped soil units.

Based on soil borings conducted and summarized in the 2025 Preliminary Geotechnical Investigation, the general soil profile of undisturbed areas consisted of sandy topsoil overlying glacially deposited sand and gravel materials. The topsoil samples consisted of fine-grained silty sand and clayey sand and ranged from about 1 to 2 feet thick. Samples of glacial deposits consisted mainly of silty sand with gravel, but contrast was found in different boring locations. One of the soil borings encountered a blockage, likely a buried boulder. There was also a large boulder observed at the surface, therefore, cobbles and boulders should be anticipated during excavation of the Project area.

The Project would significantly alter the existing soil and topographic conditions through grading and construction activities. It is anticipated that approximately 25.8 acres of the Project area would be permanently disturbed by grading and filling activities (see Figure 3, Appendix A). The disturbance area would generally be graded flat to prepare the site for facility construction. Approximately 121,377 cubic yards of clean imported fill soil would be needed. Most grading activity would utilize the imported fill material to level the construction area, as opposed to cutting into native soil.

The Project would adhere to erosion and sediment control practices during construction and operations per conditions of the Project's Stormwater Pollution Prevention Plan (SWPPP), National Pollution Discharge Elimination System (NPDES) Construction Stormwater Permit, and any local permitting conditions. See EAW Item 12.b.ii for details on stormwater management and erosion and sediment control.

Table 7. NRCS Soil Map Units within the Project area

Map Unit Symbol	Map Unit Name	Hydrologic Group	Wind Erodibility Group	Water Erodibility Factor (K*f*)	Acres	% of Project area
325	Prebish sandy loam, depressional	B/D	3	0.20	4.50	7.1%
163B	Brainerd fine sandy loam, 1 to 4 percent slopes	C/D	3	0.24	0.46	0.7%
1113	Haslie, Seelyeville, and Cathro soils, frequently ponded, 0 to 1 percent slopes	B/D	8	*not rated*	3.90	6.2%
119B	Pomroy fine sand, 1 to 6 percent slopes	A	1	0.10	24.95	39.6%
218	Watab loamy fine sand	C/D	2	0.17	29.21	46.4%
				Total	**63.02**	**100.0**

The hydrologic soil groups are:

- **Group A**: Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.
- **Group B**: Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained, or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.
- **Group C**: Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.
- **Group D**: Soils having a very slow infiltration rate (high runoff potential). These consist chiefly of soils with high clay content, soils that have a high-water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.
- **Dual Groups**: Dual Group designations (A/D, B/D, or C/D) are used to indicate wet soils that belong to Group D due to a high water table but would meet the drainage or textural criteria for Group A, B, or C if drained. Dual Group soils should be treated as Group D soils in the absence of effective artificial drainage.

The soil erodibility factors are:

- **Wind Erodibility Group**: Soils are assigned a Wind Erodibility Group (WEG) rating based on their inherent vulnerability to soil particle detachment from wind forces. Values range from 1 (most erodible) to 8 (least erodible).
- **Water Erodibility Factor (K*f*):** The Soil Erodibility Factor (K*f*) is a unitless quantitative description of the inherent vulnerability of a soil to water erosion. It provides a measurement of soil particles' susceptibility to detachment from rain drops or surface runoff. Values range from 0.02 (least erodible) to 0.69 (most erodible).

12. Water Resources

a. Describe surface water and groundwater features on or near the site in a.i. and a.ii. below.

i. Surface water - lakes, streams, wetlands, intermittent channels, and county/judicial ditches. Include any special designations such as public waters, shoreland classification and floodway/floodplain, trout stream/lake, wildlife lakes, migratory waterfowl feeding/resting lake, and outstanding resource value water. Include the presence of aquatic invasive species and the water quality impairments or special designations listed on the current MPCA 303d Impaired Waters List that are within 1 mile of the Project. Include MnDNR Public Waters Inventory number(s), if any.

Surface Waters
There are no streams, lakes, or Minnesota Public Waters within the Project area. See Figure 10, Appendix A. The closest surface water is the Mississippi River, which is approximately 350 feet east of the eastern Project property boundary. The Watab River is approximately 2,100 feet north of the Project area. Table 8 below lists the named Public Waters basins within one mile of the Project area. Table 9 provides details on MPCA-listed 303d impaired waters.

Table 8. Public Waters within One Mile of the Project area[14]

Water Resource	Type	PW ID/ Kittle No.	On Impaired Waters List?
Within Project area			
No surface waters within the Project area.			
Within One Mile of the Project area			
Mississippi River	River	103383	Y
Watab River, South Fork	River	110522	Y
Davenport Lake	Lake	18877	N
Unnamed	Public Waters Wetland	18878	N

Table 9. 303d Impaired Waters within One Mile of the Project area[15]

Waterbody Name	AUID*	Affected Designated Use	Pollutant or Stressor	TMDL² ID
Mississippi River	07010201-631	Aquatic Consumption	Mercury in Fish Tissue	PRJ07770-001
Watab River, South Fork	07010201-554	Aquatic Life, Aquatic Recreation	Fish bioassessments, E. coli bacteria	PRJ06864-001

[2]*Total Maximum Daily Load (TMDL)*

Wetland Resources

A wetland delineation was conducted within and adjacent to the Project area in 2023 by Short Elliot Hendrickson (SEH) and approved by the local Wetland Conservation Act (WCA) authority, the City of Sartell. The investigation identified one constructed stormwater pond and two natural wetlands within the Project area. A total of 8.01 acres of wetland were delineated. See Table 10 below and Figure 11, Appendix A.

Table 10. Wetlands Within the Project Area

Wetland ID	Circular 39	Cowardin	Eggers and Reed	Acres within Project area
Wetland 3	Type 3	PEM1C	Shallow Marsh	0.198
Wetland 4	Type 2, 5, and 6	PEM1B, PUBG, PSS1C	Fresh (wet) Meadow, Shrub-Carr, Shallow Open Water	7.68
Pond 1	n/a	n/a	n/a	0.13

Floodplain

The Project area is within a Federal Emergency Management Agency (FEMA) Flood Hazard Zone X, which indicates minimal annual risk of flooding.

ii. Groundwater – aquifers, springs, seeps. Include: 1) depth to groundwater; 2) if Project is within a MDH wellhead protection area; 3) identification of any onsite and/or nearby wells, including unique numbers and well logs if available. If there are no wells known on site or nearby, explain the methodology used to determine this.

There are no known springs, seeps, or karst features present in the Project area, and the Project area is not within a wellhead protection area.

Groundwater can be expected to be within 20 feet of the surface depending on the time of year and regional groundwater conditions. A review of the MDH MWI[16] identified no verified wells within the Project area and six verified wells within a quarter-mile radius of the Project area. These wells are presented in Table 11 and Figure 12, Appendix A. The depth to static water level in the MWI well log reports ranges from approximately seven to 27 feet. Well log reports are included in Appendix C. A geotechnical investigation was commissioned by Niron in March 2025. Six borings were conducted, each between 15 to 20 feet below ground level. Static water table was observed within 20 feet of the surface in two of the borings.[17]

[16] MDH. 2025. MWI. Available at: https://www.health.state.mn.us/communities/environment/water/mwi/index.html. Accessed January 2026.
[17] SEH. 2025. “Preliminary Geotechnical Investigation”. Available upon request.

Table 11. Verified MWI Wells Near the Project Area

Well ID	Use Type	Distance from Project	Status	Depth (ft.)	Static Water Level (ft.)
135955	Domestic	Approximately 200 feet east	Active	76	Not reported
472168	Monitoring	Approximately 600 feet west of southwest corner	Sealed	14	7
472169	Monitoring	Approximately 600 feet west of southwest corner	Sealed	62	22
594766	Monitoring	Approximately 200 feet southwest	Active	30	20
594767	Monitoring	Approximately 200 feet southwest	Active	60	27
680557	Monitoring	Approximately 800 feet south of southwest corner	Active	22	16

According to the MDH Source Water Protection Map[18], the Project area is not within an MDH Wellhead Protection Area or Drinking Water Supply Management Area (DWSMA). However, as shown in Figure 12, Appendix A, the Fischers Garden Mobile Home Park Wellhead Protection Area and DWSMA limits are located approximately 1,000 feet and 500 feet east of the Project area, respectively. This DWSMA has a vulnerability ranking of high.

b. Describe effects from Project activities on water resources and measures to minimize or mitigate the effects in Item b.i. through Item b.iv. below.

i. Wastewater - For each of the following, describe the sources, quantities and composition of all sanitary, municipal/domestic and industrial wastewater produced or treated at the site.

1) If the wastewater discharge is to a publicly owned treatment facility, identify any pretreatment measures and the ability of the facility to handle the added water andwaste loadings, including any effects on, or required expansion of, municipal wastewater infrastructure.

At full production upon completion of both phases, the Proposed facility would generate an estimated 290,400 gallons per day (GPD) of industrial wastewater related to manufacturing processes and includes 16,400 GPD of residential strength wastewater from an estimated 175 full time daily employees. Table 12 below breaks down the estimated wastewater flow by facility source.

[18] MDH (2025). Source Water Protection Map Web Viewer. Available at: https://www.health.state.mn.us/communities/environment/water/swp/mapviewer.html. Accessed January 2026.

Table 12. Estimated Wastewater Flows

Source	Waste Strength	Estimated Daily Flow (gal)	Estimated Yearly Flow (gal)	Pre-Treatment Required?
Employees (175)	Domestic	16,438	6,000,000	No
Plating Process	Industrial	21,918	8,000,000	Yes (pH, metals)
Cooling Towers	Industrial	57,534	21,000,000	No
Reverse Osmosis Reject	Industrial	35,616	13,000,000	No
Oxide Building	Industrial	95,890	35,000,000	Yes (pH)
All other industrial discharges	Industrial	63,014	23,000,000	No
TOTAL		**290,410**	**106,000,000**	

The proposed facility's wastewater would discharge to an existing public sanitary sewer in the 4th Avenue right-of-way and the west-east public sanitary sewer between the south edge of the Project site and the Sartell landfill. Wastewater would be conveyed to the St. Cloud Nutrient, Energy, and Water Recovery Facility (WRF) in St. Cloud, MN for final treatment. The St. Cloud WRF discharges to the Mississippi River per the conditions of their MPCA NPDES permit requirements (permit #MN0040878). The St. Cloud WRF has a permitted design flow capacity of 17.9 million GPD (6.5 billion gallons per year) and has affirmed to Niron that the treatment facility has existing capacity to accept the estimated flows.

All wastewater conveyed from the proposed facility to the public sanitary system must meet effluent quality standards from the St. Cloud WRF. Niron anticipates that some industrial wastewater sources would need pH adjustment prior to discharge to the public sanitary sewer, and the plating process wastewater would pass through its own pre-treatment process to reduce metals concentrations. Chloride would be the primary constituent of concern for the wastewater discharged to the public system, with an estimated maximum concentration of 8,000 parts per million. The facility's oxide process system would be the primary source of excess chloride. Niron is currently in discussions with St. Cloud WRF authorities regarding the anticipated chloride concentrations.

2) *If the wastewater discharge is to a subsurface sewage treatment systems (SSTS), describe the system used, the design flow, and suitability of site conditions for such a system. If septic systems are part of the Project, describe the availability of septage disposal options within the region to handle the ongoing amounts generated as a result of the Project. Consider the effects of current Minnesota climate trends and anticipated changes in rainfall frequency, intensity and amount with this discussion.*

Not applicable.

3) *If the wastewater discharge is to surface water, identify the wastewater treatment methods and identify discharge points and proposed effluent limitations to mitigate impacts. Discuss any effects to surface or groundwater from wastewater discharges, taking into consideration how current Minnesota climate trends and anticipated climate change in the general location of the Project may influence the effects.*

   Not applicable.

ii. Stormwater - Describe changes in surface hydrology resulting from change of land cover. Describe the routes and receiving water bodies for runoff from the Project site (major downstream water bodies as well as the immediate receiving waters). Discuss environmental effects from stormwater discharges on receiving waters post construction including how the Project will affect runoff volume, discharge rate and change in pollutants. Consider the effects of current Minnesota climate trends and anticipated changes in rainfall frequency, intensity and amount with this discussion. For Projects requiring NPDES/SDS Construction Stormwater permit coverage, state the total number of acres that will be disturbed by the Project and describe the stormwater pollution prevention plan (SWPPP), including specific best management practices to address soil erosion and sedimentation during and after Project construction. Discuss permanent stormwater management plans, including methods of achieving volume reduction to restore or maintain the natural hydrology of the site using green infrastructure practices or other stormwater management practices. Identify any receiving waters that have construction-related water impairments or are classified as special as defined in the Construction Stormwater permit. Describe additional requirements for special and/or impaired waters.

Under existing conditions, the Project area primarily consists of grassland, recently fallowed cropland, wetlands, and several groves of trees. There are no impervious surfaces present. The site's topography is generally bowl-shaped, and slopes from most directions toward a large wetland that runs north-south across the center-eastern side of the Project area. A topographic ridge on the east side of the Project area limits surface runoff.

Under proposed conditions, most of the Niron-owned property west of the large wetland would be graded and partially leveled for facility construction. Imported fill would be used to level the work area. See Figure 3, Appendix A and draft civil design drawings in Appendix B. The Project would result in approximately 23.6 acres of new impervious surface. Increased impervious surface area can result in different runoff rates and volumes compared to the existing conditions, and a change in potential runoff pollutants. For a 100-year storm, Niron estimated a pre-development peak surface runoff rate of 125 cubic feet per second (cfs), and a post-development peak runoff rate of 48 cfs.

A Stormwater Pollution Prevention Plan (SWPPP) would be prepared as part of the Project's National Pollutant Discharge Elimination System (NPDES) Construction Stormwater Permit issued by MPCA (permit #C00073325). The SWPPP would conform to permit requirements and address sediment and erosion control Best Management Practices (BMPs) during construction. The Project must also adhere to the City of Sartell's Land Disturbance Permit requirements and the Erosion and Sediment Control Ordinance.[19] Sediment and erosion control BMPs may include bio-rolls, silt fence, rock construction entrances, inlet protection devices, erosion control blankets, erosion stabilization mats, and/or other similar devices to prevent soil erosion and sediment transport. Temporary sedimentation basins would be utilized during construction to store runoff and capture sediment. Per City of Sartell rules, all disturbed soils would be stabilized within seven days of inactivity, and seeded areas must show proper vegetation establishment within three weeks. All construction erosion and sediment control BMPs must be inspected by the permit holder within 24 hours of a significant rain event (>0.5 inches). Inspections and repairs must be documented in writing. City staff may also conduct inspections at their discretion.

[19] Sartell City Code, Title 10, Chapter 21. Erosion and Sediment Control Ordinance: https://cms5.revize.com/revize/sartell/Title%2010%20Zoning%20Regulations%20RV%202025%20KH%20Edits.pdf?t=202511251020390&t=202511251020390.

Per the MPCA's General Stormwater Permit conditions, permittees must utilize infiltration BMPs to reduce the volume of stormwater runoff discharged from the site, unless infiltration practices are prohibited due to certain site conditions described in the Permit. Infiltration BMPs are prohibited for this Project due to unfavorable soil conditions. Infiltration basins must feature at least 36 inches of vertical separation between the basin floor and seasonal groundwater (General Permit Section 16.17), and the soils in the vicinity of the stormwater management system are rated as Hydrologic Group C/D (see EAW Question 11b). Hydrologic Group C/D soils feature poor infiltration rates due to shallow groundwater. MPCA rules also explicitly prohibit infiltration practices within Hydrologic Group D soils (General Permit Section 16.18). In addition, infiltration practices are prohibited if they could adversely impact the hydrology of wetlands on site and there was concern that significantly reducing the overall volume of runoff to the wetland could starve it of water during dry years (General Permit Section 16.3).

If infiltration BMPs are not allowed, filtration systems are the next preferred type of BMP for volume control per MPCA guidance, if feasible. It was determined that a filtration basin for this Project would require a significantly larger footprint in terms of area and elevation to handle the anticipated flows from large storm events than the proposed wet sedimentation basin. In addition, filtration systems require intense maintenance to preserve the efficiency and effectiveness of the filtration which can lead to increased risk of reduced water quality.

During operations, stormwater runoff would be directed to an approximately 4.2-acre wet sedimentation stormwater pond system along the south and east sides of the facility. See draft civil design drawings in Appendix B. The pond system would consist of a forebay and a wet sedimentation basin. At a minimum, a sedimentation basin must be able to store the equivalent volume of a 1-inch rainfall across all impervious surfaces. The wet sedimentation basin is designed to provide live runoff storage of 136,900 cubic feet, which is more than double the estimated runoff generated by a one-inch rainfall (66,066 cubic feet). Any overflow would be discharged to the adjacent wetland through a control structure. The control structure would feature a skimmer device designed to reduce total suspended solids by up to 90%.

Due to the proposed facility type, an MPCA Industrial Stormwater Permit would be required prior to commencement of facility operations. This permit addresses stormwater that may come in contact with industrial materials, equipment, or supplies that may be stored outside. The facility would not store any harmful materials outdoors.

There would be no direct discharge of managed stormwater to a lake or stream. The Mississippi River is 1,000 feet east of the receiving wetland, but due to the site's topography there is no direct surface drainage connection to the river. The Mississippi River is not listed for any construction stormwater-related impairments. All site stormwater would be contained within the project area.

iii. Water appropriation - Describe if the Project proposes to appropriate surface or groundwater (including dewatering). Describe the source, quantity, duration, use and purpose of the water use and if a MnDNR water appropriation permit is required. Describe any well abandonment. If connecting to an existing municipal water supply, identify the wells to be used as a water source and any effects on, or required expansion of, municipal water infrastructure. Discuss environmental effects from water appropriation, including an assessment of the water resources available for appropriation. Discuss how the proposed water use is resilient in the event of changes in total precipitation, large precipitation events, drought, increased temperatures, variable surface water flows and elevations, and longer growing seasons. Identify any measures to avoid, minimize, or mitigate environmental effects from the water appropriation. Describe contingency plans should the appropriation volume increase beyond infrastructure capacity or water supply for the Project diminish in quantity or quality, such as reuse of water, connections with another water source, or emergency connections.

Construction excavation into native soil would be limited to buried utilities and pits for those pieces of equipment that need to extend below the facility's floor elevation. Depending on the time of year and

groundwater conditions, construction dewatering may be needed within these excavations. The construction contractor would obtain a dewatering permit from MNDNR as needed.

The facility would require an estimated 429,000 gpd of water during Phase 2 operations. The City of Sartell has affirmed the municipal water treatment system has both physical and permit capacity to support the Project's water needs. The municipal water supply is drawn from nine wells owned by the City of Sartell. Alternatively, Niron is considering construction of their own private water supply well for the Project to mitigate the increased draw on the City of Sartell's water infrastructure. The well would be located on Niron's property, outside of Sartell's wellhead protection areas. Prior to securing a water appropriation permit from MNDNR or drilling a well, a Well Construction Assessment and aquifer test would be conducted to evaluate potential groundwater impacts. The well driller would notify Minnesota Department of Health prior to drilling the well. The Project area is not within a drinking water supply management area (DWSMA), though the Fischer's Garden Mobile Home Park DWSMA's western boundary is approximately 500 feet east of the Project area.

As described in EAW Item 7a, Stearns County (and much of Minnesota) is expected to see a moderate increase in average annual precipitation and large storm events. This trend should result in greater groundwater recharge rates compared to current conditions.

iv. Surface Waters

a) Wetlands - Describe any anticipated physical effects or alterations to wetland features such as draining, filling, permanent inundation, dredging and vegetative removal. Discuss direct and indirect environmental effects from physical modification of wetlands, including the anticipated effects that any proposed wetland alterations may have to the host watershed, taking into consideration how current Minnesota climate trends and anticipated climate change in the general location of the Project may influence the effects. Identify measures to avoid (e.g., available alternatives that were considered), minimize, or mitigate environmental effects to wetlands. Discuss whether any required compensatory wetland mitigation for unavoidable wetland impacts will occur in the same minor or major watershed and identify those probable locations.

The Project may result in approximately 300 square feet of fill impact to Wetland 4 related to the stormwater basin's outlet structure. By design, the basin would discharge treated stormwater to the wetland. The discharge outlet would utilize approximately 300 square feet of riprap (or other energy dissipation materials) to prevent scour erosion around the outlet. This feature may be moved out of the wetland if feasible. If not, Niron would submit a WCA No-Loss application under a "de minimis" exemption, which allows for up to 1/10th acre of permanent impact to the affected wetland type without the need for mitigation.

b) Other surface waters- Describe any anticipated physical effects or alterations to surface water features (lakes, streams, ponds, intermittent channels, county/judicial ditches) such as draining, filling, permanent inundation, dredging, diking, stream diversion, impoundment, aquatic plant removal and riparian alteration. Discuss direct and indirect environmental effects from physical modification of water features, taking into consideration how current Minnesota climate trends and anticipated climate change in the general location of the Project may influence the effects. Identify measures to avoid, minimize, or mitigate environmental effects to surface water features, including in-water Best Management Practices that are proposed to avoid or minimize turbidity/ sedimentation while physically altering thewater features. Discuss how the Project will change the number or type of watercraft on any water body, including current and Projected watercraft usage.

No other waters would be impacted by the Project.

13. Contamination/Hazardous Materials/Wastes

a. Pre-Project site conditions - Describe existing contamination or potential environmental hazards on or in close proximity to the Project site such as soil or ground water contamination, abandoned dumps, closed landfills, existing or abandoned storage tanks, and hazardous liquid or gas pipelines. Discuss any potential environmental effects from pre-Project site conditions that would be caused or exacerbated by Project construction and operation. Identify measures to avoid, minimize or mitigate adverse effects from existing contamination or potential environmental hazards. Include development of a Contingency Plan or Response Action Plan.

A Phase 1 Environmental Site Assessment (ESA) was conducted on behalf of Niron in March, 2025 by Short Elliott Hendrickson (SEH). The ESA did not identify any onsite contamination risks. The nearest identified potential contamination risk was the closed landfill immediately south of the Project area. SEH prepared a Landfill and Groundwater Quality Review report in November 2025 related to the landfill site. The report states "…*based on the landfill's design with liners, leak detection systems, leachate collection, and groundwater monitoring systems, the potential for future landfill-related groundwater impacts to the Site is minimal. Because [the] landfills are regulated facilities with active, ongoing monitoring with more than 30 years of water quality data, no additional investigation to establish existing groundwater quality on the Site [was] warranted*."

Soil or groundwater contamination is not anticipated within the Project area. However, due to the close proximity of the landfill site, Niron Magnetics commissioned SEH to prepare a Soil and Groundwater Management Plan (Plan) for the proposed Project. The Plan provides guidance for identifying contaminated soils or groundwater and provides detailed plans for the handling and testing of any potentially contaminated materials encountered during construction.[20]

A review of MPCA's *What's in My Neighborhood* (WIMN) database was conducted to identify documented potentially contaminated sites within or in the vicinity of the Project area.[21] No known contaminated sites were identified within the Project area, though the Project's approved Construction Stormwater Permit is included in the WIMN database. Eleven WIMN sites were identified within one-quarter mile of the Project area. Table 13 summarizes these findings and Figure 13, Appendix A, illustrates the location of WIMN sites in close proximity to the Project.

Table 13. MPCA WIMN Sites within One-Quarter Mile of the Project area

Site ID	Site Name	Activity	Status	Location
264817	Niron Magnetics	Construction Stormwater	Active	310 4th Ave South
6838	Sartell Heights South Improvements	Construction Stormwater	Inactive	No street address
265782	Sartell Public Works	Aboveground Tanks	Active	306 4th Ave South
191371	Brown Residence	Petroleum Remediation, Leak Site	Active	1909 High View Drive

[20] The SEH reports cited above are available upon request.
[21] MPCA, 2026. What's in My Neighborhood. Available at: What's in My Neighborhood | Minnesota Pollution Control Agency (state.mn.us). Accessed January 2026.

Site ID	Site Name	Activity	Status	Location
220938	Sartell Holdco	Construction Stormwater	Active	4th Ave South

b. Project related generation/storage of solid wastes - Describe solid wastes generated/stored during construction and/or operation of the Project. Indicate method of disposal. Discuss potential environmental effects from solid waste handling, storage and disposal. Identify measures to avoid, minimize or mitigate adverse effects from the generation/storage of solid waste including source reduction and recycling.

Construction waste would be primarily non-hazardous and would be managed as municipal solid waste (MSW) or construction/demolition debris. Hazardous wastes in the form of used oils/lubricants, waste paints, or other materials may be generated during construction. The contractor would be required to manage and dispose of all construction-generated waste in accordance with MPCA requirements and all other applicable regulatory requirements. Construction waste would either be recycled or stored in approved containers and disposed of in the proper facilities. Any excess soil material that is not suitable for use onsite would become the property of the contractor and would be disposed of properly.

Operational solid waste would consist of typical municipal solid waste and recyclable materials. The collection of solid waste would be managed by a licensed waste hauler. The Project would adhere to all MPCA requirements and other regulations pertaining to the use, handling, and disposal of solid waste. Recycling areas would be provided in compliance with the Minnesota State Building code.

c. Project related use/storage of hazardous materials - Describe chemicals/hazardous materials used/stored during construction and/or operation of the Project including method of storage. Indicate the number, location and size of any new above or below ground tanks to store petroleum or other materials. Indicate the number, location, size and age of existing tanks on the property that the Project will use. Discuss potential environmental effects from accidental spill or release of

hazardous materials. Identify measures to avoid, minimize or mitigate adverse effects from the use/storage of chemicals/hazardous materials including source reduction and recycling. Include development of a spill prevention plan.

Construction equipment may require the limited use of potentially hazardous materials, such as gasoline or diesel fuels, engine motor oils, hydraulic fluids, and other lubricants. Vehicles responsible for the transportation of hazardous materials would be equipped with spill kits for rapid response to any spills and refueling procedures would be implemented to eliminate leakage. Additionally, all fuels, oils, and lubricants would be stored in containment apparatuses while not in use. Construction staff would be trained to spot and appropriately respond to potential spills. In the event that a leak or spill incident occurs, the contractor would be required to respond in accordance with MPCA containment and remedial action procedures. A SPCC plan would be prepared by a Minnesota Professional Engineer pursuant to federal regulations.

Niron anticipates using materials like ammonia, hydrogen, methanol, and corrosive liquids in their manufacturing process. Facilities for storing and using these hazardous materials would be constructed and operated per building codes, fire codes, industry best practices, and federal Chemical Accident Prevention requirements of 40 CFR 68.[22] Niron anticipates chemical inventories will exceed EPA's Risk Management Program thresholds and Niron would create a Risk Management Program and submit a Risk Management Plan to EPA for review and approval.

Niron would register Aboveground Storage Tanks with MPCA after tank designs are completed. Niron would create a Spill Prevention Control and Countermeasure (SPCC) plan for oil storage. Niron would have HAZWOPER-trained employees and establish Memorandums of Understanding for supplementary 3rd party spill response support capabilities. Local- and State- Emergency Planning Committees would receive annual reports of hazardous chemical inventories, per Section 312 of the federal Emergency Planning and Community Right-to-Know Act (EPCRA).

The Project would not utilize underground storage tanks during construction or operations.

d. Project related generation/storage of hazardous wastes - Describe hazardous wastes generated/stored during construction and/or operation of the Project. Indicate method of disposal. Discuss potential environmental effects from hazardous waste handling, storage, and disposal. Identify measures to avoid, minimize or mitigate adverse effects from the generation/storage of hazardous waste including source reduction and recycling

Project construction-related hazardous wastes in the form of used oils/lubricants, waste paints, or other materials may be generated during construction. The contractor would be required to manage and dispose of all construction-generated waste in accordance with MPCA requirements and all other applicable regulatory requirements.

Niron anticipates the facility would operate under an MPCA Large Quantity Generator (LQG) license and would submit an appropriate license application through MPCA's e-Services website prior to waste generation. Niron would create a Resource Conservation Recovery Act (RCRA) Contingency Plan to manage risks related to hazardous waste incidents. All wastes would be shipped offsite for disposal. Niron intends to recycle and purify for reuse certain feedstocks. Byproducts, like still bottoms, would be created and managed as a hazardous waste. "Still bottoms" are residues that accumulate at the bottom of distillation units.

[22] Code of Federal Regulations. Date unknown. Title 40, Chapter I, Subchapter C, Part 68. Available here: https://www.ecfr.gov/current/title-40/chapter-I/subchapter-C/part-68?toc=1.

14. Fish, Wildlife, Plant Communities, and Sensitive Ecological Resources (Rare Features)

a. Describe fish and wildlife resources as well as habitats and vegetation on or in near the site.

The Project area is located in the Minnesota and Northeast Morainal Section (222M) and Eastern Broadleaf Forest Province (222) as defined by the Minnesota Department of Natural Resources (DNR) in the *Field Guide to the Native Plant Communities of Minnesota – The Eastern Broadleaf Forest Province*.[23] Pre-settlement vegetation consisted primarily of oak barrens, openings, brushland, upland prairie, and floodplain forest. Characteristic trees included burr oak (*Quercus macrocarpa*), jack pine (*Pinus banksiana*), and northern pin oak (*Quercus ellipsoidalis*), among other species. Current land use within this subsection consists of wetlands, woodland, cropland, and urban development.[24]

Land cover within the 63.02-acre Project area was reviewed and is described in EAW Item 8 (Cover Types). Most of the Project area (43.50 acres, 69%), consists of brush/grassland and recently fallowed cropland. Other cover types present within the Project area include forested areas (11.51 acres, 18%), wetlands (7.88 acres, 12.5%), and two small historic stormwater ponds (0.13 acres, 0.21%). Figure 4, Appendix A illustrates land cover types within the Project area based on geospatial analysis.

The presence of brush/grassland, forested areas, and wetlands are likely to provide nesting, foraging, or travel habitat to a variety of urban wildlife species, including squirrels, mice, rabbits, deer, coyotes, foxes, passerine birds, raptors, and other small mammals. Suitable roosting habitat for bats may be present within the forested areas. Wetlands may provide habitat for amphibian species such as turtles, frogs and toads, or minnows and other aquatic species depending on the hydrologic regime of the wetland.

b. Describe rare features state-listed (endangered, threatened or special concern) species, native plant communities, Minnesota Biological Survey Sites of Biodiversity Significance, and other sensitive ecological resources on or within close proximity to the site. Provide the license agreement number (LA-) and/or correspondence number (MCE) from which the data were obtained and attach the Natural Heritage Review letter from the DNR. Indicate if any additional habitat or species survey work has been conducted within the site and describe the results.

Native Plant Communities and Sites of Biodiversity Significance

Based on a review of the DNR Minnesota Conservation Explorer (MCE) portal, there are no DNR Native Plant Communities, Minnesota Biological Survey (MBS) Sites of Biodiversity Significance, DNR Old Growth Stands, Lakes of Biological Significance, or calcareous fens located within the Project area.[25]

State-Listed Species

Under Stantec's Limited License to Use Copyrighted Material (2024-057) related to Rare Features Data, the DNR Natural Heritage Information System (NHIS) was searched in March 2025 and updated in January 2026 to identify rare features records within the Project area and within a one-mile radius of the Project area. The NHIS search did not identify rare species records within the Project area, but records of three rare species were identified within the one-mile radius of the Project area:

- Butternut tree (*Juglans cinerea*) – Endangered
- Black sandshell mussel (*Ligumia recta*) – Special Concern
- Peregrine falcon (*Falco peregrinus*) - Special Concern

A formal NHIS review request was also submitted to the DNR through the MCE portal[26] for the Project area on March 24, 2025. A final response from the DNR was received on June 24, 2025 (MCE-2025-

[23] Aaseng, N. (2005). *Field Guide to the Native Plant Communities of Minnesota – The Eastern Broadleaf Forest Province*. St. Paul: DNR.

[26] MNDNR (2)

00309). Individual state-listed species were not identified for the Project from this review, but the DNR recommends that tree removal be avoided during the bat pupping season (June 1 to August 15). Appendix D provides a copy of the DNR MCE response letter.

The state-listed species identified through this review are described below.

Butternut

The butternut is a tree species that occurs in mesic hardwood forest systems, often along river terraces in loamy, alluvial, or sandy soils.[27] No mesic hardwood forest systems were identified during the review of the DNR MCE portal. Therefore, impacts to the butternut as a result of the Project are not anticipated.

Black sandshell

The black sandshell mussel inhabits riffles and runs of medium to large rivers that have sand or gravel substrate.[28] No medium or large rivers are located within the Project area. The Mississippi River is located within 0.1 miles of the Project area, but direct impacts are not anticipated and mitigation strategies would limit the risk of indirect impacts to this resource. As such, impacts to the black sandshell as a result of the Project are not anticipated.

Peregrine falcon

The peregrine falcon nests along cliff ledges over rivers or lakes as well as on bridges and buildings in urban settings. Foraging habitat generally consists of open, non-forested areas for direct aerial pursuit of prey.[29] No cliff ledges or buildings or bridges suitable for peregrine falcon nesting are located within the Project area. Open, non-forested areas for hunting are located within the Project area, so the peregrine falcon may occur in this area. However, the lack of nesting habitat and the overall high mobility of the peregrine falcon make impacts unlikely to occur as a result of the Project. Once construction begins, this species is likely to be deterred from using the Project area.

Federally-Listed Species

A review of the United States Fish and Wildlife Service (USFWS) Information for Planning and Consultation (IPaC) tool[30] was conducted initially in March 2025 to identify federally listed species, those species proposed for federal listing, and candidates for federal listing with the potential to occur within the Project area. An updated official species list under the same Project Code (2025-0073129) was obtained on January 20, 2026. Six species were identified from this review:

- Northern long-eared bat (*Myotis septentrionalis*) – Endangered
- Tricolored bat (*Perimyotis subflavus*) – Proposed Endangered
- Suckley's cuckoo bumble bee (*Bombus suckleyi*) – Proposed Endangered
- Monarch butterfly (*Danaus plexippus*) – Proposed Threatened
- Western regal fritillary (*Argynnis idalia occidentalis*) – Proposed Threatened
- Whooping crane (*Grus americana*) – Non-essential experimental population

No proposed or designated critical habitats were identified from this review. Appendix E includes the species list generated through the USFWS IPaC tool.

[27] Smith, W. 2008. Rare Species Guide: Butternut (*Juglans cinerea*). Minnesota Department of Natural Resources. Updated 2018. Available at: https://www.dnr.state.mn.us/rsg/profile.html?action=elementDetail&selectedElement=PDJUG02030. Accessed January 2026.

[29] Stucker, S.P. 2018. Rare Species Guide: Peregrine Falcon (*Falco peregrinus*). Minnesota Department of Natural Resources. Available at: https://www.dnr.state.mn.us/rsg/profile.html?action=elementDetail&selectedElement=ABNKD06070. Accessed January 2026.
[30] USFWS. 2025-2026. Information for Planning and Consultation. Available at: https://ipac.ecosphere.fws.gov/. Accessed March and June 2025 and January 2026.

These species and their habitat requirements are described below.

Northern long-eared bat

Suitable roosting, forage, and travel habitat for northern long-eared bat (NLEB) in the summer consists of a wide variety of contiguous forested and wooded habitats with varying tree density and amounts of canopy closure. While roosting, NLEB is generally found in deep crevices in areas such as forests and woodlots (i.e. live trees and/or snags greater than or equal to three inches in diameter at breast height that have exfoliating bark, cracks, crevices, and/or cavities) as well as linear features such as fence rows, riparian forests, and other wooded corridors. NLEB roosts in both live trees and snags.[31,32,33] Additional summer habitat for the NLEB consists of areas adjacent to wooded areas, namely emergent wetlands and edges of agricultural fields, old fields, and pastures. The NLEB has also been observed roosting in human-made structures, such as buildings, barns, bridges, and bat houses.[34] During winter months, NLEB hibernates in caves or abandoned mines.[35]

Suitable summer roosting habitat and foraging habitat for the NLEB is present within the Project area and the USFWS interactive map for modeled NLEB habitat indicates that there is potential NLEB habitat within and in the Project area.[36] Therefore, the NLEB may occur within the Project area.

According to the DNR NHIS review conducted in March 2025 and January 2026, no known records of NLEB were identified within the Project area or within one mile of the Project area. Additionally, according to the USFWS-issued Northern Long-eared Bat and Tricolored Bat Range-wide Determination Key, there are no known NLEB hibernacula within one-half mile of the Project area, no known NLEB-occupied culverts within one-quarter mile of the Project area, and no known NLEB roost sites within 150 feet of the Project area.

Review of the NLEB relies on the USFWS-issued Northern Long-eared Bat and Tricolored Bat Range-wide Determination Key within the IPaC system and a determination of “May Affect” was reached for this species (Appendix E). Approximately 3.25 acres of tree clearing is proposed for the Project, primarily concentrated in the southwest corner of the Project area (see draft civil design drawings in Appendix B). If tree clearing occurs during the bat active season (April 15 to October 31), then impacts to the NLEB may occur. If feasible, tree clearing during the bat inactive season (November 1 to April 14), which also avoids the June 1 to August 15 pupping season, is recommended to avoid impacts.

Tricolored bat

During the non-hibernating seasons, tricolored bats will roost primarily in leaf clusters of live or dead deciduous hardwood trees. Tricolored bats have also been observed roosting among pine needles and in human-made structures such as barns, bridges, roofs, and other concrete structures. Non-hibernating season roosting is rarely observed in caves. During the winter, tricolored bats hibernate in caves and mines.[37]

The tricolored bat may occur within the Project area. Tree canopy is present within the Project area that may provide suitable roosting habitat for the tricolored bat. The USFWS interactive map for

modeled tricolored bat habitat indicates that there is potential habitat within and in the Project area.[38]

According to the DNR NHIS review conducted in March 2025 and January 2026, no known records of tricolored bats were identified within the Project area or within one mile of the Project area. Additionally, according to the USFWS-issued Northern Long-eared Bat and Tricolored Bat Range-wide Determination Key, there are no known tricolored bat hibernacula within one-half mile of the Project area and no known tricolored bat occupied culverts within one-quarter mile of the Project area.

Review of the tricolored bat relies on the USFWS-issued Northern Long-eared Bat and Tricolored Bat Range-wide Determination Key within the IPaC system and a determination of "May Affect" was reached for this species (Appendix E). Approximately 3.25 acres of tree clearing is proposed for the Project, primarily concentrated in the southwest corner of the Project area (see draft civil design drawings in Appendix B). If tree clearing occurs during the bat active season (April 15 to October 31), then impacts to the NLEB may occur. If feasible, tree clearing during the bat inactive season (November 1 to April 14), which also avoids the June 1 to August 15 pupping season, is recommended to avoid impacts.

Suckley's cuckoo bumble bee

The Suckley's cuckoo bumble bee (SCBB) is a parasitic species that relies exclusively on other bumble bees as hosts. The SCBB historically occurs across a wide variety of habitats, including woodlands, prairies, meadows, agricultural areas, and urban areas where host bumble bee nests are present. While this species has historically occurred in portions of western and northern Minnesota, no extant populations are known to occur in Minnesota at present. The last confirmed sighting in the United States was in 2016 in Oregon.[39]

It is anticipated that the Project would have no effect on the SCBB. The USFWS Minnesota-Wisconsin Determination Key and Technical Assistance letter (Appendix E) did not cover the SCBB under its "No Effect" determination. Woodlots within the Project area may provide suitable habitat for nesting bumble bee host species. However, the lack of extant populations of the SCBB within the state of Minnesota and the fact that the last SCBB was observed in Minnesota prior to 2000 make the likelihood of occurrence of this species in the Project area very low.

Monarch butterfly

The monarch butterfly is a migratory butterfly that exists in two main populations within the United States divided by the Rocky Mountains: the eastern population that overwinters in the mountains of Mexico, and the western population that overwinters along the southern pacific coast of California.[40] Monarch butterflies are a widespread species found in fields, prairies, savannahs, and most places where their host plant milkweed (*Asclepias* spp.) occurs throughout the United States and southern Canada. This species generally occurs in areas with high densities of native nectar sources. During late summer and migration, adults use nectar species such as black-eyed Susan (*Rudbeckia hirta*), narrow-leaved coneflower (*Echinacea angustifolia*), and rough blazing star (*Liatris aspera*).[41] However, the presence of milkweed is required as it is the only plant on which monarch caterpillars can feed.[42]

It is anticipated that the Project would have no adverse effect on the monarch butterfly. Grasslands within the Project area may provide milkweed and flowering resources to support the monarch butterfly. While ground and vegetation disturbance is proposed for the Project, impacts could be mitigated through the

[38] USFWS. undated(b). Tricolored Bat (*Perimyotis subflavus*) Interactive Map. Available at: https://www.fws.gov/species/tricolored-bat-perimyotis-subflavus/map. Accessed January 2026.

[39] USFWS. 2024b. Endangered Species Status for Suckley's Cuckoo Bumble Bee. Available at: https://www.fws.gov/species-publication-action/endangered-species-status-suckleys-cuckoo-bumble-bee. Accessed October 2025.
[40] United States Department of Agriculture [USDA] Forest Service. undated-a. Migration and Overwintering. Available at: https://www.fs.fed.us/wildflowers/pollinators/Monarch_Butterfly/migration/. Accessed November 2021.
[41] MNDNR. 2022. Butterfly Gardens. Available at: https://www.dnr.state.mn.us/gardens/butterfly/index.html. Accessed March 2022.
[42] National Wildlife Federation. undated. Monarch Butterfly. Available at: https://www.nwf.org/Educational-Resources/Wildlife-Guide/Invertebrates/Monarch-Butterfly. Accessed December 2021.

use of native seed in revegetation plans. The effect determination for this species relies on the USFWS Minnesota- Wisconsin Determination Key within the IPaC system and a determination of "No Effect" was made for the monarch butterfly. The Technical Assistance letter is provided in Appendix E.

Western regal fritillary

Western regal fritillary requires large, intact grasslands at a landscape scale, with violets for larvae; nectar sources for adults; and native warm-season bunch grasses for shelter at all life stages. The grasslands need to be large and contiguous, generally more than 3.86 square miles, and be maintained by periodic disturbances. Voilet species (*Viola* sp.) are required as the exclusive source of larval forage.[43]

It is anticipated that the Project would have no effect on the western regal fritillary. The USFWS Minnesota-Wisconsin Determination Key and Technical Assistance letter (Appendix E) did not cover the western regal fritillary under its "No Effect" determination. However, quality native prairie habitat is not known to be present within or near the Project area, nor was it identified during the review of the DNR MCE portal.

Whooping crane

The whooping crane is a migratory bird species that once nested in northern prairies but now breeds in remote northern forests in Canada as well as in an experimental population in Wisconsin, preferably within coniferous habitat containing swamps and nearby lakes or ponds. Winter habitat consists of coastal marshes (e.g., Texas, Louisiana, and Florida).[44]

It is anticipated that the Project would have no effect on the whooping crane. Suitable habitat for the whooping crane, prairies and coniferous habitat with nearby swamps, is not present within the Project area. Additionally, the Project is located within the Mississippi Flyway while the wild population of whooping crane uses the Central Flyway located further west in the Great Plains. Any occurrence of a whooping crane within the Project area would likely be from the experimental population based out of Wisconsin that is not federally regulated. The effect determination for this species relies on the USFWS Minnesota-Wisconsin Determination Key within the IPaC system and a determination of "No Effect" was made for the whooping crane. The Technical Assistance letter is provided in Appendix E.

Migratory Birds

The USFWS IPaC review also provides information on potential eagle species and Birds of Conservation Concern (BCC) that have the potential to occur within the Project area. One eagle species and five BCC species have the potential to occur within the Project area (Appendix E). These species and their habitat requirements are detailed in Table 14.

Table 14. Migratory Birds Listed as BCC with Potential to Occur within the Project Area

Common Name	Scientific Name	Nesting, Foraging, and/or Migration Stopover Habitat[45]
Bald eagle[1]	*Haliaeetus leucocephalus*	Forested areas (conifers and deciduous trees) near large bodies of open water. Open uplands near open water in winter.

[43] USFWS. 2024c. Endangered and Threatened Wildlife and Plants; Endangered Status for the Eastern Regal Fritillary, and Threatened Status With Section 4(d) Rule for the Western Regal Fritillary. 89 FR 63888. August 6, 2024.
[44] Audubon. undated. Whooping Crane. Available at: https://www.audubon.org/field-guide/bird/whooping-crane. Accessed December 2025.
[45] Cornell Lab of Ornithology. undated. All About Birds. Available at: https://www.birds.cornell.edu/home/. Accessed January 2026.

Common Name	Scientific Name	Nesting, Foraging, and/or Migration Stopover Habitat[45]
Canada warbler	*Cardellina canadensis*	Breeds in mixed conifer and deciduous forest with shrubby and mossy understory near water; forested wetlands. Found in parks, forest edges, and woodlots during migration.
Chimney swift	*Chaetura pelagica*	Breeds in rural and urban settings in chimneys, tree cavities, and caves. Forage over open habitats, forests, ponds, and residential areas.
Grasshopper sparrow	*Ammodramus savannarum perpallidus*	Grasslands, prairies, hayfields, and open pastures with little scrub and some bare ground.
Red-headed woodpecker	*Melanerpes erythrocephalus*	Breeds in mature deciduous woodlands that contain dead or dying trees that can act as nest cavities. Oak, oak-hickory, maple, ash, and beech are often used in the northern portion of their range.
Rusty blackbird	*Euphagus carolinus*	Breeds in wet forests with fens, bogs, muskeg, or beaver ponds and winters in swamps, wet woodlands, and pond edges.
[1]This species is not listed as BCC but warrants special attention under the Bald and Golden Eagle Protection Act (BGEPA).		

The bald eagle is the protected migratory species most likely to occur within or near the Project area. This species is not listed as BCC but warrants special attention under the Bald and Golden Eagle Protection Act (BGEPA). Forested areas within and in the vicinity of the Project area may provide suitable nesting sites for the bald eagle, especially given the proximity to the Mississippi River.

The forested areas, grasslands, and wetlands within the Project area may provide nesting, foraging, and/or migration stopover habitat for the Canada warbler, chimney swift, grasshopper sparrow, red-headed woodpecker, rusty blackbird and other non-BCC migratory bird species.

If vegetation clearing activities can occur outside the peak breeding window for these and other migratory birds in Minnesota (approximately May 15 to August 1), then impacts on these species are unlikely to occur. If this is not feasible, a pre-construction breeding bird survey would be recommended as described below in the mitigation strategies.

c. Discuss how the identified fish, wildlife, plant communities, rare features and ecosystems may be affected by the project including how current Minnesota climate trends and anticipated climate change in the general location of the project may influence the effects. Include a discussion on introduction and spread of invasive species from the project construction and operation. Separately discuss effects to known threatened and endangered species.

Impacts Analysis for Native Plant Communities and Sites of Biodiversity Significance

Based on a review of the DNR MCE portal, there are no DNR Native Plant Communities, MBS Sites of Biodiversity Significance, DNR Old Growth Stands, Lakes of Biological Significance, or calcareous fens located within the Project area. Therefore, there would be no impacts on these resources.

Impacts Analysis for State-Listed Species

Butternut

Impacts on the butternut are not anticipated given that suitable habitat, river terraces and mesic hardwood forest systems, are not present within the Project area. These habitats

With an increase in more intense storms in Minnesota as a result of climate change, flooding events have become more common. These conditions favor siltation and flood scouring, both of which are unfavorable for the butternut.[46] Given that the Project area does not provide suitable habitat, the Project would not exacerbate the impacts of climate change on this species.

Black sandshell

Impacts on the black sandshell are not anticipated given that suitable habitat, medium to large rivers, is not present within the Project area. While the Mississippi River is located near the Project, no direct or indirect impacts to this resource are anticipated. Appropriate erosion and sediment control devices would be used to avoid indirect impacts to wetlands and waterbodies.

Freshwater mussels, such as the black sandshell, rely on burrowing behavior to escape predation. However, United States Geological Survey (USGS) studies have shown that increasing water temperatures lead to increased stress and decreased burrowing activity, resulting in mussels being more exposed.[47] Given that the Project area does not provide suitable habitat, the Project would not exacerbate the impacts of climate change on this species.

Peregrine falcon

Impacts on the peregrine falcon are unlikely given the lack of nesting habitat, cliffs or tall buildings, within the Project area. Construction within the Project area would likely deter peregrine falcons from hunting in the immediate vicinity.

Given the warming climate trend in Minnesota, overall suitable habitat for the peregrine falcon is anticipated to increase, but this comes at the expense of a loss of wintering grounds for the species.[48]

Impacts Analysis for Federally-Listed Species

Northern long-eared bat

The Project may affect the NLEB due to proposed tree clearing within the Project area, which can cause direct mortalities as well as habitat loss for the species. The use of temporary and/or permanent lighting may also affect this species when directed at suitable bat habitat. Tree clearing during the bat inactive season (November 1 to April 14) is recommended to avoid adverse effects on the NLEB.

As discussed in EAW Item 7 (Climate Adaptation and Resilience), Minnesota's climate is trending warmer with more extreme precipitation events. Changes in temperature and precipitation may influence the NLEBs available suitable roosting and foraging habitat, as well as prey availability.[49] Although a less significant stressor compared to white-nose syndrome, climate change variables may negatively affect

the NLEB.[50]

Tricolored bat

The Project may affect the tricolored bat due to proposed tree clearing within the Project area, which can cause direct mortalities as well as habitat loss for the species. The use of temporary and/or permanent lighting may also affect this species when directed at suitable bat habitat. Tree clearing during the bat inactive season (November 1 to April 14) is recommended to avoid adverse effects on the tricolored bat.

The tricolored bat is susceptible to climate change. For instance, areas that are experiencing more intense rainfall, such as Minnesota, may also see decreased foraging behavior from the tricolored bat along with decreased insect availability.[51]

Suckley's cuckoo bumble bee

The Project is anticipated to have no effect on the SCBB. While suitable nesting habitat (woodlots) is present within the Project area that may support hosts of this species, no extant populations of SCBB are known in Minnesota at present.

Climate change is anticipated to impact the SCBB in a variety of ways. Drought events are anticipated to increase and bloom dates for floral resources are occurring earlier, resulting in frost damage and overall fewer nectar species for SCBB and the host species it depends on. According to various different climate scenarios, widespread declines in bumble bee species are also predicted.[52]

Monarch butterfly

Given the wide range of habitats the species occupies, the removal and damage of vegetation within the Project area could result in habitat loss for the monarch butterfly as well as potential individual fatalities. If a native seed mix is used to revegetate the site post-construction, then development within the Project area may be a net positive for the species.

Climate change is anticipated to result in increasing temperatures in Minnesota, which may increase the number of days and the area in which monarch butterfly populations would be exposed to unsuitably high temperatures. This can result in them using up fat stores too quickly and may result in them incorrectly judging when to enter and exit states of dormancy (diapause).[53]

Western regal fritillary

The Project is anticipated to have no effect on the western regal fritillary due to the lack of native prairie habitat within the Project area. Permanent conversion of brush/grassland is proposed, but this habitat would not support this species due to its limited size (<0.1 square miles) and lack of native forage.

The western regal fritillary relies on violets for their life cycle, and their abundance is closely linked to violet density.[54,55] With an increase in more intense storms and droughts in Minnesota, invasive species are likely to become more dominant and push violet numbers down, thus furthering the decline of western

regal fritillary habitat.

Whooping crane

The Project is anticipated to have no effect on the whooping crane due to the lack of coniferous forest and swamp habitat within the Project area. Impacts to wetlands present within the Project area would be avoided. The Project area is also not within the range of the wild population of whooping cranes. Any unlikely occurrences of this species within the Project area would likely be from the unregulated experimental population based in Wisconsin.

Based on models that consider various climate factors, it has been predicted that climate change may impact the juvenile recruitment and population growth of the whooping crane. For instance, increased precipitation during fall migration and the breeding season indicated lower recruitment and increased atmospheric carbon dioxide indicated lower population growth rates and recruitment.[56]

Impacts Analysis for Migratory Birds

Construction activities and development within the Project area may cause impacts to migratory birds and/or their nests. Based on the IPaC species review results (Appendix E), the majority of the BCC species with the potential to occur in the Project area are most likely to be nesting in the Project area between May 1 and August 31. Some of these species, as well as other migratory birds, may use the wetlands within the Project area, but impacts to wetlands would be avoided. If construction activities occur within vegetated areas of the Project area, it may cause impacts to migratory birds, eggs, young, and/or active nests if conducted during the bird nesting timeframe in Minnesota.

Impacts Analysis for Urban Wildlife

Urban wildlife such as squirrels, mice, rabbits, raccoons, deer, coyotes, foxes, and other small mammals may be impacted by the development within the Project area, such as through the removal of grasslands, forest, and/or wetlands. Additionally, lighting may have the potential to negatively impact wildlife. These species are generally adaptable to change and would likely relocate to other undeveloped areas.

Invasive Species

Noxious weeds and invasive species in Minnesota are managed through the Minnesota Department of Agriculture (MDA) under Minnesota Statutes Section 18.78, the DNR, and local ordinances. Best management practices (BMPs) during construction activities and operation within the Project area should be implemented where practicable to minimize the introduction or spread of noxious weeds and invasive species. These practices include cleaning vehicles and equipment of mud and dirt from other construction areas, removing seeds that attach to clothing or equipment, minimizing soil disturbance, not moving potentially contaminated materials between sites, and staying on designated roads/trails.[57,58]

d. Identify measures that will be taken to avoid, minimize, or mitigate the adverse effects to fish, wildlife, plant communities, ecosystems, and sensitive ecological resources.

- Sightings of any rare species during future development within the Project area should be reported to the DNR Nongame Wildlife specialist as soon as possible and their guidance should be followed before proceeding with work. Do not attempt to handle or move the species or its nest unless the animal is at immediate risk of injury and the action is being done under agency approval.
- If a bald eagle or bald eagle nest are discovered, work near the nest tree(s) would immediately

[56] Butler, M. J., Metzger, K. L., & Harris, G. M. (2017). Are whooping cranes destined for extinction? Climate change imperils recruitment and population growth. *Ecology and Evolution*, *7*(8), 2821-2834.

[57] USDA National Invasives Species Information Center. undated. Best Management Practices. Available at: https://www.invasivespeciesinfo.gov/subject/best-management-practices. Accessed January 2023.

[58] DNR. 2023. Terrestrial Invasive Species. Available at: https://www.dnr.state.mn.us/invasives/terrestrial/index.html. Accessed January 2023.

cease and USFWS would be consulted.

- The DNR Project review is valid for one year. If Project details change or the Project has not occurred within one year, the Project should be resubmitted for review.
- Wildlife-friendly erosion control devices should be used both to protect wetlands and other habitats from sediment-laden stormwater runoff and to prevent injury to wildlife. Typical DNR recommendations include:

    - Biodegradable netting should be used, preferably natural materials with short degradation periods. Erosion control blankets should be limited to bio-netting or natural netting types due to the risk of entanglement of small animals.
    - Identify acceptable materials in MnDOT Category 3N or 4N mulches.
    - Do not use products that require UV-light to degrade (also called “photodegradable”), as they do not degrade properly when covered/shaded.
    - Do not use products containing plastic mesh netting or other plastic components.
    - Do not use mulch products that contain synthetic (plastic) fiber additives near waterbodies.
    - See https://files.dnr.state.mn.us/eco/nongame/wildlife-friendly-erosion-control.pdf for more information.

- Native seed would be used for revegetation within the Project area in order to provide suitable habitat for species like the monarch butterfly and to prevent the spread of invasive plants and noxious weeds.
- Although the DNR NHIS review did not identify records of the NLEB or tricolored bat within the Project area, tree clearing is recommended to occur during the bat inactive season (November 1 to April 14, inclusive) when possible. If this is not possible, tree clearing should be conducted to avoid the bat pupping season of June 1 to August 15 per DNR recommendations.
- Niron would follow the City of Sartell’s tree replacement rule (Sartell City Code Title 10, Chapter 12) which states that one tree is to be planted per 1,000 square feet of building floor square footage or per 100 feet of lot perimeter, whichever is greater. The number of new required trees can be reduced based on the number of existing mature trees not removed by the Project. Niron must submit a Landscaping Plan to the City for approval.
- The use of downward facing, full cut-off lens lights are recommended for any permanent lighting used on the Project. Any temporary lighting should also be directed away from suitable bat habitat during the bat active season (April 15 – October 31).
- When possible, removal of vegetation should occur outside of the bird nesting window to minimize potential impacts to migratory birds.

15. Historic Properties

Describe any historic structures, archeological sites, and/or traditional cultural properties on or in close proximity to the site. Include: 1) historic designations, 2) known artifact areas, and 3) architectural features. Attach letter received from the State Historic Preservation Office (SHPO). Discuss any anticipated effects to historic properties during Project construction and operation. Identify measures that will be taken to avoid, minimize, or mitigate adverse effects to historic properties.

Stantec reviewed the SHPO previous survey report data as well as the Office of the State Archaeologist (OSA) Portal and the Minnesota Statewide Historic Inventory Portal in January 2026[59,60]. The literature search focused on previously identified cultural resources (archaeological sites and above-ground historic resources) within and adjacent to the Project area. Traditional Cultural Properties within or adjacent to the Project area are unknown as a Tribal Cultural Property identification survey has not been conducted for this Project. In addition, Stantec reviewed archival resources including General Land Office (GLO) maps, county atlases, the University of Minnesota Borchert Map Library, Trygg maps, and historical aerial imagery to identify potential cultural features in the Project area.

No previously conducted archaeological surveys overlap with the Project area.

No previously recorded archaeological sites are located within the Project area. Seven previously recorded archaeological sites are documented within 1-mile of the Project area (Table 15). Of the seven archaeological sites, two are eligible for the National Register of Historic Places (NRHP), one site is not eligible and the remaining four sites are unevaluated. Additionally, two of the archaeological sites within 1-mile of the Project area are precontact burial mounds located on the opposite side of the Mississippi River. Burial sites in Minnesota are protected under Minnesota Statute 307.08.

Table 15. Previously Recorded Archaeological Sites within 1-Mile of the Project Area

Site Number	Site Name	Site Type	Cultural Affiliation	NRHP Status
21BN0001	-	Burial Mound	Precontact	Unevaluated
21BN0002	-	Burial Mound	Precontact	Eligible
21BN0006	East Terrace	Artifact Scatter	Precontact: Paleo Indian, Archaic, Woodland	Eligible
21BN0017	Municipal Park	Lithic Scatter	Precontact	Unevaluated
21BN0036	Sartell Paper Mill	Paper Mill	Historic	Not Eligible
21SNt	Sartell	Structural Ruin (Mill)	Historic	Unevaluated
21SNaq	-	Artifact Scatter		Unevaluated

The MnModel, available on the OSA online portal, shows that the Project is located almost entirely within an area of unknown archaeological site potential. The southeastern edge of the Project area is within an area of low archaeological site potential. The MnModel dataset classifies archaeological site potential based on the number and distribution of archaeological sites and surveys, the resolution of environmental data, and the degree to which the environmental data represents the historic and precontact landscape. According to the OSA Portal, during the precontact period the Project area was mostly wetland, with small pockets of permanently wet areas. Deciduous forest was present in the eastern portion of the Project area along the Mississippi River while the western portion was interspersed deciduous forest and savanna.

[59] Minnesota Office of the State Archaeologist (OSA). 2026. Office of the State Archaeologist Portal. Electronic database, https://osaportal.gisdata.mn.gov/, accessed January 20, 2026.
[60] Minnesota State Historic Preservation Office (SHPO). 2026. Minnesota Statewide Historic Inventory Portal. Electronic database, https://mnship.gisdata.mn.gov/, accessed January 20, 2026.

No previously identified burial sites/cemeteries are recorded in the Project area. Two previously identified historic cemeteries (Oak Hill Cemetery and St. Francis Xavier Cemetery) are located within 1-mile of the Project area. Both cemeteries are mapped at the 40-acre level on the OSA Portal and are unevaluated for the NRHP. The cemeteries are protected through Minnesota Statute 307.08.

No previously identified above-ground historic resources are recorded in the Project area. Six previously identified above-ground historic resources are documented within 0.25-mile of the Project area; of which four are not eligible for the NRHP and two are unevaluated (Table 16).

Table 16. Previously Identified Above-Ground Historic Resources within 0.25-Mile of the Project Area

Resource No.	Name	Resource Type	Address/Location	NRHP Status
BN-LAN-00006	Brainerd Branch: Sauk Rapids to Brainerd Railroad	Structure	-	Unevaluated
SN-STC-00005	Farmstead	Building	600 Riverside Ave.	Unevaluated
XX-ROD-00037	Trunk Highway 10: Anoka to Little Falls Segment	Structure	Trunk Highway 47 in Anoka to Hilton Rd in Little Falls	Not Eligible
XX-RRD-NPR022	St. Paul and Northern Pacific Railway Company/Northern Pacific Railway Company: Staples to St. Paul	Structure	Staples and its terminus at Union Depot, St Paul	Not Eligible
XX-RRD-NPR024	St. Paul and Northern Pacific Railway Company/Northern Pacific Railway Company: Brainerd to St. Paul	Structure	Brainerd and terminus at Union Depot St Paul	Not Eligible
XX-RRD-NPR025	Western Railroad Company of Minnesota/St. Paul and Northern Pacific Railway Company/Northern Pacific Railway Company	Structure	Brainerd and junction with St Paul and Pacific Sauk Rapids	Not Eligible

Historic Document Review

An unnamed road extends through the Project area on the original GLO survey map from 1858 running parallel to the Mississippi River. No structures are mapped within the Project area or the vicinity in 1858; however, fields are mapped to the south of the Project Area, and a sawmill is mapped to the north. A handwritten note across the township map describes the township as rolling swamp, with other areas containing prairie, Tamarack, Ash, Lynn, Aspen, and Timber Oak[61].

Stantec reviewed atlas maps from 1874, 1896, 1916, 1925, and 1947 [62,63,64,65,66]. Riverside Avenue, extending along the eastern boundary of the Project area, first appears in the current alignment in 1874. A mapped

[64] State of Minnesota. 1916. State of Minnesota Plat Book. John R. Borchert Map Library, https://geo.lib.umn.edu/plat_books/stateofmn1916/counties/stearns.htm, accessed January 21, 2026.

[65] Thomas O. Nelson Co. 1947. Plat Book of Stearns County, Minnesota, https://historicmapworks.com/Atlas/US/33049/Stearns+County+1947/, accessed January 21, 2026.

[66] W.W. Hixson & Co. 1925. Minnesota State Atlas, https://historicmapworks.com/Atlas/US/32714/, accessed January 21, 2026.

structure identified on all reviewed atlas maps aligns with the location of a house immediately adjacent to the Project area. No structures or cultural features are depicted within the Project area on any reviewed atlas maps. Development to the north of the Project area along the Watab River in Section 21 is first identified in 1896 when numerous labeled structures are first depicted on atlas maps. By 1916 the area is labeled as "Sartell" and by 1947 the NE1/4 NE1/4 of Section 28 and most of Section 27, overlapping with the Project area, are within the limits of Sartell.

Stantec reviewed United States Geological Survey (USGS) topographic maps from 1952, 1966, 1973, 1976, and 1993[67]. The above-mentioned structure mapped immediately adjacent to the Project area and Riverside Avenue also appeared on all reviewed USGS maps. A trailer park immediately north of the Project area and sewage disposal ponds south of the Project area first appear in 1976. Additional structures to the north of the Project area, as well as Heritage Drive/4th Ave South, extending along the western boundary of the Project area, first appear in 1993. No structures are depicted within the Project area on any reviewed USGS map.

The earliest aerial imagery of the Project area from 1938 shows a farmstead with numerous outbuildings at the location of the above-mentioned structure identified on atlas and topographic maps. Sparse trees surround the farmstead and extend to the north, within the northeastern portion of the Project area. The remainder of the Project area appears as grassland and cultivated land. A water-filled depression and a cattle trail are located within the grassland portion of the Project area. A structure associated with a house directly north of the Project area lies along the northern boundary of the Project area in 1938 and is absent by 1965. In 1965 a water-filled depression appears in the southwestern portion of the Project area. The Project area appears relatively unchanged as cultivated land and grassland in aerial imagery from 1938 to 1973[68,69].

In 1985, the western portion of the Project area transitions to grassland and a gravel road following the current alignment of Heritage Drive/4th Ave South first appears on aerial imagery. A disturbed area is noted in the northwest corner of the Project area, across the street from a house that first appears in aerial imagery in 1973. The disturbed area is visible in aerial imagery from 1985 to the present and appears largely as a rock and hay bale pile in recent aerial imagery. Between 1985 and 1991 a channel was constructed between the water-filled depression in the southwestern corner of the Project area and the agricultural field and is visible on all aerial imagery from 1991 to the present day as a cut on the landscape. Additional ground disturbance, evidenced by two circular newly disturbed areas, along the western border of the Project Area is first seen in 2021, continues to present day[70]. Based on historic aerial imagery, primary land use within the Project area consists of cultivated land and grassland since 1938.

Stantec understands that ground disturbing work, including grading and introduction of fill, has occurred within the western portion of the Project area. Available aerial imagery does not extend to dates that would illustrate the disturbance.

Despite previous disturbance, the Project area yields a moderate potential for intact cultural resources along the eastern half due to the proximity to the Mississippi River, as well as the presence of moderately well-drained soils within the Project Area.

Conclusions

Archaeology

- As construction and ground disturbance has already begun, and the Project area has not been previously surveyed, Stantec cannot recommend a determination of effect. A Phase I archaeological reconnaissance investigation is recommended if a thorough determine of the potential for the Project to impact historic properties is deemed necessary.

[67] United States Geological Survey. 2026. Historical Topo Map Explorer, https://livingatlas.arcgis.com/topomapexplorer/#maps=&loc=-94.20,45.60&LoD=13.66, accessed January 21, 2026.

- Should the Project require significant federal funding or permitting, a Section 106 review would be required along with consultation with the SHPO.

Architectural

- No previously identified above-ground historic resources documented within 0.25-mile of the Project area are listed on or eligible for the NRHP based on the desktop review.
- Based on the preliminary desktop review, a historic architectural property survey is not recommended at this time. Should the Project require significant federal funding or permitting, a Section 106 review would be required along with consultation with the SHPO.

16. Visual

Describe any scenic views or vistas on or near the Project site. Describe any Project related visual effects such as vapor plumes or glare from intense lights. Discuss the potential visual effects from the Project. Identify any measures to avoid, minimize, or mitigate visual effects.

Project area primarily consists of grassland, recently fallowed cropland, wetlands, and several groves of trees. No designated scenic views or vistas are present in the vicinity of the Project. The Project area is easily visible along its 4th Avenue frontage. The landscape immediately surrounding the site consists of single-family residential neighborhoods to the north and east, light industrial and vacant land to the west, and a landfill to the south.

The facility would operate 24 hours a day and would be illumated at night using downward-facing lights. Brightness would be the minmimum needed for safety and security. The cooling tower may create a downwind cloud-like water vapor plume, visible during the day from the river or adjacent neighborhoods. The size and density of the plume would vary with weather conditons.

The proposed Project would significantly alter the appearance of the site. The primary public vantage points are from 4th Avenue and from the adjacent residential neighborhood to the north, though mature trees provide partial screening along the north side of the Project area. The building façades from the street view would be designed to meet City requirements. The facility buildings would be painted white with green and black accents. Most structures would be less than 50 feet tall though several elements would be taller, including the Nitriding Structure (105 feet) and the Flare Structure (82 feet). Table 1 under EAW Item #6 lists the proposed heights of the facility's structures. The taller structures would be located in the rear of the facility and largely obscured from public view. Below is a rendering of the proposed facility at full build-out, looking from 4th Avenue. Also see draft civil design drawings in Appendix B.

17. Air

a. Stationary source emissions - Describe the type, sources, quantities and compositions of any emissions from stationary sources such as boilers or exhaust stacks. Include any hazardous air pollutants, criteria pollutants. Discuss effects to air quality including any sensitive receptors, human health or applicable regulatory criteria. Include a discussion of any methods used assess the Project's effect on air quality and the results of that assessment. Identify pollution control equipment and other measures that will be taken to avoid, minimize, or mitigate adverse effects from stationary source emissions.

The Facility is permitted under an Option D Registration Permit, number 14500196-101, issued by MPCA on August 28, 2025.

Construction of the Project would be expected to be completed in two phases over four years. Emission units included in Phase 1 of construction were included in the Option D Registration Permit application. The emission units include: a spray dryer, spray booths with spray painting guns, methanol solvent reclaim, ammonia gas reclaim, two natural gas-fired emergency generators, and a hot oil process heater. Insignificant activities under Minn. R. 7007.1300 Subp. 3(F) include: process bins with fabric filters, dry milling machines with HEPA filters, and natural gas heating units. Although Insignificant Activities are not required to be included in an Option D air permit application, they are included in the calculations for reference in relation to the EAW.

Table 17 describes all air emissions sources that were included in the Option D Registration Permit application.

Table 17. Data From Option D Registration Permit application

Emission Unit Description	Pollutants Generated	Pollutant Control Equipment (if applicable)
Spray Dryer	PM, PM_{10}, $PM_{2.5}$, SO_2, NO_x, VOC, CO, CO_2e, Lead, HAPs	Fabric Filter for PM/PM_{10}/$PM_{2.5}$ control
Solvent Reclaim	VOC, HAPs	None
Paint Booth Spray Gun (2)	PM, PM_{10}, $PM_{2.5}$, VOC	Wall Filter for PM/PM_{10}/$PM_{2.5}$ control
Ammonia Gas Reclaim	PM, PM_{10}, $PM_{2.5}$	Spray Tower for Ammonia control
Hot Oil Heater	PM, PM_{10}, $PM_{2.5}$, SO_2, NO_x, VOC, CO, CO_2e, Lead, HAPs	None
Emergency Generator (2)	PM, PM_{10}, $PM_{2.5}$, SO_2, NO_x, VOC, CO, CO_2e, HAPs	None
Bins and Hoppers (4)	PM, PM_{10}, $PM_{2.5}$	Fabric Filters for PM/PM_{10}/$PM_{2.5}$ control
Dry Milling (2)	PM, PM_{10}, $PM_{2.5}$	HEPA Filters for PM/PM_{10}/$PM_{2.5}$ control
Natural Gas Heating Units (5)	PM, PM_{10}, $PM_{2.5}$, SO_2, NO_x, VOC, CO, CO_2e, Lead, HAPs	None

The facility's actual air emissions for equipment included in the Option D Registration Permit application are provided in Table 18 below.

Table 18. Emissions Summary from Option D Registration Permit Application

Pollutant	Existing Facility Actual Emissions (tpy)	Option D Permit Threshold (tpy)
PM	1.82	50
PM_{10}	1.82	50
$PM_{2.5}$	1.82	NA
SO_2	0.080	50
NO_x	13.67	50
VOC	25.10	50

Pollutant	Existing Facility Actual Emissions (tpy)	Option D Permit Threshold (tpy)
CO	11.99	50
CO_2e	15,825	50,000
Lead	6.61E-05	0.5
Single HAP (Methanol)	1.30	5
Total HAPs	3.46	12.5

Niron has updated plans for the Phase 1 facility to include several design improvements. These design improvements are expected to reduce emissions from some sources in the originally proposed facility design and include an emergency flare and a hot oil burner optimized for ammonia combustion, which will replace the wet scrubber originally scoped for Phase 1. Niron would add additional air emission equipment to the facility in Phase 2 of construction. Additional equipment anticipated to be added to the facility in Phase 2 includes three nickel plating lines. Facility production is anticipated to increase with the implementation of Phase 2, which would increase air emissions from emissions equipment included in the Option D Registration Permit application.

Table 19 describes all air emissions sources that are proposed second phase of the Project.

Table 19. Phase 2 Emission Sources, Pollutants, and Pollution Control Equipment

Emission Unit Description	Pollutants Generated	Pollutant Control Equipment (if applicable)	Equipment Status
Ammonia Gas Reclaim	PM, PM_{10}, $PM_{2.5}$	Spray Tower for Ammonia control	Spray Tower not needed.
Hot Oil Heater	NO_x, PM, PM_{10}, $PM_{2.5}$, CO, VOC	Burner optimized for Ammonia combustion	Addition
Nickel Plating Lines (3)	PM, PM_{10}, $PM_{2.5}$, HAPs	Controls per NESHAP WWWWWW	Addition

Niron anticipates the Facility will still qualify for its Option D Registration Permit after the completion of Phase 2 of the Project. Process equipment design and associated air emissions are still under Facility review and expected air emissions will be updated as information becomes available. The Registration Permit Option D thresholds are lower than thresholds for MPCA's state permit, Part 70 permit, or Prevention of Significant Deterioration permit types. Given the relatively low levels of expected actual emissions through both phases of the Project, the potential for significant environmental effects from Facility air emissions is low. MPCA's air modeling guidance does not require modeling for Registration Permit facilities.

The following is included to describe ongoing air-related compliance requirements. Two natural gas-fired emergency generators were originally scoped but were replaced with a single natural gas-fired emergency generator. The natural gas-fired emergency generator will be subject to 40 CFR 60 Subpart JJJJ: Standards of Performance for Stationary Spark Ignition Internal Combustion Engines (NSPS JJJJ). NSPS JJJJ applies to all spark ignition internal combustion engines used for emergency purposes with a maximum engine power greater than 25 hp manufactured on or after January 1, 2009. In addition, the emergency generator engine will be subject to NESHAP ZZZZ. However, since the new unit is subject to NSPS JJJJ and located at an area source of HAPs, there are no applicable requirements under NESHAP ZZZZ. A subsequent review identified the hot oil heater may be subject to NSPS Dc, to which Niron would update any application materials as appropriate. The powder metallurgy technology used in the Niron process may be subject to 40 CFR 63 NESHAP XXXXXX. If so, application materials would be updated.

The nickel plating line would be subject 40 CFR 63 Subpart WWWWWW: National Emissions Standards for Hazardous Air Pollutants: Area Source standards for Plating and Polishing Operations (NESHAP WWWWWW). NESHAP WWWWWW applies to plating facilities that emit one or more plating and polishing metal HAP, including cadmium, chromium, lead, manganese, or nickel. The nickel plating line will have emissions of nickel. Therefore, NESHAP WWWWWW applies to the line.

The facility is not subject to any other NSPS or Area-Source NESHAPs, as summarized below:

- All tanks that will be used to store volatile organic liquids (VOL) will have capacities of less than 20,000 gallons; therefore, NSPS Kc does not apply.
- All natural gas heaters will have individual capacities of less than 10 MMBtu/hr; therefore, NSPS Dc does not apply to the natural gas heaters.
- The hot oil heater and natural gas heaters are not Industrial, Commercial, or Institutional Boilers; therefore, NESHAP JJJJJJ does not apply.
- The hot oil heater does not combust liquid wastes, solid wastes or containerized gases, therefore NSPS CCCC does not apply.

The facility is not subject to any other NSPS or Area-Source NESHAPs. The facility is also not one of the 28 listed source categories.

The facility would be subject to and would manage the facility to comply with Chemical Accident Prevention regulations (aka, Risk Management Program) in both 40 CFR 68 and 29 CFR 1910 (Process Safety Management).

b. Vehicle emissions - Describe the effect of the Project's traffic generation on air emissions. Discuss the Project's vehicle-related emissions effect on air quality. Identify measures (e.g. traffic operational improvements, diesel idling minimization plan) that will be taken to minimize or mitigate vehicle-related emissions.

The Project is not located within a CO or PM maintenance or non-attainment area. Traffic at the proposed Facility will be minimal and will consist of approximately 70 employee vehicles and up to 15 delivery trucks per day. Relative to existing traffic patterns in Sartell and the surrounding area, the minor increases in operational traffic would not result in significant vehicle-related emissions, nor would they result in significant vehicle-related impacts. The project is expected to generate minimal increases in temporary vehicle emissions during the approximately 30- to 36-month construction period. Niron will encourage the use of ultra-low-sulfur diesel fuel for construction equipment. Equipment idling will be minimized, and equipment will be shut off when not in use.

c. Dust and odors - Describe sources, characteristics, duration, quantities, and intensity of dust and odors generated during Project construction and operation. (Fugitive dust may be discussed under item 17a). Discuss the effect of dust and odors in the vicinity of the Project including nearby sensitive receptors and quality of life. Identify measures that will be taken to minimize or mitigate the effects of dust and odors.

Temporary dust and odors may be generated during construction of the Project. Project construction is anticipated to occur for approximately 30 to 36 months. Potential odors would likely be associated with exhaust from diesel engines and fuel storage, but anticipated odors from construction are not expected to be substantial. Dust will be mitigated with good dust management practices during the construction phase.

No significant sources of dust are associated with the Project. Dust from facility operations will be negligible because all facility parking lots and roads will be paved. All facility operations will occur indoors; therefore, no operational increases in levels of dust would occur. Ammonia emissions from industrial processes will be routed to the Hot Oil Heater for heat recovery. With these ammonia mitigation

strategies, odor emissions generated from operation are expected to be minimal.

Ammonia would be handled in fully enclosed systems. The basis of design of the facility would be to ensure that during operation there would be no impact (nuisance or otherwise) to the surrounding areas. Emergency systems would be designed to mitigate offsite impacts. See EAW Question 13 for discussion of hazardous materials storage and handling.

18. Greenhouse Gas (GHG) Emissions/Carbon Footprint

a. GHG Quantification: For all proposed Projects, provide quantification and discussion of Project GHG emissions. Include additional rows in the tables as necessary to provide Project-specific emission sources. Describe the methods used to quantify emissions. If calculation methods are not readily available to quantify GHG emissions for a source, describe the process used to come to that conclusion and any GHG emission sources not included in the total calculation.

GHG emissions would be generated during construction and operation of the Project and are summarized below in Table 20. Scope 1 emissions are those emitted as a direct result of the Project's operations, including construction operations. Scope 2 emissions are those emitted from the off-site production of electricity for the Facility. Scope 3 emissions are those emitted from the off-site treatment of waste generated at the Facility.

Table 20. Emission Categories for Carbon Footprint

Category	Scope	Project Phase	Type of Emissions
Direct Emissions	Scope 1	Construction	Combustion (On-Road Mobile Sources)
	Scope 1	Construction	Combustion (Off-Road Mobile Sources)
	Scope 1	Construction	Building Materials
	Scope 1	Construction	Land Use Change
	Scope 1	Operations	Combustion (Mobile Sources)
	Scope 1	Operations	Combustion (Stationary Sources)
	Scope 1	Operations	HFC Leakage
Indirect Emissions	Scope 2	Operations	Purchased Electricity
	Scope 3	Operations	Off-site Waste Management

Table 21 presents estimated annual emissions associated with the construction and operation of the Project. Emissions have been calculated using the Environmental Quality Board (EQB) Minnesota Climate Calculator with supplementary calculations prepared for truck deliveries during construction. Additional calculation details are provided below the table.

Table 21. GHG Emissions Summary (CO2e in short tons per year)

Scope	Source	Project Emissions (tons)
Direct Emissions		
Scope 1	Construction – On-Road Mobile Sources[1]	61
Scope 1	Construction – Off-Road Mobile Sources[1]	28
Scope 1	Construction – Building Materials	117
Scope 1	Construction – Land Use Change	0.12
Scope 1	Operations – Stationary Combustion	30,822
Scope 1	Operations – Mobile Sources	373
Scope 1	Operations – HFC Leakage	25

Scope	Source	Project Emissions (tons)
Indirect Emissions		
Scope 2	Operations – Purchased Electricity	212
Scope 3	Operations – Off-Site Waste Management	61
Total		**31,700**

[1]*Note that construction emissions are annualized over the life of the project, estimated to be 50 years.*

Construction Emissions

On-road mobile source combustion emissions include diesel construction and delivery vehicles for building materials and construction laborers' vehicle emissions. The EQB Minnesota Climate Calculator defaults were used for the average employee one-way commute length and transportation mode breakout. It was assumed that an average of 300 employees would be needed for all stages of construction except for demolition, which is not required for the project as it is being constructed on a greenfield site. GHG emissions for the transportation of materials were calculated with the Minnesota Climate Calculator using the number of tons of material expected to be used for the construction. The Minnesota Climate Calculator is unable to account for emissions from the delivery of fill and miscellaneous materials used for site grading and construction. Supplementary calculations were prepared for on-road emissions from the delivery trucks. Diesel fuel usage per mile was taken from the U.S. Department of Transportation, Federal Highway Administration, Highway Statistics 2024, Table VM-1. Greenhouse gas emission factors were taken from EPA's Emission Factors Hub.

Off-road mobile source combustion emissions were calculated using the default number of hours per day by construction stage from the Minnesota Climate Calculator for all phases of construction except for demolition, which is not required for the Project.

GHG emissions from building materials were calculated with the Minnesota Climate Calculator using the estimated quantities of building materials needed for construction of the Project. All materials were assumed to be sourced domestically. Default values for construction waste from the Minnesota Climate Calculator were used to calculate waste emissions. Emissions from the disposal of construction waste are included in the emissions from building materials.

GHG emissions from land use conversion were also considered for the Project using the estimated number of acres of each land use type prior to and after construction.

Operational Emissions

Operational stationary combustion sources include natural gas-fired heaters, industrial equipment, and emergency generators. It was assumed that natural gas-fired heaters and industrial equipment will operate 8,760 hours per year. The emergency generators were assumed to operate up to 500 hours per year as the units are subject to the EPA September 6, 1995, "Calculating Potential to Emit (PTE) for Emergency Generators" memorandum from John Seitz to the Directors of EPA Regions I-X. This is an overestimation of the actual facilities emissions as heaters will not operate at full capacity in warm months, and emergency generators will only be operated for maintenance and emergencies.

Operational mobile combustion sources include employee vehicle traffic and delivery truck traffic. Emission calculations assumed a daily average of 70 employee vehicles per day and 15 delivery trucks per week traveling up to 50 miles per day. Vehicles were assumed to travel at the fleet average speed provided in the Minnesota Climate Calculator.

Emissions may also be generated from hydrofluorocarbons (HFCs) that are used in air conditioning and refrigeration equipment. Leakage of HFCs happens during equipment installation, operation, servicing, and disposal. Calculations for HFC leakage assume that 100% of the Facility utilizes air conditioning or refrigeration equipment.

Operational emissions also include emissions from purchased electricity and off-site waste management. Emission calculations for purchased electricity are based on the square footage of the proposed Facility. Emission calculations for off-site waste treatment assume an average of 70 employees at the Facility each day for industrial activities with the default waste treatment practices from the Minnesota Climate Calculator.

b. GHG Assessment

i. Describe any mitigation considered to reduce the Project's GHG emissions.

To reduce GHG emissions from construction, equipment would idle as little as possible in an efficient manner. Travel distances may be shorter than estimated.

To mitigate GHG emissions from operation, Niron would only use electricity and natural gas for equipment and building power, and no diesel-fired or oil-fueled equipment would be used on site.

ii. Describe and quantify reductions from selected mitigation, if proposed to reduce the Project's GHG emissions. Explain why the selected mitigation was preferred.

On-road construction emissions would be reduced proportionally to the reduced travel distance compared to the assumed 26.4 miles. Calculations used the Minnesota Climate Calculator default travel distance of 13.2 miles each direction. Actual travel distances may be shorter, and on-road construction emissions would be reduced proportionally to the shorter travel distance.

In the Minnesota Climate Calculator, electricity has a CO_2e emission factor of 29.83 kg/MMBtu, and natural gas has a CO_2e emission factor of 65.15 kg/MMBtu. Diesel has a CO_2e emission factor of 90.31 kg/MMBtu. On a per MMBtu basis, combusting diesel produces three times more CO_2e emissions than electricity and 1.4 times more CO_2e emissions than natural gas. Therefore, the use of electric and natural gas-fired equipment results in a reduction of CO_2e emissions for the Project.

iii. Quantify the proposed Projects predicted net lifetime GHG emissions (total tons/# of years) and how those predicted emissions may affect achievement of the Minnesota Next Generation Energy Act goals and/or other more stringent state or local GHG reduction goals.

Construction would last approximately 30-36 months. The lifetime GHG emissions from construction are 10,942 tons. Assuming a 50-year lifetime, GHG emissions from operation are 1,669,157 tons CO_2e. Total Project lifetime GHG emissions are 1,680,098 tons.

Minnesota's Climate Action Framework aims to reduce emissions by 50% by 2030 and achieve net-zero emissions by 2050. The Project is not anticipated to significantly negatively affect Minnesota's GHG reduction goals.

19. Noise

Describe sources, characteristics, duration, quantities, and intensity of noise generated during Project construction and operation. Discuss the effect of noise in the vicinity of the Project including 1) existing noise levels/sources in the area, 2) nearby sensitive receptors, 3) conformance to state noise standards, and 4) quality of life. Identify measures that will be taken to minimize or mitigate the effects of noise.

Existing noise sources near the Project area include moderate traffic noise along 4th Avenue and existing commercial and industrial uses adjacent to 4th Avenue. There are no major noise emitters in the immediate area. Nearby sensitive receptors include residents of the nearby residential neighborhoods to the north, west, and east of the Project area.

The City of Sartell's noise regulations prohibit loud construction activities between 9:00 p.m. and 6:00 a.m. and generally prohibit construction activities on Sundays. The City's General Industrial District Ordinance requires that facility noise needs to be "muffled so as not to become objectionable due to intermittence, beat frequency, shrillness or intensity. The sound pressure level of noise in an octave band frequency radiated continuously from a facility shall not exceed the noise area classification established by the MPCA".[71]

During construction, noise levels would temporarily increase and vary in intensity based on the types of construction equipment being used and distance from the noise source. See Table 22 below. To minimize the effects of this noise, construction would be limited to daytime hours consistent with the City's construction and noise ordinances. In addition, construction equipment would be fitted with mufflers that would be maintained throughout the construction process.

Table 22. Estimated Noise for Typical Construction Equipment

Equipment	Impact Device (Yes/No)	Lmax Sound dBA*
Backhoe	No	78
Front loader	No	79
Dozer	No	82
Dump truck	No	76
Excavator	No	81
Grader	No	85
Scraper	No	84
Impact pile driver	Yes	101

**Noise levels listed represent the A-weighted maximum sound level (Lmax), measured at a distance of 50 feet from the construction equipment.*

Source: FHWA. Roadway Construction Noise Model (RCNM) Version 1 User Guide. Table 1. CA/T equipment noise emissions and acoustical usage factors database. January 2006. https://www.fhwa.dot.gov/environment/noise/construction_noise/rcnm/rcnm.pdf

[71] Sartell City Code, Title 10, Chapter 7. General Industrial District Ordinance: https://cms5.revize.com/revize/sartell/Title%2010%20Zoning%20Regulations%20RV%202025%20KH%20Edits.pdf?t=202511251020390&t=202511251020390.

The State of Minnesota's noise rules (Minn. Rules Ch. 7030) establish noise limits by noise area classifications (NACs) based on land use at the location of the person that hears noise. Table 23 below identifies state noise standards for each NAC. The MPCA enforces noise standards at industrial facilities for which it has issued an air permit. It is not anticipated that the Project would generate operational noise that would exceed state and local noise standards.

During operations, the facility would generate noise from compressors and other facility processes as well as daily vehicle traffic. Large truck traffic and compressors would likely be the loudest noise generators during operations. The facility would utilize soundproofing materials in their structures where feasible. Niron is currently developing a noise study to estimate operational facility peak noise levels at the property boundary.

The quality of life for nearby sensitive receptors would not be affected by the Project. The facility's vehicle traffic would enter and exit via 4th Avenue. Three or fewer delivery or shipping trucks would visit the facility on an average day. The nearest homes to the vehicle entrances are over 800 feet away and screened by mature trees. The compressors would be partially muffled by adjacent structures and sound mitigating materials. The nearest homes to the compressors would be approximately 850 feet away and partially screened my mature trees. The noise from the facility and truck traffic should not be audible to most nearby residences and would not exceed the limits below for any nearby sensitive receptor.

Table 23. Noise Area Classifications

NAC	Common land use associated with the Noise Area Classification	Daytime (dBA)		Nighttime (dBA)	
		L_{10}	L_{50}	L_{10}	L_{50}
1	Residential housing, religious activities, camping and picnicking areas, health services, hotels, educational services	65	60	55	50
2	Retail, business and government services, recreational activities, transit passenger terminals	70	65	70	65
3	Manufacturing, fairgrounds and amusement parks, agricultural and forestry activities	80	75	80	75

20. Transportation

a. Describe traffic-related aspects of Project construction and operation. Include: 1) existing and proposed additional parking spaces, 2) estimated total average daily traffic generated, 3) estimated maximum peak hour traffic generated and time of occurrence, 4) indicate source of trip generation rates used in the estimates, and 5) availability of transit and/or other alternative transportation modes.

The Project area is currently undeveloped and receives no traffic. The Project would create 120 parking spaces for staff and visitors and four loading docks for deliveries and shipping. Niron estimates up to 15 delivery and shipping truck trips per week during operations and up to 25 delivery trips per week during construction. The facility would have up to 175 total full-time employees spread across three shifts. Peak traffic times would be centered around shift changes at 7:00 AM, 3:00 PM, and 11:00 PM. Some staff may be able to carpool together. Estimated daily trips are summarized below.

- 175 employees x 2 trips per day = 350 daily trips.
- 15 truck operations deliveries/week x 2 trips / 7 = 4.29 daily trips.
- Total estimated daily trips during operations: 354.29.

Construction traffic would consist primarily of daily trips by construction staff as well as delivery of equipment and materials. Up to 300 workers may be on site during peak construction activity and most would likely drive alone (as opposed to carpooling or other transit modes). Most construction workers would arrive between 6:00 and 8:00 am and depart in the early evening. Equipment and materials delivery traffic would vary considerably based on a given day's planned construction activities. The highest rates of daily delivery traffic would include dump trucks bringing fill soil for grading and trucks delivering concrete during construction of building slabs. Much of the fill soil delivery has already been completed.

The site is accessible by bicycle and pedestrian traffic, though public transit is not available.

b. Discuss the effect on traffic congestion on affected roads and describe any traffic improvements necessary. The analysis must discuss the Project's impact on the regional transportation system. If the peak hour traffic generated exceeds 250 vehicles or the total daily trips exceeds 2,500, a traffic impact study must be prepared as part of the EAW. Use the format and procedures described in the Minnesota Department of Transportation's Access Management Manual, Chapter 5 (available at: http://www.dot.state.mn.us/accessmanagement/resources.html) or a similar local guidance.

All traffic would enter the facility via one of two driveways off 4th Avenue, a two-lane local thoroughfare with a center turn lane. The road was designed to accommodate development between 3rd Street South and Heritage Drive and connects to 2nd Street to the north and Heritage Drive to the south. Heritage Drive and 2nd Street provide access to regional transportation corridors including Highway 10, Highway 15, and Highway 120 It is anticipated that most truck traffic would approach the facility from the south via Highway 15 and Heritage Drive.

Anticipated traffic volumes are well below the threshold for a mandatory traffic impact study, which is required if peak hour traffic exceeds 250 vehicles or the total daily trips exceeds 2,500. Approximately 355 total daily trips are anticipated, including both employee trips and deliveries. Employee trips would be concentrated around shift changes and deliveries would generally occur during daytime hours. The peak shift change traffic at 7:00 AM, 3:00 PM, and 11:00 PM would create approximately 117 trips (58 or 59 employees coming and going).

c. Identify measures that will be taken to minimize or mitigate Project related transportation effects.

No specific mitigation or minimization is planned by Niron. The City of Sartell has targeted 4th Avenue for

a major reconstruction project to include utility maintenance, full road reconstruction, and new turn lanes to improve traffic flow and safety. Planning for the 4th Avenue project began before Niron obtained the Project property and the reconstruction project would proceed irrespective of the proposed Niron project.

21. Cumulative Potential Effects

*(**Preparers can leave this item blank if cumulative potential effects are addressed under the applicable EAW Items)***

a. Describe the geographic scales and timeframes of the Project related environmental effects that could combine with other environmental effects resulting in cumulative potential effects.

The Project would permanently disturb approximately 25.8 acres over a four-year construction timeframe. The primary ongoing environmental effects of the Project are related to facility air emissions. Air emissions for this facility type are closely regulated by MPCA and the Project would adhere to permit requirements. No cumulative effects are anticipated.

b. Describe any reasonably foreseeable future Projects (for which a basis of expectation has been laid) that may interact with environmental effects of the proposed Project within the geographic scales and timeframes identified above.

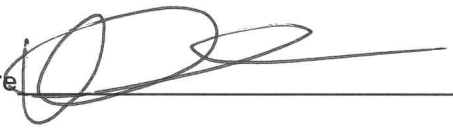
Niron and the City of Sartell are not aware of any reasonably foreseeable development projects nearby that could interact with the proposed Project's effects. Nearby land uses are expected to remain as they are now for the foreseeable future.

c. Discuss the nature of the cumulative potential effects and summarize any other available information relevant to determining whether there is potential for significant environmental effects due to these cumulative effects.

Not applicable.

22. Other Potential Environmental Effects

If the Project may cause any additional environmental effects not addressed by items 1 to 19, describe the effects here, discuss the how the environment will be affected, and identify measures that will be taken to minimize and mitigate these effects.

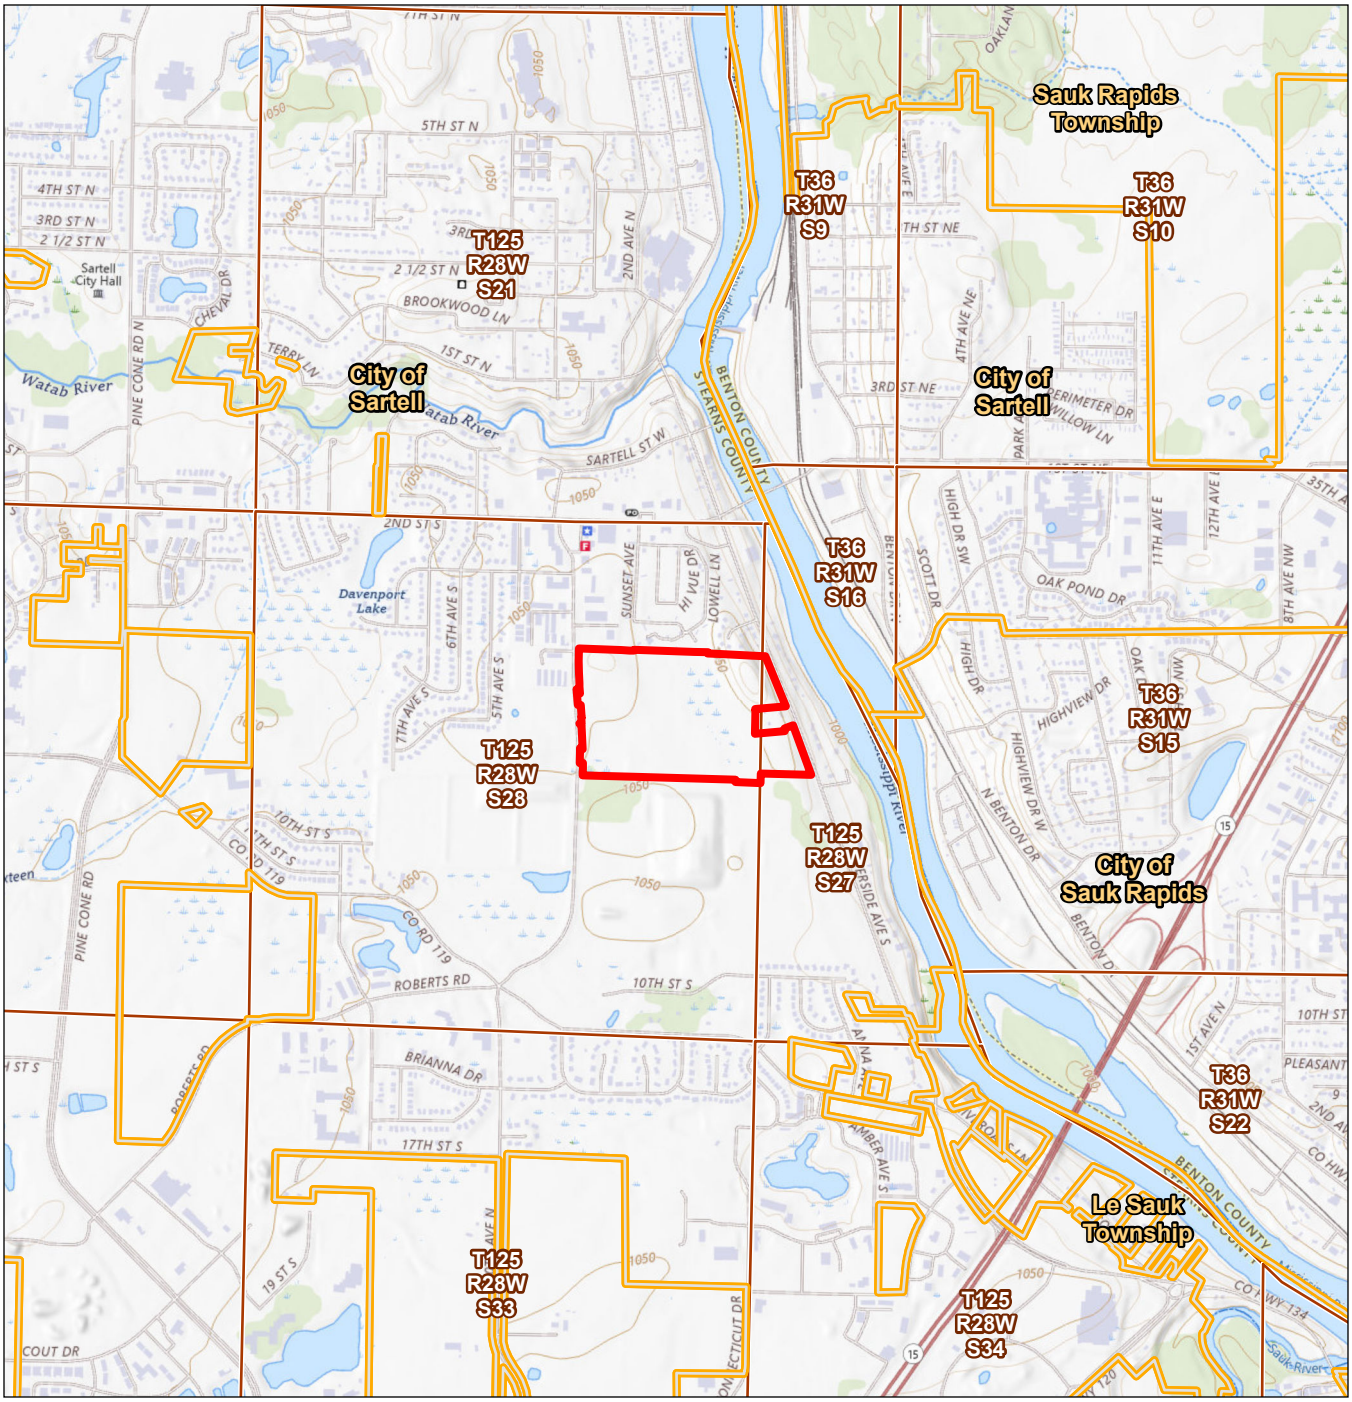


No other potential environmental effects are anticipated that are not addressed by Items 1 through 21.

RGU CERTIFICATION

*(The Environmental Quality Board will only accept **SIGNED** EnvironmentalAssessment Worksheets for public notice in the EQB Monitor.)*

I hereby certify that:



- The information contained in this document is accurate and complete to the best of myknowledge.
- The EAW describes the complete Project; there are no other Projects, stages or components other than those described in this document, which are related to the Project as connected actions or phased actions, as defined at Minnesota Rules, parts 4410.0200, subparts 9c and 60,respectively.
- Copies of this EAW are being sent to the entire EQB distribution list.

GENERAL NOTES
1. GENERAL NOTES APPLICABLE TO ALL DRAWINGS.
2. THE HORIZONTAL COORDINATE SYSTEM USED ON THESE DRAWINGS IS THE PLANT GRID COORDINATE SYSTEM AND NAVD88 VERTICAL DATUM.TRANSLATION FROM NAD83 MINNESOTA DOT STEARNS COUNTY COORDINATE SYSTEM TO PLANT COORDINATE SYSTEM SHALL BE SHIFT FROM BASE POINT N 219998.789, E 740933.980 TO BASE POINT N 2000.000, E 2000.000, NO ROTATION. SURVEY CONTROL MONUMENT DATA TO BE PROVIDED BY OWNER FOR SURVEYOR'S/SUE CONSULTANT'S USE AND VERIFICATION AND/OR ADJUSTMENT OF THE RECORD HORIZONTAL COORDINATE AND ELEVATION DATA.
3. ALL WORK TO BE PERFORMED SHALL CONFORM TO ALL APPLICABLE CODES AND ORDINANCES OF AUTHORITIES HAVING JURISDICTION OVER THE PROJECT.
4. PROJECT SITE LIES IN THE AREA OF MINIMAL FLOOD HAZARD ZONE OF ZONE X - OUTSIDE THE 0.2% ANNUAL FLOOD CHANCE FLOOD PLAIN, PER THE FLOOD INSURANCE RATE MAP OF STEARNS COUNTY, MINNESOTA, MAP NUMBER 27145C0627E, EFFECTIVE DATE FEBRUARY 16, 2012.
5. CONTRACTOR SHALL BE RESPONSIBLE FOR MAINTAINING CONTINUOUS PUBLIC ACCESS DURING CONSTRUCTION ACTIVITIES.

UTILITY NOTES
1. CONTRACTOR SHALL BE RESPONSIBLE FOR LOCATING AND PROTECTING ALL UTILITIES WHICH ARE TO REMAIN IN USE WHETHER OR NOT UTILITIES ARE SHOWN ON THE DRAWINGS. CONTRACTOR OR UTILITY COMPANY SHALL EXCAVATE TO EXPOSE UNDERGROUND UTILITIES WHERE NEEDED FOR VERIFICATION AT CRITICAL LOCATIONS AND/OR CROSSINGS. THE CONTRACTOR SHALL NOTIFY ALL PUBLIC UTILITY COMPANIES AND OWNERS OF PRIVATE UTILITIES WITHIN THE CONSTRUCTION AREA 3 BUSINESS DAYS PRIOR TO THE START OF CONSTRUCTION.
2. IT SHALL BE THE CONTRACTOR'S RESPONSIBILITY TO CONTACT THE OWNER'S REPRESENTATIVE AND MINNESOTA 811 THREE (3) FULL BUSINESS DAYS BEFORE ANY EXCAVATIONS OF ANY KIND TAKE PLACE TO LOCATE EXISTING UNDERGROUND UTILITIES. THE LOCATION, SIZE, AND OTHER DESCRIPTIONS OF EXISTING UTILITIES INDICATED ON THESE DRAWINGS ARE BASED UPON INFORMATION AVAILABLE AT THE TIME OF DRAWING PREPARATION. NO GUARANTEE IS MADE OR INTENDED AS TO THE ACCURACY OR COMPLETENESS OF THIS INFORMATION.
3. SEE ELECTRICAL DRAWINGS FOR UNDERGROUND ELECTRICAL DUCT BANK DESIGN AND LOCATIONS.

EARTHWORK & DRAINAGE NOTES
1. CONTRACTOR SHALL BE RESPONSIBLE FOR LOCATING, PROTECTING, AND RELOCATING ALL UNDERGROUND UTILITIES AND STORM WATER SYSTEMS WHICH ARE TO REMAIN IN PLACE WHETHER OR NOT SAID UTILITIES ARE SHOWN ON THE DRAWINGS. CONTRACTOR OR UTILITY COMPANY SHALL LOCATE TO EXPOSE THE UNDERGROUND SYSTEM TO DETERMINE THE PHYSICAL SIZE(S), HORIZONTAL LOCATION(S) AND VERTICAL ELEVATION(S) AT CRITICAL LOCATIONS AND/OR CROSSINGS. THE CONTRACTOR SHALL NOTIFY THE OWNER'S REPRESENTATIVE AND AFFECTED UTILITY OWNERS A MINIMUM OF THREE FULL BUSINESS DAYS BEFORE ANY EXCAVATIONS TAKE PLACE TO LOCATE THE PHYSICAL LOCATIONS.
2. SPOT ELEVATIONS AND CONTOURS SHOWN ON THESE DRAWINGS ARE TOP OF FINISHED GRADE. CONTRACTOR SHALL SUBTRACT FINISH SURFACING MATERIAL THICKNESS(ES) TO OBTAIN TOP OF SUBGRADE. GRADE SHALL SLOPE UNIFORMLY TO DRAIN BETWEEN CONTOURS AND SPOT ELEVATIONS SHOWN ON THE PLANS.
3. THE CONTRACTOR SHALL INSTALL AND MAINTAIN ALL OF THE PERIMETER EROSION AND SEDIMENTATION CONTROL MEASURES INDICATED AS AN INITIAL STEP IN THE CONSTRUCTION PROCESS BEFORE ANY OTHER LAND DISTURBING ACTIVITIES COMMENCE. THE CONTRACTOR SHALL BE RESPONSIBLE TO MONITOR AND REMOVE ACCUMULATED SEDIMENT FROM ALL EROSION AND SEDIMENTATION CONTROL BMP'S WHEN THE MAXIMUM ALLOWABLE LEVELS ARE REACHED. THE CONTRACTOR SHALL STABILIZE REMOVED SEDIMENT ON THE PROJECT SITE AT LOCATION(S) APPROVED BY THE OWNER'S REPRESENTATIVE AND GEOTECHNICAL ENGINEER OR OTHERWISE THE CONTRACTOR SHALL LEGALLY DISPOSE OF THE SEDIMENT OFF-SITE.
4. MAXIMUM TEMPORARY CONSTRUCTION SLOPE ON SITE SHALL BE 3 FEET HORIZONTAL TO 1 FOOT VERTICAL, UNLESS NOTED ON THE PLANS OR OTHERWISE MANDATED BY OSHA.

EROSION AND SEDIMENTATION CONTROL NOTES
1. CONTRACTOR SHALL COMPLY WITH ALL EROSION AND SEDIMENT CONTROL MEASURES DESCRIBED AND DETAILED IN THE DRAWINGS, PROJECT SPECIFIC SWPPP, AND ALL REQUIREMENTS OF MPCA GENERAL STORM WATER PERMIT FOR CONSTRUCTION ACTIVITY MNR100001.
2. EROSION AND SEDIMENT CONTROL MEASURES SHALL BE IMPLEMENTED PRIOR TO, AND MAINTAINED DURING, CONSTRUCTION UNTIL FINAL STABILIZATION.
3. ALL TEMPORARY STOCKPILES SHALL BE PROTECTED BY INSTALLING AND MAINTAINING TEMPORARY STABILIZATION MEASURES AND SEDIMENTATION BARRIERS AROUND THE PERIMETER. SLOPES SHALL NOT EXCEED 3:1. ALL STOCKPILES SHALL BE SURFACE ROUGHENED AND STABILIZED OR OTHERWISE COVERED WITHIN THE REQUIRED TIME FRAMES.
4. ALL ENTRANCES INTO PROJECT SHALL HAVE A STABILIZED CONSTRUCTION ENTRANCE / EXIT.
5. ADDITIONAL BMP'S MAY BE REQUIRED DURING CONSTRUCTION TO CONTROL EROSION AND SEDIMENTATION CAUSED BY CONSTRUCTION ACTIVITIES. CONTRACTOR SHALL BE RESPONSIBLE TO INSTALL AND MAINTAIN ALL BMPS NECESSARY TO ACHIEVE THIS OBJECTIVE.
6. UPON FINAL STABILIZATION OF THE SITE, ALL TEMPORARY EROSION AND SEDIMENT CONTROL BMP'S SHALL BE REMOVED AND THE ASSOCIATED REMOVAL AREAS SHALL BE STABILIZED.

AUTOMATED RESULTS: FURTHER REVIEW IS NEEDED
As requested, the above project has undergone an automated review for potential impacts to rare features. Based on this review, one or more rare features may be impacted by the proposed project and further review by the Natural Heritage Review Team is needed. You will receive a separate notification email when the review process is complete and the Natural Heritage Review letter has been posted.

Please refer to the table on the cover page of this report for a summary of potential impacts to rare features. For additional information or planning purposes, use the Explore Page in Minnesota Conservation Explorer to view the potentially impacted rare features or to create a Conservation Planning Report for the proposed project.

If you have additional information to help resolve the potential impacts listed in the summary results, please attach related project documentation in the Edit Details tab of the Project page. Relevant information includes, but is not limited to, additional project details, completed habitat assessments, or survey results. This additional information will be considered during the project review.

RE: Natural Heritage Review of the proposed **Niron Sartell Project**,
T125N R28W Sections 27 and 28; Stearns County

Dear Mia Bauer,

For all correspondence regarding the Natural Heritage Review of this project please include the project ID **MCE-2025-00309** in the email subject line.

As requested, the Minnesota Natural Heritage Information System has been reviewed to determine if the proposed project has the potential to impact any rare species or other significant natural features. Based on the project details provided with the request, the following rare features may be impacted by the proposed project:

State-listed Species

- The Natural Heritage Information System (NHIS) tracks bat roost trees and hibernacula plus some acoustic data, but this information is not exhaustive. Even if there are no bat records listed nearby, all of Minnesota's bats, including the federally endangered northern long-eared bat (*Myotis septentrionalis*), can be found throughout Minnesota. During the active season (approximately April-November) bats roost underneath bark, in cavities, or in crevices of both live and dead trees. Tree removal can negatively impact bats by destroying roosting habitat, especially during the pup rearing season when females are forming maternity roosting colonies and the pups cannot yet fly. To minimize these impacts, **the DNR recommends that tree removal be avoided from June 1 through August 15.**

- Please visit the DNR Rare Species Guide for more information on the habitat use of these species and recommended measures to avoid or minimize impacts.

- Please report incidental sightings of state-listed species via the DNR Plant and Animal Observation Form.

Federally Protected Species

- To ensure compliance with federal law, conduct a federal regulatory review using the U.S. Fish and Wildlife Service's (USFWS) online Information for Planning and Consultation (IPaC) tool.

Environmental Review and Permitting

- Please include a copy of this letter and the MCE-generated Final Project Report in any state or local license or permit application. Please note that measures to avoid or minimize disturbance to the above rare features may be included as restrictions or conditions in any required permits or licenses.

The Natural Heritage Information System (NHIS), a collection of databases that contains information about Minnesota's rare natural features, is maintained by the Division of Ecological and Water Resources, Department of Natural Resources. The NHIS is continually updated as new information becomes available and is the most complete source of data on Minnesota's native plant communities, rare species, and other rare features. However, the NHIS is not an exhaustive inventory and does not contain the locations of all rare features in the state. Therefore, ecologically significant features for which we have no records may exist within the project area. If additional information becomes available regarding rare features in the vicinity of the project, further review may be necessary.

For environmental review purposes, the results of this Natural Heritage Review are valid for one year; the results are only valid for the project location and project description provided with the request. **If project details change or the project has not occurred within one year, please resubmit the project for review within one year of initiating project activities.** Resubmit by selecting *Clone Project as Draft* on the project page in MCE.

The Natural Heritage Review does not constitute project approval by the Department of Natural Resources. Instead, it identifies issues regarding known occurrences of rare features and potential impacts to these rare features. Visit Natural Heritage Review for additional information regarding this process, survey guidance, and other related information. For information on the environmental review process or other natural resource concerns, please contact your DNR Regional Environmental Assessment Ecologist.

Thank you for consulting us on this matter and for your interest in preserving Minnesota's rare natural resources.

Sincerely,
Molly Barrett

Subject: List of threatened and endangered species that may occur in your proposed project location or may be affected by your proposed project

To Whom It May Concern:

This response has been generated by the Information, Planning, and Conservation (IPaC) system to provide information on natural resources that could be affected by your project. The U.S. Fish and Wildlife Service (Service) provides this response under the authority of the Endangered Species Act of 1973 (16 U.S.C. 1531-1543), the Bald and Golden Eagle Protection Act (16 U.S.C. 668-668d), the Migratory Bird Treaty Act (16 U.S.C. 703-712), and the Fish and Wildlife Coordination Act (16 U.S.C. 661 *et seq.*).

Threatened and Endangered Species
The enclosed species list identifies threatened, endangered, proposed and candidate species, as well as proposed and final designated critical habitat, that may occur within the boundary of your proposed project and may be affected by your proposed project. The species list fulfills the requirement for obtaining a Technical Assistance Letter from the U.S. Fish and Wildlife Service under section 7(c) of the Endangered Species Act (Act) of 1973, as amended (16 U.S.C. 1531 *et seq.*).

New information based on updated surveys, changes in the abundance and distribution of species, changed habitat conditions, or other factors could change this list. Note that under 50 CFR 402.12(e) of the regulations implementing section 7 of the Act, the accuracy of this species list should be verified after 90 days. The Service recommends that verification be completed by visiting the IPaC website at regular intervals during project planning and implementation for updates to species lists and information. An updated list may be requested through the IPaC system by completing the same process used to receive the enclosed list.

Consultation Technical Assistance
Please refer to refer to our Section 7 website for guidance and technical assistance, including step-by-step instructions for making effects determinations for each species that might be present and for specific guidance on the following types of projects: projects in developed areas, HUD, CDBG, EDA, USDA Rural Development projects, pipelines, buried utilities, telecommunications, and requests for a Conditional Letter of Map Revision (CLOMR) from FEMA.

We recommend running the project (if it qualifies) through our **Minnesota-Wisconsin Federal Endangered Species Determination Key (Minnesota-Wisconsin ("D-key"))**. A demonstration video showing how-to access and use the determination key is available. Please note that the Minnesota-Wisconsin D-key is the third option of 3 available d-keys. D-keys are tools to help Federal agencies and other project proponents determine if their proposed action has the potential to adversely affect federally listed species and designated critical habitat. The Minnesota-Wisconsin D-key includes a structured set of questions that assists a project proponent in determining whether a proposed project qualifies for a certain predetermined consultation outcome for all federally listed species found in Minnesota and Wisconsin (except for the northern long-eared bat- see below), which includes determinations of “no effect” or “may affect, not likely to adversely affect." In each case, the Service has compiled and analyzed the best available information on the species’ biology and the impacts of certain activities to support these determinations.

If your completed d-key output letter shows a "No Effect" (NE) determination for all listed species, print your IPaC output letter for your files to document your compliance with the Endangered Species Act.

For Federal projects with a “Not Likely to Adversely Affect” (NLAA) determination, our concurrence becomes valid if you do not hear otherwise from us after a 30-day review period, as indicated in your letter.

If your d-key output letter indicates additional coordination with the Minnesota-Wisconsin Ecological Services Field Office is necessary (i.e., you get a “May Affect” determination), you will be provided additional guidance on contacting the Service to continue ESA coordination outside of the key; ESA compliance cannot be concluded using the key for “May Affect” determinations unless otherwise indicated in your output letter.

Note: Once you obtain your official species list, you are not required to continue in IPaC with d-keys, although in most cases these tools should expedite your review. If you choose to make an effects determination on your own, you may do so. If the project is a Federal Action, you may want to review our section 7 step-by-step instructions before making your determinations.

Using the IPaC Official Species List to Make No Effect and May Affect Determinations for Listed Species

1. If IPaC returns a result of “There are no listed species found within the vicinity of the project,” then project proponents can conclude the proposed activities will have **no effect** on any federally listed species under Service jurisdiction. Concurrence from the Service is not required for **no effect** determinations. No further consultation or coordination is required. Attach this letter to the dated IPaC species list report for your records.
2. If IPaC returns one or more federally listed, proposed, or candidate species as potentially present in the action area of the proposed project – other than bats (see below) – then project proponents must determine if proposed activities will have **no effect** on or **may affect** those species. For assistance in determining if suitable habitat for listed, candidate, or proposed species occurs within your project area or if species may be affected by project activities, you can obtain Life History Information for Listed and Candidate Species on our office website. If no impacts will occur to a species on the IPaC species list (e.g., there is no habitat present in the project area), the appropriate determination is **no effect**. No further consultation or coordination is required. Attach this letter to the dated IPaC species list report for your records.

3. Should you determine that project activities **may affect** any federally listed, please contact our office for further coordination. Letters with requests for consultation or correspondence about your project should include the Consultation Tracking Number in the header. Electronic submission is preferred.

Northern Long-Eared Bats
Northern long-eared bats occur throughout Minnesota and Wisconsin and the information below may help in determining if your project may affect these species.

Suitable summer habitat for northern long-eared bats consists of a wide variety of forested/wooded habitats where they roost, forage, and travel and may also include some adjacent and interspersed non-forested habitats such as emergent wetlands and adjacent edges of agricultural fields, old fields and pastures. This includes forests and woodlots containing potential roosts (i.e., live trees and/or snags ≥3 inches dbh for northern long-eared bat that have exfoliating bark, cracks, crevices, and/or hollows), as well as linear features such as fencerows, riparian forests, and other wooded corridors. These wooded areas may be dense or loose aggregates of trees with variable amounts of canopy closure. Individual trees may be considered suitable habitat when they exhibit the characteristics of a potential roost tree and are located within 1,000 feet (305 meters) of forested/wooded habitat. Northern long-eared bats have also been observed roosting in human-made structures, such as buildings, barns, bridges, and bat houses; therefore, these structures should also be considered potential summer habitat and evaluated for use by bats. If your project will impact caves or mines or will involve clearing forest or woodland habitat containing suitable roosting habitat, northern long-eared bats could be affected. For bat activity dates, please review Appendix L in the Range-wide Indiana Bat and Northern Long-Eared Bat Survey Guidelines.

Examples of unsuitable habitat include:
- Individual trees that are greater than 1,000 feet from forested or wooded areas,
- Trees found in highly developed urban areas (e.g., street trees, downtown areas),
- A pure stand of less than 3-inch dbh trees that are not mixed with larger trees, and
- A monoculture stand of shrubby vegetation with no potential roost trees.

If IPaC returns a result that northern long-eared bats are potentially present in the action area of the proposed project, project proponents can conclude the proposed activities **may affect** this species **IF** one or more of the following activities are proposed:
- Clearing or disturbing suitable roosting habitat, as defined above, at any time of year,
- Any activity in or near the entrance to a cave or mine,
- Mining, deep excavation, or underground work within 0.25 miles of a cave or mine,
- Construction of one or more wind turbines, or
- Demolition or reconstruction of human-made structures that are known to be used by bats based on observations of roosting bats, bats emerging at dusk, or guano deposits or stains.

If none of the above activities are proposed, project proponents can conclude the proposed activities will have **no effect** on the northern long-eared bat. Concurrence from the Service is not required for **No Effect** determinations. No further consultation or coordination is required. Attach this letter to the dated IPaC

species list report for your records.

If any of the above activities are proposed, and the northern long-eared bat appears on the user's species list, the federal project user will be directed to either the northern long-eared bat and tricolored bat range-wide D-key or the Federal Highways Administration, Federal Railways Administration, and Federal Transit Administration Indiana bat/Northern long-eared bat D-key, depending on the type of project and federal agency involvement. Similar to the Minnesota-Wisconsin D-key, these d-keys helps to determine if prohibited take might occur and, if not, will generate an automated verification letter. Additional information about available tools can be found on the Service's northern long-eared bat website.

Whooping Crane
Whooping crane is designated as a non-essential experimental population in Wisconsin and consultation under Section 7(a)(2) of the Endangered Species Act is only required if project activities will occur within a National Wildlife Refuge or National Park. If project activities are proposed on lands outside of a National Wildlife Refuge or National Park, then you are not required to consult. For additional information on this designation and consultation requirements, please review "Establishment of a Nonessential Experimental Population of Whooping Cranes in the Eastern United States."

Other Trust Resources and Activities
Bald and Golden Eagles - Although the bald eagle has been removed from the endangered species list, this species and the golden eagle are protected by the Bald and Golden Eagle Act and the Migratory Bird Treaty Act. It is the responsibility of the project proponent to survey the area for any migratory bird nests. If there is an eagle nest on-site while work is on-going, eagles may be disturbed. We recommend avoiding and minimizing disturbance to eagles whenever practicable. If you cannot avoid eagle disturbance, you may seek a permit. A nest take permit is always required for removal, relocation, or obstruction of an eagle nest. For communication and wind energy projects, please refer to additional guidelines below.

Migratory Birds - The Migratory Bird Treaty Act (MBTA) prohibits the taking, killing, possession, transportation, and importation of migratory birds, their eggs, parts, and nests, except when specifically authorized by the Service. The Service has the responsibility under the MBTA to proactively prevent the mortality of migratory birds whenever possible and we encourage implementation of recommendations that minimize potential impacts to migratory birds. Such measures include clearing forested habitat outside the nesting season (generally March 1 to August 31) or conducting nest surveys prior to clearing to avoid injury to eggs or nestlings.

Communication Towers - Construction of new communications towers (including radio, television, cellular, and microwave) creates a potentially significant impact on migratory birds, especially some 350 species of night-migrating birds. However, the Service has developed voluntary guidelines for minimizing impacts.

Transmission Lines - Migratory birds, especially large species with long wingspans, heavy bodies, and poor maneuverability can also collide with power lines. In addition, mortality can occur when birds, particularly hawks, eagles, kites, falcons, and owls, attempt to perch on uninsulated or unguarded power poles. To minimize these risks, please refer to guidelines developed by the Avian Power Line Interaction Committee and the Service. Implementation of these measures is especially important along sections of lines adjacent to wetlands or other areas that support large numbers of raptors and migratory birds.

Wind Energy - To minimize impacts to migratory birds and bats, wind energy projects should follow the Service's Wind Energy Guidelines. In addition, please refer to the Service's Eagle Conservation Plan Guidance, which provides guidance for conserving bald and golden eagles in the course of siting, constructing, and operating wind energy facilities.

State Department of Natural Resources Coordination
While it is not required for your Federal section 7 consultation, please note that additional state endangered or threatened species may also have the potential to be impacted. **Please contact the Minnesota or Wisconsin Department of Natural Resources for information on state listed species that may be present in your proposed project area.**

Bloomington, MN 55425-1659
(952) 858-0793

PROJECT SUMMARY

Project Code: 2025-0073129
Project Name: Niron Sartell Project
Project Type: Mixed-Use Construction
Project Description: Niron Magnetics (Niron) proposes to construct a manufacturing facility that produces industrial magnets on an undeveloped site located on 4th Avenue South between Heritage Drive and 3rd Street South in Sartell, Minnesota. The process converts iron oxide into a magnetic material, iron nitride. The iron nitride is processed further and then pressed and formed into magnets of various shapes. The finished magnets are given a protective coating before shipping to customers. The processes may use gases or chemicals, and the specific processes and chemicals are still under development. The processes are enclosed and feedstocks are planned to be reused to the extent possible.

Additional outdoor structures like tanks or reactor columns will be installed. Controls like secondary containment, stormwater ponds, and waste management will be employed in the operation of the facility. Site construction is anticipated to take up to four years and would be completed over two phases.

A design change was implemented in January 2026 that increased the gross square footage above 200,000 square feet. The increase in proposed gross square footage was the result of adding a second floor to some buildings and did not expand the originally proposed and permitted overall ground disturbance footprint. The primary activities already completed are limited to preliminary grading and stockpiling of imported fill soil.

Project Location:

The approximate location of the project can be viewed in Google Maps: https://www.google.com/maps/@45.609588349999996,-94.20530387930691,14z

Counties: Stearns County, Minnesota

ENDANGERED SPECIES ACT SPECIES

There is a total of 6 threatened, endangered, or candidate species on this species list.

Species on this list should be considered in an effects analysis for your project and could include species that exist in another geographic area. For example, certain fish may appear on the species list because a project could affect downstream species.

IPaC does not display listed species or critical habitats under the sole jurisdiction of NOAA Fisheries[1], as USFWS does not have the authority to speak on behalf of NOAA and the Department of Commerce.

See the "Critical habitats" section below for those critical habitats that lie wholly or partially within your project area under this office's jurisdiction. Please contact the designated FWS office if you have questions.

---

1. NOAA Fisheries, also known as the National Marine Fisheries Service (NMFS), is an office of the National Oceanic and Atmospheric Administration within the Department of Commerce.

MAMMALS

NAME	STATUS
Northern Long-eared Bat *Myotis septentrionalis* No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/9045	Endangered
Tricolored Bat *Perimyotis subflavus* No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/10515	Proposed Endangered

BIRDS

NAME	STATUS
Whooping Crane *Grus americana* Population: U.S.A. (AL, AR, CO, FL, GA, ID, IL, IN, IA, KY, LA, MI, MN, MS, MO, NC, NM, OH, SC, TN, UT, VA, WI, WV, western half of WY) No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/758	Experimental Population, Non-Essential

INSECTS

NAME	STATUS
Monarch Butterfly *Danaus plexippus* There is **proposed** critical habitat for this species. Your location does not overlap the critical habitat. Species profile: https://ecos.fws.gov/ecp/species/9743	Proposed Threatened
Suckley's Cuckoo Bumble Bee *Bombus suckleyi* Population: No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/10885	Proposed Endangered
Western Regal Fritillary *Argynnis idalia occidentalis* No critical habitat has been designated for this species. Species profile: https://ecos.fws.gov/ecp/species/12017	Proposed Threatened

CRITICAL HABITATS

THERE ARE NO CRITICAL HABITATS WITHIN YOUR PROJECT AREA UNDER THIS OFFICE'S JURISDICTION.

YOU ARE STILL REQUIRED TO DETERMINE IF YOUR PROJECT(S) MAY HAVE EFFECTS ON ALL ABOVE LISTED SPECIES.

USFWS NATIONAL WILDLIFE REFUGE LANDS AND FISH HATCHERIES

Any activity proposed on lands managed by the National Wildlife Refuge system must undergo a 'Compatibility Determination' conducted by the Refuge. Please contact the individual Refuges to discuss any questions or concerns.

THERE ARE NO REFUGE LANDS OR FISH HATCHERIES WITHIN YOUR PROJECT AREA.

BALD & GOLDEN EAGLES

Bald and Golden Eagles are protected under the Bald and Golden Eagle Protection Act [2] and the Migratory Bird Treaty Act (MBTA) [1]. Any person or organization who plans or conducts activities that may result in impacts to Bald or Golden Eagles, or their habitats, should follow appropriate regulations and consider implementing appropriate avoidance and minimization measures, as described in the various links on this page.

---

1. The Bald and Golden Eagle Protection Act of 1940.
2. The Migratory Birds Treaty Act of 1918.
3. 50 C.F.R. Sec. 10.12 and 16 U.S.C. Sec. 668(a)

There are Bald Eagles and/or Golden Eagles in your project area.

Measures for Proactively Minimizing Eagle Impacts
For information on how to best avoid and minimize disturbance to nesting bald eagles, please review the National Bald Eagle Management Guidelines. You may employ the timing and activity-specific distance recommendations in this document when designing your project/ activity to avoid and minimize eagle impacts. For bald eagle information specific to Alaska, please refer to Bald Eagle Nesting and Sensitivity to Human Activity.

The FWS does not currently have guidelines for avoiding and minimizing disturbance to nesting Golden Eagles. For site-specific recommendations regarding nesting Golden Eagles, please consult with the appropriate Regional Migratory Bird Office or Ecological Services Field Office.

If disturbance or take of eagles cannot be avoided, an incidental take permit may be available to authorize any take that results from, but is not the purpose of, an otherwise lawful activity. For assistance making this determination for Bald Eagles, visit the Do I Need A Permit Tool. For assistance making this determination for golden eagles, please consult with the appropriate Regional Migratory Bird Office or Ecological Services Field Office.

Ensure Your Eagle List is Accurate and Complete
If your project area is in a poorly surveyed area in IPaC, your list may not be complete and you may need to rely on other resources to determine what species may be present (e.g. your local FWS field office, state surveys, your own surveys). Please review the Supplemental Information

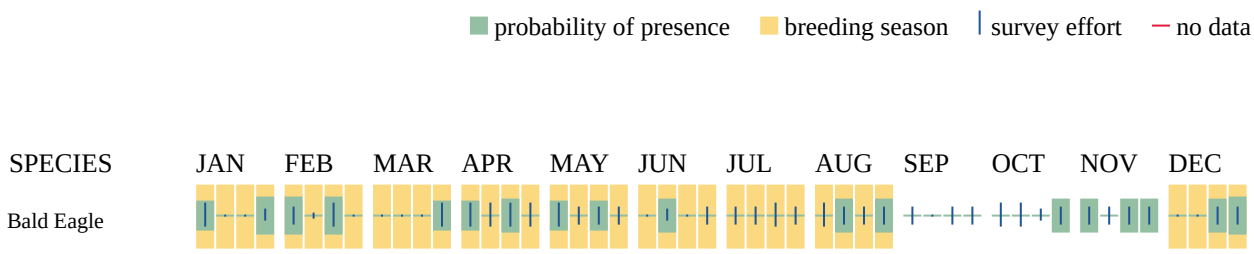
on Migratory Birds and Eagles, to help you properly interpret the report for your specified location, including determining if there is sufficient data to ensure your list is accurate.

For guidance on when to schedule activities or implement avoidance and minimization measures to reduce impacts to bald or golden eagles on your list, see the "Probability of Presence Summary" below to see when these bald or golden eagles are most likely to be present and breeding in your project area.

NAME	BREEDING SEASON
Bald Eagle *Haliaeetus leucocephalus* This is not a Bird of Conservation Concern (BCC) in this area, but warrants attention because of the Eagle Act or for potential susceptibilities in offshore areas from certain types of development or activities. https://ecos.fws.gov/ecp/species/1626	Breeds Dec 1 to Aug 31

PROBABILITY OF PRESENCE SUMMARY

The graphs below provide our best understanding of when birds of concern are most likely to be present in your project area. This information can be used to tailor and schedule your project activities to avoid or minimize impacts to birds. Please make sure you read "Supplemental Information on Migratory Birds and Eagles", specifically the FAQ section titled "Proper Interpretation and Use of Your Migratory Bird Report" before using or attempting to interpret this report.



Probability of Presence (■)

Green bars; the bird's relative probability of presence in the 10km grid cell(s) your project overlaps during that week of the year.

Breeding Season (■)
Yellow bars; liberal estimate of the timeframe inside which the bird breeds across its entire range.

Survey Effort (|)
Vertical black lines; the number of surveys performed for that species in the 10km grid cell(s) your project area overlaps.

No Data (–)
A week is marked as having no data if there were no survey events for that week.

Non-BCC
Vulnerable

- Supplemental Information for Migratory Birds and Eagles in IPaC https://www.fws.gov/media/supplemental-information-migratory-birds-and-bald-and-golden-eagles-may-occur-project-action

MIGRATORY BIRDS

The Migratory Bird Treaty Act (MBTA) [1] prohibits the take (including killing, capturing, selling, trading, and transport) of protected migratory bird species without prior authorization by the Department of Interior U.S. Fish and Wildlife Service (Service).

---

1. The Migratory Birds Treaty Act of 1918.
2. The Bald and Golden Eagle Protection Act of 1940.
3. 50 C.F.R. Sec. 10.12 and 16 U.S.C. Sec. 668(a)

For guidance on when to schedule activities or implement avoidance and minimization measures to reduce impacts to migratory birds on your list, see the "Probability of Presence Summary" below to see when these birds are most likely to be present and breeding in your project area.

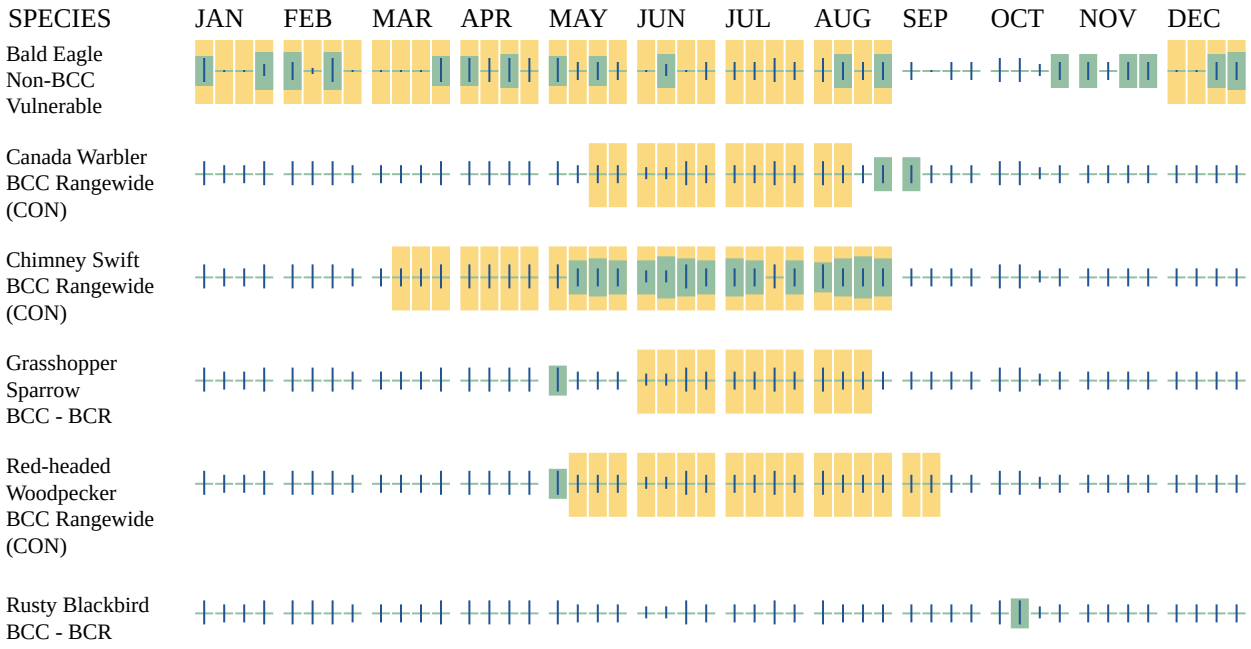
NAME	BREEDING SEASON
Bald Eagle *Haliaeetus leucocephalus* This is not a Bird of Conservation Concern (BCC) in this area, but warrants attention because of the Eagle Act or for potential susceptibilities in offshore areas from certain types of development or activities. https://ecos.fws.gov/ecp/species/1626	Breeds Dec 1 to Aug 31
Canada Warbler *Cardellina canadensis* This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska. https://ecos.fws.gov/ecp/species/9643	Breeds May 20 to Aug 10

NAME	BREEDING SEASON
Chimney Swift *Chaetura pelagica* This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska. https://ecos.fws.gov/ecp/species/9406	Breeds Mar 15 to Aug 25
Grasshopper Sparrow *Ammodramus savannarum perpallidus* This is a Bird of Conservation Concern (BCC) only in particular Bird Conservation Regions (BCRs) in the continental USA https://ecos.fws.gov/ecp/species/8329	Breeds Jun 1 to Aug 20
Red-headed Woodpecker *Melanerpes erythrocephalus* This is a Bird of Conservation Concern (BCC) throughout its range in the continental USA and Alaska. https://ecos.fws.gov/ecp/species/9398	Breeds May 10 to Sep 10
Rusty Blackbird *Euphagus carolinus* This is a Bird of Conservation Concern (BCC) only in particular Bird Conservation Regions (BCRs) in the continental USA https://ecos.fws.gov/ecp/species/9478	Breeds elsewhere

PROBABILITY OF PRESENCE SUMMARY

The graphs below provide our best understanding of when birds of concern are most likely to be present in your project area. This information can be used to tailor and schedule your project activities to avoid or minimize impacts to birds. Please make sure you read "Supplemental Information on Migratory Birds and Eagles", specifically the FAQ section titled "Proper Interpretation and Use of Your Migratory Bird Report" before using or attempting to interpret this report.

Probability of Presence (■)



Green bars; the bird's relative probability of presence in the 10km grid cell(s) your project overlaps during that week of the year.

Breeding Season (■)
Yellow bars; liberal estimate of the timeframe inside which the bird breeds across its entire range.

Survey Effort (|)
Vertical black lines; the number of surveys performed for that species in the 10km grid cell(s) your project area overlaps.

No Data (–)
A week is marked as having no data if there were no survey events for that week.

■ probability of presence ■ breeding season | survey effort – no data

WETLANDS

Impacts to NWI wetlands and other aquatic habitats may be subject to regulation under Section 404 of the Clean Water Act, or other State/Federal statutes.

For more information please contact the Regulatory Program of the local U.S. Army Corps of Engineers District.

Please note that the NWI data being shown may be out of date. We are currently working to update our NWI data set. We recommend you verify these results with a site visit to determine the actual extent of wetlands on site.

FISH AND WILDLIFE SERVICE
Minnesota-Wisconsin Ecological Services Field Office
3815 American Blvd East
Bloomington, MN 55425-1659
Phone: (952) 858-0793

In Reply Refer To: 01/21/2026 17:07:28 UTC
Project code: 2025-0073129
Project Name: Niron Sartell Project

Subject: Technical Assistance letter for 'Niron Sartell Project' for specified threatened and endangered species that may occur in your proposed project location consistent with the Minnesota-Wisconsin Endangered Species Determination Key (Minnesota-Wisconsin DKey).

Dear Mia Bauer:

The U.S. Fish and Wildlife Service (Service) received on **January 21, 2026** your effect determination(s) for the 'Niron Sartell Project' (Action) using the Minnesota-Wisconsin DKey within the Service's Information for Planning and Consultation (IPaC) system. The Service developed this system in accordance with the Endangered Species Act of 1973 (ESA) (87 Stat. 884, as amended; 16 U.S.C 1531 et seq.).

Based on your responses to the Service's Minnesota-Wisconsin DKey, you made the following effect determination(s) for the proposed Action:

Species	Listing Status	Determination
Monarch Butterfly (*Danaus plexippus*)	Proposed Threatened	No effect
Whooping Crane (*Grus americana*)	Experimental Population, Non-Essential	No effect

Determination Information

Thank you for informing the Service of your "No Effect" determination(s). No further coordination is necessary for the species you determined will not be affected by the Action.

Additional Information

Sufficient project details: Please provide sufficient project details on your project homepage in IPaC (Define Project, Project Description) to support your conclusions. Failure to disclose important aspects of your project that would influence the outcome of your effects determinations may negate your determinations and invalidate this letter. If you have site-specific information that leads you to believe a different determination is more appropriate for your

project than what the Dkey concludes, you can and should proceed based on the best available information.

Future project changes: The Service recommends that you contact the Minnesota-Wisconsin Ecological Services Field Office or re-evaluate the project in IPaC if: 1) the scope or location of the proposed Action is changed; 2) new information reveals that the action may affect federally listed species or federally designated critical habitat in a manner or to an extent not previously considered; 3) the Action is modified in a manner that causes effects to listed species or designated critical habitat; or 4) a new species is listed or critical habitat designated. If any of the above conditions occurs, additional consultation with the Service should take place before project changes are final or resources committed.

Species-specific information

Bald and Golden Eagles: Bald eagles, golden eagles, and their nests are protected under the Bald and Golden Eagle Protection Act (54 Stat. 250, as amended, 16 U.S.C. 668a-d) (Eagle Act). The Eagle Act prohibits, except when authorized by an Eagle Act permit, the "taking" of bald and golden eagles and defines "take" as "pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest or disturb." The Eagle Act's implementing regulations define disturb as "… to agitate or bother a bald or golden eagle to a degree that causes, or is likely to cause, based on the best scientific information available, (1) injury to an eagle, (2) a decrease in its productivity, by substantially interfering with normal breeding, feeding, or sheltering behavior, or (3) nest abandonment, by substantially interfering with normal breeding, feeding, or sheltering behavior."

If you observe a bald eagle nest in the vicinity of your proposed project, you should follow the National Bald Eagle Management Guidelines (May 2007). For more information on eagles and conducting activities in the vicinity of an eagle nest, please visit our regional eagle website or contact Margaret at Margaret_Martin@fws.gov. If the Action may affect bald or golden eagles, additional coordination with the Service under the Eagle Act may be required.

Additional Species Requiring Review

In addition to the species described above, the following species or critical habitats may also occur in your project area and are not covered by this conclusion:

- Northern Long-eared Bat *Myotis septentrionalis* Endangered
- Suckley's Cuckoo Bumble Bee *Bombus suckleyi* Proposed Endangered
- Tricolored Bat *Perimyotis subflavus* Proposed Endangered
- Western Regal Fritillary *Argynnis idalia occidentalis* Proposed Threatened

Coordination with the Service is not complete if additional coordination is advised above for any species.

Action Description
You provided to IPaC the following name and description for the subject Action.

1. Name

Niron Sartell Project

2. Description

The following description was provided for the project 'Niron Sartell Project':

> Niron Magnetics proposes to construct a facility that produces industrial magnets. The process converts iron oxide into a magnetic material, iron nitride. The iron nitride is processed further and then pressed and formed into magnets of various shapes. The finished magnets are given a protective coating before shipping to customers. The processes may use gases or chemicals, and the specific processes and chemicals are still under development. The processes are enclosed and feedstocks are planned to be reused to the extent possible.
>
> The total square footage of all buildings will be less than 200,000 square feet. Additional outdoor structures like tanks or reactor columns will be installed. Controls like secondary containment, stormwater ponds, and waste management will be employed in the operation of the facility. Site clearing is expected to occur in fall 2025 with buildings and structures erected in 2026.

The approximate location of the project can be viewed in Google Maps: https://www.google.com/maps/@45.609588349999996,-94.20530387930691,14z

QUALIFICATION INTERVIEW

1. This determination key is intended to assist the user in evaluating the effects of their actions on Federally listed species in Minnesota and Wisconsin. It does not cover other prohibited activities under the Endangered Species Act (e.g., for wildlife: import/export, Interstate or foreign commerce, possession of illegally taken wildlife, etc.; for plants: import/export, reduce to possession, malicious destruction on Federal lands, commercial sale, etc.) or other statutes. Additionally, this key DOES NOT cover wind development, purposeful take (e.g., for research or surveys), communication towers that have guy wires or are over 450 feet in height, aerial or other large-scale application of any chemical (such as insecticide or herbicide), and approval of long-term permits or plans (e.g., FERC licenses, HCP's).

   Click **YES** to acknowledge that you must consider other prohibitions of the ESA or other statutes outside of this determination key.

   Yes
2. Is the action being funded, authorized, or carried out by a Federal agency?

   No
3. Is the action being conducted by or on behalf of a Federally recognized Tribe?

   No
4. Does the action involve the installation or operation of wind turbines?

   No
5. Does the action involve purposeful take of a listed animal?

   No
6. Does the action involve a new communications tower?

   No
7. Does the activity involve aerial or other large-scale application of ANY chemical, including pesticides (insecticide, herbicide, fungicide, rodenticide, etc)?

   No
8. Will your action permanently affect local hydrology?

   No
9. Will your action temporarily affect local hydrology?

   No
10. Will your project have any direct impacts to a stream or river (e.g., Horizontal Directional Drilling (HDD), hydrostatic testing, stream/road crossings, new stormwater outfall discharge, dams, other in-stream work, etc.)?

    No

11. Does your project have the potential to impact the riparian zone or indirectly impact a stream/river (e.g., cut and fill; horizontal directional drilling; construction; vegetation removal; pesticide or fertilizer application; discharge; runoff of sediment or pollutants; increase in erosion, etc.)?

    Note: Consider all potential effects of the action, including those that may happen later in time and outside and downstream of the immediate area involved in the action.

    Endangered Species Act regulation defines "effects of the action" to include all consequences to listed species or critical habitat that are caused by the proposed action, including the consequences of other activities that are caused by the proposed action. A consequence is caused by the proposed action if it would not occur but for the proposed action and it is reasonably certain to occur. Effects of the action may occur later in time and may include consequences occurring outside the immediate area involved in the action. (50 CFR 402.02).

    Yes

12. Will your action disturb the ground or existing vegetation?

    Note: This includes any off-road vehicle access, soil compaction (enough to collapse a rodent burrow), digging, seismic survey, directional drilling, heavy equipment, grading, trenching, placement of fill, pesticide application (herbicide, fungicide), vegetation management (including removal or maintenance using equipment or prescribed fire), cultivation, development, etc.

    Yes

13. Will your action include spraying insecticides?

    No

14. Does your action area occur entirely within an already developed area?

    Note: Already developed areas are already paved, covered by existing structures, manicured lawns, industrial sites, or cultivated cropland, AND do not contain trees that could be roosting habitat. Be aware that listed species may occur in areas with natural, or semi-natural, vegetation immediately adjacent to existing utilities (e.g. roadways, railways) or within utility rights-of-way such as overhead transmission line corridors, and can utilize suitable trees, bridges, or culverts for roosting even in urban dominated landscapes (so these are not considered "already developed areas" for the purposes of this question). If unsure, select NO..

    No

15. [Hidden Semantic] Does the action area intersect the monarch butterfly species list area?

    Automatically answered

    Yes

16. Under the ESA, monarchs remain warranted but precluded by listing actions of higher priority. The monarch is a candidate for listing at this time. The Endangered Species Act does not establish protections or consultation requirements for candidate species. Some Federal and State agencies may have policy requirements to consider candidate species in planning. We encourage implementing measures that will remove or reduce threats to these species and possibly make listing unnecessary.

    If your project will have no effect on monarch butterflies (for example, if your project won't affect their habitat or individuals), then you can make a "no effect" determination for this project.

    Are you making a "no effect" determination for monarch?

    Yes

In Reply Refer To: 01/30/2026 20:55:29 UTC
Project code: 2025-0073129
Project Name: Niron Sartell Project

Federal Nexus: no
Federal Action Agency (if applicable):

Subject: Technical assistance for 'Niron Sartell Project'

Dear Mia Bauer:

This letter records your determination using the Information for Planning and Consultation (IPaC) system provided to the U.S. Fish and Wildlife Service (Service) on January 30, 2026, for 'Niron Sartell Project' (here forward, Project). This project has been assigned Project Code 2025-0073129 and all future correspondence should clearly reference this number. **Please carefully review this letter. Your Endangered Species Act (Act) requirements are not complete.**

Ensuring Accurate Determinations When Using IPaC

The Service developed the IPaC system and associated species' determination keys in accordance with the Endangered Species Act of 1973 (ESA; 87 Stat. 884, as amended; 16 U.S.C. 1531 et seq.) and based on a standing analysis. All information submitted by the Project proponent into IPaC must accurately represent the full scope and details of the Project. **Failure to accurately represent or implement the Project as detailed in IPaC or the Northern Long-eared Bat and Tricolored Bat Range-wide Determination Key (Dkey), invalidates this letter.**

Determination for the Northern Long-Eared Bat and Tricolored Bat

Based on your IPaC submission and a standing analysis completed by the Service, you determined the proposed Project will have the following effect determinations:

Species	Listing Status	Determination
Northern Long-eared Bat (*Myotis septentrionalis*)	Endangered	May affect
Tricolored Bat (*Perimyotis subflavus*)	Proposed Endangered	May affect

Federal agencies must consult with U.S. Fish and Wildlife Service under section 7(a)(2) of the Endangered Species Act (ESA) when an action *may affect* a listed species. Tricolored bat is proposed for listing as endangered under the ESA, but not yet listed. For actions that may affect a proposed species, agencies cannot consult, but they can *confer* under the authority of section 7(a)(4) of the ESA. Such conferences can follow the procedures for a consultation and be adopted as such if and when the proposed species is listed. Should the tricolored bat be listed, agencies must review projects that are not yet complete, or projects with ongoing effects within the tricolored bat range that previously received a NE or NLAA determination from the key to confirm that the determination is still accurate. Projects that receive a may affect determination for tricolored bat through the key, should contact the appropriate Ecological Services Field Office if they want to conference on this species.

Other Species and Critical Habitat that May be Present in the Action Area

The IPaC-assisted determination key for the northern long-eared bat and tricolored bat does not apply to the following ESA-protected species and/or critical habitat that also may occur in your Action area:

- Monarch Butterfly *Danaus plexippus* Proposed Threatened
- Suckley's Cuckoo Bumble Bee *Bombus suckleyi* Proposed Endangered
- Western Regal Fritillary *Argynnis idalia occidentalis* Proposed Threatened
- Whooping Crane *Grus americana* Experimental Population, Non-Essential

You may coordinate with our Office to determine whether the Action may cause prohibited take of the species listed above.

Conclusion

Further coordination with the Service is voluntary for those species with a determination of “May Affect.” A “May Affect” determination in this key indicates that the project, as entered, is not consistent with the questions in the key. Not all projects that reach a “May Affect” determination are anticipated to result in adverse impacts to listed species. Through the technical assistance process, the Service might be able to provide information that either indicates incidental take is not reasonably certain to occur, or the Service might be able to provide recommendations that enable the project to be conducted in a way that avoids the likelihood of incidentally taking listed bats. Please contact our Minnesota-Wisconsin Ecological Services Field Office for more information. The Service has developed interim voluntary guidance for non-federal actions involving forest habitat modification that may affect the northern long-eared bat. Review the guidance posted here for more information for NLEB: https://www.fws.gov/species/northern-long-eared-bat-myotis-septentrionalis and TCB: https://www.fws.gov/species/tricolored-bat-perimyotis-subflavus

Action Description
You provided to IPaC the following name and description for the subject Action.

1. Name

Niron Sartell Project

2. Description

The following description was provided for the project 'Niron Sartell Project':

> Niron Magnetics (Niron) proposes to construct a manufacturing facility that produces industrial magnets on an undeveloped site located on 4th Avenue South between Heritage Drive and 3rd Street South in Sartell, Minnesota. The process converts iron oxide into a magnetic material, iron nitride. The iron nitride is processed further and then pressed and formed into magnets of various shapes. The finished magnets are given a protective coating before shipping to customers. The processes may use gases or chemicals, and the specific processes and chemicals are still under development. The processes are enclosed and feedstocks are planned to be reused to the extent possible.
>
> Additional outdoor structures like tanks or reactor columns will be installed. Controls like secondary containment, stormwater ponds, and waste management will be employed in the operation of the facility. Site construction is anticipated to take up to four years and would be completed over two phases.
>
> A design change was implemented in January 2026 that increased the gross square footage above 200,000 square feet. The increase in proposed gross square footage was the result of adding a second floor to some buildings and did not expand the originally proposed and permitted overall ground disturbance footprint. The primary activities already completed are limited to preliminary grading and stockpiling of imported fill soil.

The approximate location of the project can be viewed in Google Maps: https://www.google.com/maps/@45.609588349999996,-94.20530387930691,14z

DETERMINATION KEY RESULT

Based on the answers provided, the proposed Action is consistent with a determination of “may affect” for a least one species covered by this determination key.

QUALIFICATION INTERVIEW

1. Does the proposed project include, or is it reasonably certain to cause, intentional take of listed bats or any other listed species?

   Note: Intentional take is defined as take that is the intended result of a project. Intentional take could refer to research, direct species management, surveys, and/or studies that include intentional handling/encountering, harassment, collection, or capturing of any individual of a federally listed threatened, endangered or proposed species?

   No

2. Is the action area wholly within Zone 2 of the year-round active area for northern long-eared bat and/or tricolored bat?

   Automatically answered
   No

3. Does the action area intersect Zone 1 of the year-round active area for northern long-eared bat and/or tricolored bat?

   Automatically answered
   No

4. Does any component of the action involve leasing, construction or operation of wind turbines? Answer 'yes' if the activities considered are conducted with the intention of gathering survey information to inform the leasing, construction, or operation of wind turbines.

   No

5. Is the proposed action authorized, permitted, licensed, funded, or being carried out by a Federal agency in whole or in part?

   Note for projects in Pennsylvania: Projects requiring authorization under Section 404 of the Clean Water Act and/or Section 10 of the Rivers and Harbors Act would be considered as having a federal nexus. Since the U.S. Army Corps of Engineers (Corps) has issued the Pennsylvania State Programmatic General Permit (PASPGP), which may be verified by the PA Department of Environmental Protection or certain Conservation Districts, the need to receive a Corps authorization to perform the work under the PASPGP serves as a federal nexus. As such, if proposing to use the PASPGP, you would answer ‘yes’ to this question.

   No

6. [Semantic] Is the action area located within 0.5 miles of a known bat hibernaculum or winter roost? Note: The map queried for this question contains proprietary information and cannot be displayed. If you need additional information, please contact your state wildlife agency.

   Automatically answered
   No

7. Does the action area contain any winter roosts or caves (or associated sinkholes, fissures, or other karst features), mines, rocky outcroppings, or tunnels that could provide habitat for hibernating bats?

   No

8. Does the action area contain (1) talus or (2) anthropogenic or naturally formed rock shelters or crevices in rocky outcrops, rock faces or cliffs?

   No

9. Will the action cause effects to a bridge?

   Note: Covered bridges should be considered as bridges in this question.

   No

10. Will the action result in effects to a culvert or tunnel at any time of year?

    No

11. Are trees present within 1000 feet of the action area?

    Note: If there are trees within the action area that are of a sufficient size to be potential roosts for bats answer "Yes". If unsure, additional information defining suitable summer habitat for the northern long-eared bat and tricolored bat can be found in Appendix A of the USFWS' Range-wide Indiana Bat and Northern long-eared bat Survey Guidelines at: https://www.fws.gov/media/range-wide-indiana-bat-and-northern-long-eared-bat-survey-guidelines.

    Yes

12. Does the action include the intentional exclusion of bats from a building or building-like structure? **Note:** Exclusion is conducted to deny bats' entry or reentry into a building. To be effective and to avoid harming bats, it should be done according to established standards. If your action includes bat exclusion and you are unsure whether northern long-eared bats or tricolored bats are present, answer "Yes." Answer "No" if there are no signs of bat use in the building/structure. If unsure, contact your local Ecological Services Field Office to help assess whether northern long-eared bats or tricolored bats may be present. Contact a Nuisance Wildlife Control Operator (NWCO) for help in how to exclude bats from a structure safely without causing harm to the bats (to find a NWCO certified in bat standards, search the Internet using the search term "National Wildlife Control Operators Association bats"). Also see the White-Nose Syndrome Response Team's guide for bat control in structures.

    No

13. Does the action involve removal, modification, or maintenance of a human-made building-like structure (barn, house, or other building) **known or suspected to contain roosting bats?**

    No

14. Will the action cause construction of one or more new roads open to the public?

    For federal actions, answer 'yes' when the construction or operation of these facilities is either (1) part of the federal action or (2) would not occur but for an action taken by a federal agency (federal permit, funding, etc.).

    No

15. Will the action include or cause any construction or other activity that is reasonably certain to increase average night-time traffic permanently or temporarily on one or more existing roads? **Note:** For federal actions, answer 'yes' when the construction or operation of these facilities is either (1) part of the federal action or (2) would not occur but for an action taken by a federal agency (federal permit, funding, etc.). .

    No

16. Will the action include or cause any construction or other activity that is reasonably certain to increase the number of travel lanes on an existing thoroughfare?

    For federal actions, answer 'yes' when the construction or operation of these facilities is either (1) part of the federal action or (2) would not occur but for an action taken by a federal agency (federal permit, funding, etc.).

    No

17. Will the proposed Action involve the creation of a new water-borne contaminant source (e.g., leachate pond, pits containing chemicals that are not NSF/ANSI 60 compliant)?

    Note: For information regarding NSF/ANSI 60 please visit https://www.nsf.org/knowledge-library/nsf-ansi-standard-60-drinking-water-treatment-chemicals-health-effects

    No

18. Will the proposed action involve the creation of a new point source discharge from a facility other than a water treatment plant or storm water system?

    No

19. Will the action include drilling or blasting?

    No

20. Will the action involve military training (e.g., smoke operations, obscurant operations, exploding munitions, artillery fire, range use, helicopter or fixed wing aircraft use at night)?

    No

21. Will the proposed action involve the use of herbicides or pesticides (e.g., fungicides, insecticides, or rodenticides)?

    No

22. Will the action include or cause activities that are reasonably certain to cause chronic or intense nighttime noise (above current levels of ambient noise in the area) in suitable summer habitat for the northern long-eared bat or tricolored bat during the active season?

    Chronic noise is noise that is continuous or occurs repeatedly again and again for a long time. Sources of chronic or intense noise that could cause adverse effects to bats may include, but are not limited to: road traffic; trains; aircraft; industrial activities; gas compressor stations; loud music; crowds; oil and gas extraction; construction; and mining.

    Note: Additional information defining suitable summer habitat for the northern long-eared bat and tricolored bat can be found in Appendix A of the USFWS' Range-wide Indiana Bat and Northern long-eared bat Survey Guidelines at: https://www.fws.gov/media/range-wide-indiana-bat-and-northern-long-eared-bat-survey-guidelines.

    No

23. Does the action include, or is it reasonably certain to cause, the use of permanent or temporary artificial lighting within 1000 feet of suitable northern long-eared bat or tricolored bat roosting habitat?

    Note: Additional information defining suitable summer habitat for the northern long-eared bat and tricolored bat can be found in Appendix A of the USFWS' Range-wide Indiana Bat and Northern long-eared bat Survey Guidelines at: https://www.fws.gov/media/range-wide-indiana-bat-and-northern-long-eared-bat-survey-guidelines.

    Yes

24. Will the action cause an increase in the extent of suitable forested habitat exposed to artificial lighting?

    Yes

25. Will the action use only downward-facing, full cut-off lens lights (with same intensity or less for replacement lighting) when installing new or replacing existing permanent lights?

    Or for those transportation agencies using the Backlight, Uplight, Glare (BUG) system developed by the Illuminating Engineering Society, will all three ratings (backlight, uplight, and glare) be as close to zero as is possible, with a priority of "uplight" of 0?

    Yes

26. Will the action direct any temporary lighting away from suitable northern long-eared bat or tricolored bat roosting habitat when bats may be present?

    Note: Additional information defining suitable summer habitat for the northern long-eared bat and tricolored bat can be found in Appendix A of the USFWS' Range-wide Indiana Bat and Northern long-eared bat Survey Guidelines at: https://www.fws.gov/media/range-wide-indiana-bat-and-northern-long-eared-bat-survey-guidelines.

    Yes

27. Will the action include tree cutting or other means of knocking down or bringing down trees, tree topping, or tree trimming?

    Yes

28. Is the project related to the production of coal, including projects that support the mining of coal, as well as the production and/or distribution of energy produced from coal?

    No

29. Will the proposed action occur exclusively in an already established and currently maintained utility right-of-way?

    No

30. Does the action include emergency cutting or trimming of hazard trees in order to remove an imminent threat to human safety or property? See hazard tree note at the bottom of the key for text that will be added to response letters

    Note: A "hazard tree" is a tree that is an immediate threat to lives, public health and safety, or improved property.

    No

31. Does the project intersect with the 0- 9.9% forest density category?

    Automatically answered
    Yes

32. Does the project intersect with the 10.0- 19.9% forest density category map?

    Automatically answered
    No

33. Does the project intersect with the 20.0- 29.9% forest density category map?

    Automatically answered
    No

34. Does the project intersect with the 30.0- 100% forest density category map?

    Automatically answered
    No

35. Will the action cause trees to be cut, knocked down, or otherwise brought down across an area greater than 0.5 acre in total extent?

    Yes

36. Does the action area intersect the northern long-eared bat species list area?

    Automatically answered
    Yes

37. [Semantic] Is the action area located within 0.5 miles of radius of an entrance/opening to any known NLEB hibernacula or winter roost? Note: The map queried for this question contains proprietary information and cannot be displayed. If you need additional information, please contact your State wildlife agency.

    Automatically answered
    No

38. [Semantic] Is the action area located within 0.25 miles of a culvert that is known to be occupied by northern long-eared or tricolored bats? **Note:** The map queried for this question contains proprietary information and cannot be displayed. If you need additional information, please contact your State wildlife agency.

    Automatically answered
    No

39. [Semantic] Is the action area located within 150 feet of a documented northern long-eared bat roost site?

    Note: The map queried for this question contains proprietary information and cannot be displayed. If you need additional information, please contact your State wildlife agency.Have you contacted the appropriate agency to determine if your action is within 150 feet of any documented northern long-eared bat roosts?

    Note: A document with links to Natural Heritage Inventory databases and other state-specific sources of information on the locations of northern long-eared bat roosts is available here. Location information for northern long-eared bat roosts is generally kept in state natural heritage inventory databases – the availability of this data varies by state. Many states provide online access to their data, either directly by providing maps or by providing the opportunity to make a data request. In some cases, to protect those resources, access to the information may be limited.

    Automatically answered
    No

40. Is suitable summer habitat for the northern long-eared bat present within 1000 feet of project activities?
    If unsure, answer "Yes."

    Note: Additional information defining suitable summer habitat for the northern long-eared bat and tricolored bat can be found in Appendix A of the USFWS' Range-wide Indiana Bat and Northern long-eared bat Survey Guidelines at: https://www.fws.gov/media/range-wide-indiana-bat-and-northern-long-eared-bat-survey-guidelines.

    Yes

41. Has a presence/probable absence summer bat survey targeting the northern long-eared bat following the Service's Range-wide Indiana Bat and Northern Long-Eared Bat Survey Guidelines been conducted within the project area?

    No

42. Does the action area intersect the tricolored bat species list area?

    Automatically answered
    Yes

43. Is the action area located within 0.5-mile of radius of an entrance/opening to any known tricolored bat hibernacula or winter roost?

    Note: The map queried for this question contains proprietary information and cannot be displayed. If you need additional information, please contact your state wildlife agency.

    Automatically answered
    No

44. [Semantic] Is the action area located within 0.25 miles of a culvert that is known to be occupied by northern long-eared or tricolored bats? **Note:** The map queried for this question contains proprietary information and cannot be displayed. If you need additional information, please contact your State wildlife agency.

    Automatically answered
    No

45. Has a presence/probable absence bat survey targeting the tricolored bat and following the Service's Range-wide Indiana Bat and Northern Long-Eared Bat Survey Guidelines been conducted within the project area?

    No

46. Is suitable summer habitat for the tricolored bat present within 1000 feet of project activities?
    (If unsure, answer ""Yes."")

    Note: If there are trees within the action area that may provide potential roosts for tricolored bats (e.g., clusters of leaves in live and dead deciduous trees, Spanish moss (Tillandsia usneoides), clusters of dead pine needles of large live pines) answer ""Yes."" For a complete definition of suitable summer habitat for the tricolored bat, please see Appendix A in the Service's Range-wide Indiana Bat and Northern long-eared Bat Survey Guidelines.

    Yes

47. Do you have any documents that you want to include with this submission?

    No

PROJECT QUESTIONNAIRE

Enter the extent of the action area (in acres) from which trees will be removed - round up to the nearest tenth of an acre. For this question, include the entire area where tree removal will take place, even if some live or dead trees will be left standing.

GHG Calculations

Minnesota Climate Calculator: Project Summary Report

Date Prepared: 2/17/2026

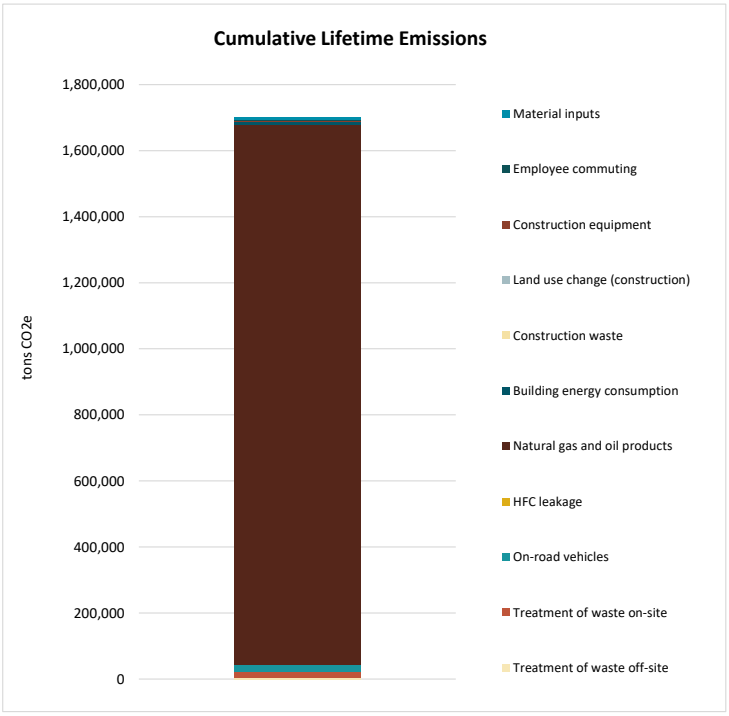
The results shown below were generated using the Minnesota Climate Calculator. The emissions quantified account for the full greenhouse gas impact of a potential project throughout the construction and operational phases of the project. This includes emissions from project activities that occur on-site as well as emissions that occur upstream and downstream of the project. The results are based on user inputs and assumptions; actual project emissions may vary.

Background Information

Project Name	Niron Magnetics - Sartell Expansion
Project Category (primary)	Subp. 14, Industrial, commercial, institutional facilities
Project Category (secondary)	
Location (County)	Stearns
Construction Start Date	4/21/2026
Operational Year	2029
Operational Lifetime (Years)	50

Electricity Provider	Xcel Energy
Portion of Building Electricity Consumption to be Generated On-Site via Renewables or Supplied through the Purchase of Renewable Energy Credits (RECs)	0%
Portion of Building Natural Gas Consumption to be Supplied from Renewable Sources	0%

Building Construction Project?	Yes



Construction Stage	Duration (Days)
Demolition	-
Site Preparation	39
Grading	77
Building Construction	609
Architectural Coatings	116
Paving and Landscaping	77

Summary Results

Project Lifetime	53
Unit	tons

Phase	CO_2e Emissions	
	Cumulative	Annualized
Construction		
Material inputs	6,187.16	116.74
Transportation of material inputs	141.52	2.67
Employee commuting	2,710.03	51.13
Construction equipment	1,509.52	28.48
Land use change (construction)	6.21	0.12
Construction waste	0.01	0.00
Operation		
Building energy consumption	11,217.99	211.66
Coal production	NA	NA
Natural gas and oil products	1,633,560.58	30,821.90
Industrial processes	NA	NA
HFC leakage	1,347.86	25.43
Land use change (operations)	NA	NA
On-road vehicles	19,786.20	373.32
Treatment of waste on-site	NA	NA
Treatment of wastewater on-site	NA	NA
Treatment of waste off-site	3,243.89	61.21
Enteric fermentation	NA	NA
Manure management	NA	NA
Total	**1,679,710.97**	**31,692.66**

Note: NA indicates that emissions were not quantified and/or are not applicable.

User Inputs

Note: NA indicates that emissions were not quantified and/or activity is not applicable.

Material Inputs

Material Type	Quantity	Unit	Geographical Sourcing
Aluminum	0.00	Tons	Unknown
Asphalt	741.64	Tons	Domestic
Brick	11.98	Tons	Domestic
Concrete	11,587.00	Cubic yards	Domestic
Glass	8.60	Tons	Domestic
Insulation (residential)	0.00	Tons	Domestic
Insulation (commercial)	158,000.00	Square feet	Domestic
Steel	1,360.00	Tons	Domestic
Wood Products	0.00	Tons	Domestic

Employee Commuting

Construction Stage	Daily Average Number of Employees Commuting
Demolition	0
Site Preparation	300
Grading	300
Building Construction	300
Architectural Coatings	300
Paving and Landscaping	300

Transportation Mode	Percent of Employees
Single Occupancy Vehicle	82%
Carpool	11%
Motorcycle	0%
Bus	2%
Transit Rail	2%
Bike/Walk	3%

Average One-Way Commute Length (miles)	13.2

Notes

General Notes	Emissions from the transportation of fill material and miscellaneous deliveries are not included in the Minnesota Climate Calculator spreadsheet and are provided separately. See the "Niron GHG Summary & Delivery Trucks_02-10-2026" spreadsheet for a summary of all project emissions.
Material inputs	Material estimates provided by Wood PLC. Aluminum usage is unknown. Wood usage is expected to be negligible. Density of asphalt assumed to be 1.1 kg/L from AP-42 Chapter 4.5 (7/79). Density of brick assumed to be 130 lb/ft3. Density of glass assumed to be 2.5 g/cm3 (156 lb/ft3).
Transportation of material inputs	All material will be sourced domestically. Emissions from the transportation of fill material and miscellaneous deliveries are not included in the Minnesota Climate Calculator spreadsheet and are provided separately.
Employee commuting	Estimate provided by Wood PLC. Site is greenfield, so no commuting is assumed for the demolition project phase.
Construction equipment	Default estimates from Minnesota Climate Calculator used. No demolition assumed as the site is greenfield.
Land use change (construction)	Provided by Niron. The number of trees to be replanted is currently unknown.
Construction waste	Default estimates from Minnesota Climate Calculator used.
Building energy consumption	Default estimates for industrial building types from Minnesota Climate Calculator used. The facility will not be used for residential, commercial, or institutional purposes.
Coal production	Not applicable to facility operations.
Natural gas and oil products	Natural gas-fired equipment includes heaters, industrial equipment, and emergency generators. Heaters and industrial equpiment assumed to operate 8,760 hours/yr. Emergency generators assumed to operate 500 hours/yr.
Industrial processes	Greenhouse gas emissions from facility industrial processes are from the combustion of natural gas and are included in emission calculations for natural gas and oil products.
HFC leakage	Default estimates for industrial building types from Minnesota Climate Calculator used.
Land use change (operations)	Not applicable to facility operations.
On-road vehicles	Assuming an average of 70 employees/day and 15 delivery trucks/week during operation and a daily commute of 50 miles/day per employee and per delivery truck. The fleet average speed was used.
Treatment of waste on-site	Not applicable to facility operations.
Treatment of wastewater on-site	Assuming an average of 70 employees/day only from industrial use. The facility will not be used for residential, commercial, or institutional purposes. Default waste generation rates were used.
Treatment of waste off-site	Default estimates from Minnesota Climate Calculator used.
Enteric fermentation	Not applicable to facility operations.
Manure management	Not applicable to facility operations.
Mitigation Measures	
Adaptation Strategies

Stantec

Stantec is a global leader in sustainable engineering, architecture, and environmental consulting. The diverse perspectives of our partners and interested parties drive us to think beyond what's previously been done on critical issues like climate change, digital transformation, and future-proofing our cities and infrastructure. We innovate at the intersection of community, creativity, and client relationships to advance communities everywhere, so that together we can redefine what's possible.

Stantec Consulting Services Inc.
733 Marquette Avenue, Suite 1000

Item 18 Greenhouse Gas (GHG) Emissions/Carbon Footprint

The guidance provided below will assist proposers and their consultants in responding to Item 18 Greenhouse Gas (GHG) Emissions/Carbon Footprint in the Environmental Assessment Worksheet (EAW) form. For additional guidance on greenhouse gas emissions calculations and Item 18, refer to the Minnesota Environmental Quality Board (EQB) EAW guidance for climate and adaptation and resilience.

18a. GHG quantifications

This section provides recommendations of tools to quantify GHG emissions, in which MPCA is the responsible government unit (RGU) per Minn. R. 4410.4300.

MPCA recommends users start with either the EQB Calculator or EPA's Simplified GHG Emissions Calculator (SEGC). Where available, additional tools can provide more refined results because of the requirement of detailed information. While most of tools recommended were designed by different organizations with different audience/purposes, and not EAW's for the State of Minnesota; after careful review, MPCA has determined that these tools are acceptable for use in an EAW application.

The level of data input and in-depth knowledge of the project varies with each tool. More refined data input can result in more refined results.

There are two sections necessary in quantifying GHG emissions under 18a:

- Construction: This includes GHG emissions associated with the construction of the project (i.e. new roads, new buildings, increasing land use for landfills). Project proposers should evaluate:
  - materials used during the constructions (i.e. tons of concrete, asphalt, etc.)
  - mobile emissions including construction equipment and increased traffic because of the construction work,
  - any change in land use (i.e. grassland converted to an impervious surface because of a new building); and
  - construction waste (i.e. any material that is disposed of because of the project).
- Operations: This includes GHG emissions associated with the day-to-day activities for the project such as:
  - combustion emissions from mobile equipment (i.e. vehicle activity such as transporting waste from the site to another location)
  - combustion from stationary equipment (i.e. energy consumption/usage from building operations)
  - non-combustion stationary equipment (i.e. enteric fermentation or wastewater treatment projects); and
  - waste management emissions (i.e. unwanted material that leaves the site)

Depending on the project, project proposers and their consultants may need to use a combination of tools to address all components of the project.

Note to Proposer: Some tools have other capabilities are not discussed in this document. Outputs of the tools vary. Users should convert units to short tons per year.

Table 1: GHG calculators.

Calculator name	Website	User guide link	Applicability (EAW category)	Description	Limitations (related to preparing EAWs)
Minnesota Climate Calculator	Climate assessments | Minnesota Environmental Quality Board	Climate Calculator, Version 1.1 Additional supporting guidance documents: • Anaerobic Digester Guide. • Feedlot Guide. • Wastewater Guide. • Landfill Guide.	All categories (with limitations)	An excel-based calculator designed specifically to address the quantification of GHG emissions from any potential project submitting an EAW.	Depending on the project category, the tool may be limited by the defaults or data entry. For example, the tool does not address the land application of biosolids from wastewater treatment plants.
EPA's Simplified GHG Emissions Calculator	Simplified GHG Emissions Calculator | US EPA	Simplified Guide to Greenhouse Gas Management for Organizations	All categories (with limitations)	An excel-based calculator designed to quantify emissions from several emission sources. This tool is excellent for quantifying emissions from mobile sources.	The tool does not provide calculation for emissions from feedlots and wastewater.
MPCA's Feedlot Tool	p-ear1-14a.xlsx	MPCA Feedlot Tool User's Guide	Subp. 29 Animal feedlots	A Minnesota specific excel-based calculator designed specifically to address the quantification of GHG emissions from feedlots (cattle, swine, and poultry).	There is limited customization of manure management strategies.
COMET Farm Tool	COMET-Farm Login	Quantifying Greenhouse Gas Fluxes in Agriculture and Forestry: Methods for Entity-Scale Inventory	Subp. 29 Animal feedlots	Web-based accounting tool that provides a full GHG assessment from on-farm emission sources based on specific operational inputs such as manure management strategies, feed, and housing.	Requires a high level of data input (such as crude protein).
Energy Performance and Carbon Emissions Assessment	ECAM v3	UserManual_FinalVersion.pdf Additional supporting guidance document:	Subp. 18 Wastewater systems	Web-based tool to model GHG emissions from the Urban Water Sector. For EAWs, a project proposer should only focus on the treatment stage. A support document is available to help	Requires a high level of data input (such as nitrogen load in the influent).

Calculator name	Website	User guide link	Applicability (EAW category)	Description	Limitations (related to preparing EAWs)
and Monitoring Tool		ECAM Guidance		project proposers understand how to use the tool to respond to EAW item 18.	
GREET 2025	GREET | Department of Energy 45ZCF-GREET	Guidelines to Determine Life Cycle Greenhouse Gas Emissions of Clean Transportation Fuel Production Pathways Using 45ZCF-GREET	Subp. 5 Fuel conversion	There are multiple excel-based GREET Models. Project Proposers of fuel conversion projects, such as ethanol production, should use the 45ZCF-GREET Model.	Requires a high level of data input and thorough understanding of the inputs. Certain parameters are fixed and may not be changed by the user.
WARM	Versions of the Waste Reduction Model | US EPA	Documentation Chapters for Greenhouse Gas Emission, Energy and Economic Factors Used in the Waste Reduction Model | US EPA	Subp. 5 Fuel Conversion and Subp. 17 Solid waste	Excel-based comparative tool for reviewing the differences in GHG emission across different waste management practices.	The tool does not include biosolids from wastewater treatment facilities, nor manure from feedlots.
Anaerobic Digestion Screening Tool	Anaerobic Digestion Screening Tool | Global Methane Initiative	User Manual, AD Screening Tool	EAWs where ADs are involved.	Excel-based tool designed as a pre-feasibility screening for multi-feedstock ADs. This tool can factor in multiple sources and combinations of feedstock, including biosolids from wastewater, animal manure, and municipal solid wastes.	Requires a high level of data input.

18b. GHG assessment

This section asks project proposers to discuss the possible mitigation of GHG emissions in three parts:

- Identify reasonably available mitigation options. Describe strategies or technologies that reduce construction and/or operational emissions (e.g., material substitutions, electrification of on-site equipment and fleets, energy efficiency, methane capture, organics diversion, process changes).
- Quantify expected reductions. For each selected mitigation, proposers should attempt to quantify the reduction in per year and summarize key assumptions so a reviewer could reproduce the estimate. Explain why a mitigation strategy is preferred.
- Discuss net lifetime emissions and state goals. Provide the project's net lifetime discuss alignment with Minnesota Next Generation Energy Act goals.

Abstract

Greenhouse gas emissions from meat and dairy production are often highly uncertain; these emissions are typically estimated using inventory-based, 'bottom-up' models, which contain uncertainties that are difficult to quantify. Modeled emissions estimates can be corroborated using atmospheric measurements—taken above and downwind of animal production regions—to produce 'top-down' emissions estimates. Top-down and bottom-up estimates of animal methane show good agreement when considering global emissions. However, in the US, where animal production is predominantly highly intensified with confined feeding operations, animal methane emissions may be 39%–90% higher than bottom-up models predict (expressed as mean differences across studies). Animal emissions may grow in the future as meat and dairy demand increases in developing countries. We examine East and Southeast Asia as a test case, where emissions from increased meat and dairy production are expected to be offset by improved efficiency from intensive methods. We adjust the share of direct emissions projected to come from intensive systems by the intensities derived from US top-down estimates. We find that region-wide emissions from meat and milk production could reach 1.52 (1.41–1.62) $GtCO_2eq$ by 2050, an amount 21% (13%–29%) higher than previously predicted. Therefore, intensification may not be as effective in mitigating emissions in developing countries as is commonly assumed.

1. Introduction: the role of intensification in sustainable development

Global meat consumption is expected to increase by 50% in the coming decades (FAO 2018a). This increase is primarily driven by rising affluence in developing low- and middle-income countries. Animal agriculture has been reported to represent 15.6% of total annual greenhouse gas (GHG) emissions globally (FAO 2017 using a 100 year global warming potential (GWP_{100}) for non-CO_2 GHGs), with emissions expected to increase in the coming decades.

Limiting GHGs from agriculture is urgent because business-as-usual agricultural growth is likely incompatible with limiting warming below 1.5 °C (Clark *et al* 2020). Reducing emissions from food systems is therefore urgent, even in scenarios in which fossil fuel usage is rapidly phased out. Sustainable intensification offers a possible solution; it is defined as the production of more meat and dairy with fewer resources, like land and feed, and lower emissions per animal (Godfray *et al* 2010).

The majority of global agricultural emissions are estimated to come from lower efficiency, pastoral systems (Steinfeld *et al* 2006). These systems include long-range grazing, backyard, and mixed crop-livestock systems, although the latter category has wide variation, and could count as intensive or semi-intensive depending on the specifics of the system (Robinson *et al* 2011). These forms of animal agriculture are referred to as extensive production systems because of their larger land footprint, and they are becoming less common globally (Gerber *et al* 2013).

Conversely, intensive production systems, like those in North America and the EU, are likely

© 2021 The Author(s). Published by IOP Publishing Ltd

responsible for fewer direct and indirect emissions, in total and per unit of meat or dairy produced (Gerber *et al* 2013). Intensively managed animals in these regions are often raised in 'landless' systems (as defined by the UN Food and Agriculture Organization, FAO), where feed inputs are traded commodities and are largely detached from the immediate local resource base (Robinson *et al* 2011). Animals like pigs and chickens are highly confined for all of their lives, while beef cattle spend the latter part of their lives being 'finished' on enriched feeds in feedlots. These systems in the US are also referred to as concentrated animal feeding operations (CAFOs). However, this term is a more stringent categorization—as CAFOs may not include a number of smaller-scale facilities that are nonetheless highly industrialized and entail confinement.

Animal feeding in intensive, landless systems is oriented toward rapid weight gain and productivity (Robinson *et al* 2011). Animals live shorter lives relative to extensively-raised animals to optimize feed requirements and other input resources (Herrero *et al* 2013). Intensive systems for raising chickens, pigs, and dairy cows, and facilities for fattening or 'finishing' mature beef cattle to reach market weight in the North America restrict animal movement. Intensive landless systems typically do not allow for the expression of natural behaviors, access to pasture, or the ability to graze or forage for food. This type of animal agricultural production, often referred to as 'industrialized production', is now proliferating globally through developing low- and middle-income countries.

Intensively-raised animal-sourced foods have lower land and feed requirements, relative to extensively-raised animal-sourced foods (Swain *et al* 2018). The benefits of improved feed requirements are commonly assumed to include fewer GHG emissions: both lower indirect emissions from feed production and grazing, and fewer direct emissions from wastes like manure, urine, and belches, per unit of food produced. However, the aggregate air and water pollution from landless facilities, along with resource depletion of fresh water, can create local problems and contribute to environmental degradation (Carrel *et al* 2016, Richter *et al* 2020).

Researchers have therefore recommended intensifying existing extensive and pastoral systems to reduce GHG emissions (e.g. Steinfeld *et al* 2006, Thornton and Herrero 2010, Swain *et al* 2018). North American meat and dairy companies frequently claim that their emissions are improving, directly attributing this trend toward more intensive management practices (Cattlemen's Beef Board 2018, McDonald's Canada 2018, National Pork Board 2020). In unity with these messages, governments and nongovernmental organizations alike have promoted intensification for food security, environmental improvements, and GHG mitigation in low and middle-income countries (De Oliveira Silva *et al* 2018, FAO 2018b, Enahoro *et al* 2019, ILRI 2019). International development banks further incentivize intensive methods through conditional lending and low-interest loans for confined production infrastructure (Wasley and Heal 2020, World Bank International Finance Corporation 2020).

Extensive production methods currently predominate in low- and middle-income regions. Animal-sourced food consumption is also likely to grow as these countries develop economically (Alexandratos and Bruinsma 2012), with rising population and rising income-related dietary shifts. However, there is an ongoing shift toward intensification in these countries, both as an economic response to rising meat and dairy production and government agendas to develop economies through 'green revolution' type programs of achieving efficiency through intensification.

This shift toward intensification is expected to offset a substantial fraction of GHG emissions. In the greater East and Southeast Asia (ESA) region, an area of both rapid consumption growth and industrialization, these two trends are expected to approximately counter-balance one another, with 39% more meat consumption in 2050 relative to present day, but little net change in total emissions (FAO 2018a), credited to the efficiency of intensification.

However, the hypothesis that intensification leads to GHG emissions mitigation, in particular that this mitigation is large enough to offset projected increases in production and consumption, has not been corroborated through independent assessments. The following review describes the model-based methods in which GHGs from animal-sourced food production are typically assessed and forecasted. We then contrast this approach with recent atmospheric measurement-based methods, along with a discussion of both methods' inherent uncertainties. Lastly, we conclude with a test case analyzing commonly-accepted emissions projections, adjusting the projection from ESA intensive systems by the same degree to which present-day emissions from North American intensive systems are possibly biased. These prospective results imply that emissions may increase in the region through 2050, contrary to existing predictions that they will plateau or decrease after 2030. This case study has important implications for the standard paradigm of agricultural development in low- and middle-income countries, as it implies that the GHG mitigation benefits of intensification may be overestimated.

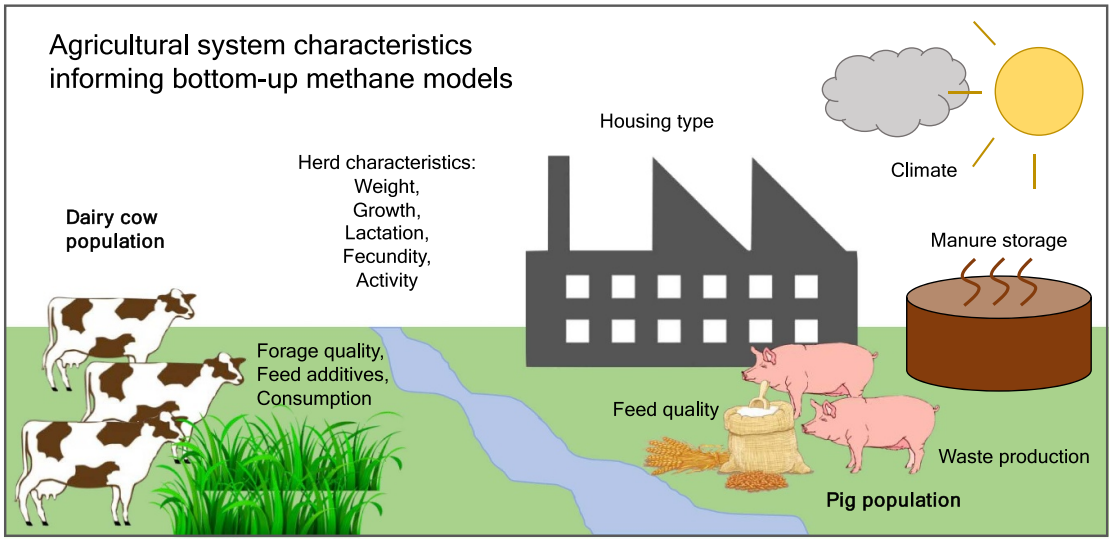

Figure 1. Characteristics of dairy cow and pig herds accounted for in bottom-up methane emissions models. Models use input variables, which are listed within this diagram and contain uncertainties, to calculate total enteric fermentation and manure management methane emissions. Models relate input variables to methane emissions using parameters (not shown), which also contain uncertainties.

2. Quantifying progress toward sustainable emissions

2.1. Bottom-up estimates of animal emissions

Present-day estimates of total GHG emissions in a given region are rarely measured directly. Rather, emissions estimates are based on animal emission models. Such models collect and integrate detailed information from multiple animals and production regions through counting, interviewing, and census-taking. Emissions models are referred to as 'bottom-up' estimates, because detailed information is collected at the ground-level, then multiplied and added up to calculate total emissions.

The predominant GHG from animal agriculture is methane. Methane is produced by enteric fermentation and manure management. Methane represents 50% of all animal emissions (direct + indirect) and 92% of direct animal emissions (FAO 2017).

Bottom-up estimates of methane are created by tallying up populations of each type of animal, known as activity data. These data are then multiplied by emissions factors—estimates of gas emitted by each animal daily or each operation annually. Separate emission factors are generally used for (a) enteric fermentation (belches) and the (b) handling and storage of their manure. Animal populations are subsequently multiplied by animal- and region-specific emissions factors, yielding an estimate of direct emissions produced. Bottom-up models are often also used to estimate indirect emissions from feed production and manure application to fields. However, this review mostly concerns direct emissions of animal agriculture, with some exceptions.

Emissions factors are calculated using detailed equations, provided in the IPCC guidelines of the Fourth Global Assessment Report (Dong *et al* 2006) and its 2019 refinement report (Gavrilova *et al* 2019). Multiple levels of detail or 'tiers' of estimates are provided, corresponding to different levels of aggregation and coarseness. Emissions factors are calculated at Tier 1 with fixed tabular values, Tier 2 with the more detailed equations that are standardized by the IPCC, or Tier 3 which are considered rigorous and detailed methods that are country-specific but nonetheless subjected to international peer review (Dong *et al* 2006). Each level reflects processed-based detailed input information on how animals are raised in each region, differing mainly in what level of detail is included by the modeler. The resulting emissions factors describe how much methane and nitrous oxide an average animal from each herd directly emits per day or year.

The development of these emissions factors requires information on how animals are raised in each region, including feed, physical activity, manure disposal, and local climate, along with their productivity, such as weight gain, lactation amount, and breeding rate (figure 1). Most of these local production and environmental characteristics are required inputs for all tiers of IPCC methods—including Tier 1 methods that rely on IPCC emissions factors and Tier 2 and 3 methods that provide detailed models that allow users to calculate their own emission factors. The remainder of this discussion will focus predominantly on Tier 2 emissions to provide a standard, if simplified framework for understanding, but there are commonalities among all three tiers.

The details used to develop methane emission factors can be incredibly fine-grained and include information on how much an average animal moves during a day, whether or not a dried crust is allowed

to form on top of the slurry tanks that handle liquid manure, the temperatures of a given animal operation and the seasonal cycle of weather conditions, and other highly specific details. This detailed information can be challenging to collect, even for countries with detailed agricultural censuses (Hristov *et al* 2017).

Detailed input information in bottom up emissions estimates contributes to their precision—the degree to which estimates can detect changes between one system or another. However, this detail does not guarantee estimates that are accurate—close to the true, real-world value. As more details are added and multiplied within the models, the model errors tend to increase. The errors in totaled emissions estimates are therefore considerably more uncertain than any single input. Ultimately, bottom-up estimates require simplifying assumptions and extrapolation from representative systems. They therefore may contain large uncertainties and compounding errors (Miller *et al* 2014, Miller and Michalak 2017) that make emissions difficult to accurately quantify, including estimates contained in national inventory reports.

The uncertainty envelopes in bottom-up emissions inventories may be underestimated, and are difficult to compare and scrutinize in existing sources. Uncertainties are required in the reporting from all UNFCCC annex-1 countries, including the United States. However, uncertainty ranges are not easily discoverable, are missing from a number of UNFCC reports and web portals, and do not clearly identify which types of the multiple types of model uncertainty they consider. The United States' inventory includes mention of uncertainty analysis performed on 185 input variables and categories, and reports resulting errors for enteric fermentation methane of approximately ±15% (US EPA O 2021). The details of the assessment are vague, stating that uncertainties for input variables 'were collected from published documents and other public sources; others were based on expert opinion and best estimates'. Conversely, the IPCC methodology states that Tier 1 and 2 uncertainty estimates for enteric fermentation may be on the order of 50% (Dong *et al* 2006), a substantially larger range than the US EPA and most other bottom up emissions inventories report. The 2019 update states that uncertainty estimates for enteric fermentation contains 'no refinement' (Gavrilova *et al* 2019). Uncertainty ranges in bottom-up estimates are possibly too small, even though they are intended to be fully comprehensive.

Furthermore, bottom-up inventories uncertainties often do not reflect uncertainties arriving from model structure and parameter selection, referred to as epistemic uncertainty (Sykes *et al* 2019), instead reflecting uncertainties arriving from input data. Bottom-up models structurally contain dozens of parameters that describe how inputs and outputs relate to one another. For instance, one commonly-used equation in Tier 1 and 2 methods for estimating the food consumption of cows uses multiple constant coefficients to relate live dairy cow body weight to quantity of dry matter ingested per day (equaions (10.18) in Dong *et al* 2006, Gavrilova *et al* 2019). These and other parameters are gleaned from small-scale studies, dating back to the early 1980s and 1990s (NRC 1989, 2001, references therein). Analyses of epistemic uncertainties studies have been done at the farm level (Sykes *et al* 2019) but are not explicitly utilized in the development of national inventories.

While these uncertainties have been detected across models may be common to all bottom-up estimates as they rely on similar assumptions and model parameters, introducing systematic biases that elude uncertainty analysis. The multiple sources of uncertainties in bottom-up estimates (input data, geographic distribution and allocation, model and parameter selection) are rarely analyzed holistically by existing studies. A recent analysis discovered that, while three different total US inventories of methane agree within 20%, their spatial discrepancies exceed 100% across certain US states (Hristov *et al* 2017). Altogether, the information used to develop bottom-up models, including input data and model parameters, may therefore lead to biases in reported estimates outcomes, due to their outdated nature, or due to a lack of representative information from the wide national and global variation in contemporary production systems (Wolf *et al* 2017).

In summary, bottom-up methods allow researchers to estimate animal emissions with a high level of precision, or fine-grained resolution, parsing out how GHG emissions differ between animal species, geographic regions, production systems, and food products, but not necessarily an accordingly high level of accuracy. The accuracy of these methods in different global regions remains poorly characterized, requiring independent methods to verify emissions estimates from animal agriculture.

2.2. Top-down estimates: evaluating animal emissions from the atmosphere

The GHG emissions estimates produced by bottom-up models can be compared against measurements taken from the air above animal operations, using sensors on tall towers, airplanes, and satellites.

Researchers use meteorological models and observations of wind direction, speed, and turbulence to link the measured GHG concentrations in the air back to their sources on the ground. These methods can be used to gauge the quantity of emissions from sources in the upwind footprint of the measurements over months or years—by measuring for prolonged periods of time and from multiple wind directions. Atmospheric estimates start by measuring GHGs in the sky, then trace those GHGs back to their source regions on the ground; these methods are referred to as 'top-down' estimates.

One limitation of top-down estimates is that these methods can only broadly distinguish among emission sources. The partitioning of sources typically depends upon differences in the spatial distribution of different source types, requiring accurate information regarding where these sources are distributed in geospatially gridded bottom-up data (e.g. Miller and Michalak 2017). For example, a top-down approach would struggle with this source partitioning if cattle are grazed amidst natural gas wells, or pig manure lagoons and natural wetlands are located in the same region.

The level of disaggregation or detail in emissions inventories also determines how finely top-down emissions estimates can be used to distinguish among source types. For example, top-down studies often employ a 'scaling factor inversion' to statistically partition sources—by scaling each emissions sector in a bottom-up inventory to match atmospheric observations. The number of these scaling factors is limited by the number of emissions categories present in the bottom-up gridded inventory and by the information content of the atmospheric observations used in the inverse model. The geospatially gridded inventories of animal emissions from EDGAR or the US EPA that are publicly available and used in the top-down analyses reviewed here are not disaggregated by type of animal or production type. Such disaggregated gridded bottom-up products would be useful for examining potential errors and biases, but could introduce further partitioning errors as the number of scaling factor coefficients would increase.

Another limitation is that top-down atmospheric estimates rely on wind observations and models with their own errors. Importantly, these atmospheric transport errors are different from the errors in bottom-up models (Pandey *et al* 2019). These errors are commonly reported in the literature and are non-compounding.

An additional challenge of top-down modeling is that these models are often under-constrained or under-determined by atmospheric observations. The number of atmospheric observation sites may be limited, while the spatial and temporal patterns of emissions can show complexity that exceeds the detection abilities of existing atmospheric observations. As a result, multiple configurations of the emissions or multiple solutions to a top-down estimation problem can reproduce the atmospheric observations within a specified error tolerance. Existing top-down models therefore have finite utility in constraining emissions at fine spatial scales. With that said, the uncertainties in top-down emissions estimate typically decrease at regional and national spatial scales (e.g. Miller *et al* 2013, 2019). The reported uncertainties at these scales are often smaller than the differences between bottom-up and top-down estimates, implying that top-down methane estimates are sufficiently robust to compare and contrast with bottom-up models at regional to continental scales (e.g. Turner *et al* 2015, Saunois *et al* 2020).

Top-down atmospheric estimates are therefore an independent way of testing the accuracy of the estimates produced by bottom-up emissions models across both small and large spatial scales, albeit with their own inherent uncertainties and limitations. To date, however, they cannot reliably distinguish between various sources that are co-located.

3. Comparing bottom-up and top-down estimates of US animal methane emissions

3.1. Quantifying differences between emissions estimates

We synthesized reports in the literature regarding top-down methane emissions estimates in regions of predominantly intensive production. We conducted literature searches on ISI Web of Science and Google Scholar for terms pertaining to top-down atmospheric estimates of methane, and filtered search results by spatial domain (state/province or larger) and whether they statistically partitioned livestock sector emissions from the total estimate. We present the results in table 1, alongside comparisons with bottom-up estimates.

Estimates from atmospheric measurements indicate that global animal methane emissions may be only slightly higher than the bottom-up models predict—about 5% higher—and within the margin of error (e.g. Turner *et al* 2015). A more recent comparison of methane estimates from total agricultural and waste sources from 2000 to 2017, which included all direct livestock emissions but also include rice crops and landfills, also found that bottom-up and top-down emissions estimates agree well within statistical uncertainty (Saunois *et al* 2020).

The difference is much greater in the United States; at least four top-down estimates of the contiguous US, representative of emissions occurring over at least one full year, indicate that direct animal methane emissions are 39%–90% higher than bottom-up models predict (Miller *et al* 2013, Wecht *et al* 2014, Turner *et al* 2015). Such comparisons are currently lacking for other predominantly intensified production regions, e.g. Europe.

This tendency is mirrored in smaller geographic regions within North America. Of five regional top-down studies, four found significantly higher methane emissions from areas of confined animal production than the bottom-up models suggest (Jeong *et al* 2016, Chen *et al* 2018, Desjardins *et al* 2018, Yu *et al* 2021). The exception is the Southeastern US, where there was close agreement between aircraft measurements and a short-term campaign (Sheng *et al* 2018). This and the Ontario Desjardins *et al* (2018) study were both conducted over an aircraft campaign lasting less than 2 months, meaning that these results may not be representative of the full annual

Table 1. Direct methane emissions from farmed animals in Tg CH_4. Scale factor refers to the relative magnitude of the top-down emissions estimate relative to the respective bottom-up estimate (e.g. 200% means top-down estimate is two times higher than bottom-up estimate). Emissions model abbreviations are EDGAR—Emissions Database for Global Atmospheric Research; EPA—Environmental Protection Agency; CALGEM—California GHG emissions measurement project. Bottom-up models reflect the models used to develop geospatially gridded datasets for comparison in the respective top-down analyses.

Region	Year	Bottom-up model	Bottom-up estimate	Top-down estimate	Scale factor	Reference
Globe USA	2009–2011	EDGAR	111 8.9	116 ± 10 14.8 ± 2.2	105% 166%	Turner *et al* (2015)
USA	2004	US EPA EDGAR	8.8 8.5	12.2 ± 1.3	139% 144%	Wecht *et al* (2014)
USA	2007–2008	US EPA EDGAR	9.3 8.9	17.0 ± 6.7	181% 190%	Miller *et al* (2013)
US Midwest	2016–2017	US EPA EDGAR	2.6 2.7	4.8 ± 1.5	185% 178%	Chen *et al* (2018)
US Upper Midwest	2017–2018	US EPA	3.3	4.11 ± 0.54	124%	Yu *et al* (2021)
California, USA	2013–2014	CALGEM	0.90	1.33 ± 0.40	149%	Jeong *et al* (2016)
E. Ontario, Canada	April–May 2011	IPCC Tier 2	0.013 ± 0.002	0.027 ± 0.006	217%	Desjardins *et al* (2018)
US Southeast	August–September 2013	US EPA	3 ± 0.5	2.9 ± 0.3	97%	Sheng *et al* (2018)

cycle. The Southeastern US is also an area of abundant wetland emissions (8–16 Tg CH_4 yr^{-1}), with close proximity to animal production areas, making accurate source partitioning challenging (Miller *et al* 2015).

The bottom-up models included in these sources use agricultural survey and census data on farmed animal populations, and use IPCC standards (predominantly Tier 2) to calculate their emissions factors. The bottom-up estimates (table 1, column 4) correspond to various base years and bottom-up models (table 1, columns 2 and 3 respectively) and model versions. Future work is therefore needed to compare bottom-up and top-down emissions estimates using the most recent bottom-up model versions across their respective regions and base years. While the models differ in assumptions made to calculate emissions factors, i.e. assumptions reflecting how animals are fed, housed, and raised, feeds tend to be energy-rich and animal production methods are intensive and confined throughout the US and Canada.

The discrepancies between bottom-up and top-down estimates in the US and Canada imply that models may under-predict the emissions intensity of animals raised in intensive, predominantly confined systems. This pattern furthermore suggests that a greater proportion of total global methane emissions from animals is coming from intensive systems than is routinely reported.

3.2. Why North American emissions may be underestimated by models

It is unclear why the modeled methane emissions from farmed animals in the US are often lower than emissions inferred from atmospheric measurements. Discrepancies do not seem specific to one animal or system. For example, Jeong *et al* (2016) analyzed airborne measurements from California and were able to partition emissions between dairy cattle and other animals. They found dairy cattle and other non-dairy animals' emissions were 45% and 69% higher, respectively, than the bottom-up model predicted. Therefore, emissions from multiple animal species may be underestimated by the bottom-up emissions models.

Bottom-up models also appear to routinely underpredict emissions from manure. Models of manure emissions are based on laboratory experiments within controlled test chambers. When methane is measured outside of the lab, in the air directly above manure tanks, pits, and piles, emissions tend to be greater than models predict, sometimes by more than 300% (Owen and Silver 2015). However, because manure represents approximately 11% of animal methane emissions, this difference is still not large enough to explain the gap in US animal methane emissions (Wolf *et al* 2017).

High methane emissions may also stem from animal disease. Infections in animals are widespread in intensive production systems; approximately one

quarter of US dairy cows have mastitis—a swelling and infection of udders accompanied by secretion of somatic cells into the milk (USDA 2016). Among beef cattle, nearly all feedlots have at least some cattle affected by bovine respiratory disease complex (BRDC or 'shipping fever') or lameness; BRDC has been detected in 16%, digestive disorders in 4%, and lameness in 2% of the entire US feedlot beef cattle population (USDA 2013). Digestive disorders and infectious parasites have multiple adverse effects on enteric fermentation emissions; they (a) decrease digestion efficiency, hence increasing overall feed requirements and methane output per unit of production (Houdijk *et al* 2017, Fox *et al* 2018) and (b) increase methane yield per unit of feed. The former tendency may be missed by bottom-up models if entirely healthy cattle are being taken as representative of the entire herd. The latter tendency cannot be represented at all by Tier 2 emissions methods models (Dong *et al* 2006, Gavrilova *et al* 2019), and would require new methods that could account for unhealthy/infected proportions of the herd. A full accounting for animal diseases, which are prevalent in modernized intensive systems, may result in bottom-up emissions that are higher than commonly reported.

The current body of top-down estimates is insufficient to understand precisely why bottom-up models may underpredict animal emissions. The metabolic processes that generate emissions (e.g. manure and belches) are highly co-located relative to the large and distant spatial scales at which atmospheric measurements for top-down estimates occur. Multiple inputs and metabolic processes contribute to the rate of methane conversion in an individual animal or manure storage system. In the future, a greater number of atmospheric measurements performed at smaller spatial scales, located in closer proximity to facilities where manure storage is separated animals enteric fermentation, could be utilized to better partition which types of animals, processes, and production systems are most responsible for driving the discrepancies.

4. Animal emissions in an international development context

4.1. Case study: intensification in East and Southeast Asia

Intensification in ESA, which includes mainland China, is expected to reduce marginal emissions substantially (Wang *et al* 2017, Yu *et al* 2018, FAO 2018a). A recent analysis of animal emissions in China recommends increasing per-capita production of animal products (Yu *et al* 2018), finding that improved efficiency will offset the increase in production and provide net methane emission reductions overall. The benefits of intensification, however, vary case by case, and by the proportions of direct and indirect GHG emissions, which can vary widely geographically (Poore and Nemecek 2018).

The following synthesis aims to approximately correct or scale future GHG emissions projections in the ESA region for direct animal emissions. We adjust the proportion of direct emissions in bottom-up emissions estimates by a mean and range of scaling factors derived from the USA top-down emissions scaling factors. This analysis serves as a prospective correction, outlining a possible consequence of business-as-usual development, but it is not a definitive prediction. The specific metabolic processes and source categories that can fully explain the discrepancy in North American emissions (table 1) are still unknown, including but not limited to manure methane fluxes influenced by climate and geography (Dong *et al* 2006). However, we expect that this analysis will approximately account for changes in the increased use of landless, intensive systems in the region, with common industrial production characteristics that are increasingly deployed in the ESA region and throughout the developing world (Wasley and Heal 2020).

The 2050 projections were taken from FAO, using regionally appropriate emissions factors from IPCC (FAO 2018a). The data are available on the online FAO data portal 'Food and Agriculture Projections through 2050 (www.fao.org/global-perspectives-studies/food-agriculture-projections-to-2050/en/). We used agricultural emissions and livestock herd size data from the 'business-as-usual' projection (FAO 2018a) and disaggregated further where necessary by supplementing this data with public data from FAO GLEAM, which further partitions emissions into production categories GHGs, and lifecycle processes (FAO 2017).

Total demand for animal-sourced foods is increasing in ESA concurrently with intensification. Emissions of each unit of production are assumed to decrease in the near future according to prospective bottom-up estimates (figure 2(A)). As a result of these two counterbalancing forces, animal emissions are expected to increase by 2030, then gradually go down until they return to early 2000s levels by 2050 (figure 2(B)). However, these bottom-up emission projections may overestimate the benefit of intensification.

If the share of direct GHG emissions projected to come from intensive systems is scaled in proportion with top-down US estimates (scaled up by 65%, the average inferred from top-down estimates, provided in table 1), future emissions per unit of meat and dairy will not decrease as much as FAO bottom-up estimates predict (figure 2(C)). Multiplying this emission intensity by total consumption, we find that the ESA region could reach 1.52 (1.41–1.62 total range) $GtCO_2eq$ by 2050, an amount 21% (13%–29%) higher than previously predicted (figure 2(D)).

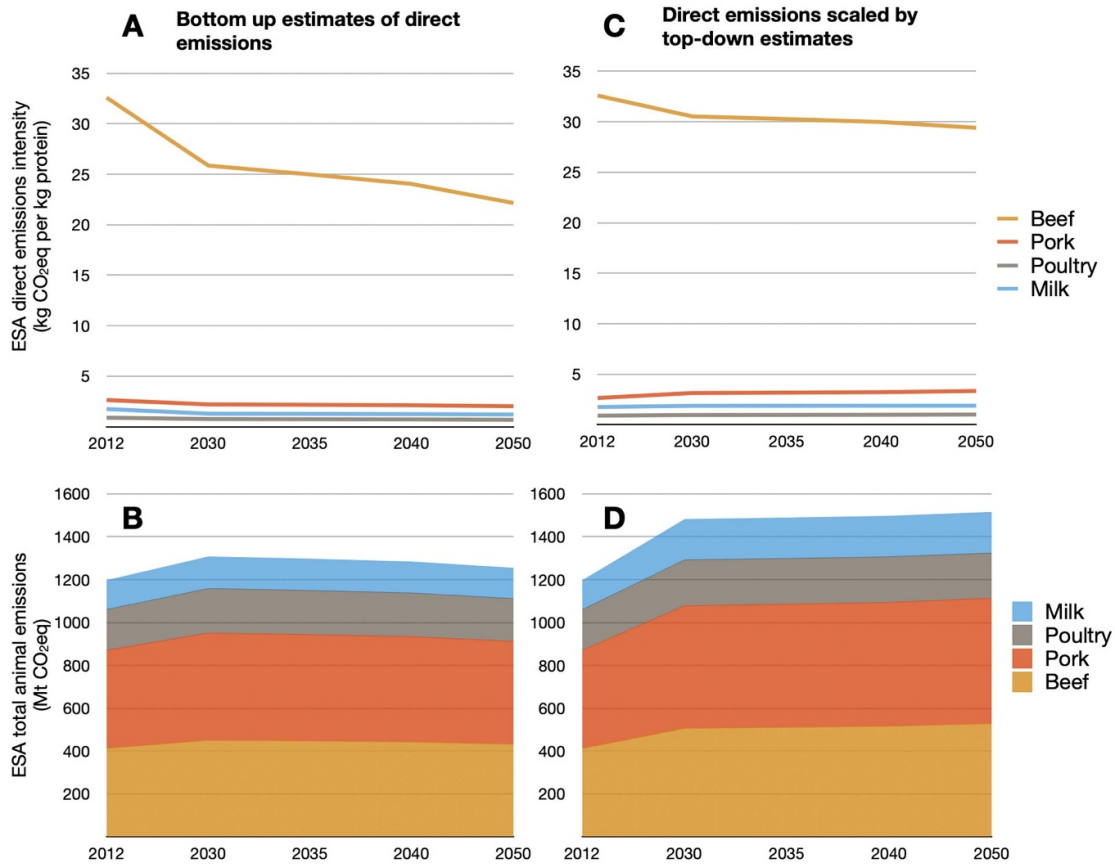

Figure 2. Present and future emissions intensities and total emissions from animal production in ESA, as estimated by bottom-up emissions models (A)–(B) and direct emissions from intensive production adjusted by a scale factor (1.65) derived from the average of top-down emissions estimates in the US (C)–(D).

Indirect emissions account for approximately 40%–50% of animal agriculture's emissions. This prospective analysis leaves indirect emissions unaltered (e.g. nitrous oxide from fertilizer applied to animal feeds and CO_2 emissions from land use change) while adjusting direct CH_4 emissions and also N_2O emissions from manure management; N_2O emissions appear to be similarly or more dramatically higher than bottom-up estimates when assessed using top-down methods (Owen and Silver 2015). Estimates of CO_2 from fossil fuel and land use change, which are indirect emissions processes in animal agricultural production, generally show good agreement among bottom-up and top-down assessments (Friedlingstein *et al* 2020). However, the implications for animal agriculture in developing contexts is highly uncertain, due to large geographic and seasonal variation in the discrepancies between emissions patterns and because patterns of feed crop trade through 2050 are uncertain. These complexities would make assessing the effects of indirect emissions estimates adjustments substantially more speculative, hence an assessment of indirect emissions estimate corrections was outside of our scope. By not altering indirect emissions, we produce a conservative estimate.

This case study is limited in terms of the confidence with which we can project and scale such differences, however. Uncertainties are not reported by FAO in their ESA regional emissions through 2050, which is a common tendency in bottom-up emissions estimates and projections. We discuss measures needed to improve uncertainty analysis in section 2.1. A fuller analysis regarding how uncertainties in this and other bottom-up emissions compound is outside of the scope of this review and prospective analysis, but is urgently needed.

We express emissions in our ESA case study in CO_2 equivalence (CO_2e) using GWP_{100}, although we acknowledge that this is limited in by placing short- and long-lived gases on the same scale. Recent analyses and commentary have proposed a new approach of GWP*, which includes information about the rate of change in shorter-lived pollutants like methane (Collins *et al* 2020, Lynch *et al* 2020). We share the concerns motivating the development of an alternative CO_2 equivalence metric. However, we did not adopt this new method for recalculating CO_2e due to (a) maintaining consistency for a comparison with previous FAO summary findings and (b) a lack of consensus regarding the appropriateness of assumptions embedded in GWP*, still inspiring active debate on topic (e.g. Rogelj and Schleussner 2019, Smith and Balmford 2020). Ultimately, there are limitations to any method of calculating an equivalence of all

climate pollutants to just one chemical species, rather than directly calculating their effects on temperature. However, this is only a limitation of our ESA case study and not the discrepancies found in our review of methane emissions themselves (table 1), in which we compare Tg of CH_4 directly.

Our prospective analysis demonstrates that animal emissions in the ESA region may not plateau in by 2030, as has previously been projected. While the majority of emissions increase is expected to occur by 2030 (figure 2(B)), this increase may be higher than expected (figure 2(D)) and total emissions may still slightly increase for multiple decades as consumer demand in the region continues to rise.

Despite this uncertainty, our illustrative example of ESA demonstrates that widescale adaptation of intensive production methods in low- and middle-income countries may have limited benefits to GHG emissions, especially if demand continues to grow.

4.2. The limits of intensification for sustainable development

Recommendations to intensify animal production are ubiquitous in the scientific literature (Thornton and Herrero 2010, Gerber *et al* 2013, Swain *et al* 2018, Grossi *et al* 2019). Such suggestions shape policies that disseminate intensive production technologies to low- and middle-income countries. Such policies include sustainable lending criteria from international development banks (World Bank International Finance Corporation 2012), and government subsidies and incentives, which in turn influence and are influenced by the actions of multinational meat and dairy producers (Lazarus *et al* 2021).

Policies that incentivize landless and industrialized animal production methods risk amplifying other public health and environmental harms. Low-interest loans for such animal production operations cover the capital costs of building large shed-like facilities that confine tens to hundreds of thousands of animals indoors (Wasley and Heal 2020) in a manner that often highly restricts their movement and expressions of natural behavior (Prunier *et al* 2010, Grandin 2016, Widowski *et al* 2016). Such facilities require high levels of subtherapeutic antibiotics (Silbergeld *et al* 2008), leading to antibiotic resistance, and encourage the rapid transmission and mutation of viruses with pandemic potential (Alders *et al* 2014, Millman *et al* 2017, Lycett *et al* 2019) including highly pathogenic avian influenzas (HPAI, also known as 'bird flu'). Intensified animal production poses a litany of zoonotic disease risks (UNEP and ILRI 2020). Large concentrated quantities of production and storage also create point and non-point sources of groundwater pollution and can degrade air quality (Secchi and Mcdonald 2019, Domingo *et al* 2021).

While the efficiency of feeding and fattening allowed by intensified animal production can reduce indirect land use, confined forms of animal production including landless and industrialized systems Intensification can lead to further homogeneity of food systems and exacerbates zoonotic disease risks (UNEP and ILRI 2020) including interspecies transmissions of and other infectious viruses.

Public and private institutions must fully evaluate socio-environmental externalities and risks of intensified animal production systems in their policies that finance and incentivize their expansion. Continuing to export these technologies and practices to developing regions could achieve less GHG mitigation than commonly assumed while exacerbating other socio-environmental harms.

4.3. The climate mitigation potential of agricultural development

The climate impacts of growing demand for meat and dairy have implications for keeping global warming within safe limits. Most countries have not committed to reducing non-CO_2 gases (Climate Action Tracker, Wang *et al* 2018), including methane and nitrous oxide from animals. Previous analysis has demonstrated that if countries aggressively limit CO_2 from fossil fuels, growth in meat and dairy consumption would be sufficient to cause warming of above 2 °C even with aggressive mitigation in other sectors (Harwatt *et al* 2020) and business-as-usual growth in animal sourced food production, efficiency, and consumption would exceed the entire GHG budget compatible with a 1.5 °C threshold of warming (Clark *et al* 2020). The aforementioned findings were all informed by bottom-up models, which may underestimate emissions from intensive production systems that are proliferating globally. Growth in meat and dairy production and consumption therefore may be even more incompatible with limiting global warming than previously reported.

Our prospective analysis demonstrates that GHG emissions could increase as developing regions intensify production. On one hand, intensive systems could achieve GHG mitigation with improved technologies such as anaerobic manure digestors that capture biomethane for fuel usage (Paolini *et al* 2018) and concentrated feeds supplemented with enteric fermentation suppressants such as 3-nitrooxypropanol and seaweeds (Machado *et al* 2016, Jayanegara *et al* 2018). On the other hand, ambitious interventions and improvements in efficiencies have the potential to mitigate less than a quarter of annual agricultural emissions relative to business-as-usual (Höglund-Isaksson *et al* 2020).

GHG emissions are not the only indicator of sustainability, and GHG suppression measures for intensively-raised animals could incentivize animal concentration at larger scales, exacerbating co-impacts such as water pollution load and antimicrobial resistance, especially if such technologies require additional subsidies to remain economically

viable (Eker *et al* 2019). Sustainability encompasses multiple dimensions, including multiple environmental impacts, social equity, and economic feasibility. Effective sustainable development strategies for food systems are uncommon because they must provide benefits across multiple dimensions and goals (Rasmussen *et al* 2018).

Socio-environmental benefits could be realized by providing resources in areas of pastoral production for intensification practices that do not involve confinement to similar levels of intensive US 'landless' systems. Such practices include improved animal veterinary care, improved forage seeds and pasture management, and more precise nutrient application. Improved coordination between smallholder and midsize producers, government, and NGOs can hasten these benefits (Swain *et al* 2018, FAO 2018b, IPCC 2019). Intensification may be effective in optimizing co-benefits in some circumstances, especially in regions where indirect emissions are large (e.g. ongoing land-use change, including deforestation).

Reducing externalities of further intensification also depends upon limiting overall consumer demand, particularly in regions where animal-sourced food consumption already exceeds nutritional requirements. Improved productivity and lower prices can lead to runaway effects of stimulating greater demand a feedback process known as Jevons Paradox (Garnett *et al* 2015), and stimulate more production by decreasing input costs (Kreidenweis *et al* 2018). Feedback effects between supply and demand can therefore undermine or worsen the environmental impacts that intensification efforts seek to mitigate. Mitigation policies should address the overconsumption of animal-sourced foods to avoid these feedback effects, rather than merely focusing on improving production.

Managing both supply and demand of animal-sourced foods must be considered within efforts to reform and develop food systems sustainably while mitigating climate change (IPCC 2019, Clark *et al* 2020, Harwatt *et al* 2020). Such efforts could include reforming dietary recommendations to reflect regional environmental impacts and planetary boundaries (Willett *et al* 2019, Springmann *et al* 2020), developing public-private partnerships to stimulate production and demand of plant-based proteins (Attwood *et al* 2019), and changing taxation and subsidy structures to reflect the true environmental costs of meat and dairy production across multiple impacts (IPCC 2019).

In addition to limiting overall consumption, more steps are necessary to ensure that intensification strategies maximize co-benefits and constrain potential externalities. These include (a) marrying intensification with strong environmental conservation policies (Garrett *et al* 2018, Kreidenweis *et al* 2018) (b) improving farmer livelihoods and disincentivizing industry consolidation that can crowd out smallholder producers, and (c) avoiding extreme forms of confinement entailed in many landless and industrialized systems, which also promote zoonotic disease emergence and antimicrobial resistance (UNEP and ILRI 2020). This last criterion may prove an exceedingly difficult needle to thread if demand for animal-sourced foods continues to increase unabated. All of the above and more is required to ensure that the intensification of animal agriculture does not further amplify multiple environmental risks including climate change, biodiversity loss, and the emergence of potentially pandemic zoonotic diseases.

10. EMISSIONS FROM LIVESTOCK AND MANURE MANAGEMENT

Users are expected to go to Mapping Tables in Annex 1 Volume 4 (AFOLU), before reading this chapter. This is required to correctly understand both the refinements made and how the elements in this chapter relate to the corresponding chapter in the 2006 IPCC Guidelines.

10.1 INTRODUCTION

This chapter provides guidance on methods to estimate emissions of methane from Enteric Fermentation in livestock, and methane and nitrous oxide emissions from Manure Management. Carbon dioxide (CO_2) emissions from livestock are not estimated because annual net CO_2 emissions are assumed to be zero – the CO_2 photosynthesized by plants is returned to the atmosphere as respired CO_2. A portion of the C is returned as methane (CH_4) and for this reason CH_4 requires separate consideration.

Livestock production can result in CH_4 emissions from enteric fermentation and both CH_4 and nitrous oxide (N_2O) emissions from livestock manure management systems. Cattle are an important source of CH_4 in many countries because of their large population and high CH_4 emission rate due to their ruminant digestive system. Methane emissions from manure management tend to be smaller than enteric emissions, with the most substantial emissions associated with confined animal management operations where manure is handled in liquid-based systems. Nitrous oxide emissions from manure management vary significantly between the types of management system used and can also result in indirect emissions due to other forms of nitrogen loss from the system. The calculation of the nitrogen loss from manure management systems is also an important step in determining the amount of nitrogen that will ultimately be available in manure applied to managed soils, or used for feed, fuel, or construction purposes – emissions that are calculated in Chapter 11, Section 11.2 (N_2O emissions from managed soils).

The methods for estimating CH_4 and N_2O emissions from livestock require definitions of livestock subcategories, annual populations and, for higher Tier methods, feed intake and characterisation. The procedures employed to define livestock subcategories, develop population data, and characterize feed are described in Section 10.2 (Livestock Population and Feed Characterisation). Suggested feed digestibility coefficients for various livestock categories have been provided to help estimation of feed intake for use in calculation of emissions from enteric and manure sources. A coordinated livestock characterisation as described in Section 10.2 should be used to ensure consistency across the following source categories:

Section 10.3 - CH_4 emissions from Enteric Fermentation;

Section 10.4 - CH_4 emissions from Manure Management;

Section 10.5 - N_2O emissions from Manure Management (direct and indirect);

Chapter 11, Section 11.2 - N_2O emissions from Managed Soils (direct and indirect).

In calculating agricultural emissions, it is important to establish consistency among the different emission sources. Key drivers of emissions such as animal weight and productivity must be treated using the same parameters for emissions of enteric and manure management CH_4, as well as N_2O from manure management. Further, Section 10.5.4 discusses the coordination between N_2O emissions from Manure Management and Managed Soils. Emissions of N_2O from nitrogen excretion should be assessed following a nitrogen mass flow approach which is further explained in Section 10.5.6 and illustrated in Figure 10.5.

10.2 LIVESTOCK POPULATION AND FEED CHARACTERISATION

10.2.1 Steps to define categories and subcategories of livestock

No refinement.

10.2.2 Choice of method

TIER 1: BASIC CHARACTERISATION FOR LIVESTOCK POPULATIONS

Basic characterisation for Tier 1 is likely to be sufficient for most animal species in most countries. For this approach it is *good practice* to collect the following livestock characterisation data to support the emissions estimates:

Livestock species : A complete list of all livestock populations by species that have default emission factor values must be developed (e.g., dairy cows, other cattle, buffalo, sheep, goats, camels, llamas, alpacas, deer, horses, rabbits, mules and asses, swine, and poultry) if these species are relevant to the country. Populations by species can also be further subdivided by category. Category refers to classification inside a species by different relevant attributes as sex, age or productive purpose in a relevant production system in any given country (e.g. in the case of cattle: mature males and females, replacement heifers, calves, etc.). More detailed categories should be used if the data are available. For example, more accurate emission estimates can be made if poultry populations are further subdivided (e.g., layers, broilers, turkeys, ducks, and other poultry), as the waste characteristics among these different populations vary significantly.

Annual population: If possible, inventory compilers should use population data from official national statistics or industry sources. Food and Agriculture Organisation (FAO) data, FAOSTAT and other FAO statistics, can be used if national data are unavailable. Seasonal births or slaughters may cause the population size to expand or contract at different times of the year which will require the population numbers to be adjusted accordingly. It is important to fully document the method used to estimate the annual population, including any adjustments to the original form of the population data as it was received from national statistical agencies or from other sources. When population by species is subdivided by categories it is important to fully document any adjustments done in the population to match the categories used in the inventory compilation.

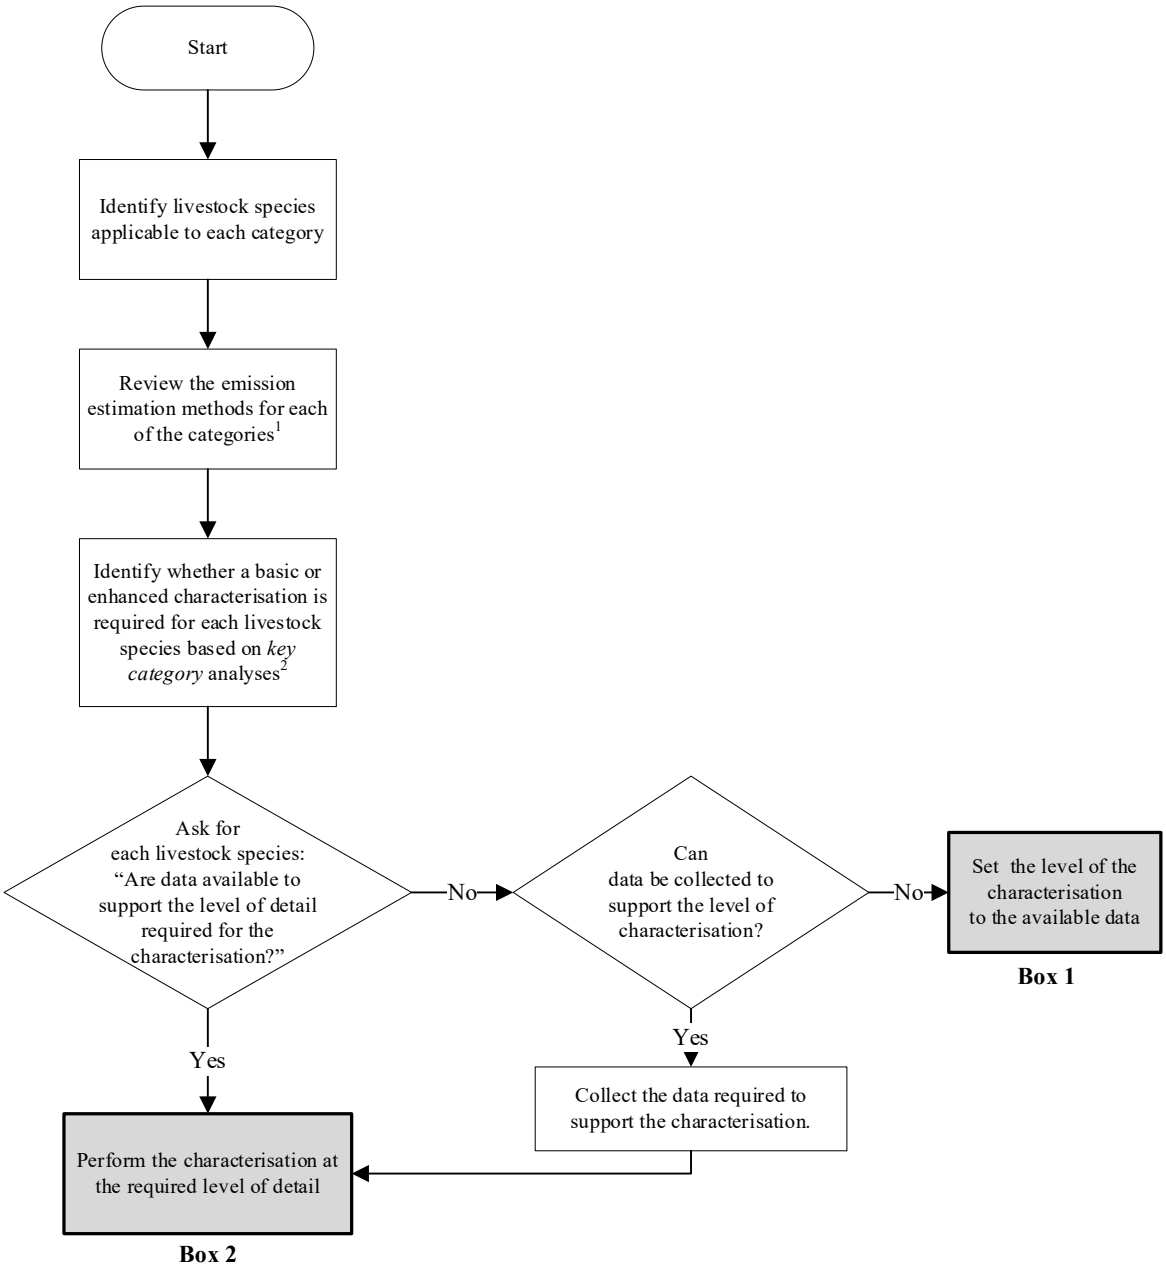
Compilers could consider to communicate/share the annual population data needs with the national statistical agency and/or the other sources from which the data was obtained, so this sources are better aware of the needs of inventory compilers. In addition, national statistical agencies and agencies responsible for inventory compilation can work closely together to ensure that official statistics better meet the needs of the inventory compilers.

Annual average populations are referred to as the number of head of livestock species per category within a given country ($N_{(T)}$). This can be estimated in various ways, depending on the available data and the nature of the animal population. In the case of static animal populations (e.g. dairy cows, breeding swine, layers), estimating the number of head of a given livestock species in the country ($N_{(T)}$) may be as simple as obtaining data related to one-time animal inventory data. However, estimating $N_{(T)}$ for a growing population (e.g., meat animals, such as broilers, turkeys, beef cattle, and market swine) requires more evaluation. Most animals in these growing populations are alive for only part of a complete year. Animals should be included in the populations regardless if they were slaughtered for human consumption or die of natural causes. Equation 10.1 estimates $N_{(T)}$.

EQUATION 10.1 (UPDATED)
ANNUAL AVERAGE POPULATION

$$N_T = Days_alive \bullet \left(\frac{NAPA}{365} \right)$$

Where:



N_T = the number of head of livestock species / category T in the country (equivalent to annual average population)

$NAPA$ = number of animals produced annually

Broiler chickens are typically grown approximately 60 days before slaughter. Estimating $N_{(T)}$ as the number of grown and slaughtered over the course of a year would greatly overestimate the population, as it would assume each lived the equivalent of 365 days. Instead, one should estimate the average annual population as the number of animals grown divided by the number of growing cycles per year. For example, if broiler chickens are typically grown in flocks for 60 days, an operation could turn over approximately 6 flocks of chickens over the period of one year. Therefore, if the operation grew 60,000 chickens in a year, their average annual population would be 9,863 chickens. For this example the equation would be:

Annual average population = 60 days * 60,000 / 365 days / yr = 9,863 chickens

Figure 10.1 Decision tree for livestock population characterisation

Note:

1: These categories include: CH_4 from Enteric Fermentation, CH_4 from Manure Management, N_2O from Manure Management.

2: See Volume 1 Chapter 4, "Methodological Choice and Identification of Key Categories" (noting Section 4.1.2 on limited resources), for discussion of *key categories* and use of decision trees.

Consideration of differing Productivity systems (Tier 1a)

In certain countries agricultural production systems may be transitioning from low productivity local subsistence systems to higher productivity systems aimed at fulfilling national and export markets or may simply have dual agricultural systems, with coexistence of low and high productivity systems clearly identified. In these cases inventory compilers may wish to use the Tier 1a approach in which they are able to better track the transitions and

changes in the productivity of their agricultural systems and related emissions over time. Tier 1a emission factors (on a per head basis) have been developed for use with basic population estimates separated by low and high productivity systems according to the definitions below.

In this case animal populations by species may be divided by productivity systems. For each animal species high and low productivity systems may be defined according to characteristics such as: feedbase, genetics, purpose (draft, cultural reasons, self-consumption, market), production objectives (e.g. milk, meat, eggs), and level of inputs and outputs.

Definitions of High and Low Productivity Systems

Dairy Cattle and milk production:

The dairy cow population is estimated separately from other cattle (see Table 10.1). Dairy cows are defined in this method as mature cows (first lactation and beyond) that are producing milk in commercial quantities for consumption. This definition corresponds to the dairy cow population reported in FAO, IDF, IFCN (2014). Dairy cow population should not be confused with multi-purpose cows that may be used for more than one production purpose milk, meat or draft.

In some countries the dairy cow population is comprised of two well-defined segments:

High-productivity systems are based on high-yielding dairy cows that are concentrated in confinement production systems or grazing on high quality pastures with supplements. The farms are 100 percent market oriented for commercial milk production, for national markets and/or export; Purebred or crossbred cattle are genetically improved through selective breeding for milk production (FAO, IDF, IFCN 2014). Indicative levels of high milk productivity by cow corresponding to a given region are included in Table 10.11 to guide the selection of the emission factors.

Low productivity systems are based on low-yielding dairy cows, grazing non-improved pastures, and using locally produced roughage (e.g. crop residues), and agro-industrial by-products. Local breeds or crossbred cows are bred locally, without intensive selection for milk productivity. Milk production is mostly for local market and local consumption (FAO, IDF, IFCN. 2014). Indicative levels of low milk productivity by cow corresponding to a given region are included in Table 10.11 to guide the selection of the emission factors.

Dairy buffalo may be categorized in a similar manner to dairy cows.

Other cattle:

High-productivity systems are based on animal feeding systems using forage (e.g. high-quality grass) and concentrates in confinement production systems or grazing with supplements or on improved pastures, producing high rates of daily weight gain. Animals can be purebred or crossbred and are genetically improved through selective breeding for improved commercial meat production. Growing cattle may be finished young in "intensive grazing with supplements" or feedlot systems, and meat is produced for national markets and/or export (FAO, IDF, IFCN 2014).

Low productivity systems are based on animal feeding systems where locally produced roughage (e.g. crop residues) or low quality rangelands represent the major source of feed utilized, producing low rates of daily weight gain. Animals can be represented by local breeds or may be crossbred and can also be used for multiple purposes such as draft, meat and milk for self consumption and markets (FAO, IDF, IFCN 2014).

Other livestock species:

High-productivity systems, which are 100 percent market oriented with high level of capital input requirements and high level of overall herd (flock) performance. Feed is purchased from local or international market or intensively produced on farm. Animals are improved through breeding practices for commercial production. The high-productivity systems are common in swine, poultry, goats and sheep production (MacLeod *et al*. 2017).

Low productivity systems which are mainly driven by local market or by self-consumption, with low capital input requirements and low level of overall herd (fowl) performance typically using large areas for production or backyards. Locally produced feed represents the major source of feed utilized or animals are kept-free range for major part or all of their production cycle, the yield of the activity being linked to the natural fertility of the land and the seasonal production of the pastures. The low-productivity systems are common in swine, poultry, goats and sheep production (MacLeod *et al*. 2017).

International statistics sources for activity data, parameters and tools related to animal population

FAO provides international statistical information for livestock characterization, including population and production. Relevant sources are: FAOSTAT Production database and FAO World Census of Agriculture 2020. Additionally, FAO provides a free access e-learning course to support developing countries in the preparation of the national GHG inventory for the agriculture sector. FAO also provides tools that may be useful for inventory compilers in the agriculture sector as the FAOSTAT Emissions Analysis Tools, to identify data gaps and perform QA/QC analysis. Another tool is the Global Livestock Environmental Accounting Model (GLEAM), which is a GIS-based model for livestock production activities and related resource flows in all countries. The FAO-IPCC-IFAD workshop report (IPCC, 2015), identifies the list of all FAOSTAT and other FAO data sources in support of National Inventory compilation in the AFOLU sector.

TIER 2: ENHANCED CHARACTERISATION FOR LIVESTOCK POPULATIONS

The Tier 2 livestock characterisation requires detailed information on:

- Definitions for livestock subcategories;
- Livestock population by subcategory, with consideration for estimation of annual population as per Tier 1; and
- Feed intake estimates for the typical animal in each subcategory.

The livestock population subcategories are defined to create relatively homogenous sub-groupings of animals. By dividing the population into these subcategories, country-specific variations in age structure and animal performance within the overall livestock population can be reflected.

The Tier 2 characterisation methodology seeks to define animals, animal productivity, diet quality and management circumstances to support a more accurate estimate of feed intake for use in estimating methane production from enteric fermentation. The same feed intake estimates should be used to provide harmonised estimates of manure and nitrogen excretion rates to improve the accuracy and consistency of CH_4 and N_2O emissions from manure management.

Definitions for livestock subcategories

It is *good practice* to classify livestock populations into subcategories for each species according to age, type of production, and sex. Representative livestock categories for doing this are shown in Table 10.1. Further subcategories are also possible:

- Cattle and buffalo populations should be classified into at least three main subcategories: mature dairy, other mature, and growing cattle. Depending on the level of detail in the emissions estimation method, subcategories can be further classified based on animal or feed characteristics. For example, growing / fattening cattle could be further subdivided into those cattle that are fed with a high-grain diet and housed in dry lot vs. those cattle that are grown and finished solely on pasture.
- Subdivisions similar to those used for cattle and buffalo can be used to further segregate the sheep population in order to create subcategories with relatively homogenous characteristics. For example, growing lambs could be further segregated into lambs finished on pasture vs. lambs finished in a feedlot. The same approach applies to national goat herds.
- Subcategories of swine could be further segregated based on production conditions. For example, growing swine could be further subdivided into growing swine housed in intensive production facilities vs. swine that are grown under free-range conditions.
- Subcategories of poultry could be further segregated based on production conditions. For example, poultry could be divided on the basis of production under confined or free-range conditions.

TABLE 10.1 (UPDATED)
Representative livestock categories[1,2]

Main categories	Production categories Tier 1a	Subcategories
Mature Dairy Cow or Mature Dairy Buffalo	High Productivity Systems	High-producing cows that have calved at least once and are used principally for milk production
	Low Productivity Systems	Low-producing cows that have calved at least once and are used principally for milk production
Other Mature Cattle or Mature Non-dairy Buffalo	High Productivity Systems	Females:
		• Cows used to produce offspring for meat
		• Cows used for more than one production purpose: milk, meat, draft
		Males:
		• Bulls used principally for breeding purposes
	Low Productivity Systems	Females:
		• Cows that may be used for more than one production purpose: milk, meat, draft
		Males:
		• Bulloks used principally for draft power
Growing Cattle or Growing Buffalo	High Productivity Systems	• Calves pre-weaning
		• Replacement dairy heifers
		• Growing / fattening cattle or buffalo post-weaning
		• Feedlot-fed cattle on diets containing > 85% concentrates
	Low Productivity Systems	• Calves pre-weaning
		• Growing / fattening cattle or buffalo post-weaning
Mature Sheep	High productivity systems	• Breeding ewes for production of offspring and wool production
		• Milking ewes where commercial milk production is the primary purpose
		• Other Mature Sheep (> 1 year)
	Low productivity systems	• Breeding ewes for production of offspring and wool production
		• Other Mature Sheep (> 1 year)
Growing Sheep (lambs)	High productivity systems	• Intact Males, Castrates and Females, concentrate-fed.
	Low productivity systems	• Castrates and Females, grass-fed.

TABLE 10.1 (UPDATED) (CONTINUED)
Representative livestock categories[1,2]

Main categories	Production categories Tier 1a	Subcategories
Goats	High productivity systems	• Dairy Does
		• Mature does
		• Yearlings
		• Bucks
		• Kids (<1 yr)
	Low productivity systems	• Mature does
		• Yearlings
		• Bucks
		• Kids (<1 yr)
Mature Swine	High Productivity Systems	• Sows in gestation
		• Sows which have farrowed and are nursing young
		• Boars that are used for breeding purposes
	Low Productivity Systems	• Sows in gestation
		• Sows which have farrowed and are nursing young
		• Boars that are used for breeding purposes
Growing Swine	High Productivity Systems	• Nursery
		• Growing/Finishing
		• Gilts that will be used for breeding purposes
		• Growing boars that will be used for breeding purposes
	Low Productivity Systems	• Growing / fattening swine
		• Free-range growing swine
		• Gilts/boars that will be used for breeding purposes
Chickens	High Productivity Systems	• Broiler chickens grown for producing meat in confinement systems • Breeder Broiler chickens grown in confinement systems
		• Layer chickens for producing eggs, where manure is managed in dry systems (e.g., high-rise houses)
		• Layer chickens for producing eggs, where manure is managed in wet systems (e.g., lagoons)
		• Chickens under free-range conditions for egg or meat production
	Low Productivity Systems	• Chickens under free-range conditions for egg or meat production
Turkeys	High Productivity Systems	• Breeding turkeys in confinement systems
		• Turkeys grown for producing meat in confinement systems
		• Turkeys under free-range conditions for meat production
	Low Productivity Systems	• Turkeys under free-range conditions for meat production

	• Rabbits	
	• Horses	
	• Deer	
	• Ostrich	
	• Geese	
[1] Source IPCC Expert Group [2] Emissions should only be considered for livestock species used to produce food, fodder or raw materials used for industrial processes.		

For large countries or for countries with distinct regional differences, it may be useful to designate regions and then define categories within those regions. Regional subdivisions may be used to represent differences in climate, feeding systems, diet, and manure management. However, this further segregation is only useful if correspondingly detailed data are available on feeding and manure management system usage by these livestock categories.

The livestock classification that is chosen should be consistent for all emission sources, enteric and manure management methane and N_2O from manure management. For each of the representative animal categories defined, the following information is required:

- Annual average population (number of livestock or poultry as per calculations for Tier 1);
- Average daily feed intake (megajoules (MJ) per day or kg per day); and
- Methane conversion factor (Y_m) percentage of feed energy converted to methane;

Generally, data on average daily feed intake are not available, particularly for grazing livestock. Consequently, the following general data should be collected for estimating the feed intake for each representative animal category;

- Weight (kg);
- Average weight gain per day (kg)[1];
- Feeding situation: confined, grazing, pasture conditions;
- Average milk production per day (kg/day), fat and protein content;
- Average amount of work performed per day (hours day^{-1});
- Percentage of females that give birth in a year[2];
- Wool growth;
- Number of offspring;
- Digestibility of feed, expressed as the percentage of digestible energy in feed gross energy (DE, percent);
- Crude protein in diet (CP, percent);

[1] This may be assumed to be zero for mature animals.

[2] This is only relevant for mature females.

- Neutral Detergent Fibre (NDF, % DMI), proportion of feed composed of insoluble fibres, hemicellulose, cellulose, lignin and some protein fractions.

Feed intake estimates

Tier 2 emissions estimates require feed intakes for a representative animal in each subcategory. Feed intake is typically measured in terms of gross energy (e.g., mega joules (MJ) per day) or dry matter (e.g., kilograms (kg)) consumed per day. Dry matter is the amount of feed consumed (kg) after it has been corrected for the water content in the complete diet. For example, consumption of 10 kg of a diet that contains 70 percent dry matter would result in a dry matter intake of 7 kg. To support the enteric fermentation Tier 2 method for cattle, buffalo, and sheep (see Section 10.3), detailed data requirements and equations to estimate feed intake are included in the guidance below. Constants in the equations have been combined to simplify overall equation formats. The remainder of this subsection presents the typical data requirements and equations used to estimate feed intake for cattle, buffalo, sheep and goats. Feed intake for other species can be estimated using similar country-specific methods appropriate for each.

For all estimates of feed intake, *good practice* is to:

- Collect data to describe the animal's typical diet and performance in each subcategory;
- Estimate feed intake required from the animal performance and diet data for each subcategory.

In some cases, the equations may be applied on a seasonal basis, for example under conditions in which livestock gain weight in one season and lose weight in another. This approach may require a more refined variation of Tier 2 or more complex Tier 3 type methodology.

The following animal performance data are required for each animal subcategory to estimate feed intake for the subcategory:

Weight (W), kg: Live-weight data should be collected for each animal subcategory. It is unrealistic to perform a complete census of live-weights, so live-weight data should be obtained from representative sample studies or statistical databases if these already exist. Comparing live-weight data with slaughter-weight data is a useful cross-check to assess whether the live-weight data are representative of country conditions. However, slaughter-weight data should not be used in place of live-weight data as it fails to account for the complete weight of the animal. Additionally, it should be noted that the relationship between live-weight and slaughter-weight varies with breed and body condition. For cattle, buffalo and mature sheep, the yearly average weight for each animal category (e.g., mature beef cows) is needed. For young animals, weights are needed at birth, weaning, one year of age or at slaughter if slaughter occurs within the year. Slaughter weights can be utilized in live weight estimations if slaughter ages, dressing percentages and growth curves are also available.

Average weight gain per day (WG), kg day^{-1}: Data on average weight gain are generally collected for feedlot animals and young growing animals. Mature animals are generally assumed to have no net weight gain or loss over an entire year. Mature animals frequently lose weight during the dry season or during temperature extremes and gain weight during the following season. However, increased emissions associated with this weight change are likely to be small. Reduced intakes and emissions associated with weight loss are largely balanced by increased intakes and emissions during the periods of gain in body weight.

Mature weight (MW), kg: The mature weight of the adult animal of the inventoried group is required to define a growth pattern, including the feed and energy required for growth. For example, mature weight of a breed or category of cattle or buffalo is generally considered to be the body weight at which skeletal development is complete. The mature weight will vary among breeds and should reflect the animal's weight when in moderate body condition. This is termed 'reference weight' (AAC 1990) or 'final shrunk body weight' (NRC 1996). Estimates of mature weight are typically available from livestock specialists and producers. Mature weights of bulls may be 1.5 times higher than cows in the same genotype (Doren *et al*. 1989).

Average number of hours worked per day: For draft animals, the average number of hours worked per day must be determined.

Feeding situation: The feeding situation that most accurately represents the animal subcategory must be determined using the definitions shown below (Table 10.5). If the feeding situation is intermediate to the definitions given, the feeding situation should be described in detail. This detailed information may be needed when calculating the enteric fermentation emissions, because interpolation between the feeding situations may be necessary to assign the most appropriate coefficient value. Table 10.5 defines the feeding situations for cattle, buffalo, sheep and goats. For poultry and swine, the feeding situation is assumed to be under confinement conditions and consequently the activity coefficient (C_a) is assumed to be zero as under these conditions very little energy is expended in acquiring feed. Activity coefficients have not been developed for free-ranging swine or

poultry, but in most instances these livestock subcategories are likely to represent a small proportion of the national inventory.

Mean winter temperature (ºC): Detailed feed intake models consider ambient temperature, wind speed, hair and tissue insulation and the heat of fermentation (NRC, 2001; AAC, 1990) and are likely more appropriate in Tier 3 applications. A more general relationship adapted from North America data suggest adjusting the Cf_i of Equation 10.3 during the cold months for maintenance requirements of open-lot fed cattle in colder climates according to the following equation (Johnson, 1986):

EQUATION 10.2
COEFFICIENT FOR CALCULATING NET ENERGY FOR MAINTENANCE

$$Cf_i(in_cold) = Cf_i + 0.0048 \bullet (20 - °C)$$

Where:

Cf_i = a coefficient which varies for each animal category as shown in Table 10.4 (Coefficients for calculating NE_m), MJ day^{-1} kg^{-1}

$°C$ = mean daily temperature during winter season

Considering the average temperature during winter months, net energy for maintenance (NE_m) requirements may increase by as much as 30 percent in northern North America. This increase in feed use for maintenance leads to greater methane emissions. The Nutrient Requirements of Beef Cattle, 8th Revised Edition (2016) cautions that the general response to cold temperature can vary with thermal susceptibility of the animal, acclimation, and diet. Thus, Equation 10.2 may not be applicable for adapted animals, or for those protected by wind-breaks or shelter during cold weather. The equation should be applied to adjust the annual Cf_i for unsheltered animals during the period in which they are first exposed to sub-zero (ºC) temperatures, prior to their acclimation (a period of one to two months depending on the region).

Average daily milk production (kg day^{-1}): These data are for milking ewes, milking does, dairy cows and buffalo. The average daily production should be calculated by dividing the total annual production by 365, or reported as average daily production along with days of lactation per year, or estimated seasonal production divided by number of days per season. If using seasonal production data, the emission factor must be developed for seasonal period.

Fat content (percent): Average fat content of milk is required for lactating cows, buffalo, sheep and goats producing milk for human consumption.

Protein content (percent): Average protein content of milk is required for lactating cows, buffalo, sheep, and goats producing milk for human consumption.

Percent of females that give birth in a year: This is collected for cattle, buffalo, sheep and goats.

Number of off spring produced per year: This is relevant to female livestock that have multiple births per year (e.g., ewes).

Weaning age of calves: Prior to weaning and to the development of an active rumen, calves do not emit methane. Since calves pre-weaning is a livestock subcategory, it will in any case be necessary for a country to determine the weaning age and the diet composition pre-weaning to choose the appropriate emission factor.

Feed digestibility (DE): The portion of gross energy (GE) in the feed not excreted in the faeces is known as digestible energy expressed as a percentage (percent). Feed digestibility is commonly expressed as a percentage of GE or as TDN (total digestible nutrients). The percentage of feed that is not digested represents the percent of GE intake that will be excreted as faeces. Typical digestibility (DE) values for a range of livestock classes and diet types are presented in Table 10.2 as a guideline. The values have been refined compared to the *2006 IPCC Guidelines*, based on more recent information (Table 10.2). For ruminants, common ranges of feed digestibility are 45-55 percent for crop by-products and range lands[3]; 55-80 percent for managed pastures, well preserved forages, crop by-products and grain supplemented forage-based diets; and 72-85 percent for grain-based diets fed

[3] Rangelands are defined as land primarily covered by natural grasslands, savannas, woodlands (not meeting the definition of Forest Land) and shrublands, including introduced plant species that are naturalised (Grice *et al*. 2008).

in feedlots. Variation in diet digestibility results directly in major variation in the estimated amount of feed needed to meet animal requirements and consequently is a main cause of variation in associated methane emissions and in the amounts of manure excreted (next to variation in yield of methane per unit of digested GE as explained further in Section 10.3).

A low digestibility of feed will lead to lower feed intake and consequently reduced growth but at the same time a larger production of associated methane per unit of growth or production. Conversely, feeds with high digestibility will often result in higher feed intake and increased growth but at the same time a smaller amount of feed required per unit of growth and consequently lower associated methane production per unit growth or production. A factor directly affecting feed digestibility is the rate of passage of feed in the digestive tract, in particular in high productivity dairy cows (NRC 2001; Nousiainen *et al*. 2009) with direct impact on methane production as well, though in current Tier 2 methodology this impact is resolved through the selection of appropriate methane conversion rates instead of appropriate digestibility estimates (see Section 10.3.2).

A change of 10 percent in DE will be magnified to change in 12 to 20 percent when estimating methane emissions and even more (20 to 45 percent) for amounts of manure excreted (volatile solids). It is important to note that feed requirements, feed digestibility, production and growth, and yield of methane from digested GE (explained further in Section 10.3) are co-dependent phenomena.

Digestibility data should be based on measured values for the dominant feeds or forages being consumed by livestock with consideration for seasonal variation. In general, the digestibility of forages decreases with increasing maturity and is typically lowest during hot weather or dry season. Due to significant variation, digestibility values should be obtained from local scientific data wherever possible. Although a complete census of digestibility is considered unrealistic, at a minimum digestibility data from research studies should be consulted. While developing the digestibility data, associated feed characteristic data should also be recorded when available, such as feed content of neutral detergent fiber (NDF), acid detergent fiber (ADF), crude protein, crude fat, ash and the presence of anti-nutritional factors (e.g., alkaloids, phenolics). NDF and ADF are feed characteristics measured in the laboratory that are used to indicate the nutritive value of the feed for ruminant livestock. Determination of these values can enable DE to be predicted as defined in the last dairy National Research Council (2008) publication. The concentration of crude protein in the feed can be used in the process of estimating nitrogen excretion (Section 10.5.2). Accurate estimation of the crude fat content of feed is important, especially in the case of high-fat feeds, for accurate estimation of the GE content in feed, which is needed to calculate feed intake needed to achieve GE requirements (Section 10.2.2.).

Protein content in diet (CP, percent) – the total amount of protein present in animal diet. It is determined by analysing the nitrogen content in animal feed and multiplying by 6.25. The data on CP percent is required for the calculation of N excretion using a Tier 2 method.

Average annual wool production per sheep and goats (kg yr^{-1}): The amount of wool produced in kilograms (after drying out but before scouring) is needed to estimate the amount of energy allocated for wool production. For goats this is only applicable if the country has relevant numbers of fibre-producing goats.

TABLE 10.2 (UPDATED)
REPRESENTATIVE FEED DIGESTIBILITY FOR VARIOUS LIVESTOCK CATEGORIES

Main categories	Class	Digestibility (DE as percent)
Swine[1]	Mature Swine – confinement	70 - 80
	Growing Swine - confinement	80 - 90
	Swine – free range	50 - 70
Cattle and other ruminants	Feedlot animals fed with > 85% concentrate or high-grain diet	72 - 85
	Pasture / mixed-diet fed animals	55 - 80
	Animals fed – low quality forage	45 - 55
Poultry[1]	Broiler Chickens –confinement	85 - 93
	Layer Hens – confinement	70 - 80
	Poultry – free range	55 - 90[1]
	Turkeys – confinement	85 - 93
	Geese – confinement	80 - 90

[1] The range in digestibility of feed consumed by free-range swine and poultry is extremely variable due to the selective nature of these diets. Often it is likely that the amount of manure produced in these classes will be limited by the amount of feed available for consumption as opposed to its degree of digestibility. In instances where feed is not limiting and high quality feed sources are readily accessible for consumption, digestibility may approach values that are similar to those measured under confinement conditions.

Gross energy calculations

Animal performance and diet data are used to estimate feed intake which is the amount of energy (MJ/day) animal needs for maintenance and for such as growth, lactation, and pregnancy. For inventory compilers who have well-documented and recognised country-specific methods for estimating intake based on animal performance data, it is *good practice* to use the country-specific methods. The following section provides methods for estimating gross energy intake for the key ruminant categories of cattle, buffalo, sheep and goats. The equations listed in Table 10.3 are used to derive this estimate. If no country-specific methods are available, intake should be calculated using the equations listed in Table 10.3. As shown in the table, separate equations are used to estimate net energy requirements for sheep and goats as compared with cattle and buffalo. The equations used to calculate GE are as follows:

TABLE 10.3 (UPDATED)
SUMMARY OF THE EQUATIONS USED TO ESTIMATE DAILY GROSS ENERGY INTAKE FOR CATTLE, BUFFALO AND SHEEP AND GOATS

Metabolic functions and other estimates	Equations for cattle and buffalo	Equations for sheep and goats

Gross Energy	Equation 10.16	Equation 10.16

Source: Cattle and buffalo equations based on NRC (1996) and sheep and goats based on AFRC (1993; 1995).
NA means 'not applicable'.
* Applies only to the proportion of females that give birth.

Net energy for maintenance: (NE_m) is the net energy required for maintenance, which is the amount of energy needed to keep the animal in equilibrium where body energy is neither gained nor lost (Jurgens 1988).

EQUATION 10.3
NET ENERGY FOR MAINTENANCE

$$NE_m = Cf_i \bullet (Weight)^{0.75}$$

Where:

NE_m = net energy required by the animal for maintenance, MJ day^{-1}

Cf_i = a coefficient which varies for each animal category as shown in Table 10.4 (Coefficients for calculating NE_m), MJ day^{-1} kg^{-1}

Weight = live-weight of animal, kg

TABLE 10.4 (UPDATED)
COEFFICIENTS FOR CALCULATING NET ENERGY FOR MAINTENANCE (NE_M)

ANIMAL CATEGORY	C_{FI} (MJ D^{-1} KG^{-1})	COMMENTS
Cattle/Buffalo	0.322	All non-lactating cows, steers, heifers and calves
Cattle/Buffalo (lactating cows)	0.386	Maintenance energy requirements are 20% higher during lactation
Cattle/Buffalo (bulls)	0.370	Maintenance energy requirements are 15% higher for intact males than non lactating females
Sheep (lamb to 1 year)	0.236	This value can be increased by 15% for intact males
Sheep (older than 1 year)	0.217	This value can be increased by 15% for intact males.
Goats	0.315	

Source: NRC (1996) and AFRC (1993; 1995).

Net energy for activity: (NE_a) is the net energy for activity, or the energy needed for animals to obtain their food, water and shelter. It is based on its feeding situation rather than characteristics of the feed itself. As presented in Table 10.3, the equation for estimating NE_a for cattle and buffalo is different from the equation used for sheep and goats. Both equations are empirical with different definitions for the coefficient C_a.

EQUATION 10.4
NET ENERGY FOR ACTIVITY (FOR CATTLE AND BUFFALO)

$$NE_a = C_a \bullet NE_m$$

Where:

NE_a = net energy for animal activity, MJ day^{-1}

C_a = coefficient corresponding to animal's feeding situation (Table 10.5, Activity coefficients), dimensionless

NE_m = net energy required by the animal for maintenance (Equation 10.3), MJ day^{-1}

EQUATION 10.5
NET ENERGY FOR ACTIVITY (FOR SHEEP AND GOATS)

$$NE_a = C_a \bullet (weight)$$

Where:

NE_a = net energy for animal activity, MJ day^{-1}

C_a = coefficient corresponding to animal's feeding situation (Table 10.5), MJ day^{-1} kg^{-1}

weight = live-weight of animal, kg

For Equations 10.4 and 10.5, the coefficient C_a corresponds to a representative animal's feeding situation as described earlier. Values for C_a are shown in Table 10.5. If a mixture of these feeding situations occurs during the year, NE_a must be weighted accordingly.

TABLE 10.5 (UPDATED)
ACTIVITY COEFFICIENTS CORRESPONDING TO ANIMAL'S FEEDING SITUATION

Situation	Definition	C_a
Cattle and Buffalo (unit for C_a is dimensionless)		
Stall	Animals are confined to a small area (i.e., tethered, pen, barn) with the result that they expend very little or no energy to acquire feed.	0
Pasture	Animals are confined in areas with sufficient forage requiring modest energy expense to acquire feed.	0.17
Grazing large areas	Animals graze in open range land or hilly terrain and expend significant energy to acquire feed.	0.36
Sheep and goats (unit for C_a = MJ d^{-1} kg^{-1})		
Housed ewes	Animals are confined due to pregnancy in final trimester (50 days).	0.0096
Grazing flat pasture	Animals walk up to 1000 meters per day and expend very little energy to acquire feed.	0.0107
Grazing hilly pasture	Animals walk up to 5,000 meters per day and expend significant energy to acquire feed.	0.024
Housed fattening lambs	Animals are housed for fattening.	0.0067
Lowland goats	Animals walk and graze in lowland pasture.	0.019
Hill and mountain goats	Animals graze in open range land or hilly terrain and expend significant energy to acquire feed.	0.024

***Net energy for growth*:** (NE_g) is the net energy needed for growth (i.e., weight gain). Equation 10.6 is based on NRC (1996). Equation 10.7 is based on Gibbs *et al*. (2002). Constants for conversion from calories to joules and live to shrunk and empty body weight have been incorporated into the equation.

EQUATION 10.6
NET ENERGY FOR GROWTH (FOR CATTLE AND BUFFALO)

$$NE_g = 22.02 \bullet \left(\frac{BW}{C \bullet MW} \right)^{0.75} \bullet WG^{1.097}$$

Where:

NE_g = net energy needed for growth, MJ day^{-1}

BW = the average live body weight (BW) of the animals in the population, kg

C = a coefficient with a value of 0.8 for females, 1.0 for castrates and 1.2 for bulls (NRC, 1996)

MW = the mature body weight of an adult animal individually, mature females, mature males and steers) in moderate body condition[4], kg

WG = the average daily weight gain of the animals in the population, kg day^{-1}

[4] Since statistical offices may collect and report data on highly disaggregated number of cattle population (e.g., bovines less than one year old or bovines aged under 8 months, cattle aged between one and two years old), hence, this parameter (i.e., mature weight) may refer to target weight related to stage of growth. Herewith, the number of days needed for animals to reach from the beginning of growing stage to target weight of this growing stage should be taken into consideration.

EQUATION 10.7
NET ENERGY FOR GROWTH (FOR SHEEP AND GOATS) (UPDATED)

$$NE_g = \frac{WG_{lamb/kid} \bullet \left(a + 0.5b\left(BW_i + BW_f\right)\right)}{365}$$

Where:

NE_g = net energy needed for growth, MJ day^{-1}

$WG_{lamb/kid}$ = the weight gain ($BW_f - BW_i$), kg yr^{-1}

BW_i = the live bodyweight at weaning, kg

BW_f = the live bodyweight at 1-year old or at slaughter (live-weight) if slaughtered prior to 1 year of age, kg

a, b = constants as described in Table 10.6.

Note that lambs will be weaned over a period of weeks as they supplement a milk diet with pasture feed or supplied feed. The time of weaning should be taken as the time at which they are dependent on milk for half their energy supply.

The NE_g equation used for sheep and goats includes two empirical constants (a and b) that vary by animal species/category (Table 10.6).

TABLE 10.6 (UPDATED)
CONSTANTS FOR USE IN CALCULATING NE_G FOR SHEEP AND GOATS

Animal species/category	a (MJ kg^{-1})	b (MJ kg^{-1})
Intact males (Sheep)	2.5	0.35
Castrates (Sheep)	4.4	0.32
Females (Sheep)	2.1	0.45
Goats (all categories)	5.0	0.33

Source: AFRC (1993; 1995).

***Net energy for lactation*:** (NE_l) is the net energy for lactation. For cattle and buffalo the net energy for lactation is expressed as a function of the amount of milk produced and its fat content expressed as a percentage (e.g., 4 percent) (NRC 1989):

EQUATION 10.8
NET ENERGY FOR LACTATION (FOR BEEF CATTLE, DAIRY CATTLE AND BUFFALO)

$$NE_l = Milk \bullet \left(1.47 + 0.40 \bullet Fat\right)$$

Where:

NE_l = net energy for lactation, MJ day^{-1}

Milk = amount of milk produced, kg of milk day^{-1}

Fat = fat content of milk, percent by weight

Two methods for estimating the net energy required for lactation (NE_l) are presented for sheep. The first method (Equation 10.9) is used when the amount of milk produced is known, and the second method (Equation 10.10) is used when the amount of milk produced is not known. Generally, milk production is known for ewes kept for

commercial milk production, but it is not known for ewes that suckle their young to weaning. With a known amount of milk production, the total annual milk production is divided by 365 days to estimate the average daily milk production in kg/day (Equation 10.9). When milk production is not known, AFRC (1990) indicates that for a single birth, the milk yield is about 5 times the weight gain of the lamb. For multiple births, the total annual milk production can be estimated as five times the combined weight gain of all lambs birthed by a single ewe. The daily average milk production is estimated by dividing the resulting estimate by 365 days as shown in Equation 10.10.

EQUATION 10.9 (UPDATED)
NET ENERGY FOR LACTATION FOR SHEEP AND GOATS (MILK PRODUCTION KNOWN)

$$NE_1 = Milk \bullet EV_{milk}$$

Where:

NE_1 = net energy for lactation, MJ day^{-1}

$Milk$ = amount of milk produced, kg of milk day^{-1}

EV_{milk} = the net energy required to produce 1 kg of milk.

EQUATION 10.10
NET ENERGY FOR LACTATION FOR SHEEP AND GOATS (MILK PRODUCTION UNKNOWN)

$$NE_1 = \left[\frac{(5 \bullet WG_{wean})}{365} \right] \bullet EV_{milk}$$

Where:

NE_1 = net energy for lactation, MJ day^{-1}

WG_{wean} = the weight gain of the lamb between birth and weaning, kg

EV_{milk} = the energy required to produce 1 kg of milk, MJ kg^{-1}. A default EV_{milk} value of 4.6 MJ/kg (sheep) (AFRC 1993; AFRC 1995) and 3 MJ/kg (goats) (AFRC 1998) can be used which corresponds to a milk fat content of 7 percent and 3.8 percent by weight for sheep and goats, respectively. Milk fat can vary greatly among breeds. Compilers are encouraged to use country-specific milk fat content to derive EV_{milk} when available

***Net energy for work*:** (NE_{work}) is the net energy for work. It is used to estimate the energy required for draft power for cattle and buffalo. Various authors have summarised the energy intake requirements for providing draft power (Bamualim & Kartiarso 1985; Ibrahim 1985; Lawrence 1985). The strenuousness of the work performed by the animal influences the energy requirements, and consequently a wide range of energy requirements have been estimated. The values by Bamualim and Kartiarso show that about 10 percent of a day's NE_m requirements are required per hour for typical work for draft animals. This value is used as follows:

EQUATION 10.11
NET ENERGY FOR WORK (FOR CATTLE AND BUFFALO)

$$NE_{work} = 0.10 \bullet NE_m \bullet Hours$$

Where:

NE_{work} = net energy for work, MJ day^{-1}

NE_m = net energy required by the animal for maintenance (Equation 10.3), MJ day^{-1}

$Hours$ = number of hours of work per day

Net energy for wool production: (NE_{wool}) is the average daily net energy required for sheep to produce a year of wool. The NE_{wool} is calculated as follows:

EQUATION 10.12 (UPDATED)
NET ENERGY TO PRODUCE WOOL (FOR SHEEP AND GOATS)

$$NE_{wool} = \left(\frac{EV_{wool} \bullet Pr_{wool}}{365} \right)$$

Where:

NE_{wool} = net energy required to produce wool, MJ day^{-1}

EV_{wool} = the energy value of each kg of wool produced (weighed after drying but before scouring), MJ kg^{-1}. A default value of 24 MJ kg^{-1} can be used for sheep estimate. For goats this energy value is not considered unless fibre-producing goat numbers are relevant for a country (AFRC 1995).

Pr_{wool} = annual wool production per sheep/goat, kg yr^{-1}

For fibre-producing sheep NE_{wool} can be estimated that 0.25 MJ day^{-1} is retained in the fibre (AFRC 1993; AFRC 1995). For fibre-producing goats NE_{wool} can be estimated that 0.25 and 0.08 MJ/day for angora and cashmere breeds (AFRC 1993; AFRC 1995), respectively.

Net energy for pregnancy: (NE_p) is the energy required for pregnancy. For cattle and buffalo, the total energy requirement for pregnancy for a 281-day gestation period averaged over an entire year is calculated as 10 percent of NE_m. For sheep, the NE_p requirement is similarly estimated for the 147-day gestation period, although the percentage varies with the number of lambs born (Table 10.7, Constant for Use in Calculating NE_p in Equation 10.13). Equation 10.13 shows how these estimates are applied.

EQUATION 10.13 (UPDATED)
NET ENERGY FOR PREGNANCY (FOR CATTLE/BUFFALO AND SHEEP AND GOATS)

$$NE_p = C_{pregnancy} \bullet NE_m$$

Where:

NE_p = net energy required for pregnancy, MJ day^{-1}

$C_{pregnancy}$ = pregnancy coefficient (see Table 10.7)

NE_m = net energy required by the animal for maintenance (Equation 10.3), MJ day^{-1}

TABLE 10.7 (UPDATED)
CONSTANTS FOR USE IN CALCULATING NE_P IN EQUATION 10.13

Animal category	$C_{pregnancy}$
Cattle and Buffalo	0.10
Sheep/Goats	
Single birth	0.077
Double birth (twins)	0.126
Triple birth or more (triplets)	0.150

Source: Estimate for cattle and buffalo developed from data in NRC (1996). Estimates for sheep developed from data in AFRC (1993); AFRC (1995), taking into account the inefficiency of energy conversion.

When using NE_p to calculate GE for cattle, sheep and goats, the NE_p estimate must be weighted by the portion of the mature females that actually go through gestation in a year. For example, if 80 percent of the mature females in the animal category give birth in a year, then 80 percent of the NE_p value would be used in the GE equation below.

To determine the proper coefficient for sheep/goats, the portion of ewes/does that have single births, double births, and triple births is needed to estimate an average value for $C_{pregnancy}$. If these data are not available, the coefficient can be calculated as follows:

- If the number of lambs/kids born in a year divided by the number of ewes that are pregnant in a year is less than or equal to 1.0, then the coefficient for single births can be used.
- If the number of lambs/kids born in a year divided by the number of ewes/does that are pregnant in a year exceeds 1.0 and is less than 2.0, calculate the coefficient as follows:

$$C_{pregnancy} = [(0.126 \bullet \text{Double birth fraction}) + (0.077 \bullet \text{Single birth fraction})]$$

Where:

Double birth fraction = [(lambs born / pregnant ewes) – 1]

Single birth fraction = [1 – Double birth fraction]

***Ratio of net energy available in diet for maintenance to digestible energy consumed (REM)*:** For cattle, buffalo, sheep and goats, the ratio of net energy available in a diet for maintenance to digestible energy (REM) is estimated using the following equation (Gibbs & Johnson 1993):

EQUATION 10.14
RATIO OF NET ENERGY AVAILABLE IN A DIET FOR MAINTENANCE TO DIGESTIBLE ENERGY

$$REM = \left[1.123 - \left(4.092 \bullet 10^{-3} \bullet DE\right) + \left(1.126 \bullet 10^{-5} \bullet \left(DE\right)^2\right) - \left(\frac{25.4}{DE}\right)\right]$$

Where:

REM = ratio of net energy available in diet for maintenance to digestible energy

DE = digestibility of feed expressed as a fraction of gross energy (digestible energy/gross energy*100, i.e. DE%)

***Ratio of net energy available for growth in a diet to digestible energy consumed (REG)*:** For cattle, buffalo, sheep and goats the ratio of net energy available for growth (including wool growth) in a diet to digestible energy consumed (REG) is estimated using the following equation (Gibbs & Johnson 1993):

EQUATION 10.15
RATIO OF NET ENERGY AVAILABLE FOR GROWTH IN A DIET TO DIGESTIBLE ENERGY CONSUMED

$$REG = \left[1.164 - \left(5.16 \bullet 10^{-3} \bullet DE \right) + \left(1.308 \bullet 10^{-5} \bullet \left(DE \right)^2 \right) - \left(\frac{37.4}{DE} \right) \right]$$

Where:

REG = ratio of net energy available for growth in a diet to digestible energy consumed

DE = digestibility of feed expressed as a fraction of gross energy (digestible energy/gross energy*100, i.e. DE%)

Gross energy, GE: As shown in Equation 10.16, GE requirement is derived based on the summed net energy requirements and the energy availability characteristics of the feed(s). Equation 10.16 represents *good practice* for calculating GE requirements for cattle, buffalo, sheep and goats using the results of the equations presented above.

In using Equation 10.16, only those terms relevant to each animal category are used (see Table 10.3).

EQUATION 10.16 (UPDATED)
GROSS ENERGY FOR CATTLE/BUFFALO, SHEEP AND GOATS

$$GE = \left[\frac{\left(\frac{NE_m + NE_a + NE_l + NE_{work} + NE_p}{REM} \right) + \left(\frac{NE_g + NE_{wool}}{REG} \right)}{DE} \right]$$

Where:

GE = gross energy, MJ day^{-1}

NE_m = net energy required by the animal for maintenance (Equation 10.3), MJ day^{-1}

NE_a = net energy for animal activity (Equations 10.4 and 10.5), MJ day^{-1}

NE_l = net energy for lactation (Equations 10.8, 10.9, and 10.10), MJ day^{-1}

NE_{work} = net energy for work (Equation 10.11), MJ day^{-1}

NE_p = net energy required for pregnancy (Equation 10.13), MJ day^{-1}

REM = ratio of net energy available in a diet for maintenance to digestible energy (Equation 10.14)

NE_g = net energy needed for growth (Equations 10.6 and 10.7), MJ day^{-1}

REG = ratio of net energy available for growth in a diet to digestible energy consumed (Equation 10.15)

NE_{wool} = net energy required to produce a year of wool (Equation 10.12), MJ day^{-1}

DE = digestibility of feed expressed as a fraction of gross energy (digestible energy/gross energy, i.e. DE%/100)

Once the values for GE are calculated for each animal subcategory, the feed intake in units of kilograms of dry matter per day (kg day^{-1}) should also be calculated. To convert from GE in energy units to dry matter intake (DMI), divide GE by the energy density of the feed. A default value of 18.45 MJ kg^{-1} of dry matter can be used if feed-specific information is not available. The resulting daily dry matter intake should be in the order of 2 percent to 3 percent of the body weight of the mature or growing animals. In high producing milk cows, intakes may exceed 4 percent of body weight.

Feed intake estimates using a simplified Tier 2 method

Prediction of DMI for cattle based on body weight and estimated dietary net energy concentration (NE_{mf}) and digestibility values (DE): It is also possible to predict dry matter intake for mature and growing cattle based on body weight of the animal, and either the dietary net energy of maintenance concentration of the feed NE_{mf} (MJ kg^{-1} DM) (National Academies of Sciences, Engineering and Medicine 2016) or DE, and for lactating dairy cows, fat corrected milk production. Dietary NE_{mf} concentration can range from 3.0 to 9.0 MJ kg^{-1} of dry matter. Typical values for high, moderate and low quality diets are presented in Table 10.8a. These figures can also be used to estimate NE_{mf} values for mixed diets based on estimate of diet quality. For example, a mixed forage-grain diet could be assumed to have a NE_{mf} value similar to that of a high-quality forage diet. A mixed grain-straw diet could be assumed to have a NE_{mf} value similar to that of a moderate quality forage. Nutritionists within specific geographical areas should be able to provide advice with regard to the selection of NE_{mf} values that are more representative of locally fed diets.

Dry matter intake for calves is estimated using the following equation:

EQUATION 10.17 (NEW)
ESTIMATION OF DRY MATTER INTAKE FOR CALVES

$$DMI = BW^{0.75} \bullet \left[\frac{\left(0.0582 \bullet NE_{mf} - 0.00266 \bullet NE_{mf}^{2} - 0.1128\right)}{0.239 \bullet NE_{mf}} \right]$$

Where:

DMI = dry matter intake, kg day^{-1}

BW = live body weight, kg

NE_{mf} = estimated dietary net energy concentration of diet or default values in Table 10.8a, MJ kg^{-1}

Dry matter intake for growing cattle is estimated using the following equation:

EQUATION 10.18 (NEW)
ESTIMATION OF DRY MATTER INTAKE FOR GROWING CATTLE

$$DMI = BW^{0.75} \bullet \left[\frac{\left(0.0582 \bullet NE_{mf} - 0.00266 \bullet NE_{mf}^{2} - 0.0869\right)}{0.239 \bullet NE_{mf}} \right]$$

Where:

DMI = dry matter intake, kg day^{-1}

BW = live body weight, kg

NE_{mf} = estimated dietary net energy concentration of the feed or diet with default values in Table 10.8a, MJ kg^{-1} DM^{-1}

Dry matter intake for feedlot cattle (on high grain diets) is estimated using the following equation:

EQUATION 10.18A (UPDATED)
ESTIMATION OF DRY MATTER INTAKE FOR STEERS AND BULLS

$$DMI = 3.83 + 0.0143 \bullet BW \bullet 0.96$$

ESTIMATION OF DRY MATTER INTAKE FOR HEIFERS

$$DMI = 3.184 + 0.01536 \bullet BW \bullet 0.96$$

Where:

DMI = dry matter intake, kg day^{-1}

BW = live body weight, kg

For mature beef cows use the following values (National Academies of Sciences, Engineering and Medicine 2016)

TABLE 10.8 (NEW)
DMI REQUIRED BY MATURE NON DAIRY COWS BASED ON FORAGE QUALITY

Forage type	Digestibility (DE, %)	Forage DMI capacity (kg/day), % of BW (kg)	
		Non-lactating	Lactating
Low quality	<52	1.8	2.2
Average quality	52-59	2.2	2.5
High quality	>59	2.5	2.7

For lactating dairy cows the following equation can be used (Cornell Net Carbohydrate and Protein System (CNCPS), Fox *et al*. 1992) as modified by Arnerdal (2005):

EQUATION 10.18B (UPDATED)
ESTIMATION OF DRY MATTER INTAKE FOR LACTATING DAIRY COWS

$$DMI = 0.0185 \bullet BW + 0.305 \bullet FCM$$

Where:

DMI = dry matter intake, kg day^{-1}

BW = live body weight, kg

FCM = Fat corrected milk, kg day^{-1}, 3.5 percent * [(0.4324 * kg of milk) + (16.216 * kg of fat)].

Equations 10.17, 10.18, 10.18A and 10.18B and values in Table 10.8 provide a good check to the main Tier 2 method to predict feed intake. They can be viewed as asking 'what is an expected intake for a given diet quality?' and in the case that countries do not have the data required to carry out a full estimate of gross energy use for their catle herd, these equations could be used to independently predict DMI from BW, diet quality (NE_{mf} or DE percent) and milk production. In contrast, the main Tier 2 method predicts DMI based on how much feed must be consumed to meet estimated energy requirements (i.e., NE_m and NE_g) and does not consider the biological capacity of the animal to in fact consume the predicted quantity of feed. While the Tier 2 estimate of gross energy is the preferred method, the simplified Tier 2 method can be used to confirm that DMI values derived from the main Tier 2 method are biologically realistic. These estimates are also subject to the cross check that dry matter intake should be in the order of 2 percent to 3 percent of the bodyweight of the mature or growing animals and up to 4 percent for high yielding lactating dairy cattle.

TABLE 10.8A (UPDATED)
EXAMPLES OF NE_{MF} CONTENT OF TYPICAL DIETS FED TO CATTLE FOR ESTIMATION OF DRY MATTER INTAKE IN EQUATIONS 10.17 AND 10.18

Diet type	NE_{mf} (MJ (kg dry matter)$^{-1}$)
High grain diet > 90%	7.5 - 8.5
High quality forage (e.g., vegetative legumes & grasses)	6.5 - 7.5
Moderate quality forage (e.g., mid-season legume & grasses)	5.5 - 6.5
Low quality forage (e.g., straws, mature grasses)	3.5 - 5.5

Source: Estimates obtained from predictive models in NRC (1996), NE_{mf} can also be estimated using the equation: NE_{mf} = REM * 18.45 * DE%/100

10.2.3 Uncertainty assessment

No refinement.

10.2.4 Characterisation for livestock without species: Specific emission estimation methods

Some countries may have domesticated livestock for which there are currently no Tier 1 or Tier 2 emissions estimating methods (e.g., wapiti, bison or emus). *Good practice* in estimating emissions from these livestock is to first assess whether their emissions are likely to be significant enough to warrant characterising them and developing country-specific emission factors. Volume 1, Chapter 4 (Methodological Choice and Identification of *Key Categories*) presents guidance for assessing the significance of individual source categories within the national inventory. Similar approaches can be used to assess the importance of subsource categories (i.e. species) within a source category. If the emissions from a particular sub-species are determined to be significant, then country-specific emission factors should be developed, and a characterisation should be performed to support the development of the emission factors. Research into the estimation of emission levels from these non-characterized species should be encouraged. The data and methods used to characterise the animals should be well documented.

As emissions estimation methods are not available for these animals, approximate emission factors based on 'order of magnitude calculations' are appropriate for conducting the assessment of the significance of their emissions. One approach for developing the approximate emission factors is to use the Tier 1 emissions factor for an animal with a similar digestive system and to scale the emissions factor using the ratio of the weights of the animals raised to the 0.75 power. The Tier 1 emission factors can be classified by digestive system as follows:

- Ruminant animals: Cattle, Buffalo, Sheep, Goats, Camels;
- Non-ruminant herbivores: Horses, Mules/Asses;
- Poultry: Chickens, Ducks, Turkeys, Geese;
- Non-poultry monogastric animals: Swine.

For example, an approximate enteric fermentation methane emissions factor for wapiti could be estimated from the emissions factor for deer (also a ruminant animal) as follows:

Approximate emissions factor = $[(\text{wapiti weight}) / (\text{deer weight})]^{0.75}$ * deer emissions factor

Similarly, an approximate manure methane emissions factor could be estimated for emus using the Tier 1 emission factor for ostriches. Approximate emission factors developed using this method can only be used to assess the significance of the emissions from the animals, and are not considered sufficiently accurate for estimating emissions as part of a national inventory.

10.3 METHANE EMISSIONS FROM ENTERIC FERMENTATION

Methane is produced in herbivores as a by-product of enteric fermentation, a digestive process by which carbohydrates are broken down by micro-organisms into simple molecules for absorption into the bloodstream.

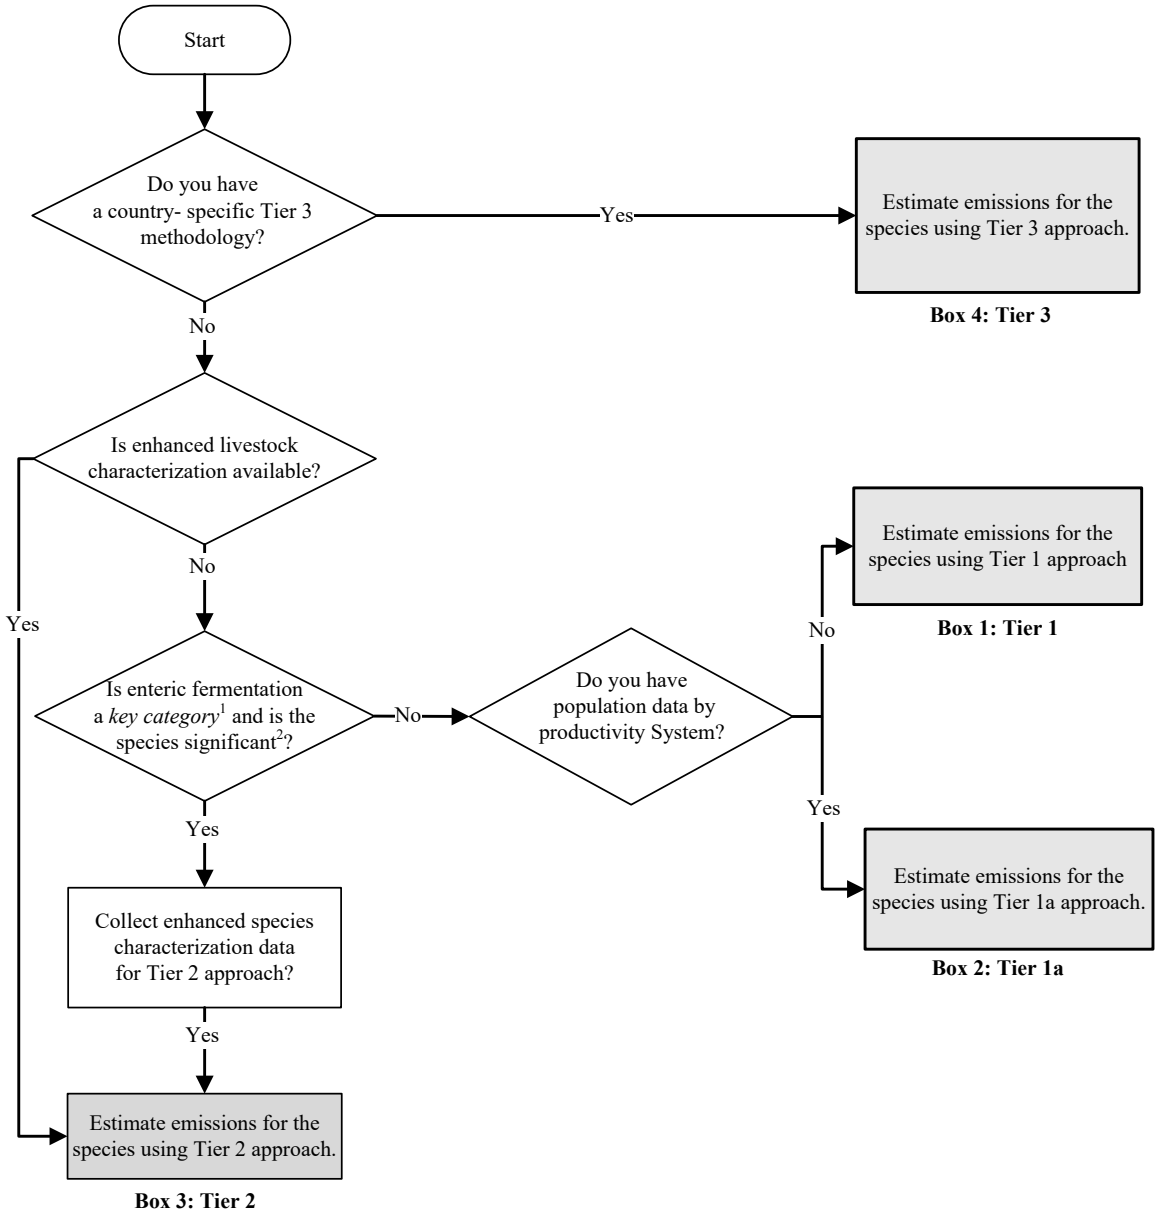
The amount of methane released depends on the type of digestive tract, age, and weight of the animal, and the quality and quantity of the feed consumed. Ruminant livestock (e.g., cattle, sheep) are major sources of methane with moderate amounts produced from non-ruminant livestock (e.g., pigs, horses). The ruminant gut structure fosters extensive enteric fermentation of their diet.

Digestive system

The type of digestive system has a significant influence on the rate of methane emission. Ruminant livestock have an expansive chamber known as the rumen, located at the fore-part of their digestive tract. The rumen supports intensive microbial fermentation of the diet, which yields several nutritional advantages including the capacity to digest cellulose (the major component of fiber). The main ruminant livestock are cattle, buffalo, goats, sheep, deer and camelids. Non-ruminant livestock (horses, mules, asses) and monogastric livestock (swine) have relatively lower methane emissions because much less methane-producing fermentation takes place in their digestive systems.

Feed intake

Methane is produced by the fermentation of feed within the animal's digestive system. Generally, the higher the feed intake, the higher the methane emission. Although, methane production is also affected by the composition of the diet. Feed intake is positively related to animal size, growth rate, and production (e.g., milk production, wool growth, or pregnancy).



To reflect the variation in emission rates among animal species, the population of animals should be divided into subgroups, and an emission rate per animal is estimated for each subgroup. Types of population subgroups are provided in Section 10.2 (Livestock and Feed Characterisation). The amount of methane emitted by a population subgroup is calculated by multiplying the emission rate per animal by the number of animals within the subgroup.

Natural wild ruminants are not considered in the derivation of a country's emission estimate. Emissions should only be considered from animals under domestic management (e.g., farmed deer, elk, and buffalo).

10.3.1 Choice of method

It is *good practice* to choose the method for estimating methane emissions from enteric fermentation according to the decision tree in Figure 10.2. The method for estimating methane emission from enteric fermentation requires three basic steps:

Figure 10.2 (Updated) Decision Tree for CH_4 Emissions from Enteric Fermentation

Note:
1. See Volume 1 Chapter 4, 'Methodological Choice and Identification of *Key Categories*' (noting Section 4.1.2 on limited resources), for discussion of *key categories* and use of decision trees.
2. As a rule of thumb, a livestock species would be significant if it accounts for 25-30% or more of emissions from the source category.

Step 1: Divide the livestock population into subgroups and characterize each subgroup as described in Section 10.2. It is recommended that national experts use annual averages estimated with consideration for the impact of production cycles and seasonal influences on population numbers.

Step 2: Estimate emission factors for each subgroup in terms of kilograms of methane per animal per year.

Step 3: Multiply the subgroup emission factors by the subgroup populations to estimate subgroup emission, and sum across the subgroups to estimate total emission.

These three steps can be performed at varying levels of detail and complexity. This chapter presents the following three approaches:

Tier 1

A simplified approach that relies on default emission factors established in these guidelines that were either drawn from the literature or calculated using regional data taken from the literature and derived using the Tier 2 method.

The Tier 1 method is likely to be suitable for most animal species in countries where enteric fermentation is not a key source category, or where enhanced characterization data are not available. When approximate enteric emissions are derived by extrapolation from main livestock categories they should be considered to be a Tier 1 method.

Tier 1a

An advanced Tier 1 method, applicable in particular to countries that have differentiated production systems with coexistence of low and high productivity systems, or whose agricultural production systems are transitioning from low to high productivity. Countries can consider the split in their production systems, yet still use default emission factors, to customize their emission estimates based on populations of high and low productivity animals and therefore track change in their emissions related to improved productivity.

Tier 2

A more complex approach that requires detailed country-specific data on gross energy intake and methane conversion factors for specific livestock categories. The Tier 2 method should be used if enteric fermentation is a key source category for the animal category that represents a large portion of the country's total emissions.

Tier 3

Some countries for which livestock emissions are particularly important may wish to go beyond the Tier 2 method and incorporate additional country-specific information in their estimates. This approach could employ the development of sophisticated models that consider diet composition in detail, concentration of products arising from ruminant fermentation, seasonal variation in animal population or feed quality and availability, and possible mitigation strategies. Many of these estimates would be derived from direct experimental measurements. Although countries are encouraged to go beyond the Tier 2 method presented below when data are available, these more complex analyses are only briefly discussed here. A Tier 3 method should be subjected to a wide degree of international peer review such as that which occurs in peer-reviewed publications to ensure that they improve the accuracy and / or precision of estimates.

Countries with large populations of domesticated animal species for which there are no IPCC default emission factors (e.g., llamas and alpacas) are encouraged to develop national methods that are similar to the Tier 2 method and are based on well-documented research (if it is determined that emissions from these livestock are significant). The approach is described in Section 10.2.4 under the heading 'Characterisation for livestock without species-specific emission estimation methods' for more information.

Table 10.9 summarises the suggested approaches for the livestock emissions included in this inventory.

10.3.2 Choice of emission factors

Tier 1 Approach for methane emissions from Enteric Fermentation

This Tier 1 method is simplified so that only readily-available animal population data are needed to estimate emissions. Default emission factors are presented for each of the recommended population subgroups. Each step is discussed in turn.

Step 1: Animal population and productivity system

The animal population data should be obtained using the approach described in Section 10.2.

Step 2: Emission factors

The purpose of this step is to select emission factors that are most appropriate for the country's livestock characteristics. Default emission factors for enteric fermentation have been drawn from previous studies, and are organised by region and by productivity system for ease of use.

The data used to estimate the default emission factors for enteric fermentation are presented in Annex 10A.1.

TABLE 10.9 (UPDATED)
SUGGESTED EMISSIONS INVENTORY METHODS FOR ENTERIC FERMENTATION

Livestock	Suggested emissions inventory methods
Dairy Cow	Tier 2[a]/Tier 3
Other Cattle	Tier 2[a]/Tier 3
Buffalo	Tier 1/Tier 2
Sheep	Tier 1/Tier 2
Goats	Tier 1/Tier 2
Camels	Tier 1
Horses	Tier 1
Mules and Asses	Tier 1
Swine	Tier 1
Poultry	Not developed
Other (e.g., Llamas, Alpacas, Deer, Ostrich)	Tier 1

[a] The Tier 2 method is recommended for countries with large livestock populations. Implementing the Tier 2 method for additional livestock subgroups may be desirable when the category emissions are a large portion of total methane emissions for the country.

Table 10.10 shows the enteric fermentation emission factors for each of the animal species except cattle and buffalo. As shown in the table, emission factors for sheep, goats and swine vary for low and high productivity systems and it is important to consider that these conditions may exist within individual countries. The differences in the emission factors are driven by differences in feed intake (as related to animal size) and feed characteristic assumptions. Table 10.11 presents the enteric fermentation emission factors for cattle and buffaloes, accordingly. A range of emission factors is shown for typical regional conditions.

Animal size and milk production are important determinants of emission rates for dairy cows. Relatively smaller dairy cows with low levels of production are found in Asia, Africa, and the Indian subcontinent. Relatively larger dairy cows with high levels of production are found in North America, Western Europe and several countries of Latin America.

Animal size and population structure and production systems implemented are important determinants of emission rates for other cattle. Relatively smaller other cattle are found in Asia, Africa, and the Indian subcontinent. Also, many of the other cattle in these regions are young. Other cattle in North America, Western Europe and Oceania are larger, and young cattle constitute a smaller portion of the population.

For countries with highly differentiated agricultural systems in which there is a coexistence of low and high productivity systems or whose agricultural systems are transitioning from local low input productivity systems to higher productivity systems and do not have the information necessary for implementing Tier 2 method, the use of the diversification of emission factors given for an animal category provides an alternative or intermediary option. This approach can reflect changes in activity data and productivity with time, whereas the Tier 1a approach only takes into account changes in the number of animals in a country.

To select emission factors from Tables 10.10 and 10.11 identify the region most applicable to the country being evaluated. Scrutinise the tabulations in Annex 10A.1 to ensure that the underlying animal characteristics such as weight, growth rate and milk production used to develop the emission factors are similar to the conditions in the country. The data collected on the average annual milk production by dairy cows should be used to help select a dairy cow emission factor. If necessary, interpolate between dairy cow emission factors shown in the table using the data collected on average annual milk production per head.

Note that using the same Tier 1 emission factors for the inventories of successive years means that no allowance is being made for changing livestock productivity, such as increasing milk productivity or trend in live weight. If it is important to capture the trend in methane emission that results from a trend in livestock productivity, then livestock emissions can become a key source category based on trend and a Tier 2 calculation should be used.

TABLE 10.10 (UPDATED)[2,3]
ENTERIC FERMENTATION EMISSION FACTORS FOR TIER 1 METHOD (KG CH_4 $HEAD^{-1}$ YR^{-1})

Livestock	High Productivity Systems[1]	Low Productivity Systems	Liveweight[7]
Sheep	9	5	65 kg – high productivity systems 45 kg – low productivity systems
Swine[6]	1.5	1	72 kg - high productivity systems 52 kg - low productivity systems
Goats[5]	9	5	50 kg – high productivity systems 28 kg – low productivity systems
Horses	18		550 kg
Camels	46		570 kg
Mules and Asses	10		245 kg
Deer	20		120 kg
Ostrich[4]	5		120 kg
Poultry	Insufficient data for calculation		
Llamas and Alpacas	8		65 kg
Other (e.g., bison)	To be determined		
All estimates have an uncertainty of ±30-50%.			

Sources:

Emission factors: camels from Gibbs & Johnson (1993); Alpacas from Pinares-Patino *et al*. (2003); Deer from Clark *et al*. (2003); Sheep (High productivity systems) derived from Swainson *et al*. (2016). Sources and assumptions to calculate goats EFs are detailed in Annex 10B.3. Emission factors for other livestock from Crutzen *et al*. (1986),

[1] For the application of the simple Tier 1, for all regions other than North America, Europe and Oceania the Tier 1 default values are the low productivity EFs.

[2] One approach for developing the approximate emission factors is to use the Tier 1 emissions factor for an animal with a similar digestive system and to scale the emissions factor using the ratio of the weights of the animals raised to the 0.75 power. Liveweight values have been included for this purpose. Emission factors should be derived on the basis of characteristics of the livestock and feed of the animals and compilers should not base their decision of an emission factor entirely on regional characteristics.

[3] The enteric fermentation emission factor shall be applied for the whole livestock population including non-mature animals.

[4] CH_4 EF for ostrich was calculated based on Frei *et al*. (2015) and Danish NIR (Nielsen *et al*. 2018).

[5] Sources and assumptions to adjust weight of goats for low- and high-productivity systems are detailed in Annex 10B.3.

[6] The values of swine weight for low and high productivity systems were obtained from FAO GLEAM databases (FAO 2017). More detailed data on swine weight are reported in Annex 10A.2 (in Table 10A.5). Crutzen *et al*. (1986) did not report weights for swine. Regional Tier 2 calculations for swine have been carried out by the FAO GLEAM research group, countries could consult these values for consistency with their production systems for refinement to their emission factors.

[7] If a country-specific liveweight of animal category is different from those reported in Table 10.10, an inventory-compiler may use the approach presented in section 10.2.4 of the current chapter.

It is recommended to continue to use Tier 1 emission factor uncertainty ranges as defined in Section 10.3.4 of the *2006 IPCC Guidelines*.

Step 3: Total emission

To estimate total emission, the selected emission factors are multiplied by the associated animal population (Equation 10.19) and summed (Equation 10.20):

EQUATION 10.19 (UPDATED)
ENTERIC FERMENTATION EMISSIONS FROM A LIVESTOCK CATEGORY (TIER 1)

$$E_T = \sum_{(P)} EF_{(T,P)} \bullet \left(\frac{N_{(T,P)}}{10^6} \right)$$

Where:

E_T = methane emissions from Enteric Fermentation in animal category T, Gg CH_4 yr^{-1}

$EF_{(T,P)}$ = emission factor for the defined livestock population T and the productivity system P, in kg CH_4 $head^{-1}$ yr^{-1}

$N_{(T,P)}$ = the number of head of livestock species / category T in the country classified as productivity system P

T = species/category of livestock

P = productivity system, either high or low productivity for use in advanced Tier 1a – omitted if using Tier 1 approach

EQUATION 10.20 (UPDATED)
TOTAL EMISSIONS FROM LIVESTOCK ENTERIC FERMENTATION (TIER 1)

$$Total\ CH_{4\ Enteric} = \sum_{i,P} E_{i,P}$$

Where:

$Total\ CH_{4\ Enteric}$ = total methane emissions from Enteric Fermentation, Gg CH_4 yr^{-1}

$E_{i,P}$ = is the emissions for the ith livestock categories and subcategories based on production systems (P)

Tier 1 method entails multiplying the total number of livestock population and CH_4 emission factor for each category of livestock (Table 10.10 or Table 10.11). Tier 1a method relies on number of livestock population in each productivity system (i.e., low-productivity systems and high-productivity systems) and CH_4 emission factor for each category of livestock developed per head of animal kept in the specified productivity system (Table 10.10 or Table 10.11).

TABLE 10.11 (UPDATED)
TIER 1 AND TIER 1A ENTERIC FERMENTATION EMISSION FACTORS FOR CATTLE AND BUFFALO[1]

Regional characteristics[8]	Animal category	Tier 1 and Tier 1a Emission Factor[2,3] (kg CH_4 $head^{-1}$ yr^{-1})	Comments[7]
North America			
Cattle: Highly productive commercialised dairy sector feeding high quality forage and grain. Separate beef cow herd, primarily grazing with feed supplements seasonally. Fast-growing beef steers/heifers finished in feedlots on grain. Dairy cows are a small part of the population. There are no buffalo herds, but American bison may be raised.	**Dairy Cattle**	138	Average milk production of 10,250 kg $head^{-1}$ yr^{-1}.
	Other cattle	64	Includes mature males, mature females, calves, growing steers/heifers, and feedlot cattle.
Western Europe			
Cattle: Highly productive commercialised dairy sector feeding high quality forage and grain. Dairy cows also used for beef calf production. Separated beef cow herd. Minor amount of feedlot feeding with grains.	**Dairy Cattle**	126	Average milk production of 7,410 kg $head^{-1}$ yr^{-1}.
	Other cattle	52	Includes mature males, calves, and growing steers/heifers.
Buffalo: Buffalo farming system is exclusively intensive. The concentrates are largely used only during the lactation phase. Animals are maintained in paddocks, grazing practices are not widespread.	**Buffalo**	78	Includes mature females, mature males, growing animals and calves.
Eastern Europe			
Cattle: Commercialised dairy sector feeding based on forages and grains. Separate beef cow herd, primarily grazing. Minor amount of feedlot feeding with grains.	**Dairy cattle**	93	Average milk production of 4,000 kg $head^{-1}$ yr^{-1}.
	Other cattle	58	Includes mature males, mature females, growing and replacement animals, and calves.
Buffalo: Commercialized buffalo sector feeding primarily with roughages. Buffaloes are managed according to their categories. Animals are maintained paddock and tied up during the winter, in summer they are allowed to graze	**Buffalo**	68	Includes mature females, mature males, growing animals and calves.
Oceania[4]			
Cattle: Commercialised dairy sector based on grazing. Separate beef cow herd, primarily grazing rangelands[5] and hill country of widely varying forage quality. Growing amount of feedlot feeding with grains. Dairy cows are a small part of the population. No Buffalo herd.	**Dairy cattle**	93	Average milk production of 4,400 kg $head^{-1}$ yr^{-1}.
	Other cattle	63	Includes mature males, mature females and young.

TABLE 10.11 (UPDATED) (CONTINUED)
TIER 1 AND TIER 1A ENTERIC FERMENTATION EMISSION FACTORS FOR CATTLE AND BUFFALO[1]

Regional characteristics[8]	Animal category	Tier 1 and Tier 1a Emission Factor[2,3] (kg CH_4 $head^{-1}$ yr^{-1})	Comments[7]
Latin America			
Cattle: Commercialised dairy sector based on grazing. Separate beef cow herd grazing pastures and rangelands. Minor amount of feedlot feeding with grains. Growing non-dairy cattle comprise a large portion of the population.	**Dairy Cattle**	87	Average milk production of 2,050 kg $head^{-1}$ yr^{-1}
	High productivity systems	103	Average milk production of 3,400 kg $head^{-1}$ yr^{-1}
	Low productivity systems	78	Average milk production of 1,250 kg $head^{-1}$ yr^{-1}
	Other cattle	56	Includes mature females, mature males, growing steers/heifers and calves.
	High productivity systems	55	
	Low productivity systems	58	
Buffalo: Buffalo husbandry is based on extensive systems in native or cultivated pastures in lowlands and uplands, most often without supply of concentrated feed. Milk production is based on pasture with frequent supplementation of roughage (sugar cane, silage, etc.), with a predominance of one single milking.	**Buffalo**	68	Includes mature females, mature males, growing animals and calves.
Asia			
Cattle: Commercialised dairy sector is experienced fundamental changes due to increasing number of large farms with intensive production system based on grains and forage. Cattle kept in traditional production systems are multi-purpose, providing draft power and some milk within farming regions. Cattle of all types are smaller than those found in most other regions.	**Dairy cattle**	78	Average milk production of 3,200 kg $head^{-1}$ yr^{-1}
	High productivity systems	96	Average milk production of 5,000 kg $head^{-1}$ yr^{-1}
	Low productivity systems	71	Average milk production of 2,600 kg $head^{-1}$ yr^{-1}
	Other cattle	54	Includes mature males, mature females, growing and replacement animals, and calves.
	High productivity systems	43	
	Low productivity systems	56	
Buffalo: Buffaloes are generally swamp type. Buffaloes are raised by smallholder farmers as source of draft power. Animals are commonly grazed in field and fed on agriculture residual products. Milk yield per cow is low. Nevertheless, the dairy buffalo breeding is rapidly developing in countryside of Asia.	**Buffalo**	68	Includes mature females, mature males, growing animals and calves.

TABLE 10.11 (UPDATED) (CONTINUED)
TIER 1 AND TIER 1A ENTERIC FERMENTATION EMISSION FACTORS FOR CATTLE AND BUFFALO[1]

Regional characteristics[8]	Animal category	Tier 1 and Tier 1a Emission Factor[2,3] (kg CH_4 head^{-1} yr^{-1})	Comments[7]
Africa[6]			
Cattle: Commercialised dairy sector based on grazing with low production per cow. Most cattle are multi-purpose, providing draft power and some milk within farming regions. Some cattle graze over very large areas. Cattle are smaller than those found in most other regions.	**Dairy cattle**	76	Average milk production of 1,300 kg head^{-1} yr^{-1}
	High productivity systems	86	Average milk production of 2,200 kg head^{-1} yr^{-1}
	Low productivity systems	66	Average milk production of 500 kg head^{-1} yr^{-1}
	Other cattle	52	Includes mature males, multi-purpose mature females, growing and replacement animals, and calves.
	High productivity systems	60	
	Low productivity systems	48	
Buffalo: Small-scale buffalo sector well-integrated with cropland. Animals are raised for multi-purpose. Feeding primarily depends on roughages and crop-residues. Minor commercial dairy buffalo farms feeding with concentrate feed mixture.	**Buffalo**	81	Includes breeding and working males and females, growing animals and calves
Middle East			
Cattle: Majority of cattle population is still kept by small holders in the traditional production systems. The animals are fed primarily by crop residues and are grazed. Most animals are dual-purpose. In contrast to the small-scale farms, commercial dairy sector is generally intensive, mainly based on compound feed and grains.	**Dairy cattle**	76	Average milk production of 2,500 kg head^{-1} yr^{-1}
	High productivity systems	94	Average milk production of 3,900 kg head^{-1} yr^{-1}
	Low productivity systems	62	Average milk production of 1,300 kg head^{-1} yr^{-1}
	Other cattle	60	Includes mature males, multi-purpose mature females, growing and replacement animals, and calves.
	High productivity systems	61	
	Low productivity systems	55	
Buffalo: Buffalo farming system primarily based on smallholders rearing animals for meat, milk and draught. Animals obtain their feeding by grazing. Minor commercialized buffalo sector feeding forage and concentrate supplemented feed.	**Buffalo**	67	Includes breeding and working males and females, growing animals and calves

TABLE 10.11 (UPDATED) (CONTINUED)
TIER 1 AND TIER 1A ENTERIC FERMENTATION EMISSION FACTORS FOR CATTLE AND BUFFALO[1]

Regional characteristics[8]	Animal category	Tier 1 and Tier 1a Emission Factor[2,3] (kg CH_4 $head^{-1}$ yr^{-1})	Comments[7]
Indian Subcontinent			
Cattle: Commercialised dairy sector based on crop by-product feeding with low production per cow. Most bullocks provide draft power and cows provide some milk in farming regions. Cattle in this region are the smallest compared to cattle found in all other regions.	**Dairy cattle**	73	Average milk production of 1,900 kg $head^{-1}$ yr^{-1}
	High productivity systems	70	Average milk production of 2,600 kg $head^{-1}$ yr^{-1}
	Low productivity systems	74	Average milk production of 1,700 kg $head^{-1}$ yr^{-1}
	Other Cattle	46	Includes mature males, multi-purpose mature females, growing and replacement animals, and calves.
	High productivity systems	41	
	Low productivity systems	47	
Buffalo: Smallholder buffalo sector feeding poor quality roughages and crop-residues. Buffaloes are primarily free grazing. Concentrates are fed to dairy animals during last months of pregnancy. Dairy and meat production are intimately related. Animals are used as draft power. Minor commercialized buffalo sector providing animals with balanced ration.	**Buffalo**	85	Includes breeding and working males and females, growing animals and calves

[1] Emission factors should be derived on the basis of the characteristics of the cattle and feed of the animals and compilers should not base their decision of an emission factor entirely on regional characteristics.

[2] The values represent averages within region. Existing values were derived using Tier 2 method and the data in Tables 10A.1–10A.4. Data on a livestock population mix corresponding to low- and high-productivity systems were used.

[3] Uncertainty values from the *2006 IPCC Guidelines* were validated during the development of the emission factors using a Monte Carlo analysis in the *2019 Refinement*, based on data compiled during the emission factor development process. It is recommended to continue to use Tier 1 emission factor uncertainty ranges as defined in Section 10.3.4 of the *2006 IPCC Guidelines*.

[4] All data are weighted values, representative of Australia and New Zealand. For Pacific Island nations, GHG inventory compilers may refer to Asian values. GHG inventory compilers from the Island nations of Oceania who wish to use a Tier 1a method could use values from Asia for low productivity systems and the high productivity Tier 1a emission factor from Oceania, whichever is more representative of their production systems.

[5] Rangelands are defined as land primarily covered by woodlands, shrublands, grasslands and savannas, as well as introduced plant species that are naturalised (Grice *et al*. 2008).

[6] North African countries may wish to use values derived for the Middle East if productions systems are more similar.

[7] Buffalo mature females livestock sub-category includes lactating dairy mature females.

Tier 2 Approach for methane emissions from Enteric Fermentation

The Tier 2 method is applied to more disaggregated livestock population categories and used to calculate emission factors, as opposed to default values. The key considerations for the Tier 2 method are the development of emission factors and the collection of detailed activity data.

Step 1: Livestock population

The animal population data and related activity data should be obtained following the approach described in Section 10.2.

Step 2: Emission factors

When the Tier 2 method is used, emission factors are estimated for each animal category using the detailed data developed in Step 1.

The emission factors for each category of livestock are estimated based on the gross energy intake and methane conversion factor for the category. The gross energy intake data should be obtained using the approach described in Section 10.2. The following two sub-steps need to be completed to calculate the emission factor under the Tier 2 method:

1. Obtaining the methane conversion factor (Y_m)

The extent to which feed energy is converted to CH_4 depends on several interacting feed and animal factors and that rate of conversion is embodied in the methane conversion factor (Y_m), defined as the percentage of gross energy intake converted to methane.

There are a wide variety of factors that influence methane conversion rates and due to national circumstances related to breeds, genetic pools as well as particularities of feed and herd interactions, the Y_m factors may vary from region to region. Considering interactions between feed (type and quality) and animals (breed and genetics), it is *good practice* for countries to derive their own Y_m values considering their herds and their typical feed characteristics.

Nonetheless, numerous empirical studies demonstrate the statistical significance of improved feed quality on methane emission rates and biochemical modelling exhibits the biochemical processes that impact methane production with the introduction of improved feeds and concentrates to ruminant diets (Mills *et al.* 2001; Mills *et al.* 2003; Ellis *et al.* 2006; Ellis *et al.* 2007; Ellis *et al.* 2009; Ellis *et al.* 2010; Alemu *et al.* 2011; Bannink *et al.* 2011; Ellis *et al.* 2014; Escobar-Bahamondes *et al.* 2016; Kebreab *et al.* 2016). When country specific Y_m factors for cattle and buffalo are unavailable, the values provided in Table 10.12 can be used. These estimates are a guide based on the general feed characteristics and production practices found in many countries. It is *good practice* for compilers to justify their choice of Y_m factors based on detailed feed data and research.

In Table 10.12, the Y_m of dairy cows is linked to annual milk production levels and to feed quantity and quality. The lowest Y_m value is associated with highest producing dairy cattle that are fed diets of greater than 70 percent digestibility, and that have percentage of NDF in DMI of less than 35 percent. These diets may be further supplemented with additives or supplements that impact feed efficiency. In cases where countries are achieving high production on high quality silage diets that have digestibility greater than 70 percent but also NDF greater than 35 percent of DMI, compilers should use Y_m values that are midway between the high production and the mid-range productivity Y_m values (6.0 percent GEI).

Diets with digestible fractions that range from 63 to 70 percent and NDF greater than 37 percent DMI, consisting of good quality forages, silages and some grains and have associated milk production between 5000 to 8500 kg $year^{-1}$, are advised to use Y_m values of 6.3 percent GEI. For low production dairy systems with feed digestibility less than 62 percent and NDF fractions greater than 38 percent, the Y_m factor from the *2006 IPCC Guidelines* (6.5) has been maintained as there is a paucity of reliable globally representative data that could be used to revise that value. In cases where dairy cattle are strictly grazed on low quality forage diets, compilers should use the non-dairy low quality forage value of 7.0 percent GEI.

It is important for inventory compilers to base their decision to select the Y_m on a thorough understanding of national feeding systems. In the case of dairy cows, milk production is presented as a proxy for feed quality and Y_m values in Table 10.12 represent the relationship between feed quality and methane yield. It is possible for a country's national herd, or for parts of the national herd, to have production levels that are inconsistent with the feed quality bounds that are defined by the categories in Table 10.12. In these cases, it is *good practice* to develop their own country-specific Y_m factors, and they should also use their information on animal diets to validate their choice of Y_m against methane yield equations recommended in Niu *et al.* (2018).

With the non-dairy animal category, the non-feedlot diets can be differentiated between forage based diets for which the Y_m value of 7.0 should be used, and mixed concentrate diets or high quality forage diets for which compilers should use the value of 6.3. Reliable estimates for grazing cattle on very poor quality diets are not available, and due to the lack of data, the value of 7.0 is recommended. Countries that have large cattle herds consuming these types of diets are encouraged to develop country-specific values and research efforts should focus on providing more data on these cattle herds.

Emissions from feedlot animals are influenced by the type of grain fed to the animals during the finishing stage, the lowest value of 3.0 can be used when steam-flaked corn is fed at rates greater than 90 percent of the diet in combination with ionophores. Low forage diets of less than 15 percent that incorporate other grains are recommended to use the value of 4.0.

A methane conversion rate of zero is assumed for all juveniles consuming only milk (i.e., milk-fed lambs and calves). While some studies have demonstrated low level emissions from calves during the activation of their rumens (Gerrits *et al*. 2014), the Y_m for the addition of small quantities of emission from unweaned calves does not significantly influence emission factors. For weaned animals the Y_m values indicated for the non-dairy animal category are recommended.

Due to the importance of Y_m in driving emissions, ongoing research is aimed at improving estimates for different livestock and feed combinations. It is important to better understand the mechanisms involved in methanogenesis with a view to designing emission abatement strategies, as well as to identify different values for Y_m according to animal husbandry practices.

Significant improvements are needed for grazing animals in general, but in particular for low producing dairy cattle on diverse diets and grazing animals on low quality forages particularly in tropical regions as the available data are currently very sparse.

Regional, national and global estimates of enteric methane generation rely on small-scale determinations both of Y_m and of the influence of feed and animal properties upon Y_m. Traditional methods for measuring Y_m include the use of respiration calorimeters and head enclosures for housing individual animals (Johnson & Johnson 1995). A tracer technique using SF_6 enables methane emissions from individual animals to be estimated under both housed or grazing conditions (Johnson *et al.* 1994). Hammond *et al.* (2015) present an in-depth review of the advantages and limitations of methane measurement techniques used to determine Y_m values.

TABLE 10.12 (UPDATED)[6]
CATTLE/BUFFALO METHANE CONVERSION FACTORS (Y_M)

Livestock category	Description	Feed Digestibility (DE %) and Neutral Detergent Fibre (NDF, % DMI)	MY, g CH_4 kg DMI^{-1}	Y_m[3] (%)
[1,4]Dairy cows and Buffalo	High-producing cows[5] (>8500 kg/head/yr^{-1})	DE ≥ 70 NDF ≤ 35	19.0	5.7
	High-producing cows[5] (>8500 kg/head/yr^{-1})	DE ≥ 70 NDF ≥ 35	20.0	6.0
	Medium producing cows (5000 – 8500 kg yr^{-1})	DE 63-70 NDF > 37	21.0	6.3
	Low producing cows (<5000 kg yr^{-1})	DE ≤ 62 NDF >38	21.4	6.5
[2]Non dairy and multi-purpose Cattle and Buffalo	> 75 % forage	DE ≤ 62	23.3	7.0
	Rations of >75% high quality forage and/or mixed rations, forage of between 15 and 75% the total ration mixed with grain, and/or silage.	DE 62–71	21.0	6.3
	Feedlot (all other grains, 0-15% forage)	DE ≥ 72	13.6	4.0
	Feedlot (steam-flaked corn - 0-10% forage)	DE ≥ 75	10.0	3.0

[1]Expert judgement of IPCC authors in consideration of Appuhamy *et al.* (2016); Jayasundara *et al.* (2016) Hellwing *et al.* (2017) and Niu *et al.* (2018)

[2] Sources: Boadi and Wittenberg (2002); Pinares-Patiño *et al.* (2003); Boadi *et al.* (2004); Beauchemin and McGinn (2005); Beauchemin and McGinn (2006a); Beauchemin and McGinn (2006b); Chaves *et al.* (2006); Jordan *et al.* (2006a); Jordan *et al.* (2006b); Beauchemin *et al.* (2007); Hegarty *et al.* (2007); Hart *et al.* (2009); McGinn *et al.* (2009); Mc Geough *et al.* (2010a); Mc Geough *et al.* (2010b); Doreau *et al.* (2011); Hales *et al.* (2012); Kennedy and Charmley (2012); Staerfl *et al.* (2012); Chung *et al.* (2013); Hünerberg *et al.* (2013); Fiorentini *et al.* (2014); Hales *et al.* (2014); Hales *et al.* (2015); Troy *et al.* (2015); Nascimento *et al.* (2016); Vyas *et al.* (2016a); Vyas *et al.* (2016b); Baron *et al.* (2017); Hales *et al.* (2017).

[3] Uncertainty values are ± 20% based on published standard deviations from Niu *et al.* (2018) and data compilations for non dairy cattle as described in Annex 10B.2.

[4] Y_m cited for dairy cattle are for lactating dairy cows. For dairy cattle during their dry phase, in high and medium production systems, the non-dairy high quality forage value (6.3) should be selected and for low production systems with >75% low quality forage the value of (7.0) should be selected.

[5] The lowest Y_m factor for high producing cows refers to feeding situations in which additives or supplements may be used in production that stimulate feed use efficiency and/or milk production. The Y_m values given here do not yet account for any potential reducing effect of additives or supplements on Y_m.

[6] For details on the development of these values, refer to Annex 10B.2.

Table 10.13 proposes a common Y_m value for all sheep irrespective of feed quality values. This value is based on the mean value of raw data from New Zealand collated between 2009 and 2015 (Swainson *et al.* 2016). Data were derived from respiration chamber measurements where intake was accurately measured and covered a range of diet qualities. These replace values in the *2006 IPCC Guidelines* which were based on indirect measurements using the sulphur hexafluoride tracer technique where dry matter intake was generally estimated in grazing animals (Ulyatt *et al.* 2002a; Ulyatt *et al.* 2002b; Ulyatt *et al*. 2005). The mean value of 6.7 percent is most appropriate for situations where average dry matter intake per day is between 0.6 and 0.8 kg day^{-1} with a value of 7.0 percent being more appropriate where average intake is <0.6 kg day^{-1}, and a value of 6.5 percent being more appropriate where average intakes are >0.8kg day^{-1}. Table 10.13 also includes a Y_m value for goats (*2006 IPCC Guidelines* did not propose any specific value for goats). This value is based on the analysis of 65 studies that calculated in-vivo enteric CH_4 production from a varied sample of countries and goat breeds (sources and assumptions are explained in Annex 10B.3).

TABLE 10.13 (UPDATED)
SHEEP AND GOATS CH_4 CONVERSION FACTORS (Y_M)

Category	Y_m [1]
Sheep	6.7% ± 0.9
Goats	5.5% ± 1.0

Sources and assumptions to calculate the Y_m for goats are detailed in Annex 10B.3.
[1] The ± values are the standard deviation of the mean of the Y_m.

Note that in some cases, CH_4 conversion factors may not exist for specific livestock types. In these instances, CH_4 conversion factors from the reported livestock that most closely resembles those livestock types can be used. For example, CH_4 conversion factors for other cattle or buffalo could be applied to estimate an emission factor for camels.

2. Emission factor development

Using the energy balance Tier 2 approach an emission factor for each animal category should be developed following Equation 10.21:

EQUATION 10.21
METHANE EMISSION FACTORS FOR ENTERIC FERMENTATION FROM A LIVESTOCK CATEGORY

$$EF = \frac{GE \bullet \left(\frac{Y_m}{100}\right) \bullet 365}{55.65}$$

Where:

EF = emission factor, kg CH_4 head^{-1} yr^{-1}

GE = gross energy intake, MJ head^{-1} day^{-1}

Y_m = methane conversion factor, per cent of gross energy in feed converted to methane

The factor 55.65 (MJ/kg CH_4) is the energy content of methane

In cases in which the inventory compiler has used the simplified Tier 2 the emission factors should be calculated following equation 10.21a:

EQUATION 10.21A (NEW)
METHANE EMISSION FACTORS FOR ENTERIC FERMENTATION FROM A LIVESTOCK CATEGORY

$$EF = DMI \bullet \left(\frac{MY}{1000}\right) \bullet 365$$

Where:

EF = emission factor, kg CH_4 head^{-1} yr^{-1}

DMI = kg DMI day^{-1}

MY = Methane yield, g CH_4 kg DMI^{-1} (Table 10.12)

365 = days per year

1000 = conversion from g CH_4 to kg CH_4

These emission factor equations assume that the emission factors are being developed for an animal category for an entire year (365 days). While a full year emission factor is typically used, in some circumstances the animal category may be defined for a shorter period (e.g., for the wet season of the year or for a 150-day feedlot feeding period). In this case, the emission factor would be estimated for the specific period (e.g., the wet season) and the

365 days would be replaced by the number of days in the period. The definition of the period to which the emission factor applies is described in Section 10.2, defined according the the enhanced livestock characterisation that is used in calculation methodology.

Step 3: Total emissions

To estimate total emissions, the selected emission factors are multiplied by the associated animal population and summed. As described above under Tier 1, the emissions estimates should be reported in gigagrams (Gg).

Potential for refinement of Tier 2 or development of a Tier 3 method to enteric methane emission inventories

Increased accuracy and identification of causes of variation in emissions are at the heart of inventory purpose. Improvements in country methodology, whether as components of current Tier 1 or 2 or if additional refinements are implemented with Tier 3, are encouraged.

Tier 1 and Tier 2 enteric methane emissions factors and estimation procedures are driven by first estimating daily and annual gross energy consumption by individual animals within an inventory class which are then multiplied by an estimate of CH_4 loss per unit of feed (Y_m). There is considerable room for improvement in Tier 2 prediction of both feed intake and in Y_m. Factors potentially impacting feed requirements and/or consumption may include:

- depression in digestibility with increasing levels of consumption or due to rumen acidification, feed preparation or diet composition putting limits to feed intake;
- breed or genotype variation in maintenance requirement; and
- heat and cold stress effects on feed intake and maintenance requirements.

Likewise, a host of interacting factors cause variation in the rumen microbiome and its fermentation profile, and hence in hydrogen production which delivers the main substrate for methanogens. These factors lead to variation in Y_m that may include:

- variation in feed digestibility (DE);
- breed or genotype variation;
- level of feed intake;
- chemical composition of feed;
- kinetics of particle and fluid passage and of digestion, rumen volume, rumen fermentation profile; and
- other factors (such as secondary plant compounds, additives and other products) affecting the rumen microbiome.

The values in Table 10.12 capture some aspects of these factors as they are broadly related to feed quality and animal productivity, however these estimates can be improved for country-specific circumstances using higher tier methods. Accurate estimation of diet DE is singularly important in the estimation of feed intake and enteric methane emission, as previously emphasized. A change of 10 percent in DE will be magnified to a change in CH_4 emissions ranging from 12 to 20 percent depending on the dietary circumstances for which calculations are made. The depression in DE with increasing daily amounts of feed consumed (increasing rates of passage) is not inherently considered with Tier 2 and this neglect could underestimate feed intakes of high producing dairy cows consuming mixtures of concentrates and forages as is common in the North America and Europe, and hence underestimate methane emission. The balance between both effects (i.e. a reduction of feed digestibility and of Y_m) determines the net effect on methane emission which may vary with dietary circumstances. More complex models may be developed as Tier 3 to capture the intricacies of such effects.

There have been many attempts to refine estimates of Y_m. Several researchers have developed models which relate the chemical composition of the diet consumed, or in more detail, the composition of digested carbohydrate and other chemical components to Y_m. These models typically predict diet particle and chemical component rates of passage and digestion in each enteric compartment at varying intake and the resulting H_2 balance, volatile fatty acids, and microbial and CH_4 yields. These approaches have generated Y_m values that are consistent with direct measurements (Bannink *et al*. 2011; Gregorini *et al*. 2013; Huhtanen *et al*. 2015; Dougherty *et al*. 2017). A mechanistic model has been developed in the Netherlands that employs Tier 3 approach (Bannink *et al*. 2011) to estimate CH_4 yield from dairy cattle while the US use mechanistic models (Baldwin 1995; Kebreab *et al*. 2008) to refine estimates of Y_m for dairy and beef in different states within the US.

The literature contains many examples of the positive relationship of plant cell wall digestion to high acetic to propionic end-product ratios, and to high CH_4 yields. While fibrous carbohydrate digestion is the strongest indicator of CH_4 yield, the CH_4 per digested fiber is not constant and enteric fermentation of similar fibrous feeds can result in different Y_m values. For example, grass silage made from grass cut at different stages of maturity resulted in strongly different carbohydrate and protein composition, resulting in Y_m values varying from 5.5 to 6.9 percent with increased maturity and intake (Warner *et al*. 2017). Exchange of carbohydrates may also lead to a lower Y_m as demonstrated in studies where dietary starch content is increased through a higher proportion of corn silage (Hassanat *et al*. 2013; Benchaar *et al*. 2014) or through a higher proportion of starch containing concentrates (Aguerre *et al*. 2011). Prerequisite for the use of more complex prediction models for broad country inventories is that the data need to be provided to drive these more complex models of feed intake or Y_m. It is often difficult to define animal characteristics, productivity, and DE accurately for a livestock category in various regions or various production systems in a country. Of particular importance is a good characterization of roughages when they constitute a main part of the diet.

Ongoing global research, such as the use of direct methanogen inhibitors, 3-nitrooxypropanol (3-NOP), oxygen-rich anions, fats and oils, ionophores or condensed tannins, and also genetic selection suggests a need to address how they should be reflected in inventory compilation at Tier 2 or Tier 3. First, it is *good practice* that the inventory reflect only those technologies or genotypes developed through selection, conform to QA/QC principles and have attracted a wide degree of international acceptance such as through peer-reviewed articles that include a description of the technology, its efficacy and validation under field conditions. Second, it is *good practice* that the inventory be accompanied by evidence of the uptake of the technology in agricultural practice, and apply it only to emissions by those livestock where uptake can be validated. Mitigation measures and their representation in inventory compilation should be supported by peer-reviewed publications.

Concluding, approaches to improve estimates of feed intake (i.e. of diet composition, DE and dietary GE content) and Y_m, and approaches to account for specific mitigation measures are to be encouraged, given due care on limitations of the scope and on production circumstances where mitigation measures are applied and to which predictive models or relationships must apply as well.

10.3.3 Choice of activity data

Livestock population data should be obtained using the approach described in Section 10.2. If using default enteric emission factors for livestock (Tables 10.10, 10.11) to estimate enteric emissions, a basic (Tier 1) livestock population characterisation is sufficient. To estimate enteric emissions from livestock using estimation of Gross Energy Intake (Equations 10.21, or 10.21A), a Tier 2 characterisation is needed. As noted in Section 10.2, *good practice* in characterising livestock populations is to conduct a single characterisation that will provide the activity data for all emissions sources that depend on livestock population data.

10.4 METHANE EMISSIONS FROM MANURE MANAGEMENT

This section describes how to estimate CH_4 produced during the storage and treatment of manure, and from manure deposited on pasture. The Tier 1 approach is based on default emission factors per unit volatile solid (VS) by animal category and manure storage system. The Tier 2 is based on country-specific estimates of volatile solids and the impact of interactions between manure management systems and animal categories on total CH_4 emissions during excretion and storage, including manure treatments such as the production of biogas.

The term 'manure' is used here collectively to include both dung and urine (i.e., the solids and the liquids) produced by livestock. The emissions associated with the burning of dung for fuel are to be reported under Volume 2 (Energy), or under Volume 5 (Waste) if burned without energy recovery. When manure is used in the production of biogas, the emissions reported under the manure management category are those occurring on the farm site not resulting from combustion. These include, on-farm storage of the digestion input materials - pre-digestion, leakage during the digestion process and emissions from the storage and application of digestate to agricultural fields (included in Volume 4, Chapter 11, Section 11.2, Nitrous oxide emissions from managed Soils). Emissions from biogas combustion during the production of energy, whether on or off farm should be reported under Volume 2 "Energy".

The decomposition of manure under anaerobic conditions (i.e., in the absence of oxygen), during storage and treatment, produces CH_4. These conditions occur most readily when large numbers of animals are managed in a confined area (e.g., dairy farms, beef feedlots, and swine and poultry farms), and where manure is disposed of in liquid-based systems. Emissions of CH_4 related to manure handling and storage are reported under 'Manure Management.'

The main factors affecting CH_4 emissions are the amount of manure produced and the portion of the manure that decomposes anaerobically. The former depends on the rate of waste production per animal and the number of animals, and the latter on how the manure is managed. When manure is stored or treated as a liquid (e.g., in lagoons, ponds, tanks, or pits), it decomposes anaerobically and can produce a significant quantity of CH_4. The temperature and the retention time of the storage unit greatly affect the amount of methane produced. When manure is handled as a solid (e.g., in stacks or piles) or when it is deposited on pastures and rangelands, it tends to decompose under more aerobic conditions and less CH_4 is produced.

10.4.1 Choice of method

There are three tiers to estimate CH_4 emissions from livestock manure as shown in the *2006 IPCC Guidelines*.

To be consistent with consideration of differing productivity classes in section of enteric fermentation, a new Tier 1 was developed. In some regions, particularly in developing countries, production systems can vary between high productivity systems aimed at commercial food production and low productivity systems, largely serving local food production. In this case countries may choose to use a Tier 1 method in which emission factors are defined for low and high productivity systems based on the updated volatile solids and B_0, and the values of volatile solids were aligned with the updated enteric fermentation section.

Guidance for determining which methods to use is shown in Figure 10.3 decision tree.

Tier 1

The Tier 1 method entails multiplying the total amount of VS excreted (from all livestock species/categories) in each type of manure management system by an emission factor for that type of livestock category in the specified climate zone and manure management system (see Equation 10.22). Emissions are summed over all manure management systems and livestock categories. The Tier 1 method is applied using IPCC default VS excretion rates (See Table 10.13a), default typical animal mass (see Table 10A.5), default CH_4 Emission Factors (see Table 10.14), and default animal waste management systems (AWMS). Animal waste management system (manure management systems) data have been collected for regions and countries by the FAO and average manure fractions treated by different management systems are presented in Annex 10A.2, Tables 10A.6 to 10A.9. As emissions from manure management systems are highly temperature dependent, it is *good practice* to consider the climate zone associated with the locations

where manure is managed. Breakdowns of manure management systems by regional climate zone and production system can be found in the supplemental data supplied with this chapter. Please refer to "Raw data for cattle and buffalo spreadsheet". Further finer-scale country-specific data is also available from FAO GLEAM databases (FAO 2017).

An advanced Tier 1a method has been developed as an alternative for countries with differentiated agricultural systems in which there is a coexistence of low and high productivity systems or whose agricultural systems are transitioning from local low input productivity systems to higher productivity systems. In this case, where countries do not have the information necessary for implementing Tier 2 systems, the use of the productivity based emission factors given for an animal category provides an alternative or intermediary option. The advanced Tier 1a approach will provide an estimate of the changes in both productivity and manure management that occur when a transition from lower productivity systems to higher productivity systems occurs.

Tier 2

A more complex method for estimating CH_4 emissions from manure management should be used where a particular livestock species/category represents a significant share of a country's emissions. This method requires detailed information on animal characteristics and manure management practices, which is used to develop emission factors specific to the conditions of the country.

The main differences between the Tier 1 and Tier 2 calculations is whether default information or country-specific information is used in the calculation of emissions from manure management system. The Tier 2 system provides a much wider group of options for estimating emissions from different manure management systems.

Tier 3

Some countries for which livestock emissions are particularly important may wish to go beyond the Tier 2 method and develop models for country-specific methodologies or use measurement–based approaches to quantify emission factors.

The method chosen will depend on data availability and national circumstances. *Good practice* in estimating CH_4 emissions from manure management systems entails making every effort to use the Tier 2 method, including calculating emission factors using country-specific information. The Tier 1 method should only be used if all possible avenues to use the Tier 2 method have been exhausted and/or it is determined that the source is not a *key category* or subcategory.

Regardless of the method chosen, the animal population must first be divided into categories as described in Section 10.2 that reflect the varying amounts of manure produced per animal.

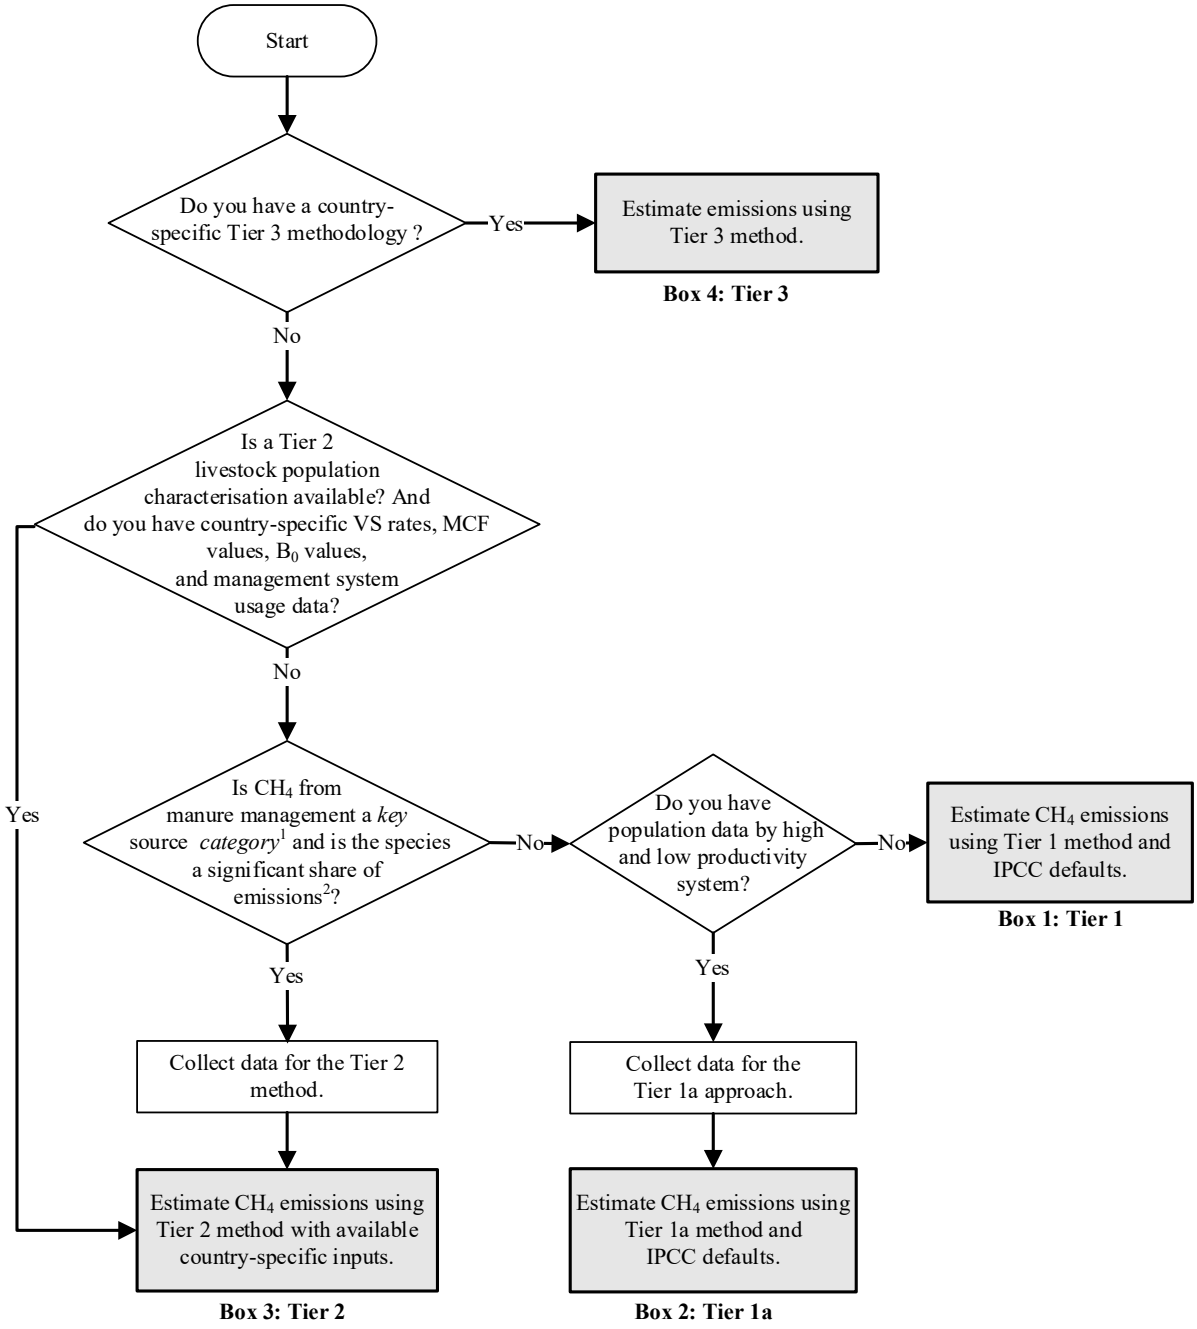
The following steps are used to estimate CH_4 emissions from manure management:

Step 1: Collect population data based on the Livestock Population Characterization (see Section 10.2).

Step 2: Identify default (Table 10A.5) or collect country-specific typical animal mass (TAM) values. Calculate volatile solid excretion according to Equation 10.22a or develop country-specific volatile solid excretion rates according to Equation 10.24.

Step 3: Collect country-specific information on manure management system methods and develop country-specific manure management system fractions or use default manure storage fractions presented in Annex Tables 10A.6 to Tables 10A.9.

Step 4: Identify either default emission factors Table 10.14 or build country-specific emission factors for each livestock subcategory based on climate zones and manure management system fractions.



- Tier 1: Identify default values (Table 10.14) for emission factors for each livestock category in terms of grams of methane per kg VS per year for the appropriate climate zone and productivity class if using advanced Tier 1a.
- Tier 2: Select local manure management specific methane conversion factors (MCF's, Table 10.17) for different climate zones and the animal categories specific maximum methane producing capacity (B_0).

Step 5: Calculate methane emission for each livestock subcategory.

- Tier 1: According to Equation 10.22 for each livestock category, climate zone (include production level if using Tier 1a) multiply the livestock category population (**Step 1**) by quantity of volatile solid (**Step 2**) by the manure storage fraction (**Step 3**) and the default emission factor (**Step 4**).
- Tier 2: According to Equation 10.23, for each livestock category and climate zone calculate the country-specific emission factor based on the country-specific or default quantity of volatile solids (**Step 2**), the manure management system fraction (AWMS) and the MCF and B_0 factors (**Step 4**); To estimate total emissions, the country specific emission factor is then multiplied by the population number (**Step 1**).

Step 6: Sum emissions from all defined livestock categories to determine national emissions.

Figure 10.3 (Updated) Decision tree for CH_4 emissions from Manure Management

Note:
1: See Volume 1 Chapter 4, "Methodological Choice and Identification of Key Categories"(noting Section 4.1.2 on limited resources), for discussion *of key categories* and use of decision trees.
2:As a rule of thumb, a livestock species would be significant if it accounts for 25-30% or more of emissions from the source category.

The calculation of CH_4 emissions from manure management for Tier 1 uses Equation 10.22 for both simple Tier 1 or advanced Tier 1a methods.

EQUATION 10.22 (UPDATED)
CH_4 EMISSIONS FROM MANURE MANAGEMENT (TIER 1)

$$CH_{4(mm)} = \left[\sum_{T,S,P} \left(N_{(T,P)} \bullet VS_{(T,P)} \bullet AWMS_{(T,S,P)} \bullet EF_{T,S,P} \right) / 1000 \right]$$

Where:

$CH_{4(mm)}$ = CH_4 emissions from Manure Management in the country, kg CH_4 yr^{-1}

$N_{(T,P)}$ = number of head of livestock species/category *T* in the country, for productivity system *P*, when applicable

$VS_{(T,P)}$ = annual average VS excretion per head of species/category *T*, for productivity system *P*, when applicable in kg VS $animal^{-1}$ yr^{-1} (Table 10.13a calculated by Equation 10.22a)

$AWMS_{(T,S,P)}$ = fraction of total annual VS for each livestock species/category *T* that is managed in manure management system *S* in the country, for productivity system *P*, when applicable; dimensionless, default regionally specific AWMS fractions are found in Tables 10A.6 through 10A.9 in Annex 10A.2

$EF_{(T,S,P)}$ = emission factor for direct CH_4 emissions from manure management system *S,* by animal species/category *T*, in manure management system *S*, for productivity system *P*, when applicable (Table 10.14), g CH_4 kg VS^{-1}

S = manure management system

T = species/category of livestock

P = high productivity system or low productivity system for use in advanced Tier 1a – omitted if using a simple Tier 1 approach

10.4.2 Choice of emission factors

The best way to determine emission factors is to conduct non-invasive or non-disturbing measurements of emissions in actual systems representative of those in use in the country. These field results can be used to develop models to estimate emission factors (Tier 3). Such measurements are difficult to conduct, and require significant resources and expertise, and equipment that may not be available. Thus, while such an approach is recommended to improve accuracy, it is not required for *good practice*. This section provides two alternatives for developing emission factors, with the selection of emission factors depending on the method (i.e., Tier 1 or Tier 2) chosen for estimating emissions.

Tier 1

When using the Tier 1 method, methane emission factors per unit of VS by livestock category or subcategory are used. Default emission factors by animal productivity class, manure management system and climate zone are presented in Table 10.14 for each of the recommended population subcategories. These emission factors represent the range in manure management practices used in each region, as well as the difference in emissions due to climate zone.

Tables 10A.5 through 10A.9 located in Annex 10A.2 present the underlying assumptions used for each region. Countries using a Tier 1 method to estimate methane emissions from manure management should review the regional variables in these tables to identify the region that most closely matches their animal operations, and use the default emission factors for that region.

Annual volatile solid excretion rates should be determined for each livestock category defined by the livestock population characterization. Country-specific rates may either be taken directly from documents or reports such as agricultural industry and scientific literature, or calculated based on estimates of dry matter intake (DMI), ash content and urinary energy (as explained below). In some situations, it may be appropriate to use excretion rates developed by other countries that have livestock with similar characteristics.

If country-specific data cannot be collected or derived, or appropriate data are not available from another country, the IPCC default volatile solid excretion rates presented in Table 10.13a can be used. These rates are presented in units of volatile solid excreted per 1000 kg of animal per day. These rates can be applied to livestock sub-categories of varying ages and growth stages using a typical average animal mass (TAM) for that population sub-category, as shown in Equation 10.22a for a Tier 1 calculation. The TAM should be consistent with median weight of the animal during its production stage. Typically, for animals used in meat production systems, this is the median weight of the animal during its growth period. Animals that are kept for the production of products (milk, eggs), draft or other uses would use the typical live weight of the animal herd.

Volatile solids should be calculated according to Equation 10.22a, either for the simple Tier 1 or the advanced Tier 1a, where parameters are split by their productivity class in the calculaton of volatile solid excretion. Note that if countries are mixing Tier 1 and Tier 2 methods and volatile solids are calculated through Equation 10.22A and are applied in Equation 10.23 (Tier 2), the constant of 365 should be removed from that equation.

EQUATION 10.22A (NEW)
ANNUAL VS EXCRETION RATES (TIER 1)

$$VS_{(T,P)} = \left(VS_{rate(T,P)} \bullet \frac{TAM_{T,P}}{1000} \right) \bullet 365$$

Where:

$VS_{(T,P)}$ = annual VS excretion for livestock category *T*, for productivity system *P* (when applicable), kg VS animal^{-1} yr^{-1}

$VS_{rate(T,P)}$ = default VS excretion rate, for productivity system *P* (when applicable), kg VS (1000 kg animal mass)$^{-1}$ day^{-1} (see Table 10.13a)

$TAM_{(T,P)}$ = typical animal mass for livestock category *T*, for productivity system *P* (when applicable), kg animal^{-1}

The calculation is a simple linear adjustment, so in the case of an animal that is 500 kg of weight, the VS emission rate will be half of the rate presented per 1000 kg live weight.

Default TAM values are provided in Table 10A.5 as well as in the Annexes of Chapter 10 of the *2006 IPCC Guidelines*. However, it is preferable to collect country-specific TAM values to be able to track changes in emissions with changes in productivity and animal size in certain animal categories. For example, market swine may vary from nursery pigs weighing less than 30 kilograms to finished pigs that weigh over 90 kilograms. By constructing animal population groups that reflect the various growth stages of market pigs, countries will be better able to estimate the total volatile solid excreted by their swine population.

Table 10.14 shows the default emission factors per kg of volatile solid excretion and year for all animal categories for each manure management system and climate zone. Emission factors are listed for the climate zone where the livestock manure is managed. It is *good practice* for countries to estimate the percentage of animal populations in different climate zones and compute a weighted average emission factor. Where this is not possible, an estimate should be made based on the proportion of area in each climate zone; however, this may not give an accurate estimate of emissions that are highly sensitive to temperature variations (e.g., liquid/slurry systems).

Separate emission factors are shown for high and low productivity systems in these t*ables, reflecting the general differences in feed intake and feed characteristics of the animals in regions that have highly differential production systems existing in the same country. Emission factors result from the MCFs in Table 10.17 and the B_0 in Table 10.16 and as a result, vary by animal category and manure management system, with liquid systems demonstrating higher emissions per unit VS. Lower emission factors associated with low productivity systems are representative of the lower B_0 values associated with lower quality feeds and manures with high C to N ratios.

TABLE 10.13A (NEW) (CONTINUED)
DEFAULT VALUES FOR VOLATILE SOLID EXCRETION RATE (KG VS (1000 KG ANIMAL MASS)-1 DAY^{-1})

[1] High PS and Low PS refer to high and low productivity systems required for Tier 1a methodology.

[2] NE is reported when values are not estimated, due to their not being adequate differences between high and low productivity production systems and NA refers to situations in which these animal categories do not occur in these regions.

[3] Values are taken from FAO GLEAM databases (FAO 2017).

[4] Values are derived from diets used in the calculation of enteric fermentation Tier 1 emission factors.

[5] Calculations are detailed in Annex 10B.3.

[6] North African countries may wish to use values from the Middle East if their production systems are more similar.

[7] All data are weighted values, representative of Australia and New Zealand. For Pacific Island nations, GHG inventory compilers may refer to Asian values. GHG inventory compilers from the Island nations from Oceania may wish to use a Tier 1a approach. In this case, they could used values from Asia, or low productivity systems and high Tier 1a emission factor from Oceania, whichever is more representative to their production systems.

[8] Values are derived directly from the parameters reported in Table 10A-9 of the *2006 IPCC Guidelines*.

TABLE 10.14 (UPDATED) (CONTINUED)
METHANE EMISSION FACTORS BY ANIMAL CATEGORY, MANURE MANAGEMENT SYSTEM AND CLIMATE ZONE (G CH_4 KG VS^{-1}) [7]

Livestock species	Productivity Class	Manure Storage System[4]	Cool	Temperate	Warm
Camels	High productivity	Solid storage	3.5	7.0	8.7
		Dry lot	1.7	2.6	0.0
	Low productivity[1]	Solid storage	2.8	5.6	7.0
		Dry lot	1.4	2.1	2.8
Horses	High productivity	Solid storage	4.0	8.0	10.1
		Dry lot	2.0	3.0	4.0
	Low productivity[1]	Solid storage	3.5	7.0	8.7
		Dry lot	1.7	2.6	3.5
Mules/ Asses	High productivity	Solid storage	4.4	8.8	11.1
		Dry lot	2.2	3.3	4.4
	Low productivity[1]	Solid storage	3.5	7.0	8.7
		Dry lot	1.7	2.6	3.5
All Animals	High and Low Productivity	Pasture Range and Paddock	0.6		

All values are calculated based on MCFs and B_0s reported in Tables 10.17 and 10.16, respectively, using the equation MCF*B_0*0.67.

[1] For the application of Tier 1, for all regions other than North America, Europe and Oceania the Tier 1 default values are the low productivity EFs. Pasture range and paddock emission factor is based on observation in the updated version of Cai *et al*. (2017) database (see Annex 10B.6). No differences were observed for animal type, region or productivity class and are therefore reported as a constant for all animal and productivity categories.

[2] Temp. is an abbreviation for temperate.

[3] Composting is the biological oxidation of organic material.

[4] Definitions of manure management systems can be found in Table 10.18.

[5] Emissions for liquid systems are calculated from manure management systems with a 6 month retention time.

[6] Buffalo emission factors are equivalent to low productivity non dairy animals.

[7] Uncertainty is ±30% consisten with the *2006 IPCC Guidelines*.

[8] Anaerobic digestion biogas values: for high productivity are based on emission estimates from high quality gas-tight digesters and average MCFs for storage whereas, for low productivity are based on emission estimates from high digester leakage rates and average MCFs for storage leakage rates. Countries should consider the type and quality of digesters used in their individual countries in evaluating what emission factors they choose to employ as opposed to the level of productivity for anaerobic digesters only.

TABLE 10.15 (UPDATED)
MANURE MANAGEMENT METHANE EMISSION FACTORS FOR DEER, REINDEER, RABBITS, OSTRICH AND FUR-BEARING ANIMALS AND DERIVATION PARAMETERS APPLIED

Livestock	CH_4 emission factor (kg CH_4 $head^{-1}$ yr^{-1})	VS (kg VS day^{-1})[4]	B_0 (m^3 kg VS)[4]
Deer[1]	0.22	NR	NR
Reindeer[2]	0.36	0.39	0.19
Rabbits[3]	0.08	0.10	0.32
Fur-bearing animals (e.g., fox, mink)[2]	0.68	0.14	0.25
Ostrich	5.67	1.16	0.25

The uncertainty in these emission factors is ±30 %.

[3] Judgement of the IPCC Expert Group.

[4] Table 10A-9 of the *2006 IPCC Guidelines*.

Tier 2

The Tier 2 method is applicable when Manure Management is a key source or when the data used to develop the default values do not correspond well with the country's livestock and manure management conditions. Because cattle, buffalo and swine characteristics and manure management systems can vary significantly by country, countries with large populations of these animals should consider using the Tier 2 method for estimating methane emissions.

The Tier 2 method relies on two primary types of inputs that affect the calculation of methane emission factors from manure:

Manure characteristics*:* Includes the amount of volatile solids (VS) produced in the manure and the maximum amount of methane able to be produced from that manure (B_0). Production of manure VS can be estimated based on feed intake and digestibility, which are the variables also used to develop the Tier 2 enteric fermentation emission factors. Alternatively, VS production rates can be based on laboratory measurements of livestock manure. B_0 varies by animal species and feed regime and is a theoretical methane yield based on the amount of VS in the manure. Bedding materials (straw, sawdust, chippings, etc.) are not included in the VS modelled under the Tier 2 method. The type and use of these materials is highly variable from country to country. Since they typically are associated with solid storage systems, their contribution would not add significantly to overall methane production. CH_4 emissions from co-digestion of on-farm organic resources (crop residues, energy crops) need to be reported under the source category '3.A2(k) – Co-digestates'.

Animal waste management system characteristics (AWMS)*:* Includes the types of systems used to manage manure and a system-specific methane conversion factor (MCF) that reflects the portion of B_o that is achieved. Regional assessments of manure management systems are used to estimate the portion of the manure that is handled with each manure management technique. A description of manure management systems is included in Table 10.18. The system MCF varies with the manner in which the manure is managed and the climate. Theoretically the value can range from 0 to 100 percent. Both temperature and retention time play an important role in the calculation of the MCF. Manure that is managed as a liquid under warm conditions for an extended period of time promotes methane formation. These manure management conditions can have high MCFs of 76 to 80 percent. Manure managed as dry material in cold climates does not readily produce methane, and consequently has an MCF of about 1 percent.

Development of Tier 2 emission factors involves determining a weighted average MCF using the estimates of the manure managed by each waste system within each climate region. The average MCF is then multiplied by the VS excretion rate and the B_o for the livestock categories. In equation form, the estimate is as follows:

EQUATION 10.23
CH_4 EMISSION FACTOR FROM MANURE MANAGEMENT[5]

$$EF_{(T)} = \left(VS_T \bullet 365\right)\left[B_{0(T)} \bullet 0.67 \bullet \sum_{S,k} \frac{MCF_{S,k}}{100} \bullet AWMS_{(T,S,k)}\right]$$

Where:

$EF_{(T)}$ = annual CH_4 emission factor for livestock category *T*, kg CH_4 animal^{-1} yr^{-1}

$VS_{(T)}$ = daily volatile solid excreted for livestock category *T*, kg dry matter animal^{-1} day^{-1}

365 = basis for calculating annual VS production, days yr^{-1}

$B_{0(T)}$ = maximum methane producing capacity for manure produced by livestock category *T*, m^3 CH_4 kg^{-1} of VS excreted

0.67 = conversion factor of m^3 CH_4 to kilograms CH_4

$MCF_{(S,k)}$ = methane conversion factors for each manure management system *S* by climate region *k*, percent

$AWMS_{(T,S,k)}$ = fraction of livestock category *T*'s manure handled using animal waste management system *S* in climate region *k*, dimensionless

Even when the level of detail presented in the Tier 2 method is not possible in some countries, country-specific data elements such as animal mass, VS excretion, and others can be used to improve emission estimates. If country-specific data are available for only a portion of these variables, countries are encouraged to calculate country-specific emission factors, using the data available in Annex 10A.1 and 10A.2 to fill gaps.There is no defined threshold to indicate how much country-specific information is required for a Tier 2 method, but it is understood that increased use of country-specific information improves emission estimates, by better representing local production characteristics.

Measurement programs can be used to improve the basis for making the estimates. In particular, measurements of emissions from manure management systems under field conditions are useful to verify MCFs. Also, measurements of B_0 from livestock in tropical regions and for varying diet regimens are needed to expand the representativeness of the default factors.

As emissions can vary significantly by region and livestock species/category, emission estimates should reflect as much as possible the diversity and range of animal populations and manure management practices between different regions within a country. This may require separate estimates to be developed for each region. Emission factors should be updated periodically to account for changes in manure characteristics and management practices. These revisions should be based on reliable scientifically reviewed data. Frequent monitoring is desirable to verify key model parameters and to track changing trends in the livestock industry.

VS excretion rates

Volatile solids (VS) are the organic material in livestock manure and consist of both biodegradable and non-biodegradable fractions. The value needed for the Equation 10.24 is the total VS (both degradable and non-biodegradable fractions) as excreted by each animal species since the B_o values are based on total VS entering the systems. The best way to obtain average daily VS excretion rates is to use data from nationally published sources. If average daily VS excretion rates are not available, country-specific VS excretion rates can be estimated from feed intake levels. Feed intake for cattle and buffalo can be estimated using the 'Enhanced' characterisation method described in Section 10.2. This will also ensure consistency in the data underlying the emissions estimates. For swine, country-specific swine production data may be required to estimate feed intake.

The VS content of manure equals the fraction of the diet consumed that is not digested and thus excreted as fecal material which, when combined with urinary excretions, constitutes manure. Countries should estimate gross

[5] When biogas is produced in on-farm plants, emissions from on-farm co-digestates can be calculated separately using a similar equation: $CH_{4(cdg)}=C_{cdg}$ *B0*0.67*(MCF/100) and added to methane totals, where C_{cdg} is the total kg dry matter of the co-digested material and other parameters are as defined in Equation 10.23

energy (GE) intake (Section 10.2, Equation 10.16) and its fractional digestibility, DE, in the process of estimating enteric methane emissions.

Once these are estimated, the VS excretion rate is estimated as:

EQUATION 10.24 (UPDATED)
VOLATILE SOLID EXCRETION RATES

$$VS = \left[GE \bullet \left(1 - \frac{DE}{100} \right) + \left(UE \bullet GE \right) \right] \bullet \left[\left(\frac{1 - ASH}{18.45} \right) \right]$$

Where:

VS	= volatile solid excretion per day on a dry-organic matter basis, kg VS day^{-1}
GE	= gross energy intake, MJ day^{-1}
DE	= digestibility of the feed in percent (e.g. 60 percent)
$(UE \bullet GE)$	= urinary energy expressed as fraction of GE. Typically 0.04GE can be considered urinary energy excretion by most ruminants (reduce to 0.02 for ruminants fed with 85 percent or more grain in the diet or for swine). Use country-specific values where available.
ASH	= the ash content of feed calculated as a fraction of the dry matter feed intake (e.g., 0.06 for sows: Dämmgen *et al*. 2011). Use country-specific values where available.
18.45	= conversion factor for dietary GE per kg of dry matter (MJ kg^{-1}). This value is relatively constant across a wide range of forage and grain-based feeds commonly consumed by livestock.

Representative DE percent values for various livestock categories are provided in Section 10.2, Table 10.2 of this report. The value for ash content fraction can range substantially between livestock types and should reflect national circumstances.

B_0 values

The maximum methane-producing capacity of the manure (B_0) varies by species and diet. The preferred method to obtain B_0 measurement values is to use data from country-specific published sources, measured with a standardised method. It is important to standardise the B_0 measurement, including the method of sampling, and to confirm if the value is based on total as-excreted VS or biodegradable VS, since the Tier 2 calculation is based on total as-excreted VS. If country-specific B_0 measurement values are not available, default values are provided in Table 10.16 where data is summarized from Table 10A-4 through 10A-9 of *2006 IPCC Guidelines*.

MCFs

MCFs are determined for a specific manure management system and represent the degree to which B_0 is achieved. Default methane conversion factors (MCFs) are provided in Table 10.17 for different manure management systems. The amount of methane generated by a specific manure management system is affected by the amount of volatile solids, the extent of anaerobic conditions present, the temperature of the system, and the retention time of organic material in the system. Default MCF values for liquid systems and lagoons presented in Table 10.17 include the effect of longer retention times.

Liquid-based systems are sensitive to temperature effects. Average annual MCF values for a specific system will largely be determined by the quantity of VS in the storage system during peak temperature periods (Balde *et al*. 2016). Emissions increase exponentially with increasing temperatures. For this reason, monthly temperature variations in combination with timing of storage and application times largely define annual MCFs rather than average annual temperatures.

Climate zones are used to differentiate variations in MCFs associated with ranges and annual monthly temperature variability. Detailed definitions of climate zones and a decision tree to determine in what climate zone a specific region falls, can be found in Annex 10A.2, Figure 10A.1. Inventory compilers should consult long-term averages from national meteorological statistics and evaluate the climate zones for each region of their country based on the criteria outlined in Annex 10A.2. It is *good practice* to assure consistency of the definition of climate zones for all sectors of the inventory that may be influenced by climate.

Manure removal statistics should be taken from farm practice surveys or from expert consultation. Compilers should develop an estimate of the average number of manure removals per year and the months of the highest

frequency of removals. If regional practices vary, compilers should develop MCFs that are representative of regional practice by entering consistent manure removal statistics with regional temperature profiles. If regional MCFs are calculated, the national MCF should be weighted based on the number of animals feeding into the regional manure management systems represented by the manure removal profile and the regional temperature profile.

In cases in which countries lie in multiple climate zones, it is *good practice* for compilers, if possible, to disaggregate livestock populations by climate zone. However, when it is not possible, compilers should select the dominant climate zone in their country or region.

Further, in cases that countries have information available on their manure spreading practices (number of times that manure storages are emptied per year) and have monthly temperature profiles it is *good practice* that they customize MCF calculations based on their monthly temperature profiles according to the example provided in Annex 10A.2. If regional MCFs are calculated, the national MCF should be weighted based on the number of animals feeding into the regional manure management systems represented by the manure removal profile and the regional temperature profile. Global temperature data can be downloaded from a number of sites such as the National Oceanic and Atmospheric Administration (NOAA) website, long-term monthly averages should be used for the development of MCFs.

Likewise, for cases in which manure is maintained in the animal housing, compilers may wish to calculate the MCF considering the temperature profile of the housing. An example of how to derive an MCF for a liquid system is provided in Annex 10A.3 and a simple spreadsheet model is available in the supplemental data supplied with this chapter. Please refer to "Raw data for cattle and buffalo spreadsheet".

For manure deposited by grazing animals onto pastures, ranges and paddocks, it is recommended to use a value that is consistent with the emission factor provided in Table 10.14. In this table, a single emission factor per unit of volatile solid excretion is provided, as an analysis of 45 data points showed that there was no significant difference between climatic zones nor were there differences per animal category (Annex 10B.6). Therefore, the MCF reported in Table 10.17 must be used in conjunction with a single B_0 value of 0.19 m^3 CH_4 kg^{-1} of VS excreted, derived from the experimental results described in Annex 10B.6. This single emission factor was judged by the expert panel to be more accurate than emission factors estimated from regionally based MCFs and animal category based B_0, considering the differences in processes that would result in methane production between excretion of VS on pasture, range and paddock relative to typical manure storage systems.

Anaerobic digestion is an important manure management technology that provides renewable energy through biogas production. There is a wide variety of digesters available of varyinig quality and use including industrial centralised biogas digester plants, and animal farm based biogas digesters. Some biogas digesters may co-digest energy crops and different types of organic waste in varying combinations. The quality of the digester and the pre- and post-storage of digester input and output (digestate) are the main factors in determining the methane that is lost to the atmosphere before, during and after digestion.

Default methane conversion factors (MCFs) of anaerobic digesters are provided in Table 10.17. Default values for biogas digesters presented include the estimated MCF from combinations of either high and low quality anaerobic digetsers with different types and qualities of storage systems. The approach to calculate these MCFs, based on Haenel *et al*. (2018) is outlined in Annex 10A.4. The main factors considered in differentiating between digester systems are the degree of leakage from the digester itself (varying between 1 and 10 percent of the methane production potential B_0) and the loss of CH_4 from the digeste storage system.

All manure management methane emission factors are based on experimental measurements that typically combine the VS and bedding. Based on current scientific literature, these two sources cannot be separated. More refined measurements of methane from manure storage and stages of storage are for further scientific development. These default values may not encompass the potentially wide variation within the defined categories of management systems. Therefore, country-specific MCFs that reflect the specific management systems used in particular countries or regions should be developed, if possible. This is particularly important for countries with large animal populations or with multiple climate regions. In such cases, and if possible, field measurements should be conducted for each climate region to replace the default MCF values. Measurements should include the following factors:

- Duration of storage and timing of application;
- Information on manure treatment and VS (including bedding) entering the storage system;
- Feed and animal characteristics at the measurement site (see Section 10.2 for the type of data that would be pertinent);
- Determination of the amount of manure left in the storage facility after emptying (methanogenic inoculum);

- Monthly temperature in the storage.

CH_4 emissions from multiple Manure Management systems

If manure is managed in multiple systems, by default, manure emission factors should be allocated to the dominant storage systems; but a country specific emission factor could be developed considering the emissions originating from all systems used in storage prior to field applicaton.

A number of combinations are possible and it is beyond the scope of these guidelines to provide guidance for all possibilities but common examples include: i.) manure flushed from a dairy freestall barn to an anaerobic lagoon that first pass through a solids separation unit where some of the manure nitrogen is removed and managed as a solid. In this case, the methodology must integrate an additional fraction to the AWMS system that tranfers those solids to a solid storage systems; ii.) pit storage that is flushed to a larger holding tank. In this case, the methodology must consider modifications to the B_0 that result from the initial storage period based on the length of the storage and the temperature dependant MCF. iii.) solid manure pack that is allowed to accumulate, and periodically transferred to heaps. Likewise in this case, the impact of the prestorage period to the B_0 of the manure in the secondary storage should be adjusted to consider the emissions that occurred during the initial storage.

In cases in which country-specific methodologies are used to estimate emissions from multiple systems rely on B_0s and MCFs as defined in Tables 10.16 and 10.17, these methodologies should assure that the total annual B_0 of the stored manure is not reduced or increased during the application of the methodology. Further, methodologies that require additional fractionation of manure must assure that calculated VS input is not reduced or increased.

TABLE 10.16A (UPDATED)
DEFAULT VALUES FOR MAXIMUM METHANE PRODUCING CAPACITY (B_0) (M^3 CH_4 KG^{-1} VS)

Category of animal [2]	Region					
	North America	Western Europe	Eastern Europe	Oceania	Other Regions[1]	
					High productivity systems	Low productivity systems
Dairy cattle	0.24				0.24	0.13
Non dairy cattle	0.19	0.18	0.17	0.17	0.18	0.13
Buffalo	0.10				0.10	0.10
Swine	0.48	0.45	0.45	0.45	0.45	0.29
Chicken-Layer	0.39				0.39	0.24
All other poultry	0.36				0.36	0.24
Sheep	0.19				0.19	0.13
Goats	0.18				0.18	0.13
Horses	0.30				0.30	0.26
Mules/ Asses	0.33				0.33	0.26
Camels	0.26				0.26	0.21
All Animals PRP	0.19					

Sources: All values are consistent with *2006 IPCC Guidelines* values from Annex 10A.2 with the exception of PRP, taken from the analysis described in Annex 10B.6.

[1] For other regions, low productivity is considered the default value for Tier 1 if not using the Tier 1a.

[2] Only presenting values for manure, compilers are recommended to consult scientific literature or develop country-specific B_0 values for the different codigestates that may be used in anaerobic digesters.

Uncertainty values are ±15 percent.

TABLE 10.17 (UPDATED) (CONTINUED)
METHANE CONVERSION FACTORS FOR MANURE MANAGEMENT SYSTEMS

[1] The initial judgement of IPCC Expert Group supported by additional new research. See Annex 10B.7 for additional details. Suggested default values are equivalent to liquid systems with 6 month retention time if retention times are unknown. A reduction of 40% due to crust cover may be applied only when a thick, dry, crust is present. Thick dry crusts occur in systems in which organic bedding is used in the barn and is allowed to be flushed into the liquid storage tank and solids are not separated from the manure stream and further the surface is not exposed to regular heavy precipitation that may disrupt the surface. Sources: Aguerre *et al*. (2012); Nielsen *et al*. (2013); VanderZaag *et al*. (2008).

New information suggests that a solid cover reduces CH_4 emissions by 25 to 50% (range: 0 to 90%). Sources: Amon *et al*. (2006), Amon *et al*. (2007); Clemens *et al*. (2006); Guarino *et al*. (2006), Matulaitis *et al*. (2015), Misselbrook *et al*. (2016), VanderZaag *et al*. (2009), Hou *et al*. (2015), VanderZaag *et al*. (2008).

[2] Pasture Range and Paddock MCFs must always be used in conjunction with a B_0 value of 0.19 m^3 CH_4 kg^{-1} of VS excreted to maintain consistency with the data in the updated version of Cai *et al*. (2017) database (see Annex 10B.6).

[3] Definitions for manure management systems are provided in Table 10.18.

[4] Composting is the biological oxidation of a solid waste including manure usually with bedding or another organic carbon source typically at thermophilic temperatures due to microbial heat production.

[5] Articles from which these values were derived were for cattle and swine, but for other animal production systems that use deep bedding these values are proposed to be used as surrogates. Suggested default values are equivalent to liquid systems with 6 month retention time.

[6] Sources and assumptions to calculate MCF values for *Solid storage categories and composting (static pile and passive windrows)* are detailed in Annex 10B.7.

[7] Judgement of IPCC Expert Group utilizing a 12 month retention time and the equations and parameters presented in Mangino *et al*. (2001). Solid-liquid separation that removes VS and diverts it to aerobic/solid management should be considered when calculating the VS loading rate into liquid systems.

[8] The avg °C for Cool Temperate Moist, Cool Temperate Dry, Warm Temperate Moist, Warm Temperate Dry, Tropical Montane, Tropical Wet, Tropical Moist, Tropical Dry were 4.6, 5.8, 13.9, 14.0, 21.5, 25.9, 25.2, 25.6 respectively.

[9] Solid-liquid separation that removes VS and diverts it to aerobic/solid management should be considered when calculating the VS loading rate into liquid systems.

[10] Judgement of IPCC 2006 Expert Group in combination with Mangino *et al*. (2001). Values are consistent with liquid systems. Values presented here are consistent with a 6 month retention time, however compilers should take into account country-specific retention time when possible.

[11] Judgement of IPCC 2006 Expert Group in combination with Moller *et al*. (2004). Expect emissions to be similar, and possibly greater, than pit storage, depending on organic content and moisture content.

[12] Expert judgement based on IPCC (2006) and update supported by Pardo *et al*. (2015). Emissions in temperate climate can be double relative to a cool climate.

[13] Expert judgement based on Pardo *et al*., (2015). Emissions in the same range than solid storage.

[14] Expert judgement based on Pardo *et al*. (2015). Estimated reduction of 75% due to bulking agent addition.

[15] Expert judgement based on Pardo *et al*. (2015). Estimated reduction of 50% due to additives addition.

[16] Judgement of IPCC 2006 Expert Group in combination with Hashimoto & Steed (1993).

[17] Hashimoto & Steed (1993).

[18] Judgement of IPCC 2006 Expert Group and Amon *et al*. (1998a). MCFs are less than half of solid storage. Not temperature dependant.

[19] Expert judgement updated based on Pardo *et al*. (2015). Estimated reduction of 50% compared to solid storage. Previously it was considered "Not temperature dependent" but now temperature influence has been considered.

[20] Judgement of IPCC Expert Group and Amon *et al*. (1998a). MCFs are slightly less than solid storage. Less temperature dependant.

[21] Expert judgement update based on Pardo *et al*. (2015). Estimated reduction of 50% compared to solid storage. Previous MCFs have been modified as they could underestimate CH_4 emissions.

[22] Judgement of 2006 IPCC Expert Group. MCFs are similar to solid storage or to dry lot but with generally constant warm temperatures.

[23] Judgement of 2006 IPCC Expert Group. MCFs are near zero. Aerobic treatment can result in the accumulation of sludge which may be treated in other systems. Sludge requires removal and has large VS values. It is important to identify the next management process for the sludge and estimate the emissions from that management process if significant.

[24] Judgement of IPCC 2006 Expert Group in combination with Safley *et al*. (1992).

[25] Calculations based on Haenel *et al*. (2018), outlined in Annex 10A.4.

10.4.3 Choice of activity data

There are two main types of activity data for estimating CH_4 emissions from manure management: (1) animal population data; and (2) manure management system usage data.

The animal population data should be obtained using the approach described in Section 10.2. As noted in Section 10.2, it is *good practice* to conduct a single livestock characterisation that will provide the activity data for all emissions sources relying on livestock population data. It is important to note, however, that the level of disaggregation in the livestock population data required to estimate emissions from manure management, may differ from those used for other sources, such as Enteric Fermentation. For example, for some livestock population species/categories, such as cattle, the enhanced characterisation required for the Tier 2 enteric fermentation estimate could be aggregated to broader categories that are sufficient for this source category. For other livestock species, such as swine, it may be preferable to have more disaggregation of weight categories for manure management calculations than for enteric fermentation. However, consistency in livestock categories should be retained throughout the inventory.

Inventory agencies in countries with varied climatic conditions are encouraged to obtain population data for each major climatic zone as defined in Volume 4, Chapter 3, Annex 3A.5, Figure 3A.5.1 or the version found in Annex 10A.2 of this Chapter. This will allow more specific selection of default factors or MCF values for those systems more sensitive to temperature changes. Ideally, the regional population breakdown can be obtained from published national livestock statistics, and the temperature data from national meteorological statistics. If regional data are not available, experts should be consulted regarding regional production (e.g., milk, meat, and wool) patterns or land distribution, which may provide the required information to estimate the regional animal distributions.

To implement the Tier 2 method, the portion of manure managed in each manure management system must also be collected for each representative animal species. Table 10.18 summarizes the main types of manure management systems. Quantitative data should be used to distinguish whether the system is judged to be a solid storage or liquid/slurry. The borderline between dry and liquid can be drawn at 15 percent dry matter content. Note that in some cases, manure may be managed in several types of manure management systems. For example, manure flushed from a dairy freestall barn to an anaerobic lagoon may first pass through a solids separation unit where some of the manure solids are removed and managed as a solid. Therefore, if manure is managed in multiple systems, it is *good practice* to report the respective CH_4 emissions from each system (see N_2O emissions from multiple Manure Management systems). Manure removal statistics should also be monitored where possible. It is recommended that agencies develop an estimate of the average number of manure removals per year and the months of the highest frequency of removals. If regional practices vary and also represent significant differences in temperature profiles, statistics that are representative of regional practice should be tracked combining the appropriate manure removal statistics together with regional temperature profiles.

The best means of obtaining manure management system distribution data is to consult regularly published national statistics. If such statistics are unavailable, the preferred alternative is to conduct an independent survey of manure management system usage. If the resources are not available to conduct a survey, experts should be consulted to obtain an opinion of the system distribution. Volume 1, Chapter 2 *Approaches to Data Collection* describes how to elicit expert judgement. Similar expert elicitation protocols can be used to obtain manure management system distribution data.

TABLE 10.18 (UPDATED)
DEFINITIONS OF MANURE MANAGEMENT SYSTEMS[3]

System		Definition
Pasture/Range/Paddock (PRP)		The manure from pasture and range grazing animals is allowed to lie as deposited, and is not managed.
Daily spread		Manure is routinely removed from a confinement facility and is applied to cropland or pasture within 24 hours of excretion.
Solid storage		The storage of manure, typically for a period of several months, in unconfined piles or stacks. Manure is able to be stacked due to the presence of a sufficient amount of bedding material or loss of moisture by evaporation. Solid stores can be covered or compacted. In some cases, bulking agent or additives are added.
Solid storage-Covered/compacted		Similar to solid storage, but the manure pile is a) covered with a plastic sheet to reduce the surface of manure exposed to air and/or b) compacted to increase the density and reduce the free air space within the material.
Solid storage - Bulking agent addition		Specific materials (bulking agents) are mixed with the manure to provide structural support. This allows the natural aeration of the pile, thus enhancing decomposition (e.g. sawdust, straw, coffee husks, maize stover).
Solid storage - Additives		The addition of specific substances to the pile in order to reduce gaseous emissions. Addition of certain compounds such as attapulgite, dicyandiamide or mature compost have shown to reduce N_2O emissions; while phosphogypsum reduces CH_4 emissions.
Dry lot		A paved or unpaved open confinement area without any significant vegetative cover. Dry lots do not require the addition of bedding to control moisture. Manure may be removed periodically and spread on fields.
Liquid/Slurry [1]		Manure is stored as excreted or with some minimal addition of water or bedding material in tanks or ponds outside the animal housing. Manure is removed and spread on fields once or more in a calendar year. Manure is agitated before removal from the tank/ponds to ensure that most of the VS are removed from the tank.
Uncovered anaerobic lagoon		A type of liquid storage system designed and operated to combine waste stabilization and storage. Lagoons have a lower depth and a much larger surface compared to liquid slurry stores. Anaerobic lagoons are designed with varying lengths of storage (up to a year or greater), depending on the climate region, the volatile solids loading rate, and other operational factors. The supernatant water from the lagoon may be recycled as flush water or used to irrigate and fertilise fields.
Pit storage below animal confinements		Collection and storage of manure usually with little or no added water typically below a slatted floor in an enclosed animal confinement facility, usually for periods less than one year. Manure may be pumped out of the storage to a secondary storage tank multiple times in one year, or stored and applied directly to fields. It is assumed that VS removal rates on tank emptying are >90%.
Anaerobic digester	Digesters of high quality and low leakage	Animal manure with and without straw is collected and anaerobically digested in a containment vessel. Co-digestion with other waste or energy crops may occur. Digesters are designed, constructed and operated according to industrial technology standard for waste stabilization by the microbial reduction of complex organic compounds to CO_2 and CH_4. Biogas is captured and used as a fuel. Digestate is stored either in open storage, in covered storage with no leakage control, or in gas tight storage with gas recovery or flaring.
	Digesters with high leakage	Animal manure with and without straw is collected and anaerobically digested in covered lagoon. Digesters are used for waste stabilization by the microbial reduction of complex organic compounds to CO_2 and CH_4. Biogas is captured and flared or used as a fuel. After anaerobic digestion, digestate is stored either openly, covered, or gas tightly.
Burned for fuel		The dung and urine are excreted on fields. The sun dried dung cakes are burned for fuel.

TABLE 10.18 (UPDATED) (CONTINUED)
DEFINITIONS OF MANURE MANAGEMENT SYSTEMS

System		Definition
Deep bedding		As manure accumulates, bedding is continually added to absorb moisture over a production cycle and possibly for as long as 6 to 12 months. This manure management system also is known as a bedded pack manure management system and may be combined with a dry lot or pasture. Manure may undergo periods where animals are present and are actively mixing the manure, or periods in which the pack is undisturbed.
Composting	In-vessel[2]	Composting, typically in an enclosed channel, with forced aeration and continuous mixing.
	Static pile	Composting in piles with forced aeration but no mixing, with runoff/leaching containment.
		Composting in piles with forced aeration but no mixing, without runoff/leaching containment.
	Intensive windrow[2]	Composting in windrows with regular (at least daily) turning for mixing and aeration, runoff/leaching containment.
		Composting in windrows with regular (at least daily) turning for mixing and aeration, no runoff/leaching containment.
	Composting - Passive windrow[2]	Composting in windrows with infrequent turning for mixing and aeration, with runoff/leaching.
		Composting in windrows with infrequent turning for mixing and aeration, no runoff/leaching.
Poultry manure with litter		Similar to cattle and swine deep bedding except usually not combined with a dry lot or pasture. Typically used for all poultry breeder flocks, for alternative systems for layers and for the production of meat type chickens (broilers) and other fowl. Litter and manure are left in place with added bedding during the poultry production cycle and cleaned between poultry cycles, typically 5 to 9 weeks in productive systems and greater in lower productivity systems.
Poultry manure without litter		May be similar to open pits in enclosed animal confinement facilities or may be designed and operated to dry the manure as it accumulates. The latter is known as a high-rise manure management system and is a form of passive windrow composting when designed and operated properly. Some intensive poultry farms installed the manure belt under the cage, where the manure is dried inside housing.
Aerobic treatment		The biological oxidation of manure collected as a liquid with either forced or natural aeration. Natural aeration is limited to aerobic and facultative ponds and wetland systems and is due primarily to photosynthesis. Hence, these systems typically become anoxic during periods without sunlight.

[1] Covers on manure management systems can impact emissions of direct N_2O, CH_4 and NH_3. With N_2O and CH_4 emission, the effect of the cover depends upon character of the cover material.

[2] Composting is the biological oxidation of a solid waste including manure usually with bedding or another organic carbon source typically at thermophilic temperatures produced by microbial heat production.

[3] Comparative definitions with the EMEP/EEA Air Pollutant Emission Inventory 2016 Guidebook can be found in Annex 10A.2, Table 10A.10.

10.5 N_2O EMISSIONS FROM MANURE MANAGEMENT

This section describes how to estimate the N_2O produced, directly and indirectly, during the storage and treatment of manure before it is applied to land or otherwise used for feed, fuel, or construction purposes. The approach is based on N excretion, emission factors for N_2O emissions, as well as volatilization and leaching factors. This section also details the principles of N flow and the connection between IPCC N_2O reporting and NH_3 and NO_x reporting required for UNECE countries.

The term 'manure' is used here collectively to include both dung and urine (i.e., the solids and the liquids) produced by livestock. The N_2O emissions generated by manure in the system 'pasture, range, and paddock' occur directly and indirectly from the soil, and are therefore reported under the category 'N_2O Emissions from Managed Soils' (see Chapter 11, Section 11.2). Direct and indirect N_2O emissions generated by manure managed in other systems and following its application to soils are also reported under the category 'N_2O Emissions from Managed Soils' (see Chapter 11, Section 11.2). The emissions associated with the burning of dung for fuel are to be reported under 'Fuel Combustion' (see Volume 2: Energy), or under 'Waste Combustion' (see Volume 5: Waste) if burned without energy recovery.

Direct N_2O emissions occur via combined nitrification and denitrification of nitrogen contained in the manure. The emission of N_2O from manure during storage and treatment depends on the nitrogen and carbon content of manure, and on the duration of the storage and type of treatment. Nitrification (the oxidation of ammonia nitrogen to nitrate nitrogen) is a necessary prerequisite for the emission of N_2O from stored animal manures. Nitrification is likely to occur in stored animal manures provided there is a sufficient supply of oxygen. Nitrification does not occur under anaerobic conditions. Nitrites and nitrates are transformed to N_2O and dinitrogen (N_2) during the naturally occurring process of denitrification, an anaerobic process. There is general agreement in the scientific literature that the ratio of N_2O to N_2 increases with increasing acidity, nitrate concentration, and reduced moisture. In summary, the production and emission of N_2O from managed manures requires the presence of either nitrites or nitrates in an anaerobic environment preceded by aerobic conditions necessary for the formation of these oxidized forms of nitrogen. In addition, conditions preventing reduction of N_2O to N_2, such as a low pH or limited moisture, must be present.

Indirect emissions result from volatile nitrogen losses that occur primarily in the forms of ammonia and NO_x. The fraction of excreted organic nitrogen that is mineralized to ammonium nitrogen during manure collection and storage depends primarily on oxygen supply, time, and on temperature. Simple forms of organic nitrogen such as urea (mammals) and uric acid (poultry) are rapidly mineralized to ammonium nitrogen, which is converted to ammonia under alkaline conditions. Ammonia is highly volatile and easily diffused into the surrounding air (Asman *et al*. 1998; Monteny & Erisman 1998). Nitrogen losses begin at the point of excretion in houses and other animal production areas (e.g., milk parlors) and continue through on-site management in storage and treatment systems (i.e., manure management systems). Nitrogen is also lost through runoff and leaching into soils from the solid storage of manure at outdoor areas, in feedlots and where animals are grazing in pastures. Emissions of nitrogen compounds from grazing livestock are considered separately in Chapter 11, Section 11.2, *N_2O Emissions from Managed Soils*.

In the case of co-digestion of animal manures with additional organic residues, energy crops, additional N enters the system. This additional N source also emits N_2O during the storage, and must be considered in the section "N_2O emissions from manure management".

Due to significant direct and indirect losses of manure nitrogen in management systems it is important to estimate the remaining amount of animal manure nitrogen available for application to soils or for use in feed, fuel, or construction purposes. This value is used for calculating N_2O emissions from managed soils (see Chapter 11, Section 11.2). The methodology to estimate manure nitrogen that is directly applied to soils, or available for use in feed, fuel, or construction purposes is described in this chapter under Section 10.5.4 "Coordination with reporting for N_2O emissions from managed soils".

10.5.1 Choice of method

The level of detail and methods chosen for estimating N_2O emissions from manure management systems will depend upon national circumstances and the decision tree in Figure 10.4 describes *good practice* in choosing a method accordingly. The following sections describe the different tiers referenced in the decision tree for calculating direct and indirect N_2O emissions from manure management systems.

Direct N_2O emissions from Manure Management

Tier 1

The Tier 1 method entails multiplying the total amount of N excretion (from all livestock species/categories) in each type of manure management system by an emission factor for that type of manure management system (see Equation 10.25). Emissions are then summed over all manure management systems. The Tier 1 method is applied using IPCC default N_2O emission factors, default nitrogen excretion data, and default manure management system data (see Annex 10A.2, Tables 10A.5 to 10A.9 for default animal weights and manure management system allocations). It is recommended to consult the methane and enteric fermentation sections to clarify how to implement the Tier 1a approach, if that is the approach selected.

Tier 2

A Tier 2 method follows the same calculation equation as Tier 1 but would include the use of country-specific data for some or all of these variables. For example, the use of country-specific nitrogen excretion rates for livestock categories would constitute a Tier 2 methodology.

Tier 3

A Tier 3 method utilizes alternative estimation procedures based on a country-specific methodology. For example, a process-based, mass balance approach which tracks nitrogen throughout the system in detail starting with feed input through final use/disposal could be utilized as a Tier 3 procedure. Tier 3 methods should be well documented to clearly describe estimation procedures.

To estimate emissions from manure management systems, the livestock population must first be divided into categories that reflect the varying amounts of manure produced per animal as well as the manner in which the manure is handled. This division of manure by type of system should be the same as that used to characterize methane emissions from manure management (see Section 10.4). For example, if Tier 1 default emission factors are used for calculating CH_4 emissions, then the manure management systems usage data from Tables 10A.5 to 10A.9 should be applied. Detailed information on how to characterise the livestock population for this source is provided in Section 10.2.

In the case of anaerobic digestion of animal manures with additional organic residues it is essential to estimate the additional N input from these organic residues and the respective N_2O emissions.

The following five steps are used to estimate direct N_2O emissions from Manure Management:

Step 1: Collect population data from the Livestock Population Characterisation;

Step 2: Use default values or develop the annual average nitrogen excretion rate per head ($Nex_{(T,P)}$) for each defined livestock species/category T, and productivity system P, when applicable;

Step 3: Use default values or determine the fraction of total annual nitrogen excretion for each livestock species/category T that is managed in each manure management system S ($AWMS_{(T,S,P)}$);

Step 4: Use default values or develop N_2O emission factors for each manure management system S ($EF_{3(S)}$); and

Step 5: For each manure management system type S, multiply its emission factor ($EF_{3(S)}$) by the total amount of nitrogen managed (from all livestock species/categories) in that system, to estimate N_2O emissions from that manure management system. Then sum over all manure management systems.

In some cases, manure nitrogen may be managed in several types of manure management systems. If manure is managed in multiple systems, it is *good practice* to estimate N_2O emissions from all systems.

The calculation of direct N_2O emissions from manure management is based on the following equation:

EQUATION 10.25 (UPDATED)
DIRECT N_2O EMISSIONS FROM MANURE MANAGEMENT

$$N_2O_{D(mm)} = \left[\sum_S \left[\sum_{T,P} \left(\left(N_{(T,P)} \bullet Nex_{(T,P)} \right) \bullet AWMS_{(T,S,P)} \right) + N_{cdg(s)} \right] \bullet EF_{3(S)} \right] \bullet \frac{44}{28}$$

Where:

$N_2O_{D(mm)}$ = direct N_2O emissions from Manure Management in the country, kg N_2O yr^{-1}

$N_{(T,P)}$ = number of head of livestock species/category *T* in the country, for productivity system *P*, when applicable

$Nex_{(T,P)}$ = annual average N excretion per head of species/category *T* in the country, for productivity system *P*, when applicable in kg N animal^{-1} yr^{-1}

$N_{cdg(s)}$ = annual nitrogen input via co-digestate in the country, kg N yr^{-1}, where the system (s) refers exclusively to anaerobic digestion

$AWMS_{(T,S,P)}$ = fraction of total annual nitrogen excretion for each livestock species/category *T* that is managed in manure management system *S* in the country, dimensionless; to consider productivity class *P*, if using a Tier 1a approach

$EF_{3(S)}$ = emission factor for direct N_2O emissions from manure management system *S* in the country, kg N_2O-N/kg N in manure management system *S*

S = manure management system

T = species/category of livestock

P = productivity class, high or low, to be considered if using the Tier 1a approach

44/28 = conversion of N_2O-$N_{(mm)}$ emissions to $N_2O_{(mm)}$ emissions

As is the case in the calculation of methane emission, countries may choose to consider if they have significantly different production systems in their country and apply a Tier 1a approach. In this case, compilers should consider the productivity class of their animal system as included in the calculation of CH_4 emissions.

There may be losses of nitrogen in other forms (e.g., ammonia and NO_x) as manure is managed on site. Nitrogen in the volatilized form of ammonia may be deposited at sites downwind from manure handling areas and contribute to indirect N_2O emissions (see below). Countries are encouraged to consider using a mass balance approach to track the manure nitrogen excreted, managed on site in manure management systems, and ultimately applied to managed soils. The estimation of the amount of manure nitrogen which is directly applied to managed soils or otherwise available for use as feed, fuel or construction purposes is described in the Section 10.5.4 Coordination with reporting for N_2O emissions from managed soils is required. See Chapter 11, Section 11.2 for procedures to calculate N_2O emissions from managed manure nitrogen applied to soils. Additional guidance on ensuring consistency in the mass balance approach and between emissions from manure in the source category N_2O Emissions from Manure Management and N_2O Emissions from Managed Soils is given in Section 10.5.6 in the subsection Consistency of nitrogen flows.

Indirect N_2O emissions from Manure Management

Tier 1

The Tier 1 calculation of N volatilisation in forms of NH_3 and NO_x from manure management systems is based on multiplication of the amount of nitrogen excreted (from all livestock categories) and managed in each manure management system by a fraction of volatilised nitrogen (see Equation 10.26). N losses are then summed over all manure management systems. The Tier 1 method is applied using default nitrogen excretion data, default manure management system data, animal weights (see Annex 10A.2, Tables 10A.5 to 10A.9) and default fractions of N loss from manure management systems (see Table 10.22):

EQUATION 10.26 (UPDATED)
N LOSSES DUE TO VOLATILISATION FROM MANURE MANAGEMENT

$$N_{volatilization-MMS} = \sum_{S}\left[\sum_{T,P}\left[\left(\left(N_{(T,P)} \bullet Nex_{(T,P)}\right) \bullet AWMS_{(T,S,P)}\right) + N_{cdg(s)}\right) \bullet Frac_{GasMS(T,S)}\right]\right]$$

Where:

$N_{volatilization-MMS}$ = amount of manure nitrogen that is lost due to volatilisation of NH_3 and NO_x, kg N yr^{-1}

$N_{(T,P)}$ = number of head of livestock species/category *T* in the country, for productivity system *P*, when applicable

$Nex_{(T,P)}$ = annual average N excretion per head of species/category *T* in the country, , for productivity system *P*, when applicable in kg N animal^{-1} yr^{-1}

$N_{cdg(s)}$ = amount of nitrogen from co-digestates added to biogas plants such as food wastes or purpose grown crops, kg N yr^{-1} where the system (s) refers exclusively to anaerobic digestion

P = productivity class, high or low, to be considered if using the Tier 1a approach

$AWMS_{(T,S,P)}$ = fraction of total annual nitrogen excretion for each livestock species/category T that is managed in manure management system S in the country, dimensionless. To consider productivity class P, if using a Tier 1a approach

$Frac_{gasMS(T,S)}$ = fraction of managed manure nitrogen for livestock category T that volatilises as NH_3 and NO_x in the manure management system S

The Tier 1 calculation of N leached and runoff from manure management systems is based on multiplication of the amount of nitrogen excreted (from all livestock categories) and managed in each manure management system by a fraction of nitrogen leached, in analogy to the approach to estimate nitrogen volatilsation (see Equation 10.26). There are limited measurement data on leaching and runoff losses from various manure management systems. The greatest N losses due to runoff and leaching typically occur where animals are on a drylot, pens, in over-wintering areas or feeding pens used during dormant growth periods for pastured animals and manure heaps or composting systems, uncovered and uncontained. In drier climates, runoff losses are smaller than in high rainfall areas and have been estimated in the range from 3 to 6 percent of N excreted (Eghball & Power 1994). Studies by Bierman *et al*. (1999) found nitrogen lost in runoff was 5 to 19 percent of N excreted and 10 to 16 percent leached into soil, while other data show relatively low loss of nitrogen through leaching in solid storage (less than 5 percent of N excreted); but greater loss could also occur (Rotz 2004). Table 10.22 contains leaching loss fractions that may be applied under very specific circumstances. Leaching can be estimated using these fractions in cases in which manure is uncovered on permeable soil, or where runoff may occur to permeable soil and runoff is not collected in a impermeable basin and redistributed to agricultural fields. Leaching losses are estimated only in cases in which manure nitrogen is being lost to the environment and not accounted for in any other N flows. Further research is needed in this area to improve the estimated losses and the conditions and practices under which such losses occur however an estimate may be provided.

EQUATION 10.27 (UPDATED)
N LOSSES DUE TO LEACHING FROM MANURE MANAGEMENT

$$N_{leaching-MMS} = \sum_{S}\left[\sum_{T,P}\left[\left(\left(N_{(T,P)} \bullet Nex_{(T,P)} \bullet AWMS_{(T,S,P)}\right) + N_{cdg(s)}\right) \bullet Frac_{LeachMS(T,S)}\right]\right]$$

Where:

$N_{leaching-MMS}$ = amount of manure nitrogen that is lost due to leaching, kg N yr^{-1}

$N_{(T,P)}$ = number of head of livestock species/category T in the country, for productivity system P, when applicable

$Nex_{(T,P)}$ = annual average N excretion per head of species/category T in the country, for productivity system P, when applicable in kg N $animal^{-1}$ yr^{-1}

$N_{cdg(s)}$ = amount of nitrogen from co-digestates added to biogas plants such as food wastes or purpose grown crops, kg N yr^{-1} where the system (s) refers exclusively to anaerobic digestion

P = productivity class, high or low, to be considered if using the Tier 1a approach

$AWMS_{(T,S,P)}$ = fraction of total annual nitrogen excretion for each livestock species/category T that is managed in manure management system S in the country, for productivity system P, when applicable, dimensionless

$Frac_{LeachMS(T,S)}$ = fraction of managed manure nitrogen for livestock category T that is leached from the manure management system S (from Table 10.22)

The indirect N_2O emissions from volatilisation of N in forms of NH_3 and NO_x ($N_2O_{G(mm)}$) are estimated using Equation 10.28:

EQUATION 10.28
INDIRECT N_2O EMISSIONS DUE TO VOLATILISATION OF N FROM MANURE MANAGEMENT

$$N_2O_{G(mm)} = \left(N_{volatilization-MMS} \bullet EF_4\right) \bullet \frac{44}{28}$$

Where:

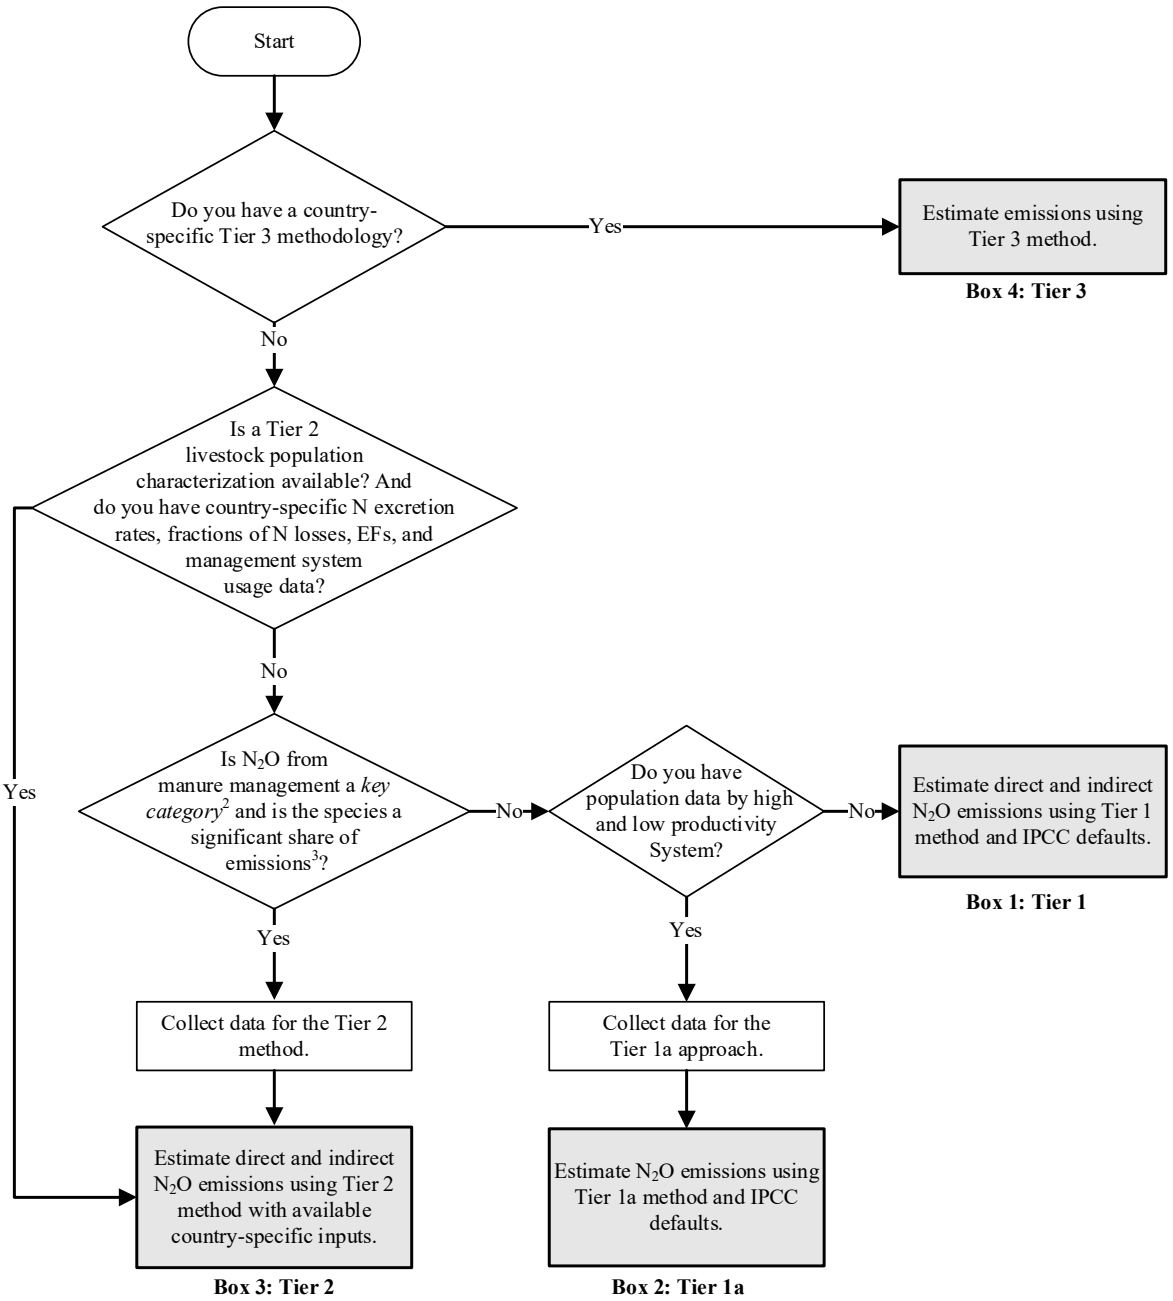
$N_2O_{G(mm)}$ = indirect N_2O emissions due to volatilization of N from Manure Management in the country, kg N_2O yr^{-1}

EF_4 = emission factor for N_2O emissions from atmospheric deposition of nitrogen on soils and water surfaces, kg N_2O-N (kg NH_3-N + NO_x-N volatilised)$^{-1}$; given in Chapter 11, Table 11.3

The indirect N_2O emissions due to leaching and runoff from Manure Management ($N_2O_{L(mm)}$) are estimated using Equation 10.29:

EQUATION 10.29
INDIRECT N_2O EMISSIONS DUE TO LEACHING FROM MANURE MANAGEMENT

$$N_2O_{L(mm)} = (N_{leaching-MMS} \bullet EF_5) \bullet \frac{44}{28}$$



Where:

$N_2O_{L(mm)}$ = indirect N_2O emissions due to leaching and runoff from Manure Management in the country, kg N_2O yr^{-1}

$N_{leaching-MMS}$ = amount of manure nitrogen that is lost due to leaching, kg N yr^{-1}

EF_5 = emission factor for N_2O emissions from nitrogen leaching and runoff, kg N_2O-N/kg N leached and runoff, given in Chapter 11, Table 11.3

Figure 10.4 (Updated) Decision tree for N_2O emissions from Manure Management[(1)]

Note:
1: N_2O emissions from manure management systems include both direct and indirect sources.
2: See Volume 1 Chapter 4, "Methodological Choice and Identification of Key Categories"(noting Section 4.1.2 on limited resources), for discussion of key categories and use of decision trees.
3:As a rule of thumb, a livestock species would be significant if it accounts for 25-30% or more of emissions from the source category.

Tier 2

Countries may wish to develop a Tier 2 methodology for better consideration of national circumstances and to reduce uncertainty of estimates as much as possible. As for direct N_2O emission from manure management, a Tier 2 method would follow the same calculation equation as Tier 1 but include the use of country-specific data for some or all of variables. For example, the use of country-specific nitrogen excretion rates for livestock categories would constitute a Tier 2 method. Tier 2 method would require more detailed characterisation of the flow of nitrogen throughout the animal housing and manure management systems used in the country. It is *good practice* to check N balance in a Tier 2 approach. Double counting of emissions associated with the application of managed manure should be avoided, as well as manure associated with pasture and grazing operations as described in Section 10.5.6. National NH_3 emission inventories developed by some countries could be used for Tier 2

estimation of NH_3 volatilisation from manure management systems. For countries reporting emissions of NH_3 and NO_x to the UN-ECE Convention on Long-Range Transboundary Air Pollution (UN-ECE LRTAP) using a Tier 2 approach as described in the EEA (2016) emission inventory guidebook, it is *good practice* to report $N_{volatilization-MMS}$ in consistency to the NH_3 and NO_x emissions reported to the UN-ECE.

Tier 3

To reduce uncertainty of the estimates, a Tier 3 method could be developed using advanced or process-based models for volatilisation and nitrogen leaching and runoff based on actual measurements.

All losses of N through manure management systems (both direct and indirect) need to be subtracted from the amount of manure N that is available for application to soils and which is reported in Chapter 11, Section 11.2 N_2O Emissions from Managed Soils. Refer to Section 10.5.4, Coordination with reporting for N_2O emissions from managed soils, for guidance on calculating total N losses from manure management systems.

10.5.2 Choice of emission factors

Annual average nitrogen excretion rates, $Nex_{(T)}$

Tier 1

Annual nitrogen excretion rates should be determined for each livestock category defined by the livestock population characterization. Country-specific rates may either be taken directly from documents or reports such as agricultural industry and scientific literature or derived from information on animal nitrogen intake and retention (as explained below). In some situations, it may be appropriate to use excretion rates developed by other countries that have livestock with similar characteristics.

If country-specific data cannot be collected or derived, or appropriate data are not available from another country, the IPCC default nitrogen excretion rates presented in Table 10.19 can be used. These rates are presented in units of nitrogen excreted per 1000 kg of animal per day. These rates can be applied to livestock sub-categories of varying ages and growth stages using a typical average animal mass (TAM) for that population sub-category, as shown in Equation 10.30.

EQUATION 10.30 (UPDATED)
ANNUAL N EXCRETION RATES

$$Nex_{(T,P)} = N_{rate(T,P)} \bullet \frac{TAM_{(T,P)}}{1000} \bullet 365$$

Where:

$Nex_{(T,P)}$ = annual N excretion for livestock category *T*, kg N animal^{-1} yr^{-1} (production level *P* if using a Tier 1 approach

$N_{rate(T,P)}$ = default N excretion rate, kg N (1000 kg animal mass)$^{-1}$ day^{-1} for animal category *T* (and production level *P*, if using a Tier 1a (see Table 10.19))

$TAM_{(T,P)}$ = typical animal mass for livestock category *T*, kg animal^{-1}

P = productivity class, high or low, to be considered if using the Tier 1a approach

Default TAM values are provided in Annex 10A.1, Table 10A.5. However, it is preferable to collect country-specific TAM values due to the sensitivity of nitrogen excretion rates to different weight categories. For example, market swine may vary from nursery pigs weighing less than 30 kilograms to finished pigs that weigh over 90 kilograms. By constructing animal population groups that reflect the various growth stages of market pigs, countries will be better able to estimate the total nitrogen excreted by their swine population.

When estimating the $Nex_{(T)}$ for animals whose manure is classified in the manure management system *burned for fuel* (Table 10.21), it should be kept in mind that the dung is burned, and the urine stays in the field. Generally, 50 percent of the nitrogen excreted is in the dung and 50 percent is in the urine. If the burned dung is used as fuel, then emissions are reported under the IPCC category *Fuel Combustion* (Volume 2: Energy), whereas if the dung is burned without energy recovery the emissions should be reported under the IPCC category *Waste Incineration* (Volume 5: Waste).

Tier 2

The annual amount of N excreted by each livestock species/category depends on the total annual N intake and total annual N retention of the animal. Therefore, N excretion rates can be derived from N intake and N retention data. Annual N intake (i.e., the amount of N consumed by the animal annually) depends on the annual amount of feed digested by the animal, and the protein content of that feed. Total feed intake depends on the production level of the animal (e.g., growth rate, milk production, draft power). Annual N retention (i.e., the fraction of N intake that is retained by the animal for the production of meat, milk, or wool) is a measure of the animal's efficiency of production of animal protein from feed protein. Nitrogen intake and retention data for specific livestock species/categories may be available from national statistics or from animal nutrition specialists. Nitrogen intake can also be calculated from data on feed and crude protein intake developed in Section 10.2. Default N retention values are provided in Table 10.20, Default values for the fraction of nitrogen in feed taken in by animals that is retained by the different animal species/categories. Rates of annual N excretion for each livestock species/category ($Nex_{(T)}$) are derived as follows:

EQUATION 10.31
ANNUAL N EXCRETION RATES, OPTION 1 (TIER 2)

$$Nex_{(T)} = N_{intake(T)} \bullet \left(1 - N_{retention_frac(T)}\right) \bullet 365$$

Where:

$Nex_{(T)}$ = annual N excretion rates, kg N animal^{-1} yr^{-1}

$N_{intake(T)}$ = the daily N intake per head of animal of species/category *T*, kg N animal^{-1} day^{-1}

$N_{retention_frac(T)}$ = fraction of daily N intake that is retained by animal of species/category *T*, dimensionless

365 = Number of days in a year[6]

EQUATION 10.31A (NEW)
ANNUAL N EXCRETION RATES, OPTION 2 (TIER 2)

$$Nex_{(T)} = \left(N_{intake(T)} - N_{retention(T)}\right) \bullet 365$$

Where:

$Nex_{(T)}$ = annual N excretion rates, kg N animal^{-1} yr^{-1}

$N_{intake(T)}$ = the daily N intake per head of animal of species/category *T*, kg N animal^{-1} day^{-1}

$N_{retention(T)}$ = amount of daily N intake by head of animal of species / category *T*, that is retained by animal of species/category *T*, kg N animal^{-1} day^{-1}

365 = Number of days in a year[6]

nitrogen excretion may be calculated based on the same dietary assumptions used in modelling enteric fermentation emissions (see Section 10.2). The amount of nitrogen excreted by cattle can be estimated as the difference between the total nitrogen taken in by the animal and the total nitrogen retained for growth and milk production. Equations 10.32, 10.32A and 10.33, 10.33A, 10.33B, 10.33C, 10.33D and 10.33E can be used to calculate the variables for nitrogen intake and nitrogen retained for use in Equations 10.31 and 10.31a. The daily nitrogen intake rate is derived as follows:

[6] Consideration should be taken of periods between production cycles, particularly for animal categories that may have multiple annual growth cycles. For livestock species with a lifetime shorter than one year, the approach suggested by Haenel *et al*. (2018) (see chapters 3.1.2.2.1 to 3.1.2.2.3) and by Rösemann *et al*. (2017) can be considered.

EQUATION 10.32
N INTAKE RATES FOR CATTLE, SHEEP AND GOATS

$$N_{\text{int}ake(T)} = \frac{GE}{18.45} \bullet \left(\frac{\frac{CP\%}{100}}{6.25} \right)$$

EQUATION 10.32A (NEW)
N INTAKE RATES FOR SWINE AND POULTRY

$$N_{\text{int}ake(T,i)} = DMI_i \bullet \left(\frac{\frac{CP\%_i}{100}}{6.25} \right)$$

Where:

$N_{\text{int}ake(T,i)}$ =daily N consumed per animal of category *T*, kg N animal^{-1} day^{-1}, per growth stage^{-1} "*i*" when applicable

GE = gross energy intake of the animal, in enteric model, based on digestible energy, milk production, pregnancy, current weight, mature weight, rate of weight gain, and IPCC constants, MJ animal^{-1} day^{-1} (used in conjunction with Tier 2 gross energy calculation for cattle, sheep and goats)

18.45 = conversion factor for dietary GE per kg of dry matter, MJ kg^{-1}. This value is relatively constant across a wide range of forage and grain-based feeds commonly consumed by livestock

DMI_i = dry matter intake per day during a specific growth stage "*i*", (kg DMI animal day^{-1})

$CP\%_i$ = percent crude protein in dry matter for growth stage "*i*". (Table 10A.1, Table 10A.2 and Table 10A.3 present default CP% values for all regions)

6.25 = conversion from kg of dietary protein to kg of dietary N, kg feed protein (kg N)$^{-1}$

As an example, the intake of N for a growing pig between 32 to 60 kg of body weight with a daily intake of 1.67 kg of a diet containing 18 percent CP would be, applying the above equation, equivalent to 0.05 kg N day^{-1}.

The daily value can be converted to a total N input per year or per growth stage by multiplying either by 365 or by the length of the growth period of interest.

TABLE 10.19 (UPDATED)
DEFAULT VALUES FOR NITROGEN EXCRETION RATE (KG N (1000 KG ANIMAL MASS)$^{-1}$ DAY^{-1})

Rabbits (kg N head^{-1} yr^{-1})[10,11]	8.10																		
Fox and Racoon (kg N head^{-1} yr^{-1})[6,11]	12.09																		

[1] High PS and Low PS refer to high- and low productivity systems required for Tier 1a methodology.

[2] NA refers to situations in which these animal categories do not occur in these regions.

[3] Values are derived from diets used in the calculation of enteric fermentation Tier 1 emission factors (Annex 10A.1).

[4] Values are taken from FAO GLEAM databases (FAO 2017).

[5] Calculations are detailed in Annex 10B.3.

[6] Data of Hutchings *et al*. (2001) (as cited in *2006 IPCC Guidelines*).

[7] Nex rate for ostrich in kg N (1000 kg animal mass)$^{-1}$ day^{-1} was calculated taking into account an average value on weight of bird (120 kg) and a rate of nitrogen excretion per head per year (15.6 kgN/head/year). Sources: Velthof (2014); Reis & Oliveira (2008); du Toit *et al*. (2013).

[8] Nex rate for deer in kg N (1000 kg animal mass)$^{-1}$ day^{-1} was calculated taking into account an average value on weight of animal (120 kg) and a rate of nitrogen excretion per head per year (29.32 kgN/head/year). Sources: Danish NIR (Nielsen *et al*. 2018), New Zealand's NIR (Ministry for the Environment 2018).

[9] Nex rate for reindeer in kg N (1000 kg animal mass)$^{-1}$ day^{-1} was calculated taking into account an average value on weight of animal (120 kg) and a rate of nitrogen excretion per head per year (5.75 kgN/head/year).Sources: Danish NIR (Nielsen *et al*. 2018); New Zealand's NIR (Ministry for the Environment 2018).

[10] Nex rate per average doe, including young reproduction stock and males. Sources: Maertens *et al*. (2005); Xiccato *et al*. (2005); Gasco *et al*. (2014); Velthof *et al*. (2015).

[11] The IPCC expert group reviewed the national inventory submissions under the UNFCCC and concluded that common distribution of systems used to manage manure as follows: 80 percent of ostrich'manure is deposited in pasture and in range and 20 percent is managed in solid based systems; deer and reindeer manure deposited mainly in pasture and in range, manure of rabbits and fur-bearing animals is managed mostly in a solid based systems. Hence, countries may apply the same allocation of MMS in the calculation of N_2O emissions from manure stored in manure management systems. However, countries are encouraged to develop a country-specific dataset on MMS used to manage manure generated by these categories of animals.

[12] The values are taken from Table 10.19 of Chapter 10 of Volume 4 of the *2006 IPCC Guidelines*.

TABLE 10.20 (UPDATED)
DEFAULT VALUES FOR THE FRACTION OF NITROGEN IN FEED INTAKE OF LIVESTOCK THAT IS RETAINED BY THE DIFFERENT LIVESTOCK SPECIES/CATEGORIES (FRACTION N-INTAKE RETAINED BY THE ANIMAL) [1]

Livestock category	$N_{retention_frac(T)}$, (kg N retained/animal/day) (kg N intake/animal/day)$^{-1}$
Cattle and Buffalo	See values in Annex 10A.1
Sheep	0.10
Goats	0.10
Camels	0.07
Swine	0.30
Horses	0.07
Poultry	0.30

This N retention values apply to non-dairy sheep and goats. For dairy sheep and goats country-specific values are recommended. Values are applied in Equation 10.31, Option 1 for the calculation of annual N excretion.

The uncertainty in these estimates is ±50%.

Source: *2006 IPCC Guidelines*, Table 10.21.

Tier 2 method for estimating nitrogen excretion for cattle

The total nitrogen retained for cattle is derived as follows:

EQUATION 10.33
N RETENTION RATES FOR CATTLE

$$N_{retention(T)} = \left[\frac{Milk \bullet \left(\frac{Milk\ PR\%}{100}\right)}{6.38}\right] + \left[\frac{WG \bullet \left[268 - \left(\frac{7.03 \bullet NE_g}{WG}\right)\right]}{6.25}\right]$$

Where:

$N_{retention(T)}$ = daily N retained per animal of category *T*, kg N animal^{-1} day^{-1}

MILK = milk production, kg animal^{-1} day^{-1} (applicable to dairy cows only)

Milk PR% = percent of protein in milk, calculated as [1.9 + 0.4 ● %Fat], where %Fat is an input, assumed to be 4% (applicable to dairy cows only), or the values reported in Table 10A.1, Table 10A.2 and Table 10A.3 can be used

6.38 = conversion from milk protein to milk N, kg Protein (kg N)$^{-1}$

WG = weight gain, input for each livestock category, kg day^{-1}

268 and 7.03 = constants from Equation 3-8 in NRC (1996), g Protein kg^{-1} animal^{-1} and g Protein MJ^{-1} animal^{-1} respectively

1000 = conversion from g protein to kg protein

NE_g = net energy for growth, calculated in livestock characterisation, based on current weight, mature weight, rate of weight gain, and IPCC constants, MJ day^{-1}

6.25 = conversion from kg dietary protein to kg dietary N, kg Protein (kg N)$^{-1}$

Nitrogen excretion is calculated using Equation 10.31a, Option 2.

Tier 2 method for estimating nitrogen excretion for pigs

The nitrogen excretion rate depends on the balance between the animal's feed N intake and its N retention in tissue. Different categories of animals (e.g. adult females, adult males and growing pigs) can have quite different N

requirements depending on, for example, their growth rates, lactation rates and yields (MacLeod *et al*. 2013). Likewise, the N retention rates can be different among different animal categories. Thus, when following a Tier 2 approach for estimating nitrogen excretion for pigs, it is a *good practice* to include N excretion estimates for at least the pig categories listed in Table 10.1.

For breeding pigs, if inventory compilers have detailed information about feed, breeding statistics piglets born and weaned and proportions of sows entering the breeding herd (optional), N retention may be calculated as follows:

EQUATION 10.33A (NEW)
N RETENTION RATES FOR BREEDING SOWS

$$N_{retention} = N_{gain} + N_{weaned\ piglets}$$

Where:

$N_{retention}$ = amount of N retained by the animal (in kg N animal^{-1} year^{-1})

N_{gain} = amount of N retained in the sow (in kg N animal^{-1} year^{-1}), calculated as (0.025 *FR * Skg)

Where:

0.025 = fraction of N retained in BW, kg N·kg BW gain^{-1}

FR = fertility rate of sows, parturitions·year^{-1}

Skg = is the sum of live weight change of sows from parturition to parturition, kg·head^{-1} and can be calculated from the litter birth weight and number (LITSIZE * Ckg/0.806

Where:

LITSIZE = litter size, heads

Ckg = live weight of piglets at birth, kg·head^{-1}

0.806 = constant to correct for the higher kg N per kg BW gain^{-1} in piglets, fraction)

$N_{weaned\ piglets}$ = amount of N in piglets weaned calculated as in Equation 10.33b (in kg N animal^{-1} year^{-1})

EQUATION 10.33B (NEW)
N RETENTION RATES FOR PIGLETS

$$N_{weaned\ piglets} = 0.025 \bullet LITSIZE \bullet FR \bullet \frac{(Wkg - Ckg)}{0.98}$$

Where:

0.025 = fraction of N retained in BW, kg N·kg BW gain^{-1}

LITSIZE = litter size, heads

FR = fertility rate of sows, parturitions·year^{-1}

Wkg = live weight of piglet at weaning age, kg·head^{-1}

Ckg = live weight of piglets at birth, kg·head^{-1} and

0.98 = protein digestibility as fraction (FAO, 2017)

TABLE 10.20A (NEW)
CALCULATION OF N RETENTION IN BREEDING SWINE FROM DIFFERENT PRODUCTION SYSTEMS, AN EXAMPLE

System	Ckg	Wkg	FR	LITSIZE	Sows Ngain[a]	Piglets Ngain
	kg	kg		heads	kg N animal^{-1} year^{-1}	kg N animal^{-1} year^{-1}
Low Productivity	0.8	6.5	1.7	9.1	0.92	2.25
High Productivity	1.2	7.0	2.1	9.2	1.38	2.85

[a] For this example, a live weight change of young sows from parturition to parturition of 12.5 kg was assumed.

The value of Skg is derived from national statistics on the average litter size and birth weight of piglets, factors that vary based on national production systems. Further, gilts will typically be mated at 125 – 140 kg of body weight, and continue to grow over several reproductive cycles to a mature weight of approximately 200 kg of body weight. The N excretion by breeding sows (Equation 10.33B) should also take into account that the sow will gain between 10 to 15 kg of body weight during the first four or five reproductive cycles (Chiba 2009). Inventory compilers are advised to: (a) use data that best describe their country production practices and/or genetic stocks employed for estimates of litter size and birth weight; (b) estimate the proportion of the breeding animals that are not at mature weight and consider the growth of these animals in their estimate of Skg. The weight of the placenta and other products of conception are not included in Tier 2 calculations as they are discarded at parturition. Countries that are able to track nitrogen in conception products may choose to do so through country specific methods

The daily N retention can be calculated by dividing the result of equation 10.33a by the total number of days in the gestational and weaning periods to provide a daily N retention in kg N day^{-1}. Nitrogen excretion is calculated using Equation 10.31a, Option 2.

For estimating N retention by growing animals, the following approach may be followed:

EQUATION 10.33C (NEW)
N RETENTION RATES FOR GROWING PIGS

$$N_{retention} = \sum_{i} (BW_{Final\,(i)} - BW_{Initial\,(i)}) \bullet N_{gain\,(i)}$$

Where:

$N_{retention}$ = amount of N retained in animal (in kg N animal^{-1} year^{-1})

$BW_{Final_{(i)}}$ = Live weight of the animal at the end of the stage (kg) per defined growth stage (*i*)

$BW_{Initial_{(i)}}$ = Live weight of the animal at the beginning of the stage (kg) per defined growth stage (*i*)

$N_{gain_{(i)}}$ = fraction of N retained at a given BW per defined growth stage *(i)*, the fraction should be calculated for the final BW of the phase. For example a finishing hog that weighed 109 kg at slaughter would use a value of 0.021 kg N kg BW gain^{-1}

These should be summed over the different production stages[7]. Daily N retention is calculated by dividing the total N retention by the length of the production period from weaning to slaughter. Nitrogen excretion is calculated using Equation 10.31a, Option 2.

[7] It should be noted that factors other than physiological stage can affect nitrogen retention, including body weight (Pettey *et al*. 2015), sex and genetic line (Wiseman *et al*. 2007).

TABLE 10.20B (NEW)
DEFAULT VALUES FOR N_{GAIN} BY GROWTH STAGE

Phase	N_{gain} (kg N kg BW^{-1})
Nursery (4 to 7 kg)	0.031
Nursery (7 to 20 kg)	0.028
Grower (20 to 40 kg)	0.025
Grower (40 to 80 kg)	0.024
Finisher (80 to 120 kg)	0.021

N_{gain} was calculated for a given BW as N_{gain} = -0.004 ln(BW) + 0.0381. Based on Shields *et al*. (1983) and further adjusted based on data from Poulsen & Kristensen (1998) and FAO (2017).

The approach used for estimating N excretion from growing pigs can be followed for gilts and growing boars that will be used for breeding purposes and for nursery, growing and finishing market pigs.

Tier 2 method for estimating nitrogen excretion for poultry

In broiler production, chicks generally cannot digest and absorb all nutrients, especially in the case of nutritional imbalance or high concentration of nutrients in feed. Thus, the surplus nutrients are broken down, and carbon is used to produce energy whereas nitrogen is excreted in faeces (Boonsinchai *et al*. 2016). Different categories of animals (for meat or eggs) can have quite different N requirements and different N retention rates (Poulsen & Kristensen 1998; Williams 2013; Velthof *et al*. 2015). Thus, when following a Tier 2 approach for estimating nitrogen excretion for poultry, it is a *good practice* to include N excretion estimations for at least the poultry categories listed in Table 10.1.

In estimating nitrogen excretion, the nitrogen balance approach is also very useful, for which information on feed intake, feed N content and animal productivity (egg production, weight gain, lengths of production stages) is required.

A suitable approach to estimate annual nitrogen retention by layer type hens is as follows (Poulsen & Kristensen 1998):

EQUATION 10.33D (NEW)
N RETENTION RATES FOR LAYER TYPE HENS

$$N_{retention,c} = \left[N_{LW} \bullet WG_c + \left(\frac{N_{EGG} \bullet EGG}{1000} \right) \right]$$

Where:

$N_{retention,c}$ = daily nitrogen retention by animal in cohort c, kg N·head^{-1}day^{-1}

N_{LW} = average content of nitrogen in live weight, kg N·kg head^{-1}. Default value of 0.028 is used

WG_c = average daily weight gain for cohort c, kg·head^{-1}·day^{-1}

N_{EGG} = average content of nitrogen in eggs, kg N·kg egg^{-1}. Default value of 0.0185 is used

EGG = egg mass production, g egg·head^{-1} day^{-1}

A suitable approach to estimate annual nitrogen retention by pullets and broilers is as follows (Poulsen & Kristensen 1998):

EQUATION 10.33E (NEW)
DAILY N RETENTION RATES FOR PULLETS OR BROILERS

$$N_{retention} = \frac{(BW_{Final} - BW_{Initial}) \bullet N_{gain}}{production_period}$$

Where:

$N_{retention}$ = amount of N retained in animal (kg N head^{-1}) day^{-1}

BW_{Final} = Live weight of the animal at the end of the stage (kg)

$BW_{Initial}$ = Live weight of the animal at the beginning of the stage (kg)

N_{gain} = the fraction of N (kg) retained per kg BW gain

$production_period$ = length of time from chick to slaughter (days)

Default value for N_{gain} = 0.028 based on data from Poulsen & Kristensen (1998) and FAO (2017)

Nitrogen excretion is calculated using Equation 10.31a, Option 2.

Emission factors for direct N_2O emissions from Manure Management

The best estimate will be obtained using country-specific emission factors that have been fully documented in peer reviewed publications. It is *good practice* to use country-specific emission factors that reflect the actual duration of storage and type of treatment of animal manure in each management system that is used. *Good practice* in the derivation of country-specific emission factors involves the measurement of emissions (per unit of manure N) from different management systems, taking into account variability in duration of storage and types of treatment. When defining types of treatment, conditions such as aeration and temperature should be taken into account. If inventory agencies use country-specific emission factors, they are encouraged to provide justification for these values via peer-reviewed documentation.

If appropriate country-specific emission factors are unavailable, inventory agencies are encouraged to use the default emission factors presented in Table 10.21, Default emission factors for direct N_2O emissions from Manure Management. This table contains default emission factors by manure management system. Note that emissions from liquid/slurry systems without a natural crust cover and anaerobic lagoons are considered negligible based on the absence of oxidized forms of nitrogen entering these systems combined with the low potential for nitrification and denitrification to occur in the system.

Emission factors for indirect N_2O emissions from Manure Management

In order to estimate indirect N_2O emissions from Manure Management, two fractions of nitrogen losses (due to volatilization, $Frac_{GasMS}$, and leaching/runoff, $Frac_{LeachMS}$), and two indirect N_2O emissions factors associated with these losses (EF_4 and EF_5) are needed. Default values for volatilization N losses are presented in the Table 10.22 for single manure systems. Values represent the sum of the loss rates for N in the forms of NH_3 and NO_x, with most of the loss in the form of NH_3. Ranges reflect values that appear in the literature. The values represent conditions without any significant nitrogen control measures in place. Countries are encouraged to develop country-specific values, particularly related to ammonia losses where component emissions may be well characterized as part of larger air quality assessments and where emissions may be affected by nitrogen reduction strategies. For example, detailed methodologies for estimating NH_3 and other nitrogen losses using mass balance/mass flow procedures are described in the EMEP/CORINAIR air pollutant emission inventory guidebook, Chapter 3B (current version: EEA 2016).

The fraction of manure nitrogen that leaches from manure management systems ($Frac_{leachMS}$) is highly uncertain and should be developed as a country-specific value applied in Tier 2 method.

N_2O emissions from multiple Manure Management systems

Consistent with CH_4 manure management, if manure is managed in multiple systems, by default, manure emission factors should be allocated to the dominant storage systems; But a country specific emission factor could be developed considering the emissions originating from all other systems used in storage prior to field applicaton.

A number of combinations are possible and as was the case with methane emissions from manure management, it is beyond the scope of these guidelines to provide guidance for all possibilities but common examples include: i.) manure flushed from a dairy freestall barn to an anaerobic lagoon that first pass through a solids separation unit

where some of the manure nitrogen is removed and managed as a solid; ii.) pit storage that is flushed to a larger holding tank; iii.) solid manure pack that is allowed to accumulate, and periodically transferred to heaps.

In these cases, emissions could be calculated based on Tier 2 factors from the separate manure fractions and weighted based on the duration of storage in the different systems. Emission factors as developed and reported in these guidelines are assumed to be for a full year of N within a given manure management system. The application of a country-specific, staged emission factor would require estimates of sub-annual emissions based on manure residency times in each stage. Further, this type of approach should consider the application of a full mass balance approach and likewise consider N loss at each stage.

Default values for EF_4 (N volatilisation and re-deposition) and EF_5 (N leaching/runoff) are given in Chapter 11, Table 11.3 (Default emission, volatilisation and leaching factors for indirect soil N_2O emissions).

Consistency should be maintained for the treatment of nitrogen flows throughout all agricultural emission calculations, including managed soils as outlined in Section 10.5.4[8].

[8] As discussed in Section 10.5.4, N losses from housing and storage have to be subtracted before the calculation of N_2O emissions (direct and indirect) from agricultural soils.

TABLE 10.21 (UPDATED)
DEFAULT EMISSION FACTORS FOR DIRECT N_2O EMISSIONS FROM MANURE MANAGEMENT[24]

System	Definition		EF_3 [kg N_2O-N (kg nitrogen excreted)$^{-1}$]
Pasture/Range/ Paddock	The manure from pasture and range grazing animals is allowed to lie as is, and is not managed.		Direct and indirect N_2O emissions associated with the manure deposited on agricultural soils and pasture, range, paddock systems are treated in Chapter 11, Section 11.2, N_2O emissions from managed soils.
Daily spread[5]	Manure is routinely removed from a confinement facility and is applied to cropland or pasture within 24 hours of excretion. N_2O emissions during storage and treatment are assumed to be zero. N_2O emissions from land application are covered under the Agricultural Soils category.		0
Solid storage[2,4,6]	The storage of manure, typically for a period of several months, in unconfined piles or stacks. Manure is able to be stacked due to the presence of a sufficient amount of bedding material or loss of moisture by evaporation.		0.010
Solid storage-Covered/compacted[4,7]	Similar to solid storage, but the manure pile is a) covered with a plastic sheet to reduce the surface of manure exposed to air and/or b) compacted to increase the density and reduce the free air space within the material.		0.01
Solid storage-Bulking agent addition[4,8]	Specific materials (bulking agents) are mixed with the manure to provide structural support. This allows the natural aeration of the pile, thus enhancing decomposition. (e.g. sawdust, straw, coffee husks, maize stover).		0.005
Solid storage – Additives[4,8]	The addition of specific substances to the pile in order to reduce gaseous emissions. Addition of certain compounds such as attapulgite, dicyandiamide or mature compost have shown to reduce N_2O emissions; while phosphogypsum reduces CH_4 emissions.		0.005
Dry lot[9]	A paved or unpaved open confinement area without any significant vegetative cover where accumulating manure may be removed periodically. Dry lots are most typically found in dry climates but also are used in humid climates.		0.02
Liquid/Slurry	Manure is stored as excreted or with some minimal addition of water to facilitate handling and is stored in either tanks or earthen ponds.	With [9] natural crust cover	0.005
		Without [10] natural crust cover	0
		Cover[11]	0.005
Uncovered[12] anaerobic lagoon	Anaerobic lagoons are designed and operated to combine waste stabilization and storage. Lagoon supernatant is usually used to remove manure from the associated confinement facilities to the lagoon. Anaerobic lagoons are designed with varying lengths of storage (up to a year or greater), depending on the climate region, the volatile solids loading rate, and other operational factors. The water from the lagoon may be recycled as flush water or used to irrigate and fertilise fields.		0
Pit storage[13] below animal confinements	Collection and storage of manure usually with little or no added water typically below a slatted floor in an enclosed animal confinement facility.		0.002
Anaerobic[14] digester	Anaerobic digesters are designed and operated for waste stabilization by the microbial reduction of complex organic compounds to CH_4 and CO_2, which is captured and flared or used as a fuel.		0.0006

TABLE 10.21 (UPDATED) (CONTINUED)
DEFAULT EMISSION FACTORS FOR DIRECT N_2O EMISSIONS FROM MANURE MANAGEMENT[24]

System	Definition		EF_3 [kg N_2O-N (kg nitrogen excreted)$^{-1}$]
Burned for fuel or as waste	The dung is excreted on fields. The sun dried dung cakes are burned for fuel.		The emissions associated with the burning of the dung are to be reported under the IPCC category 'Fuel Combustion' if the dung is used as fuel and under the IPCC category 'Waste Incineration' if the dung is burned without energy recovery.
	Urine N deposited on pasture and paddock.		Direct and indirect N_2O emissions associated with the urine deposited on agricultural soils and pasture, range, paddock systems are treated in Chapter 11, Section 11.2, N_2O emissions from managed soils.
Cattle and swine deep bedding	As manure accumulates, bedding is continually added to absorb moisture over a production cycle and possibly for as long as 6 to 12 months. This manure management system also is known as a bedded pack manure management system and may be combined with a dry lot or pasture.	No mixing[15]	0.01
		Active mixing [16]	0.07
Composting - In-Vessel[3,17]	Composting, typically in an enclosed channel, with forced aeration and continuous mixing.		0.006
Composting - Static Pile[3] (Forced aeration)[4,18]	Composting in piles with forced aeration but no mixing.		0.010
Composting - Intensive Windrow[3,19] (Frequent turning)	Composting in windrows with regular turning for mixing and aeration.		0.005
Composting- Passive windrow (infrequent turning) [4, 20]	Composting in windrows with infrequent turning for mixing and aeration.		0.005
Poultry manure with litter[21]	Similar to deep bedding systems. Typically used for all poultry breeder flocks and for the production of meat type chickens (broilers) and other fowl.		0.001
Poultry manure without litter[21]	May be similar to open pits in enclosed animal confinement facilities or may be designed and operated to dry the manure as it accumulates. The latter is known as a high-rise manure management system and is a form of passive windrow composting when designed and operated properly.		0.001

TABLE 10.21 (UPDATED) (CONTINUED)
DEFAULT EMISSION FACTORS FOR DIRECT N_2O EMISSIONS FROM MANURE MANAGEMENT[24]

System	Definition		EF_3 [kg N_2O-N (kg nitrogen excreted)$^{-1}$]
Aerobic treatment	The biological oxidation of manure collected as a liquid with either forced or natural aeration. Natural aeration is limited to aerobic and facultative ponds and wetland systems and is due primarily to photosynthesis. Hence, these systems typically become anoxic during periods without sunlight.	Natural aeration systems[22]	0.01
		Forced aeration systems[23]	0.005

[1] Also see AFRC (1995) and Dustan (2002), which compiled information from some of the original references cited.

[2] Quantitative data should be used to distinguish whether the system is judged to be a solid storage or liquid/slurry. The borderline between dry and liquid can be drawn at 15% dry matter content.

[3] Composting is the biological oxidation of a solid waste including manure usually with bedding or another organic carbon source typically at thermophilic temperatures produced by microbial heat production.

[4] Sources and assumptions to calculate N_2O EF for Solid storage systems with/without treatments and composting (static pile and passive windrows) are detailed in Annex 10B.7.

[5] *2006 IPCC Guidelines*, Table 10.21.

[6] Expert judgement based on Pardo *et al*. (2015). Median of N_2O emissions from farm-scale collected studies.

[7] Expert judgement based on Pardo *et al*. (2015). Emissions in the same range than solid storage.

[8] Expert judgement based on Pardo *et al*. (2015). Estimated reduction of 50% N_2O emissions due to bulking agent addition.

[9] Judgement of IPCC Expert Group in combination with Kulling *et al*. (2003).

[10] Judgement of IPCC Expert Group in combination with the following studies: Harper *et al*. (2000), Lague *et al*. (2004), Monteny *et al*. (2001), and Wagner-Riddle & Marinier (2003). Emissions are believed negligible based on the absence of oxidized forms of nitrogen entering systems in combination with low potential for nitrification and denitrification in the system.

[11] A detailed literature review carried out during the *2019 Refinement* revealed only few new datasets on the measurement of N_2O emissions from manure stores. These datasets emcompass a large range of N_2O emissions from a 50% reduction to a 100 % increase in N_2O emissions when slurry stores are covered. The *2019 Refinement* therefore suggest to use the emission factor of natural crust cover.

[12] Judgement of IPCC Expert Group in combination with the following studies: Harper *et al*. (2000), Lague *et al*. (2004), Monteny *et al*. (2001), and Wagner-Riddle & Marinier (2003). Emissions are believed negligible based on the absence of oxidized forms of nitrogen entering systems in combination with low potential for nitrification and denitrification in the system.

[13] Judgement of IPCC Expert Group in combination with the following studies: Amon *et al*. (2001), Kulling *et al*. (2003), and Sneath *et al*. (1997).

[14] The emission mainly from storage of digestate.

[15] Judgement of IPCC Expert Group in combination with the following studies: Wang *et al*. (2016), Rodhe *et al*. (2015); Wang *et al*. (2014b); Wang *et al*. (2014a); Li (2016); Amon *et al*. (2006); Moitzi *et al*. (2007); Clemens *et al*. (2006). Average value based on Moller *et al*. (2000), Sommer & Møller (2000), Amon *et al*. (1998a); Amon *et al*. (1998b), and Nicks *et al*. (2003).

[16] Average value based on Nicks *et al*. (2003) and Moller *et al*. (2000). Some literature cites higher values to 20% for well maintained, active mixing, but those systems included treatment for ammonia which is not typical.

[17] Judgement of IPCC Expert Group. Expected to be similar to static piles.

[18] Expert judgement based on Pardo *et al*. (2015). Emissions in the same range than solid storage.

[19] Assuming similar range to passive windrow.

[20] Expert judgement based on Pardo *et al*. (2015). Median of N_2O emissions from farm-scale collected studies and estimated reduction of 50% due to bulking agent addition.

[21] Judgement of IPCC Expert Group based on the high loss of ammonia from these systems, which limits the availability of nitrogen for nitrification/denitrification.

[22] Judgement of IPCC Expert Group. Nitrification-denitrification is used widely for the removal of nitrogen in the biological treatment of municipal and industrial wastewaters with negligible N_2O emissions. Limited oxidation may increase emissions compared to forced aeration systems.

[23] Judgement of IPCC Expert Group. Nitrification-denitrification is used widely for the removal of nitrogen in the biological treatment of municipal and industrial wastewaters with negligible N_2O emissions.

[24] Uncertainties for emission factors are defined as varying by a factor of 2 (±100%).

10.5.3 Choice of activity data

No refinement.

10.5.4 Coordination with reporting for N_2O emissions from managed soils

Following storage or treatment in any system of manure management, nearly all the manure will be applied to land. The emissions that subsequently arise from the application of the manure to soil are to be reported under the category *N_2O emissions from managed soils*. The methods for estimating these emissions are discussed in Chapter 11, Section 11.2. In estimating N_2O emissions from managed soils, the amount of animal manure nitrogen that is directly applied to soils, or available for use in feed, fuel, or construction purposes, are considered.

A significant proportion of the total nitrogen excreted by animals in managed systems (i.e., all livestock except those in pasture and grazing conditions) is lost prior to final application to managed soils or use as feed, fuel, or for construction purposes. In order to estimate the amount of animal manure nitrogen that is directly applied to soils, or available for use in feed, fuel, or construction purposes (i.e., the value which is used in Chapter 11, Equation 11.1 or 11.2), it is necessary to reduce the total amount of nitrogen excreted by animals in managed systems by the losses of N through volatilisation of reactive nitrogen gases (i.e., NH_3 and NO_x) or through leaching and runoff (both leading to indirect emissions of N_2O), direct conversion to N_2O, or losses as inert molecular nitrogen (N_2).

nitrogen in manure is present both as organic nitrogen (Norg) and mineral nitrogen, of which the majority consists of 'Total Ammoniacal nitrogen' (TAN). The sum of Norg and TAN gives the total nitrogen available (Ntot). Volatilization of NH_3 and other forms of gaseous N arise from the mineral fraction of nitrogen in manure, TAN. Organic nitrogen in manure needs first to be converted to TAN before NH_3 volatilization can happen. The EMEP/EEA air pollutant emission inventory Guidebook 2016 (EEA 2016, Chapter 3B) therefore distinguishes the flow of TAN and Norg and the transitions between the two forms in agricultural systems. The values for the volatilisation fraction $Frac_{GASMS}$ listed in Table 10.22 attempt to account for typical TAN contents in manure for the MMS considered. However, different excretion ratios of TAN vs. total N as a consequence of changes in livestock diets are not reflected. Also, information on the TAN content in manure available for application, N_{MMS_Avb}, is not kept if using Equation 10.34. Farming practices that reduce the escape of NH_3 from MMS but not the amount of TAN available are likely to lead to higher NH_3 volatilization rates once the manure is applied to soils or used for feed, fuel, or for construction purposes.

Where organic forms of bedding material (straw, sawdust, chippings, etc.) are used, the additional nitrogen from the bedding material should also be considered as part of the managed manure N applied to soils. The same applies to additional N input from co-digestates during anaerobic digestion. Bedding is typically collected with the remaining manure and applied to soils. It should be noted, however, that since mineralization of nitrogen compounds in beddings occurs more slowly compared to manure and the concentration of ammonia fraction in organic beddings is negligible, both volatilization and leaching losses during storage of bedding are assumed to be zero. If bedding material comes from crop residues, the amount of nitrogen needs to be considered when calculating N_2O emissions from crop residues from managed soils by accounting for this quantity in $Frac_{Remove(T)}$ in Equation 11.6 of Chapter 11. Further codigestates in the production of biogas may include food waste as well as purpose grown crops. Differences in N loss that might occur with crop residue being digested or being returned directly to the fields should be considered in this case.

The estimate of managed manure nitrogen available for application to managed soils, or available for use in feed, fuel, or construction purposes is based on the following equation:

EQUATION 10.34 (UPDATED)
MANAGED MANURE N AVAILABLE FOR APPLICATION TO MANAGED SOILS, FEED, FUEL OR CONSTRUCTION USES

$$N_{MMS_{Avb}} = \sum_{S}\left\{\sum_{(T)}\left[\begin{array}{l}\left[\left(N_{(T)} \bullet Nex_{(T)} \bullet AWMS_{(T,S)} + N_{cdg}\right) \bullet \left(1 - Frac_{LossMS_{(T,S)}}\right)\right] + \\ + \left[N_{(T)} \bullet AWMS_{(T,S)} \bullet N_{beddingMS_{(T,S)}}\right]\end{array}\right]\right\}$$

Where:

$N_{MMS_{Avb}}$ = amount of managed manure nitrogen available for application to managed soils or for feed, fuel, or construction purposes, kg N yr^{-1}

$N_{(T)}$ = number of head of livestock species/category *T* in the country

$Nex_{(T)}$ = annual average N excretion per animal of species/category *T* in the country, kg N $animal^{-1}$ yr^{-1}

$AWMS_{(T,S)}$ = fraction of total annual nitrogen excretion for each livestock species/category *T* that is managed in manure management system *S* in the country, dimensionless

$Frac_{LossMS_{(T,S)}}$ = total fraction of managed manure nitrogen for livestock category *T* that is lost in the manure management system *S* in the country, dimensionless. $Frac_{LossMS}$ is calculated according to Equation 10.34a

$N_{beddingMS_{(T,S)}}$ = amount of nitrogen from bedding (to be applied for solid storage and deep bedding MMS if known organic bedding usage), kg N $animal^{-1}$ yr^{-1}

N_{cdg} = amount of nitrogen from co-digestates added to biogas plants such as food wastes or purpose grown crops, kg N yr^{-1}

S = manure management system

T = species/category of livestock

EQUATION 10.34A (NEW)
FRACTION OF MANAGED MANURE N LOST PRIOR TO APPLICATION TO MANAGED SOILS FOR THE PRODUCTION OF FEED, FUEL OR FOR CONSTRUCTION USES

$$FRAC_{LOSS_{MS_{(T,S)}}} = FRAC_{GAS_{MS_{(T,S)}}} + FRAC_{LEACHS_{MS_{(T,S)}}} + FRAC_{N_2MS_{(S)}} + EF_{3_{(S)}}$$

Where:

$FRAC_{LOSS_{MS_{(T,S)}}}$ = total fraction of managed manure nitrogen for livestock category *T* that is lost in the manure management system *S*

$FRAC_{GAS_{MS_{(T,S)}}}$ = fraction of managed manure nitrogen for livestock category *T* that is lost by volatilisation in the manure management system *S* as NH_3 or NO_X (see Table 10.22)

$FRAC_{LEACHS_{MS_{(T,S)}}}$ = fraction of managed manure nitrogen for livestock category *T* that is lost in the manure management system *S* by leaching or run-off (see Table 10.22)

$FRAC_{N_2MS_{(S)}}$ = fraction of managed manure nitrogen that is lost in the manure management system *S* as N_2 (see Equation 10.34b)

$EF_{3_{(S)}}$ = emission factor for direct N_2O emissions from manure management system *S*; in this case considered dimensionless (see Table 10.21)

The amount of managed nitrogen that is lost by denitrification to N_2 can be obtained as a ratio of N_2:N_2O emissions. Webb & Misselbrook (2004) reviewed available data and concluded that as first approximation, emissions of N_2 might be 3-times those of N_2O. $Frac_{N2MS}$ can thus be calculated according to Equation 10.34B.

EQUATION 10.34B (NEW)
ESTIMATION OF $FRAC_{N2MS}$

$$Frac_{N_2MS_{(S)}} = R_{N_2(N_2O)} \bullet EF_{3(S)}$$

Where:

$FRAC_{N_2MS_{(S)}}$ = fraction of managed manure nitrogen for livestock category *T* that is lost as N_2 in the manure management system *S*,

$EF_{3_{(S)}}$ = emission factor for direct N_2O emissions from manure management system *S* in the country, kg N_2O-N (kg N)$^{-1}$ in manure management system *S*

$R_{N_2(N_2O)}$ = Ratio of N_2 : N_2O emissions. The default value of $R_{N2(N2O)}$ is 3 kg N_2-N (kg N_2O-N)$^{-1}$ (see Table 10.23)

Bedding materials vary greatly and inventory compilers should develop values for $N_{beddingMS}$ based on the characteristics of bedding material used in their livestock industries. Limited data from scientific literature indicates the amount of nitrogen contained in organic bedding material applied for dairy cows and heifers is usually around 7 kg N animal^{-1} yr^{-1}, for other cattle is 4 kg N animal^{-1} yr^{-1}, for market and breeding swine is around 0.8 and 5.5 kg N animal^{-1} yr^{-1}, respectively. For deep bedding systems, the amount of N in litter is approximately double these amounts (Webb 2001; Döhler *et al*. 2002).

As regards $N_{beddingMS}$ a cross check with the categories "3.C.4 - Direct N_2O emissions from managed soils" (F_{CR} - volume 11, chapter 11, section 11.2.1.3), "3.C.1 - Biomass burning" (volume 4, chapter 5, section 5.2.4 Non-CO_2 greenhouse gas emissions from biomass burning) and "4.C.2 - Open burning of waste" (volume 5, chapter 5, section 5.3.2 Amount of waste open-burned) relative to the amount of agricultural residues that is removed for other purposes (i.e. bedding) other than the amount of agricultural residues returned to soils or burnt should be done. This is important to eliminate the possibility of double counting.

nitrogen content of co-digestates should be consistent in quantity and definition with the co-digests defined information in guidance on the use of co-digestates in “Energy” found in Volume 2, Chapter 2, Section 2.3.3.4 and “Waste”, Volume 5, Chapters 2 and 3, Sections 2.3.2 and 3.2.

Table 10.22 presents default values for nitrogen loss due to volatilisation of NH_3 and NO_x and N leaching and run-off of nitrogen from manure management.

Table 10.23 presents default values for total losses of N_2 from manure management systems relative to emissions of N_2O. This ratio is used in combination with Equation 10.34b to calculate default N_2 emission factors. These default values include losses that occur from the point of excretion, including animal housing losses, manure storage losses, and losses from leaching and runoff at the manure storage system where applicable.

Countries may wish to develop an alternative approach for better consideration of national circumstances and to reduce the uncertainty of estimates as much as possible. This approach would entail more detailed characterisation of the flow of nitrogen through the components of the animal housing and manure management systems used in the country, accounting for any mitigation activity (e.g., the use of covers over slurry tanks), and consideration of local practices, such as type of bedding material used. For Tier 2 or Tier 3 approaches it is *good practice* to account for the TAN fraction in total manure N along the different stages of manure management. Additional details are available in the EMEP/EEA air pollutant emission inventory Guidebook 2016 (EEA 2016, Chapter 3B and 3.D and Annex A1.4).

Source: The values are mainly from *2006 IPCC Guidelines* but other sources and analyses are discussed in Annex B.7. Values in italics are not derived specifically from literature but are taken from the most likely surrogate among the existing values and are for that reason prone to greater uncertainty.

[1] N loss due to volatilisation of NH_3+NO_x fraction of total N excreted.

[2] N loss due to leaching, fraction of total N excreted.

[3] Nitrogen losses from digestate storage strongly depend on the digestate composition and on the storage cover. Digestate with a low dry matter content and no cover can loose up to 0.5 of nitrogen. The lower range of 0.05 losses is valid for digestate with a high dry matter content and a cover. The ranges indicated also apply to co-digestates. It is advised to use the liquid slurry without cover for uncovered digestate.

[4] Uncertainty range is 0 to 0.07. Leaching values are dependant on annual rainfall. Country-specific data should be developed if leaching is observed to be a significant source based on default values and in humid climates should use the upper bound.

[5] Leaching is only included in the case of uncovered manure without confinement of runoff in which N is lost to the environment and therefore lost from the overall reactive N balance.

[6] No data indicates that no literature values were found, nor was there adequate certainty in providing a surrogate value. Country specific values should be used, or a surrogate should be selected from the table and justified based on consideration of factors controlling rates of volatilisation in the management system.

[7] Sources and assumptions to calculate NH_3 volatilization and N leaching/run-off for Solid storage and composting (static pile and passive windrows) systems are detailed in Annex 10B.7.

TABLE 10.23 (NEW)
DEFAULT VALUE FOR MOLECULAR NITROGEN (N_2) LOSS FROM MANURE MANAGEMENT

10.5.5 Uncertainty assessment

No refinement.

10.5.6 Completeness, Time series, Quality assurance/Quality control and Reporting

A complete inventory should estimate N_2O emissions from all systems of manure management for all livestock species/categories. Additional N input from organic residues and/or energy crops used for co-digestion in biogas plants must also be considered. Countries are encouraged to use manure management system definitions that are consistent with those presented in Table 10.18. Population data should be cross-checked between main reporting mechanisms (such as FAO and national agricultural statistics databases) to ensure that information used in the inventory is complete and consistent. Because of the widespread availability of the FAO database of livestock information, most countries should be able to prepare, at a minimum, Tier 1 estimates for the major livestock categories. For more information regarding the completeness of livestock characterisation, see Section 10.2.

Developing a consistent time series of emission estimates for this source category requires, at a minimum, the collection of an internally consistent time series of livestock population statistics. General guidance on the development of a consistent time series is addressed in Volume 1, Chapter 5 of this report.

In most countries, the other two activity data sets required for this source category (i.e., N excretion rates and manure management system usage data), as well as the manure management emission factors, will be kept constant for the entire time series. However, in some cases, there may be reasons to modify these values over time. For example, farmers may alter livestock feeding practices which could affect nitrogen excretion rates. A particular system of manure management may change due to operational practices or new technologies such that a revised emission factor is warranted. These changes in practices may be due to the implementation of explicit greenhouse gas mitigation measures, or may be due to changing agricultural practices without regard to greenhouse gases. Regardless of the driver of change, the parameters and emission factors used to estimate emissions must reflect the change. The inventory text should thoroughly explain how the change in farm practices or implementation of mitigation measures has affected the time series of activity data or emission factors.

It is *good practice* to implement general quality control checks as outlined in Volume 1, Chapter 6, Quality Assurance/Quality Control and Verification, and expert review of the emission estimates. Additional quality control checks and quality assurance procedures may also be applicable, particularly if higher tier methods are used to determine emissions from this source. The general QA/QC related to data processing, handling, and reporting should be supplemented with procedures discussed below:

Activity data check

The inventory agency should review livestock data collection methods, in particular checking that livestock subspecies data were collected and aggregated correctly with consideration for the duration of production cycles. The data should be cross-checked with previous years to ensure the data are reasonable and consistent with the expected trend. Inventory agencies should document data collection methods, identify potential areas of bias, and evaluate the representativeness of the data.

Manure management system allocation should be reviewed on a regular basis to determine if changes in the livestock industry are being captured. Conversion from one type of management system to another, and technical modifications to system configuration and performance, should be captured in the system modelling for the affected livestock.

National agricultural policy and regulations may have an effect on parameters that are used to calculate manure emissions, and should be reviewed regularly to determine what impact they may have. For example, guidelines to reduce manure runoff into water bodies may cause a change in management practices, and thus affect the N distribution for a particular livestock category. Consistency should be maintained between the inventory and ongoing changes in agricultural practices.

If using country-specific data for $Nex_{(T)}$ and $MS_{(T,S)}$, the inventory agency should compare these values to the IPCC default values. Significant differences, data sources, and methods of data derivation, should be documented.

The nitrogen excretion rates, whether default or country-specific values, should be consistent with feed intake data as determined through animal nutrition analyses.

Review of emission factors

The inventory agency should evaluate how well the implied N_2O emission factors and nitrogen excretion rates compare with alternative national data sources and with data from other countries with similar livestock practices. Significant differences should be investigated.

If using country-specific emission factors, the inventory agency should compare them to the default factors and note differences. The development of country-specific emission factors should be explained and documented, and the results peer-reviewed by independent experts.

Whenever possible, available measurement data, even if they represent only a small sample of systems, should be reviewed relative to assumptions for N_2O emission estimates. Representative measurement data may provide insights into how well current assumptions predict N_2O production from manure management systems in the inventory area, and how certain factors (e.g., feed intake, system configuration, retention time) are affecting emissions. Because of the relatively small amount of measurement data available for these systems worldwide, any new results can improve the understanding of these emissions and possibly their prediction.

External review

The inventory agency should utilise experts in manure management and animal nutrition to conduct expert peer review of the methods and data used. While these experts may not be familiar with greenhouse gas emissions, their knowledge of key input parameters to the emission calculation can aid in the overall verification of the emissions. For example, animal nutritionists can evaluate N production rates to see if they are consistent with feed utilization research for certain livestock species. Practicing farmers can provide insights into actual manure management techniques, such as storage times and mixed-system usage. Wherever possible, these experts should be completely independent of the inventory process in order to allow a true external review.

It is *good practice* to document and archive all information required to produce the national emissions inventory estimates as outlined in Volume 1, Chapter 6, Quality Assurance/Quality Control and Verification. When country-specific emission factors, fractions of N losses, N excretion rates, or manure management system usage data have been used, the derivation of or references for these data should be clearly documented and reported along with the inventory results under the appropriate IPCC source category.

N_2O emissions from different types of manure management systems have to be reported according to categories in Table 10.18. N_2O emissions from all types of manure management systems are to be reported under Manure Management, with two exceptions:

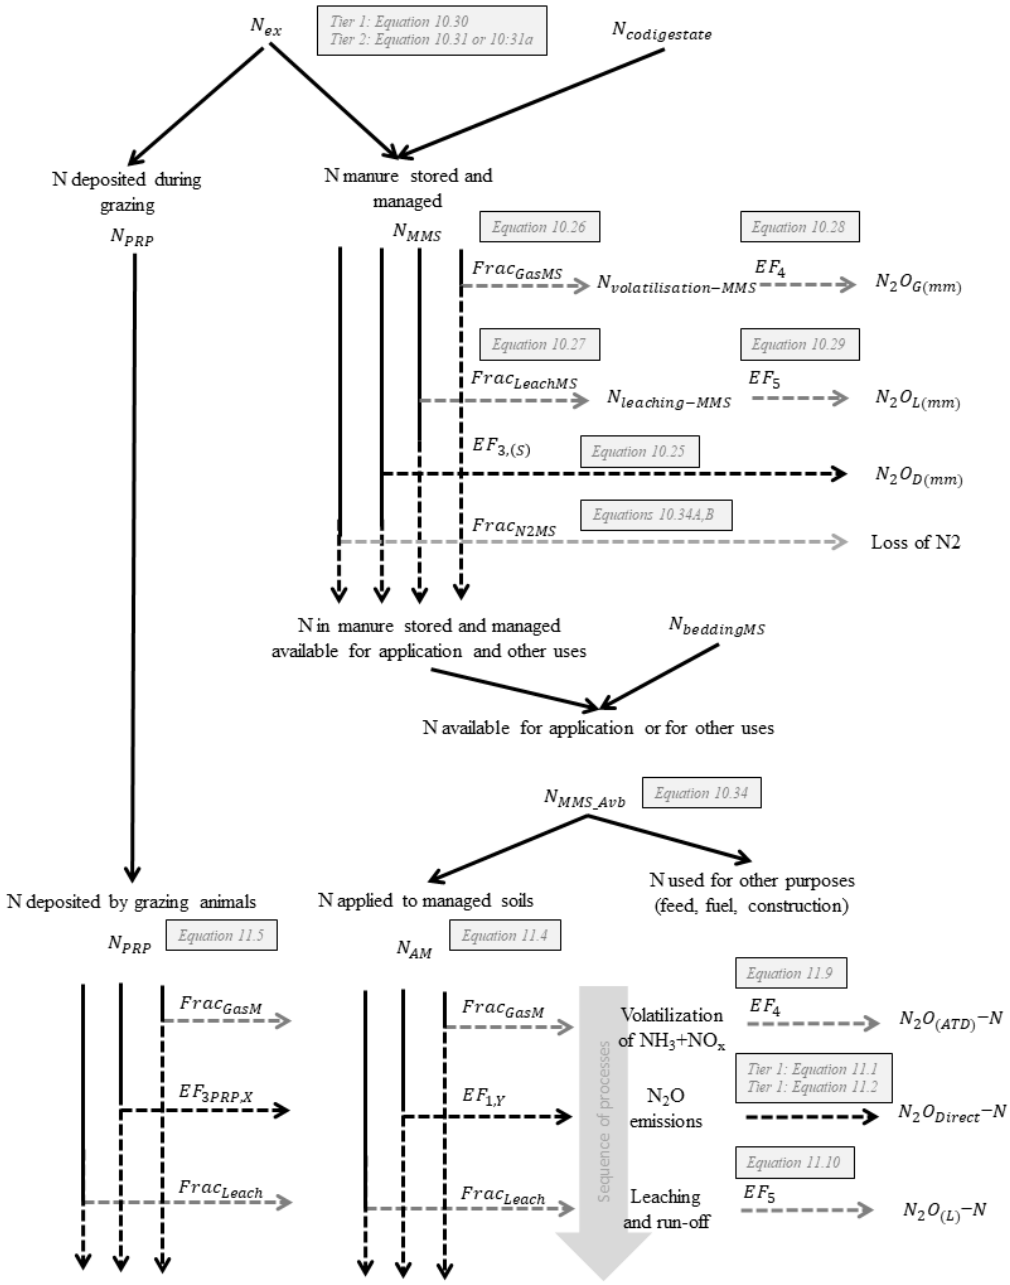
- Emissions from the manure management system for pasture, range, and paddock are to be reported under the IPCC source category N_2O emissions from managed soils because this manure is deposited directly on soils by the livestock.
- Emissions from the manure management system burned for fuel, are to be reported under the IPCC category Fuel Combustion if the dung is used as fuel and under the IPCC category Waste Incineration if the dung is burned without energy recovery. It should be noted, however, if the urine nitrogen is not collected for burning it must be reported under N_2O emissions from pasture, range, and paddock animal if deposited by grazing animals, or under manure management if collected in housed systems.

Consistency of nitrogen flows:

As discussed in Section 10.5.4, most of the manure excreted by livestock is finally applied to land or deposited to land by grazing animals, causing direct and indirect N_2O emissions from managed soils. On its way from the animal to uptake by crops or the release of N_2O, losses of nitrogen happen at all stages and in different forms. With anaerobic digestion, additional N might enter the system through co-digestates (e.g. organic residues, energy crops). The equations given in Chapters 10 and 11 follow a nitrogen balance approach, but are not capturing all effects on direct and indirect N_2O emissions that might occur as a consequence of 'upstream' changes of nitrogen flow, such as manure covers, changes in animal feeding, or nitrogen application technique, some of which are discussed in Section 10.5.4. It is also important to consider total N_2O emissions (see Equation 10.A4-1) when making a key source assessment.

The inventory agency should consult with experts to make sure that any potential effects on N_2O emissions are reflected in the total N_2O emission estimates. Annex 10A.5 lists a set of equations derived from relevant equations in Chapter 10 and 11, allowing the calculation of all direct and indirect N_2O emissions per livestock species/category. These equations can help identifying emissions estimates that might become inaccurate when

national methodologies for upstream flows are used. For example, Equation 10A.13-10A.16 and Equations 11.2-11.4 show that direct N_2O emissions from soils depend on the amount of manure N available for application, not considering any NH_3 losses that might change the amount of N available for N_2O formation. So any application technique that reduces or increases losses of NH_3, modifies the ratio of inorganic to organic N and increases or decreases the availability of N that can be transformed to N_2O must be carefully evaluated (see also Chapter 11, Sections 11.2.1.1 and 11.2.2.1). In this case, methodologies may want to consider, a correction factor that is consistent with the national method for NH_3 emissions and takes into account the forms of nitrogen that are stored, transferred and lost during these processes.



An illustration of N flows through animal and crop production systems is given in Figure 10.5. The figure follows the flow of nitrogen, starting from excretion of nitrogen by animals through livestock and crop production systems down to direct or indirect emissions of N_2O. For each flow shown in Figure 10.5, reference is made to the respective equation in Chapter 10 Emissions from livestock and manure management and Chapter 11 N_2O emissions from managed soils, and CO_2 emissions from lime and urea application. Losses to the environment are shown with broken arrows and indicate the emission factor or loss fraction to be used. Nitrogen input from bedding material and co-digestates enter the system and become part of the N available for application or for other uses.

Symbols are defined under the equations in Chapter 10 and 11 and in Annex 10A.5 of Chapter 10. In this Figure all flows denoted with N are averaged annual N flows per head of livestock species/category [kg N animal^{-1} yr^{-1}] or annual N input via co-digestates [kg N yr^{-1}]; symbols denoted with Frac are fractions in [kg N (kg N)$^{-1}$]; symbols denoted with EF are N_2O emission factors in [kg N_2O –N (kg N)$^{-1}$]. X: different EF_3 are used for cattle, pig and poultry (X=CPP) and for sheep and other animals (X=SO). Y: different EF_1 are used for flooded rice fields (Y=FR) and for other fields (no index Y used).

Broken arrows indicate flows that are split into an emission pathway and a flow of N in the agricultural system.

Note that for N deposited by grazing animals or N applied to managed soils, the flow of N is a sequence of processes with first volatilization of NH_3+NO_x and only thereafter emissions of N_2O and N leaching. This is not reflected in the equations proposed for Tier 1 methodology.

Figure 10.5 (New) Processes leading to the emission of gaseous N species from manure

10.5.7 Use of worksheets

No refinement.

Annex 10A.1 Data underlying methane default emission factors for enteric fermentation, volatile solids and nitrogen excretion and retention fractions for Cattle and Buffalo

This annex presents the data used to develop the default emission factors for methane emissions from Enteric Fermentation and Manure Management, Volatile solid and nitrogen excretion rates, and nitrogen retention fraction. The Tier 2 method was implemented with these data to estimate the default Tier 1 emission factors and rates for cattle and buffalo.

This annex also presents the data used to develop the volatile solid estimates used for methane emissions from manure management methane and for nitrogen excretion rates for cattle and buffaloes. The Tier 2 method was implemented with these data.

The literature source for these values are presented in Annex 10B.1 and spreadsheets with raw data for cattle and buffalo compiled for this refinement is available as supplemental material.

[1] The value represent milk yield in kg per day during the whole year.

[2] Y_m values are consist with those reported in Table 10.12.

[3] All data are weighted values, representative of Australia and New Zealand. For Pacific Island nations, may refer to Asia values.

[4] Data of Latin America, Asia, Africa, Middle East and Indian subcontinent were estimated as weighted average by taken into account parameter values related to low- and high-production systems and livestock population structure of low and high productivity systems.

[5] As Feeding Situation corresponding to high productivity systems is defined as Stall Fed, but for low productivity systems as Pasture/Range, a weigted activitiy coefficient was applied to estimate Net energy for activity.

[6] Y_m is a weighted annual value using the high productivity value of 5.7 from Table 10.12 for the lactating period of 305 days and the value of 6.3 for the dry period (60 days).

[7] Scientific articles and reports consulted to derive peformance parameters of dairy and non-dairy cattle are listed in Annex 10B.1.

TABLE 10A.2 (NEW) (CONTINUED)
DATA FOR ESTIMATING TIER 1 ENTERIC FERMENTATION CH_4 EMISSION FACTORS, VOLATILE SOLID AND NITROGEN EXCRETION RATES, AND N RETENTION FRACTION FOR OTHER CATTLE

[1] The value represent milk yield in kg per day during the whole year.

[2] Y_m values are consist with those reported in Table 10.12.

[3] All data are weighted values, representative of Australia and New Zealand. For Pacific Island nations, may refer to Asia values.

[4] Data of Latin America, Asia, Africa, Middle East and Indian subcontinent were estimated as weighted average by taken into account parameter values related to low production systems and high production systems and livestock population structure of low and high productivity systems. The values were estimated based on the data reported in Table 10A.3.

[5] Scientific articles and reports consulted to derive peformance parameters of dairy and non-dairy cattle are presented in Annex 10B.1.

[6] As Feeding Situation corresponding to high productivity systems is defined as Stall Fed, but for low productivity systems as Pasture/Range, a weigted activitiy coefficient was applied to estimate Net energy for activity.

[7] It was assumed that the whole population of stall fed mature females is not used for draught on the regional scale in Africa.

[8] Draft bullocks were all assumed to be castrates and CF_i values were adjusted accordingly.

[1] The value represent milk yield in kg per day during the whole year.

[2] Ym values are consist with those reported in Table 10.12.

[3] Scientific articles and reports consulted to derive pefromance parameters of buffalo are listed in Annex 10B.1.

[4] Draft bullocks were all assumed to be castrates and CF_i values were adjusted accordingly.

Annex 10A.2 Additional data and information for the calculation of methane and nitrous oxide from Manure Management

This annex presents the required default data to implement the Tier 1 method for estimation of methane and nitrous oxide emissions from manure management. Data required in both methods include animal weight data required for the calculation of average VS and N excretion per animal category as well as AWMS information for regions in the country and improved definitional data, relating IPCC AWMS and definitions used in the EMEP/EEA air pollutant emission inventory guidebook. The information is a combination of the consistent data collection for cattle and buffalo that is compiled in Annex 10A.1 and data compiled by the FAO for use in their modelling system GLEAM (FAO 2017; MacLeod *et al*. 2017). More specific information can be found, sometimes at the country level at http://www.fao.org/gleam/resources/en/. Furthermore, information is supplied on IPCC climate zones.

TABLE 10A.5 (NEW) (CONTINUED)
DEFAULT VALUES FOR LIVE WEIGHTS FOR ANIMAL CATEGORIES (KG)

Category of animal	Region																			
	North America	Western Europe	Eastern Europe	Oceania	Latin America			Africa			Middle East			Asia			India sub-continent		
					Mean	High PS[1]	Low PS[1]	Mean	High PS	Mean	High PS[1]	Low PS[1]	Mean	High PS	Mean	High PS[1]	Low PS[1]	Mean	High PS
Deer[5]	120																			
Reindeer[5]	120																			

[1] High PS and Low PS refer to high- and low productivity systems required for Tier 1a methodology.

[2] Values are derived from diets used in the calculation of enteric fermentation Tier 1 and Tier 1a emission factors (Table 10A.1 – Table 10A.4).

[3] Values are taken from FAO GLEAM databases (FAO 2017). High and low estimates are simplified extracts from the model database.

[4] Values are taken from Table 10A-9 of the *2006 IPCC Guidelines*.

[5] For more information see Table 10.10 and Table 10.19 of the *2019 Refinement*.

[1] For Other animal, the IPCC expert group reviewed the national inventory submissions as well as guidance in the *2006 IPCC Guidelines* under the UNFCCC and concluded that common distribution of systems used to manage manure as follows:

Horses, camelelids, mules and asses, and other grazing animals; should use the data supplied for goats as a proxy;

American bison should use the same manure management fractions as beef cattle in North America;

Deer and reindeer manure deposited at 100% in PRP;

Ostrich (Emu) manure is 80% in PRP and 20 percent managed in solid based systems;

Manure of rabbits and fur-bearing animals is 100% managed in a solid based system.

Hence, countries may apply the same allocation of MMS in the calculation of N_2O emissions from manure stored in manure management systems. However, countries are encouraged to develop a country-specific dataset on MMS used to manage manure generated by these categories of animals.

Information required to determine climate zones according to Chapter 3 of Volume 4 Current Guideline

Outlined below are the conditions required to determine the climate zone required for the selection of a country's MCF, according to the IPCC climate zone determination as defined in Volume 4, Chapter 3, Annex 3A.5, Figure 3A.5.2. Where possible, if countries span multiple climate zones, efforts should be made to disaggregate animal populations into climate zones. If this is not possible, partys are advised to select the climate zone covering the greatest surface area of their country or regions of their country for which they have distinct animal populations.

Briefly, all data is drawn from "The Climate Reseach Unit (CRU) or the CGIAR-Consortium for Spatial Information (CSI) 1985-2015." Climate zones are differentiated based on the factors of mean annual temperature, elevation, mean annual precipitation and the ratio of mean annual precipitation to precipitation for this 30 year average annual weather data compilation.

Therefore, as identified in Volume 4, Chapter 3, of these guidelines climate zones are defined:

Tropical Montane: has > 18°C mean annual temperature and at an elevation greater than 1000m;

Tropical Wet: has > 18°C mean annual temperature and mean annual precipitation >2000mm;

Tropical Moist: has > 18°C mean annual temperature and mean annual precipitation >1000mm;

Tropical Dry: has > 18°C mean annual temperature and mean annual precipitation < 1000mm;

Tropical Moist: has > 18°C mean annual temperature and mean annual precipitation >1000mm;

Warm temperate moist: has > 10°C mean annual temperature and a ratio of potential evapotranspiration to precipitation > 1;

Warm temperate dry: has > 10°C mean annual temperature and a ratio of potential evapotranspiration to precipitation < 1;

Cool temperate moist: has > 0°C mean annual temperature and a ratio of potential evapotranspiration to precipitation > 1;

Cool temperate dry: has > 0°C mean annual temperature and a ratio of potential evapotranspiration to precipitation < 1;

Boreal moist: has < 0°C mean annual temperature but some monthly temperatures > 10°C and a ratio of potential evapotranspiration > 1;

Boreal dry: has < 0°C mean annual temperature but some monthly temperatures > 10°C and a ratio of potential evapotranspiration to precipitation < 1;

Polar moist: has < 0°C mean annual temperature but all monthly temperatures < 10°C and a ratio of potential evapotranspiration > 1;

Polar dry: has < 0°C mean annual temperature but all monthly temperatures < 10°C and a ratio of potential evapotranspiration to precipitation < 1.

Figure 10A.1 (New) Mapping of IPCC climate zones (taken from Volume 4, Chapter 3, Annex 3A.5)

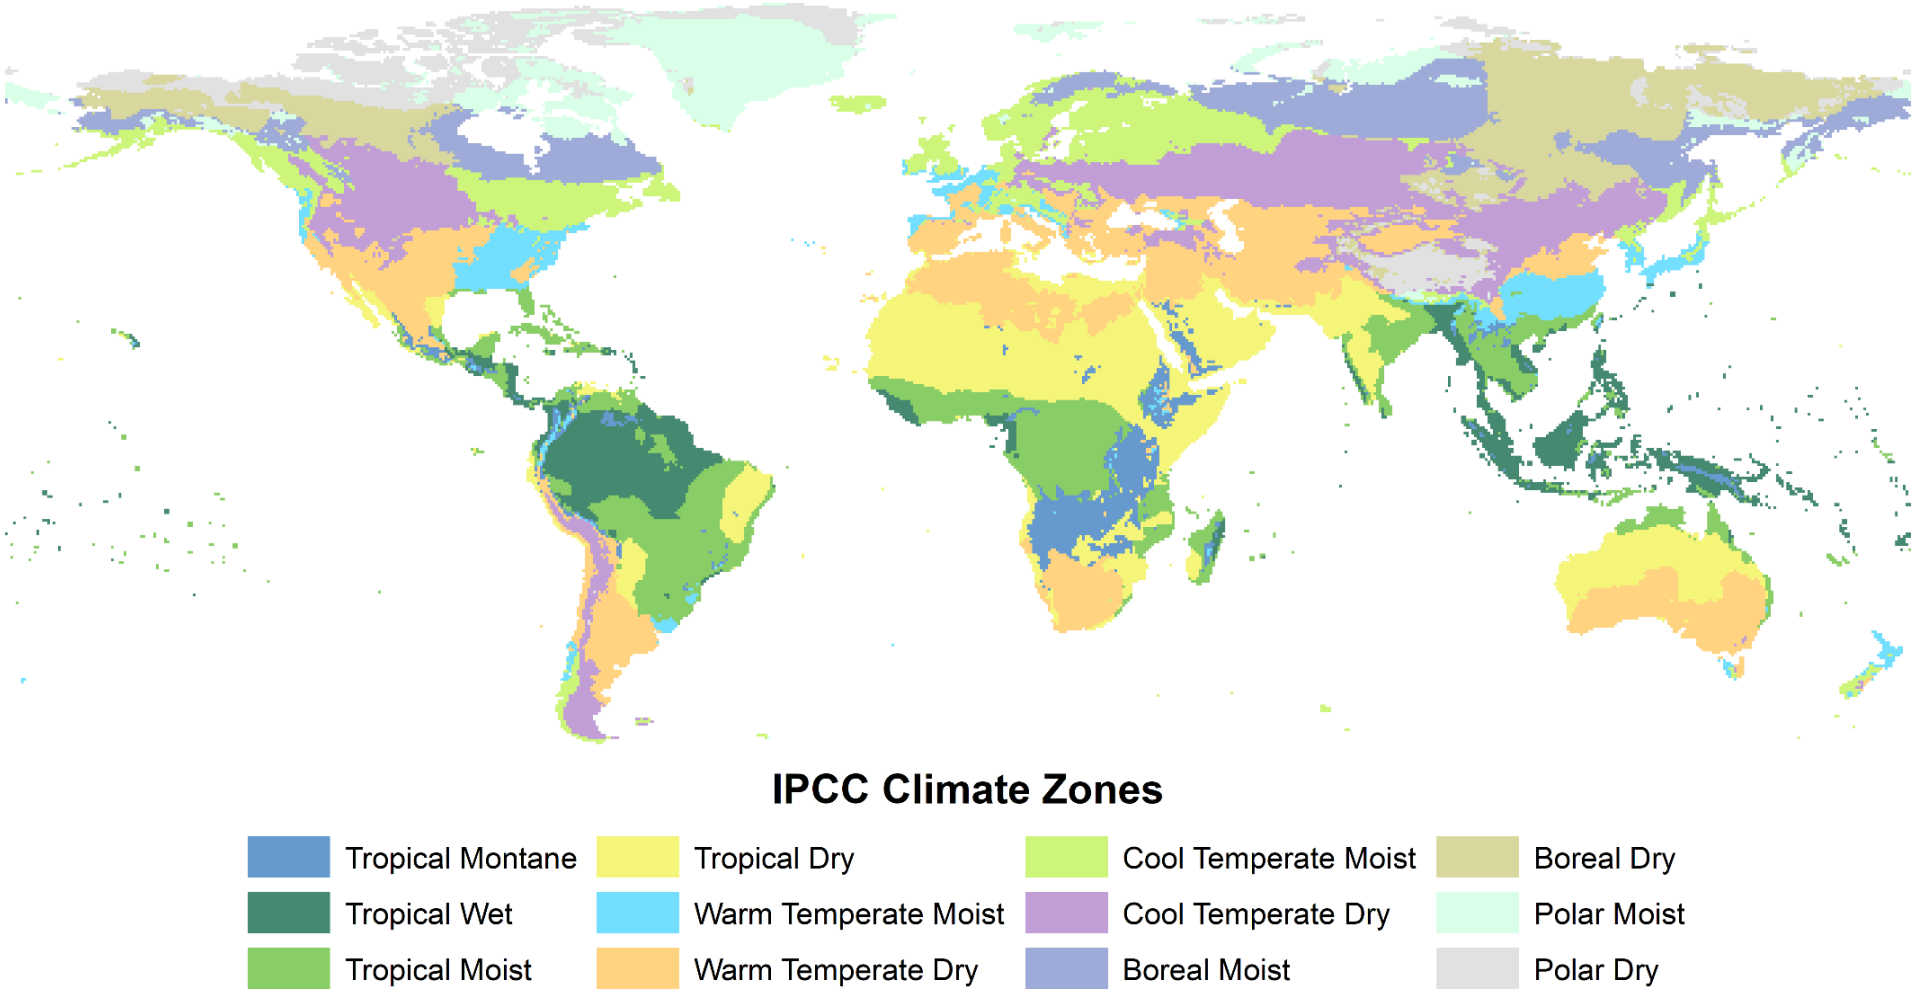

TABLE 10A.10 (NEW)
COMPARISON OF MANURE STORAGE TYPE DEFINITIONS USED BY THE IPCC AND BY THE EMEP/EEA AIR POLLUTANT EMISSION INVENTORY GUIDEBOOK 2016 (HTTPS://WWW.EEA.EUROPA.EU/PUBLICATIONS/EMEP-EEA-GUIDEBOOK-2016)

System IPCC	System EMEP / EEA	Definition
Pasture/Range/Paddock (PRP)	Grazing	The manure from pasture and range grazing animals is allowed to lie as deposited, and is not managed.
Daily spread	No definition given	Manure is routinely removed from a confinement facility and is applied to cropland or pasture within 24 hours of excretion.
Solid storage	Heaps	The storage of manure, typically for a period of several months, in unconfined piles or stacks. Manure is able to be stacked because of the presence of a sufficient amount of bedding material or loss of moisture by evaporation
Dry lot	No definition given	A paved or unpaved open confinement area without any significant vegetative cover. Dry lots do not require the addition of bedding to control moisture. Manure may be removed periodically and spread on fields.
Liquid/Slurry	Tanks	Manure is stored as excreted or with some minimal addition of water in either tanks or earthen ponds outside the livestock building, usually for periods of less than 1 year; Storage with a low surface area to depth ratio; normally steel or concrete cylinders
Liquid/Slurry, With natural crust cover	Crust	Natural or artificial layer on the surface of slurry which reduces the diffusion of gasses to the atmosphere
Liquid/Slurry, cover	Cover	Rigid or flexible structure that covers the manure and is impermeable to water and gasses
Uncovered anaerobic lagoon	Lagoons	Storage with a large surface area to depth ratio; normally shallow excavations in the soil
Pit storage below animal confinements	In-house slurry pit	Mixture of excreta and washing water, stored within the livestock building, usually below the confined animals
Anaerobic digester	Biogas treatment	Anaerobic fermentation of slurry and/or solid
Burned for fuel	No definition given	The dung and urine are excreted on fields. The sun dried dung cakes are burned for fuel.
Deep bedding	In-house deep litter	Mixture of excreta and bedding, accumulated on the floor of the livestock building

TABLE 10A.10 (NEW) (CONTINUED)
COMPARISON OF MANURE STORAGE TYPE DEFINITIONS USED BY THE IPCC AND BY THE EMEP/EEA AIR POLLUTANT EMISSION INVENTORY GUIDEBOOK 2016 (HTTPS://WWW.EEA.EUROPA.EU/PUBLICATIONS/EMEP-EEA-GUIDEBOOK-2016)

System IPCC		System EMEP / EEA	Definition
Composting	In-vessel	Forced-aeration composting	Aerobic decomposition of manure with forced ventilation
	Static pile	Composting, passive windrow	Aerobic decomposition of manure without forced ventilation
	Intensive windrow	No EMEP equivalent	
	Composting - Passive windrow	No EMEP equivalent	
Poultry manure with litter		Laying hens – solid Broilers – litter Other poultry - litter	Similar to cattle and swine deep bedding except usually not combined with a dry lot or pasture. Typically used for all poultry breeder flocks, for alternative systems for layers and for the production of meat type chickens (broilers) and other fowl. Litter and manure are left in place with added bedding during the poultry production cycle and cleaned between poultry cycles, typically 5 to 9 weeks in productive systems.
Poultry manure without litter		Laying hens – slurry	May be similar to open pits in enclosed animal confinement facilities or may be designed and operated to dry the manure as it accumulates. The latter is known as a high-rise manure management system and is a form of passive windrow composting when designed and operated properly. Some intensive poultry farms installed the manure belt under the cage, where the manure is dried inside housing.
Aerobic treatment		No EMEP equivalent	The biological oxidation of manure collected as a liquid with either forced or natural aeration. Natural aeration is limited to aerobic and facultative ponds and wetland systems and is due primarily to photosynthesis. Hence, these systems typically become anoxic during periods without sunlight.
No definition given		Slurry separation	The separation of the solid and liquid components of slurry
No definition given		Acidification	The addition of strong acid to reduce manure pH

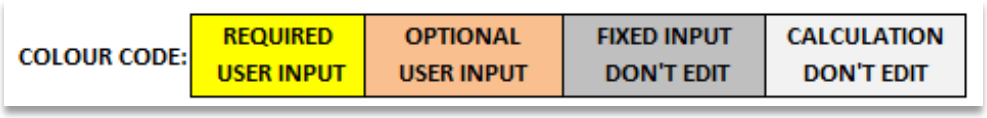
Annex 10A.3 Spreadsheet example for the calculation of a country or regions specific MCF

MCF CALCULATIONS AND EXAMPLE SPREADSHEET

This Annex was developed to explain how MCFs in the guidelines have been derived and to provide a detailed step by step protocol for inventory compilers to calculate country or region specific MCFs. Application of the model at the national scale requires national or regional monthly air temperature profiles as well as the average number and timing of the emptying of manure storages. Temperature data can be downloaded from various agencies such as the National Oceanic and Atmospheric Administration (NOAA) or the European Environmental Agency. Manure removal statistics may be taken from farm practice surveys or from expert consultation. Compilers should develop an estimate of the average number of manure removals per year and the months of the highest frequency of removals. If regional practices vary within a country, compilers should develop MCFs that are representative of regional practice by entering consistent manure removal statistics with regional temperature profiles. If regional MCFs are calculated, the national MCF should be weighted based on the number of animals feeding into the regional manure management systems represented by the manure removal profile and the regional temperature profile.

Further, to support the *2019 Refinement*, a spreadsheet was created to enable users to calculate a site-specific Methane Conversion Factor (MCF). The spreadsheet uses the same calculations that were used to calculate the MCF Table in the guidance document, but has been designed for use by inventory compilers to do calculations for their country-specific circumstances. The spreadsheed is available in the supplemental data supplied with this Chapter, identified as Supplemental Information Chapter 10, Volume IV, *2019 Refinement*, and available on the IPCC TFI website.

The calculation procedure outlined in the spreadsheet contains three main sections:



Inputs to the model;

Model calculations;

Results from the model.

As an explanation of procedures, within each section, cells are colour coded. Compilers are required to develop input data for anything that is indicated by yellow highlighted cells, and have the option of editing the orange highlighted cells if needed, but only if country-specific information is available for those parameters. Other cells are not meant to be edited by the user.

Figure 10A.2 (New) Colour code for cells in the example spreadsheet

MODEL INPUT

Temperature

The Input required to run the model at a national scale and recreate the spreadsheet is shown below (Figures 10A.3(New) and 10A.4(New)). In this section, the compiler should input 12 months of temperature data (degrees C) in cells D9:D20, based on average monthly temperatures for the region for which they wish to develop the MCF.

If the compiler has estimates of national or regional manure temperature, "Manure" should be selected in cell D6. As a result, the spreadsheet will copy the user-input temperature into cells E9:E20, for further use in the analysis.

If the compiler is using national or regional air temperature (not manure temperature), "Air" should be selected in cell D6. As a result, the spreadsheet will generate an estimate for manure temperature in cells E9:E20. The estimates are based on the following logic:

- Manure temperature lags 1-month behind air temperature.
  - e.g., Tmanure in June = Tair in May.
- The minimum manure temperature will be used (1 degree C by default; user adjustable).
  - e.g., for Tair = -9 C, Tmanure = 1 C.

If and only if the storage is emptied once per year, manure temperature will be reduced by a dampening factor (3 degrees C by default; user adjustable).

i.e. Tman = Tair – damping factor; e.g., 12 = 15 – 3

The logic equation is implemented in Excel as follows, for example, in cell E9: =IF($D$6="Manure",D9,IF($F$21>1,MAX(D20,f_Tmin),MAX(D20-f_T2damping,f_Tmin)))

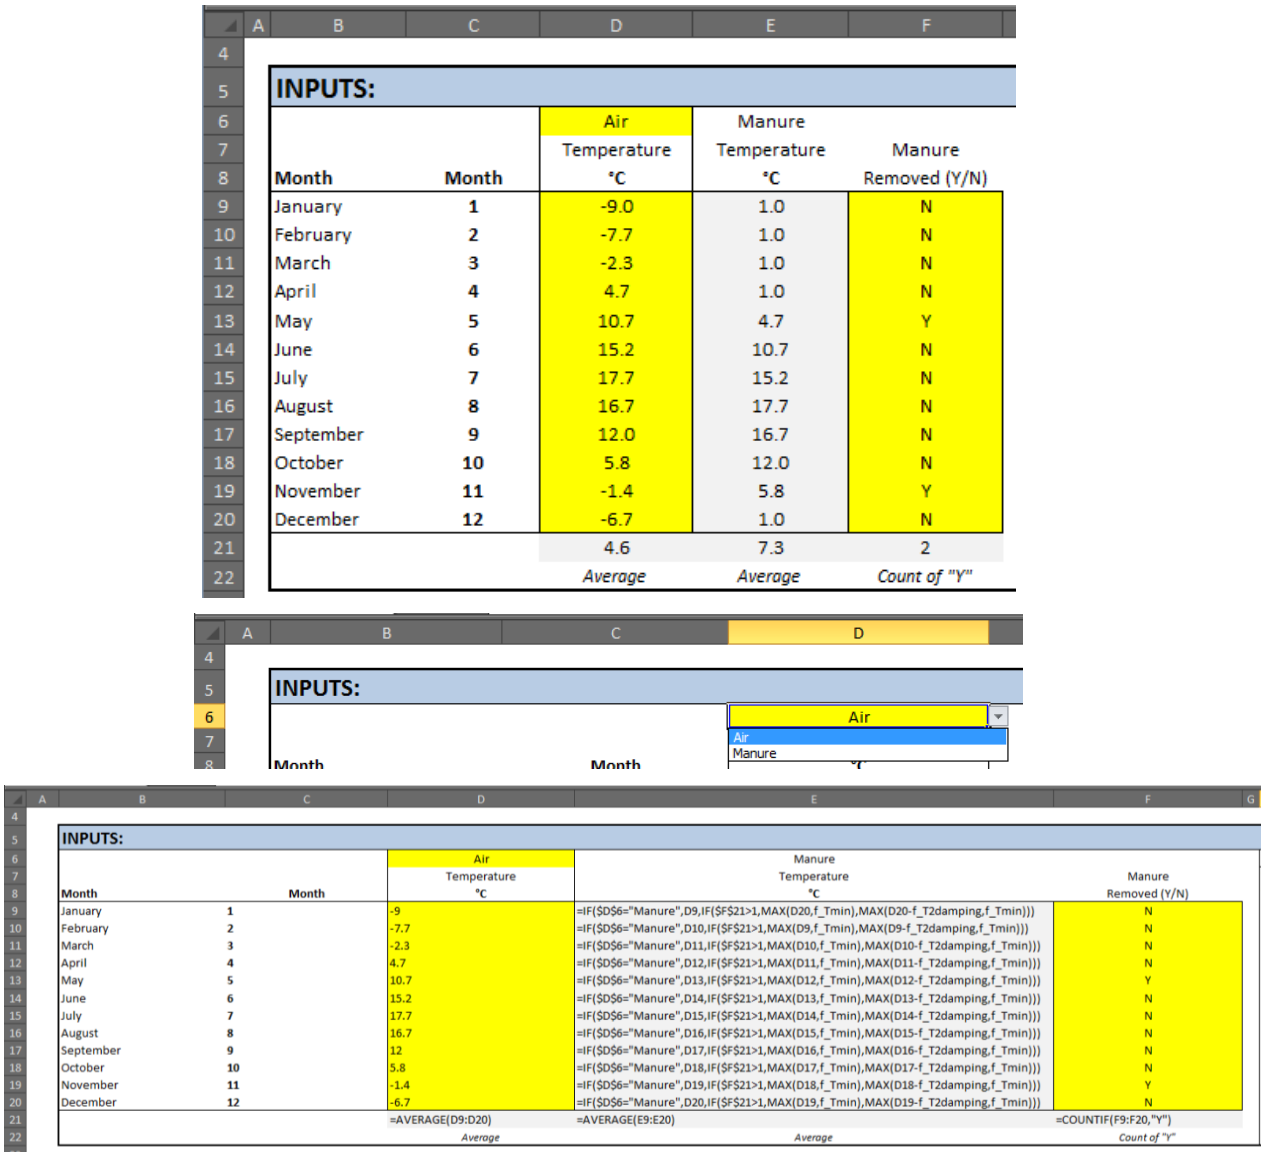
Broken into steps:

If $D$6="Manure" then the result in E9 will equal D9

If $D$6 is not "Manure" (i.e. it is “Air”) then the second IF statement is operated

IF $F$21>1 (i.e. multiple removals per year), then no damping is applied

Manure temperature is selected as air temperature from the previous month, and it is always greater or equal to the minimum temperature,
i.e. E9 will equal MAX(D20,f_Tmin). In this case, D20 (-6.7) is less than the minimum, so the result in E9 is the minimum (1.0).



IF $F$21=1 then damping is applied

Damping is applied by subtracting the damping factor: D20-f_T2damping

The temperature is always greater or equal to the minimum temperature, using the MAX() function.

The compiler should then identify the months when manure is removed from the storage in column F (F9:F20). This can be indicated by a “Y” indicating months when manure was removed, and an “N” for months when manure is not removed. The number of months when manure was removed is counted and displayed in cell F21.

Figure 10A.3 (New) Temperature and manure removal inputs to the model

INPUTS:				
Month	Month	Air Temperature °C	Manure Temperature °C	Manure Removed (Y/N)
January	1	-9.0	1.0	N
February	2	-7.7	1.0	N
March	3	-2.3	1.0	N

		Average	*Average*	*Count of "Y"*

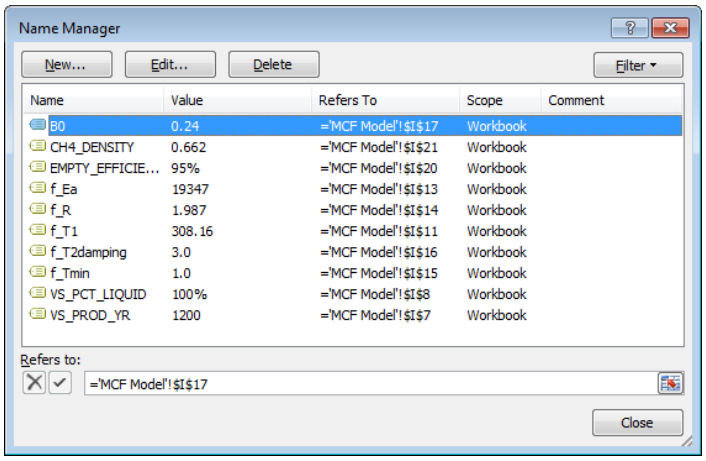
Note. Top panel: alphanumeric values in each cell. Middle panel: dropdown menu to select "Air" or "Manure". Bottom panel: all formulae are visible.

Constants and Other Input Parameters

The inventory compiler is required to provide several other inputs in the section shown below (Figure 10A.4(New)). The name of each parameter is provided in column H, the numeric value of the parameter is in column I, the units are in column J, the source of each value is given in column K, additional notes are in columns L and M, default values are in column N. To make equations more easily understood, the Microsoft Excel feature of "Named Cells" has been used to name the cells in column I, and the name of each cell is shown in column O for convenience. For example, cell I7 is given the name "VS_PROD_YR". See Figure 10A.4(New) for a full list of named cells.



Additional information about the input parameters:

- VS Excretion – based on IPCC guidance.
- VS% liquid storage – this indicates what percentage of excreted VS is handled as a liquid. For example. 100 percent indicates that all excreted VS enters the liquid storage;
- A lower number (say, 75 percent) could indicate that a portion of the solids is separated by a screwpress and handled as a solid (25 percent) while the remaining 75 percent is handled as liquid;
- The compiler must provide a B_0 value for the manure. Refer to IPCC guidance;

- The compiler may, optionally, adjust the minimum temperature (and temperature damping factors);
- The compiler also has the option to adjust the emptying efficiency, which indicates the percentage of manure removed from storage at each removal. By default this is set to 95 percent, indicating that 5 percent of the VS remain in storage after emptying. Set this value to 100 percent for complete removal.

Figure 10A.4 (New) Constants and other input parameters for the model

Parameter:	Value	Units	Source:	Notes	Default Value:	Named Cell
VS Excretion:	1200	kg/year	user input	based on VS excretion, and manure handling	n/a	VS_PROD_YR
VS % liquid storage:	100%	%	user input	% going to liquid storage (e.g. solid-liquid separat	100%	VS_PCT_LIQUID
				note emissions from solid must be handled separately		
f equation:	f = EXP((Ea*(T2-T1))/(R*T2*303.16))					
T1	308.16	K	Temperature of B0 assays		308.16	f_T1
T2	monthly input	K	user input	Enter in Column D (D9:D20)	n/a	n/a
Ea	19347	cal/mol	Petersen et al. PLoS One	(compare: 15175 from Mangino et al. 2001)	19347	f_Ea
R	1.987	cal/K.mol	Mangino et al. 2001		1.987	f_R
Minimum T2	1.0	C	Judgement.	converted to K in calculation	1.0	f_Tmin
Damping T2	3.0	C	Judgement (Rennie et al. 2017.)	applied only when manure removed once per year		f_T2damping
B0	0.24	m3/kg VS added	user input	refer to IPCC guidance for default B0 values	n/a	B0
MDP	1.0	unitless	MDP is not used (i.e. =1.0). Adjust VS % liquid storage or excretion instead.		1.0	
emptying efficiency	95%	%	Judgement. Default 95%	Percent of manure removed (1-residual)	95%	EMPTY_EFFICIENCY
CH4 density	0.662	kg/m3	IPCC guidance		0.662	CH4_DENSITY

Note. Constants and other input parameters for the model are shown in the top panel. Named Cells in column I are shown in column O, and in the Name Manager dialog box (bottom panel). No formulae exist in this part of the spreadsheet.

MODEL CALCULATIONS

The model calculations are run for three years, in order to ensure VS available has stabilized on an annual basis. For example, in Figure 10A.5(New), we see that VS Available (column J) increases substantially from the first year to the second year (J64 vs J65), and then stabilizes in the third year (J66). This is because the first year begins from a perfectly empty storage, whereas the second year is emptied according to the Emptying Efficiency parameter (95 percent removed / 5 percent remaining; Figure 10A.4(New)).

The model approach is as follows:

Column B: Month of year, over 3 years. These month numbers are used to extract input data shown in Figure 10A.3(New).

Column C: Average manure temperature in each month. This is extracted from cells E9:E20 (Figure 10A.3(New)) using a VLOOKUP function (Figure 10A.6(New)).

Column D: temperature is converted from Celsius to Kelvin, using Excel's CONVERT function 10A.6(New) .

Column E: the temperature-dependent *f* parameter is calculated using the van't Hoff-Arrhenius equation (Mangino *et al*. 2001; IPCC 2006), with updated input parameters shown in Figure 10A.4(New).

Column F: monthly VS excreted is calculated by dividing the annual VS input parameter by 12.

Column G: monthly VS loaded is calculated by multiplying VS excreted by the percentage stored as liquid. In this example, the two are equal because VS_PCT_LIQUID is 100 percent (Figure 10A.4(New)).

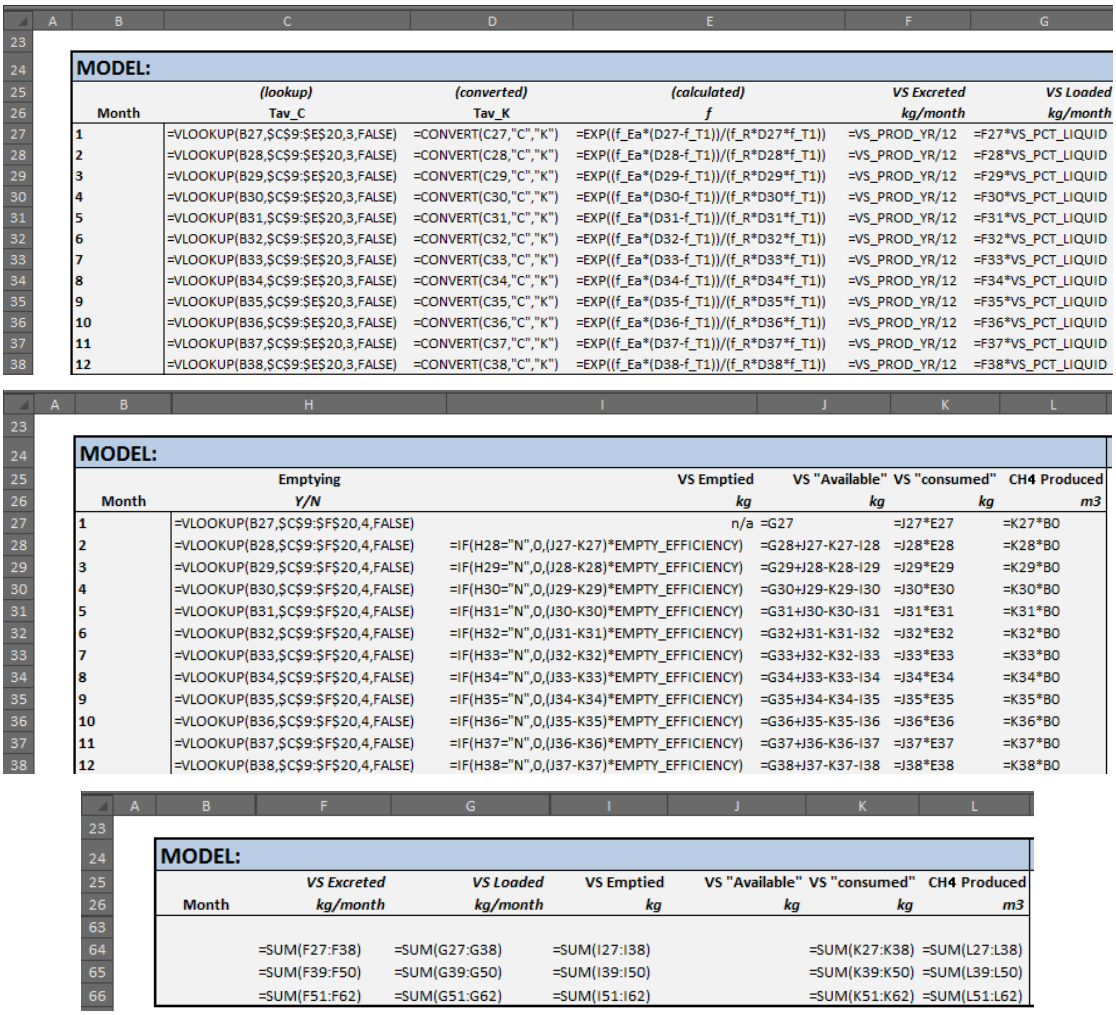
Column H: monthly manure emptying is extracted from cells F9:F20 (Figure 10A.3(New)) using a VLOOKUP function (Figure 10A.6(New)).

Column I: the quantity of VS emptied is calculated. The logic is as follows: if emptying occurred, then calculate the mass of VS available to be removed using the mass of VS available in the previous month minus the mass of VS consumed in the previous month. Then, multiply the result by the EMPTY_EFFICIENCY parameter (Figures 10A.4(New) and 10A.6(New)).

Column J: the mass of VS available for producing methane is calculated. In the first month of the first year this is equal to the mass of VS loaded. In all other months, this is calculated as the VS loaded in the current month + VS available in the previous month – VS consumed in the previous month – VS emptied in the current month.

Column K: the mass of VS consumed is calculated by multiplying VS available by *f*.

Column L: the volume of CH_4 produced is calculated by multiplying VS consumed by B_0.



Using these values and equations, the compiler should be able to reproduce graphics such as the profile of manure temperature, volatile solids and methane production shown in Figure 10A.7(New).

Note. To conserve space, only 12 months are shown. Top panel: Temperature (Column C and D), coefficient (Column E), VS excreted, (Column F) and VS loaded (Column G). Middle panel: month of emptying (Columns H), VS emptied (Column I), VS available (Column J), VS consumed (Column K) and CH_4 Produced (Column L). Bottom panel: sums in rows 64:66 for selected columns.

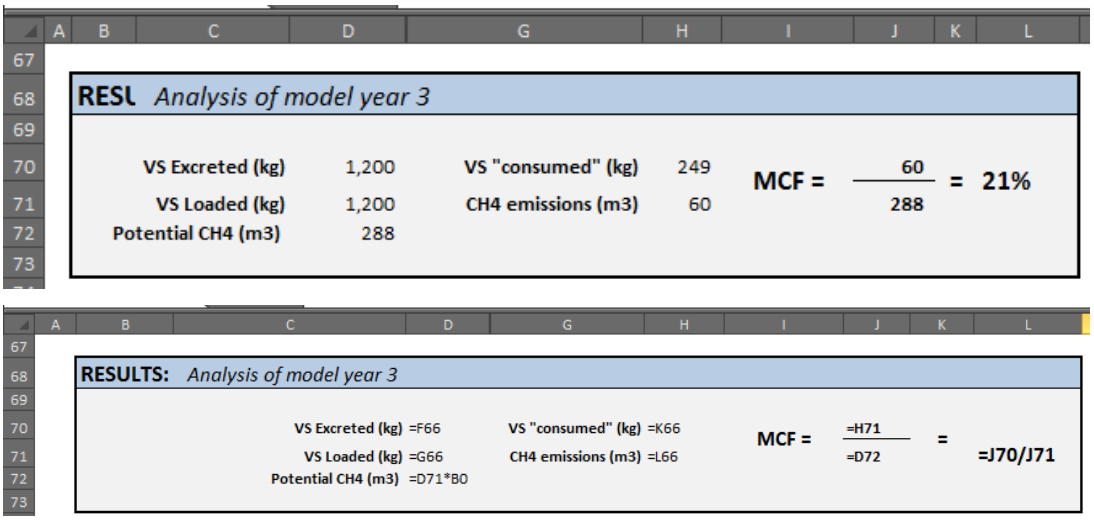

Figure 10A.7 (New) Example of monthly patterns in Year 3: manure temperature, VS available (kg), VS emptied (kg), and methane production.

MODEL RESULTS

The MCF is calculated in the Results section. This is done using the third year outputs. In this particular example, the input air temperature is from the Cool Temperate Moist region and the retention time is 6-months. The resulting MCF (21 percent) is identical with the guidance document (21 percent).

Figure 10A.8 (New) Summary of Year 3 VS and methane production, and calculation of MCF.

Note. Top panel shows results, bottom panel shows equations.

NOTE ABOUT TERMINOLOGY:

The terms "VS Available" and "VS Consumed" are used here to be consistent with the *2006 IPCC Guidelines* and Mangino *et al*. 2001 approach. However, these terms require some clarification to avoid misinterpretation: (1)

The term "VS Consumed" does not represent the real VS degraded but a conceptual quantity of VS removed from the liquid/slurry storage against the total biomethane potential at 35°C (i.e. the conceptual proportion of the B_0 consumed at that point). Therefore, just as B_0 reports the quantity of CH_4 produced per kg of VS (i.e. all fractions, degradable and non-degradable), the concept of "VS Consumed" removes all fractions of VS from storage. This approach is convenient because it uses the B_0 as the integrator of all fractions of VS degradability, and reports the total methane produced from all fractions as if they were incubated for infinite time, while the *f* parameter introduces a temperature dependence. Though this is convenient for modelling, and is consistent with the B_0, this does not represent the physical reality of the liquid/slurry storage. (2) Since "VS Consumed" does not equate with the amount of VS degraded in the storage, the "VS available" does equate with the amount of VS that would actually be measured in a storage. Therefore, researchers should not attempt to compare measured VS with "VS available". (3) The strength of this approach is its simplicity and the fact that the maximum amount of methane that can be produced is equal to the total VS produced multiplied by the B_0. In other words, the model cannot produce more methane than the B_0. (4) The MCF is the ratio of predicted "VS Consumed" to the total VS that entered the storage over one year. The method does not address VS destruction. If the "VS Consumed" were multiplied by B' (m^3 CH_4/kg VS destroyed), the result be would be erroneous because "VS Consumed" is not VS Destroyed. This is not to say that B' cannot be used to model methane production, but simply that it is not compatible with the "VS Consumed" concept. (5) Although B_0 does not need to enter the MCF calculation, the role of B_0 is to be multiplied by the MCF, as stated in equation 10.23 of the *IPCC 2006 Guidelines* and this *2019 Refinement*.

Annex 10A.4 Calculations of Methane Conversion Factors (MCFs) for biogas systems

MCFs for the biogas digester

Biogas digesters are an important manure management systems. There are different types of biogas digesters, including centralised biogas digester plants, animal farm based biogas digesters, and digesters that co-digest animal manures and organic residues. Some biogas digesters such as farm based biogas digesters may include prestorage, like pit storage below animal confinement, or outdoor storage. Co-digestion may include energy crops, and/or different types of organic waste in varying combinations.

Default MCFs of biogas digesters are provided in Table 10.17 and Table 10A.11.

MCFs depend on the amount of B_0 that is realised under on farm conditions and on the amount of produced biogas that leakes from the biogas plant either during storage or energy production. Calculations to identify default factors were carried out by varying the level of leakage from the biogas installations. Calculations are based on a modification of the default values in Table 10.17 and Table 10A.11using the equation defined in Haenel *et al*. (2018).

TABLE 10A.11 (NEW)
METHANE CONVERSION FACTOR (MCF_{DG}) INCLUDING BIOGAS DIGESTER AND DIGESTATE STORAGE[1]

Biogas digester quality	Storage gastight level	Climate Zone		
		cold	temperate	warm
high quality biogas digester, Ldig=0.01	High quality gastight storage, $L_{sto,gt}$ =0.01	1.00%	1.00%	1.00%
	Low quality gastight storage, $L_{sto,gt}$ =0.1	1.41%	1.41%	1.41%
	Open storage, $L_{sto,gt}$=1	3.55%	4.38%	4.59%
	Average	1.99%	2.27%	2.33%
low quality biogas digester, Ldig=0.1	High quality gastight storage, $L_{sto,gt}$=0.01	9.59%	9.59%	9.59%
	Low quality gastight storage, $L_{sto,gt}$ =0.1	10.00%	10.00%	10.00%
	Open storage, $L_{sto,gt}$ =1	12.14%	12.97%	13.17%
	Average	10.58%	10.85%	10.92%

[1] the value of MCF for digestate storage (MCF_{ngts}) is based on the MCF value of anaerobic lagoon.

Methane emissions from biogas digesters include the unused biogas (can be defined as leakage) and emissions from storage of the digestate. The MCF calculation from biogas digesters should be based on the following equation (Haenel *et al*. 2018):

EQUATION 10A.1 (NEW)
CALCULATION OF MCF FOR THE COMBINATION "DIGESTER + DIGESTATE STORAGE"

$$MCF_{dg} = \frac{v_{CH_4,prod} - v_{CH_4,used} - v_{CH_4,\ flared} + MCF_{residues} \bullet \left(B_0 - v_{CH_4,prod}\right)}{B_0}$$

Where:

MCF_{dg} = effective methane conversion factor for the combination "digester + digestate storage", percent

$v_{CH_4,prod}$ = specific volume of methane produced in the digester (related to VS input), m^3 CH_4 kg^{-1} VS

$v_{CH_4,used}$ = specific volume of methane used for energy production (related to VS input), m^3 CH_4 kg^{-1} VS

$v_{CH_4,\ flared}$ = specific volume of methane flared (related to VS input), m^3 CH_4 kg^{-1}VS

$MCF_{residues}$ = methane conversion factor for the storage of digested manure, percent

B_0 = maximum methane producing capacity per kg of VS input T, m^3 CH_4 kg^{-1} of VS excreted

In practice, the residence time necessary to fully exploit the maximum methane producing capacity B_0 is not fully reached in the gas collection system. In the following, the difference, i.e. the potentially still purgeable amount of gas ($B_0 - v_{CH_4,prod}$), is denoted as "potential of residual gas" that is assumed to be known, and the ratio of which to B_0 is described by the entity μ_{rg}:

EQUATION 10A.2 (NEW)
CALCULATION OF RELATIVE AMOUNT OF POTENTIAL OFF GAS RELATED TO B_0

$$\mu_{rg} = \frac{B_0 - v_{CH_4,prod}}{B_0}$$

Where:

μ_{rg} = relative amount of residual gas related to B_0 (with $0 \leq \mu_{rg} \leq 1$ m^3 m^{-3})

B_0 = maximum methane producing capacity per kg of VS, m^3 CH_4 kg^{-1} VS

$v_{CH_4,prod}$ = specific volume of methane produced in the digester (related to VS input), m^3 CH_4 kg^{-1} VS

In practice, the amount of residual gas, μ_{rg} is not given as a share of the maximum methane producing capacity B_0, but as a share of the amount of gas usable for energy production. Hence, a new entity v_{rg} can be defined which is closely related to μ_{rg} .

The μ_{rg} can be calculated as follows:

EQUATION 10A.3 (NEW)
CALCULATION OF RELATIVE AMOUNT OF RESIDUAL GAS RELATED TO B_0

$$\mu_{rg} = \frac{v_{rg}}{1 + v_{rg}}$$

Where:

μ_{rg} = relative amount of residual gas related to B_0 (with $0 \leq \mu_{rg} \leq 1$ m^3 m^{-3})

v_{rg} = relative amount of residual gas related to $v_{CH4,prod}$ (with $0 \leq v_{rg} \leq 1$ m^3 m^{-3})

EQUATION 10A.4 (NEW)
CALCULATION OF RELATIVE AMOUNT OF RESIDUAL GAS RELATED TO CH_4 PRODUCTION

$$v_{rg} = \frac{B_0 - v_{CH_4,prod}}{v_{CH_4,prod}}$$

Where:

v_{rg} = relative amount of residual gas related to $v_{CH4,prod}$ (with $0 \leq v_{rg} \leq 1$ m^3 m^{-3})

B_0 = maximum methane producing capacity per kg of VS, m^3 CH_4 kg^{-1}VS

$v_{CH_4,prod}$ = specific volume of methane produced in the digester (related to VS input), m^3 CH_4 kg^{-1}VS

The term $v_{CH_4,prod} - v_{CH_4,used} - v_{CH_4,\ flared}$ in equation 10A.1 is part of the digester's methane balance (related to VS input) which can be completed by the methane loss $v_{CH_4,leak}$ due to leakage.

EQUATION 10A.5 (NEW)
DIGESTER'S METHANE BALANCE

$$v_{CH_4,prod} - v_{CH_4,used} - v_{CH_4,\ flared} - v_{CH_4,leak} = 0$$

Where:

$v_{CH_4,prod}$ = specific volume of methane produced in the digester (related to VS input), m^3 CH_4 kg^{-1} VS

$v_{CH_4,used}$ = specific volume of methane used for energy production (related to VS input), m^3 CH_4 kg^{-1} VS

$v_{CH_4,\ flared}$ = specific volume of methane flared (related to VS input), m^3 CH_4 kg^{-1}VS

$v_{CH_4,leak}$ = specific volume of methane due to leakage and maintenance works (related to VS input), m^3 CH_4 kg^{-1} VS

The loss of methane $v_{CH_4,leak}$ due to leakage is calculated as part of the total amount of CH_4 produced in the digester. The ratio of these two quantities is defined as the leakage rate L_{dig} of the digester. L_{dig} is assumed to be known.

EQUATION 10A.6 (NEW)
CALCULATION OF METHANE LEAKAGE RATE OF DIGESTER

$$v_{CH4,leak} = L_{dig} \bullet v_{CH4,prod}$$

Where:

$v_{CH_4,leak}$ = specific volume of methane due to leakage and maintenance works (related to VS input), m^3 CH_4 kg^{-1} VS

L_{dig} = leakage rate of the digester, related to $v_{CH4,prod}$ (with $0 \leq L_{dig} \leq 1$ m^3 m^{-3}).

$v_{CH_4,prod}$ = specific volume of methane produced in the digester (related to VS input), m^3 CH_4 kg^{-1} VS

In order to give the effective methane conversion factor of the combination, "digester + digestate storage" as a function of the three parameters, "relative amount of residual gas", "leakage rate" and "MCF of the digestate storage", the methane conversion factor of the combination, "digester + digestate storage" can be calculated as follows (Equation 10A.7):

EQUATION 10A.7 (NEW)
CALCULATION OF METHANE CONVERSION FACTOR

$$MCF_{dg} = \left(1 - \mu_{rg}\right) \bullet L_{dig} + \mu_{rg} \bullet MCF_{residues}$$

Where:

MCF_{dg} = effective methane conversion factor for the combination "digester + digestate storage", percent

μ_{rg} = relative amount of residual gas related to B_0 (with $0 \leq \mu_{rg} \leq 1$ m^3 m^{-3})

L_{dig} = leakage rate of the digester, related to $v_{CH4,prod}$ (with $0 \leq L_{dig} \leq 1$ m^3 m^{-3})

$MCF_{residues}$ = methane conversion factor for the storage of digested manure, percent

For the factors of L_{dig} and μ_{rg} it is recommended to use country-specific data; if country specific data are unavailable. the following procedure is recommended: For high quality biogas digesters, the default L_{dig} is recommended to be 0.01 (Rösemann *et al*. 2017); for low quality biogas digesters, L_{dig} = 0.1 is recommended (Table 10A-4 to Table 10A-9 *2006 IPCC Guidelines*). The value of 0.046 is used for µrg based on Haenel *et al*. (2018) The values presented in Table 10A.11 are derived using Equation 10A.7 and the values cited here. Pre-storage loss estimates are not included as no default values can be identified from the literature. Also, it is assumed that these losses will be low as they represent economic losses due to lower biogas production. However equations are included below if compilers wish to adapt their emission estimates to country-specific circumstances.

It is assumed that even a gastight storage of digestate has a certain leakage. This leakage rate is described by the storage-specific leakage rate $L_{sto,gt}$. Taking into account the leakage rate and the relative share of gastight storage of digestate x_{gts} , the $MCF_{residues}$ can be calculated following Equation 10A.8:

EQUATION 10A.8 (NEW)
CALCULATION OF METHANE CONVERSION FACTOR OF RESIDUES

$$MCF_{residues} = x_{gts} \bullet L_{sto,gt} + \left(1 - \frac{x_{gts}}{100}\right) \bullet MCF_{ngts}$$

Where:

$MCF_{residues}$ = methane conversion factor for the storage of digestate, percent

x_{gts} = share of gastight storage of the digestate, percent

$L_{sto,gt}$ = leakage rate of the gastight storage (with $0 \leq L_{sto,gt} \leq 1$ m^3 m^{-3}). For high quality gastight storage of the digestate $L_{sto,gt}$ is assumed to be 0.01 m^3 m^{-3}. For low quality gastight storage of the digestate, $L_{sto,gt}$ is assumed to be 0.1 m^3 m^{-3}. For open storage of the digestate, $L_{sto,gt}$ is assumed to be 1.0 m^3 m^{-3}

MCF_{ngts} = methane conversion factor for the non-gastight storage of digestate, percent. It is assumed that MCF_{ngts} is same to the storage of raw manure.

Biogas plants that are fed with animal manures have, as a rule, a pre-storage for the feedstock before it enters the digester. The CH_4 losses from the pre-storage reduce the CH_4 production potential in the digester and the storage of the digestate. This could be taken into account by modifying equations 10A.7. As a consequence Equation (10A.7) is transformed to the MCF_{dg+ps} equation as Equation 10A.9.

EQUATION 10A.9 (NEW)
CALCULATION OF METHANE CONVERSION FACTOR FOR THE COMBINATION "PRESTORAGE + DIGESTER + DIGESTATE STORAGE"

$$MCF_{dg+ps} = MCF_{ps} + \left(1 - MCF_{ps}\right) \bullet MCF_{dg}$$
$$= MCF_{ps} + (1 - MCF_{ps}) \bullet [(1 - \mu_{rg}) \bullet L_{dig} + \mu_{rg} \bullet MCF_{residues}]$$

Where:

MCF_{dg+ps} = effective methane conversion factor for the combination "prestorage + digester +digestate storage", percent

MCF_{ps} = methane conversion factor for prestorage, percent; Table 10.17 provides the default values for different prestorage systems

MCF_{dg} = methane conversion factor for combination "digester+digestate storage", percent, see above

μ_{rg} = relative amount of residual gas related to B_0 (with $0 \leq \mu_{rg} \leq 1$ m^3 m^{-3})

L_{dig} = leakage rate of the digester, related to $\nu_{CH4,prod}$ (with $0 \leq L_{dig} \leq 1$ m^3 m^{-3})

$MCF_{residues}$ = methane conversion factor for the storage of digestate (in m^3 m^{-3}).

Annex 10A.5 Equations relating all direct and indirect N_2O emissions from manure along all stages in agricultural production for livestock

As explained in section 10.5.6, nitrogen excreted by animals contributes to several direct and indirect N_2O emission as it cascades through livestock and crop cultivation systems. It is therefore crucial to accurately estimate nitrogen excretion rates. The total direct and indirect N_2O emissions associated with the excretion of nitrogen of an animal type is an important quantity to assess the benefit from improving the estimation of the N-excretion coefficient for that animal type. However, the total direct and indirect N_2O emissions from animal excretion cannot be easily estimated using the equations given in Chapter 10 and 11 of the *2006 IPCC Guidelines* and this *2019 Refinement*. This annex provides a set of equations, based on the equations given in Chapter 10 and 11, that allows the quantification of total direct and indirect N_2O emissions from nitrogen excretion of each animal type *T*. They are reported in Equations 10A.10 through 10A27.

The definition of the symbols used in the set of equations is given below Equation 10A.27, grouped by symbols. Note that for internal consistency, the symbol *N* is used for all nitrogen flows in kg N animal^{-1} yr^{-1}; the symbol *F* is used for all animal-independent nitrogen flows or nitrogen flows for the total animal population in kg N yr^{-1}; the symbol *Frac* is used for all fractions in kg N (kg N)$^{-1}$ or percent, the symbol *EF* is used for all N_2O emission factors in kg N_2O-N (kg N)$^{-1}$, and the symbol N_2O is used for all N_2O emissions in kg N_2O-N yr^{-1} . Not in all cases therefore, the symbols are identical to those used in the Equations given in Chapters 10 and 11.

EQUATION 10A.10 (NEW)
TOTAL N_2O EMISSIONS FOR ANIMAL TYPE *T*

$$N_2O_{(T)} = N_2O_{mm(T)} + N_2O_{AM(T)} + N_2O_{PRP(T)}$$

EQUATIONS 10A.11 AND 10A.12 (NEW)
TOTAL N_2O EMISSIONS FROM MANURE MANAGEMENT FOR ANIMAL TYPE *T*

$$N_2O_{(mm,T)} = N_2O_{D(mm,T)} + N_2O_{G(mm,T)} + N_2O_{L(mm,T)}$$

$$N_2O_{mm(T)} = \left(\sum_S F_{mm(T,S)} \bullet \left[EF_{3(S)} + \left(Frac_{GasMS} \right)_{(T,S)} \bullet EF_4 + \left(Frac_{LeachMS} \right)_{(T,S)} \bullet EF_5 \right] \right) \bullet \frac{44}{28}$$

EQUATIONS 10A.13 THROUGH 10A.14 (NEW)
TOTAL, DIRECT AND INDIRECT N_2O EMISSIONS FROM THE APPLICATION OF MANURE TO MANAGED SOILS FOR ANIMAL TYPE *T*

$$N_2O_{AM(T)} = N_2O_{D,AM(T)} + N_2O_{I,AM(T)}$$

$$N_2O_{D,AM(T)} = F_{AM(T)} \bullet \left[\left(1 - Frac_{AM,Rice} \right) \bullet EF_1 + Frac_{AM,Rice} \bullet EF_{1FR} \right] \bullet \frac{44}{28}$$

$$N_2O_{I,AM(T)} = F_{AM(T)} \bullet \left[Frac_{GASM} \bullet EF_4 + Frac_{LEACH-(H)} \bullet EF_5 \right] \bullet \frac{44}{28}$$

EQUATION 10A.15 (NEW)
TOTAL AMOUNT OF ANIMAL MANURE N APPLIED TO SOILS OTHER THAN BY GRAZING ANIMALS FOR ANIMAL TYPE *T*

$$F_{AM(T)} = \left\{ \sum_{S} \left[\left(F_{mm(T,S)} \bullet \left(1 - Frac_{LossMS}\right)_{(T,S)} \right) + F_{bedding(T,S)} \right] + F_{codigestate} \right\} \bullet Frac_{APPL(T)}$$

EQUATION 10A.16 (NEW)
FRACTION OF TOTAL ANIMAL MANURE N LOST IN MANURE MANAGEMENT SYSTEMS FOR ANIMAL TYPE *T*

$$Frac_{LossMS(T,S)} = Frac_{GASMS(T,S)} + Frac_{LEACHMS(T,S)} + Frac_{N_2MS(S)} + EF_{3(S)}$$

EQUATION 10A.17 (NEW)
FRACTION OF ANIMAL MANURE N AVAILABLE FOR APPLICATION TO MANAGED SOILS, APPLIED TO MANAGED SOILS FOR ANIMAL TYPE *T*

$$Frac_{APPL(T)} = 1 - \left(Frac_{FEED(T)} + Frac_{FUEL(T)} + Frac_{CNST(T)} \right)$$

EQUATION 10A.18 THROUGH 10A.19 (NEW)
TOTAL, DIRECT AND INDIRECT N_2O EMISSIONS FROM N IN URINE AND DUNG DEPOSITED BY GRAZING ANIMALS ON PASTURE, RANGE AND PADDOCK (TIER 1) FOR ANIMAL TYPE *T*

$$N_2O_{PRP(T)} = N_2O_{D,PRP(T)} + N_2O_{I,PRP(T)}$$

$$N_2O_{D,PRP(T)} = \left[\left(F_{PRP,CPP(T)} \bullet EF_{3PRP,CPP} \right) + \left(F_{PRP,SO(T)} \bullet EF_{3PRP,SO} \right) \right] \bullet \frac{44}{28}$$

EQUATION 10A.20 (NEW)
RELATIONSHIP BETWEEN AVERAGE ANNUAL NITROGEN FLOWS ASSOCIATED WITH AN INDIVIDUAL ANIMAL [KG N ANIMAL^{-1} YR^{-1}] AND THE ANNUAL NITROGEN FLOW FOR THE ANIMAL POPULATION OF LIVESTOCK CATEGORY/SPECIES *T* IN A COUNTRY [KG N YR^{-1}]

$$F = POP_{(T)} \bullet N$$

EQUATION 10A.21 (NEW)
TOTAL MANURE-N EXCRETED

$$N_{(T)} = N_{MMS(T)} + N_{PRP(T)}$$

EQUATION 10A.22 AND 10A.23 (NEW)
NITROGEN EXCRETION CALCULATED EITHER USING A DEFAULT FRACTION OF RETENTION (TIER 1) OR DIRECTLY FROM RETENTION DATA

$$Nex_{(T)} = N_{intake(T)} \bullet \left(1 - Frac_{RET(T)}\right)$$

$$Nex_{(T)} = N_{\text{int}ake(T)} - N_{RET(T)}$$

EQUATION 10A.24 (NEW)
TOTAL MANURE-N IN MANURE MANAGEMENT SYSTEMS

$$N_{MMS(T)} = \sum_{S} \left(POP_{(T)} \bullet Nex_{(T)} \bullet Frac_{S(T,S)} \right)$$

EQUATION 10A.25 (NEW)
MANURE-N MANAGED IN SYSTEM *S*

$$N_{mm\,(T,S)} = POP_{(T)} \bullet Nex_{(T)} \bullet Frac_{S(T,S)}$$

EQUATION 10A.26 (NEW)
MANURE-N DEPOSITED BY GRAZING ANIMALS, WITH X=CPP,SO

$$N_{PRP(X)} = POP_{(X)} \bullet Nex_{(X)} \bullet Frac_{S(X,G)}$$

EQUATION 10A.27 (NEW)
N IN BEDDING MATERIAL ADDED TO MANAGED MANURE

$$N_{bedding(T,S)} = POP_{(T)} \bullet N_{beddingMS(T,S)}$$

Where,

$POP_{(T)}$ = number of head of livestock species/category *T* in the country, heads

Annual total nitrogen flows, F, and annual average nitrogen flows per head, N:

$F_{(T)}$ and $N_{(T)}$ = animal manure nitrogen excreted for livestock species/category *T* in the country, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

$F_{codigestate}$ = amount of nitrogen from co-digestates added to biogas plants, kg N yr^{-1}

$F_{MMS(T)}$ and $N_{MMS(T)}$ = animal manure nitrogen excreted for livestock species/category *T* in manure management systems in the country, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

$F_{PRP(T)}$ and $N_{PRP(T)}$ = animal manure nitrogen excreted for livestock species/category *T* on pasture, range and paddock in the country, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

$F_{PRP,CPP(T)}$ and $N_{PRP,CPP(T)}$ = animal manure nitrogen excreted for cattle, pig and poultry species/category *T* on pasture, range and paddock in the country, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

$F_{PRP,SO(T)}$ and $N_{PRP,SO(T)}$ = total animal manure nitrogen excreted for sheep and other livestock species/category *T* on pasture, range and paddock in the country, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

$F_{mm(T,S)}$ and $N_{mm(T,S)}$ = animal manure nitrogen excreted for livestock species/category *T* in manure management system *S* in the country, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

$F_{bedding(T,S)}$ and $N_{bedding(T,S)}$ = nitrogen in bedding material added for livestock species/category *T* in manure management system *S* in the country, kg N yr^{-1} and kg N in bedding $animal^{-1}$ yr^{-1}

$F_{AM(T,S)}$ and $N_{AM(T,S)}$ = annual amount of animal manure N applied to soils for each livestock species/category *T*, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

$F_{intake(T)}$ and $N_{intake(T)}$ = annual intake of N in feed for each livestock species/category *T*, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

$F_{retention(T)}$ and $N_{retention(T)}$ = annual retention of N each livestock species/category *T*, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

$F_{ex(T)}$ and $N_{ex(T)}$ = annual average N excretion of species/category *T* in the country, kg N yr^{-1} and kg N $animal^{-1}$ yr^{-1}

Annual N_2O emissions for the total population of each livestock species/category T

$N_2O_{(T)}$ = total annual N_2O emissions

$N_2O_{mm(T)}$ = total annual N_2O emissions from Manure Management for each livestock species/category *T* in the country, kg N_2O yr^{-1}

$N_2O_{D,mm(T)}$ = direct annual N_2O emissions from Manure Management for each livestock species/category *T* in the country, kg N_2O yr^{-1}

$N_2O_{G,mm(T)}$ = indirect annual N_2O emissions from volatilization of NH_3+NO_x from Manure Management for each livestock species/category *T* in the country, kg N_2O yr^{-1}

$N_2O_{L,mm(T)}$ = indirect annual N_2O emissions from leaching and run-off from Manure Management for each livestock species/category *T* in the country, kg N_2O yr^{-1}

$N_2O_{AM(T)}$ = total annual N_2O emissions from manure nitrogen applied to cultivated soils for each livestock species/category *T*, kg N_2O yr^{-1}

$N_2O_{PRP(T)}$ = total annual N_2O emissions from manure nitrogen deposited on pasture, range and paddock for each livestock species/category *T*, kg N_2O yr^{-1}

$N_2O_{D,AM(T)}$ = direct annual N_2O emissions from manure nitrogen applied to cultivated soils for each livestock species/category *T* in the country, kg N_2O yr^{-1}

$N_2O_{I,AM(T)}$ = indirect annual N_2O emissions from manure nitrogen applied to cultivated soils for each livestock species/category *T* in the country, kg N_2O yr^{-1}

$N_2O_{D,PRP(T)}$ = direct annual N_2O emissions from pasture, range and paddock for each livestock species/category *T* in the country, kg N_2O yr^{-1}

$N_2O_{I,PRP(T)}$ = indirect annual N_2O emissions from pasture, range and paddock for each livestock species/category *T* in the country, kg N_2O yr^{-1}

N_2O emission factors

EF_1 = emission factor for direct N_2O emissions from N inputs to cultivated soils, kg N_2O –N (kg N input)$^{-1}$

EF_{1FR} = emission factor for direct N_2O emissions from N inputs to flooded rice, kg N_2O –N (kg N input)$^{-1}$

$EF_{3PRP,X}$ = emission factor for direct N_2O emissions from urine and dung N deposited on pasture, range and paddock by grazing animals, kg N_2O –N (kg N input)$^{-1}$; X=CPP: Cattle, Poultry and Pigs; X=SO: Sheep and Other animals

$EF_{3(S)}$ = emission factor for direct N_2O emissions from manure management system *S* in the country, kg N_2O -N/(kg N in manure management system *S*)$^{-1}$

EF_4 = emission factor for N_2O emissions from atmospheric deposition of nitrogen on soils and water surfaces, kg N_2O -N (kg NH_3-N + NOx-N volatilised)$^{-1}$

EF_5 = emission factor for N_2O emissions from nitrogen leaching and runoff, kg N_2O -N (kg N leached and runoff)$^{-1}$

Fractions

$Frac_{S(T,S)}$ = fraction of manure N excreted that is managed in manure management system *S* for each livestock species/category *T*, dimensionless

$Frac_{S(X,G)}$ = fraction of manure N excreted that is deposited by grazing cattle, poultry or pigs (X=CPP) or sheep or other animals (X=SO), dimensionless

$Frac_{GasMS(T,S)}$ = fraction of managed manure nitrogen for livestock species/category *T* that volatilises as NH_3 and NOx in the manure management system *S*

$Frac_{LeachMS(T,S)}$ = fraction of managed manure nitrogen losses for livestock species/category *T* due to runoff and leaching during solid and liquid storage of manure in manure management system *S*

$Frac_{N_2MS}$ = fraction of managed manure nitrogen for each livestock species/category *T* that is lost in the manure management system *S*, percent as N_2

$Frac_{LossMS(T,S)}$ = total fraction of managed manure nitrogen for livestock category *T* that is lost in the manure management system *S*

$Frac_{GASM(T,S)}$ = fraction of applied organic N fertiliser materials (F_{ON}) and of urine and dung N deposited by grazing animals (F_{PRP}) that volatilises as NH_3 and NOx, kg N volatilised (kg of N applied or deposited)$^{-1}$

$Frac_{LEACH-(H)}$ = fraction of all N added to/mineralised in managed soils in regions where leaching/runoff occurs that is lost through leaching and runoff, kg N (kg of N additions)$^{-1}$

$Frac_{APPL(T)}$ = fraction of animal manure N available for application to managed soils which is applied to managed soils for each livestock species/category *T*, dimensionless

$Frac_{FEED(T)}$ = fraction of managed manure used for feed for each livestock species/category *T*, dimensionless

$Frac_{FUEL(T)}$ = fraction of animal manure N available for application to managed soils used for fuel for each livestock species/category *T*, dimensionless

$Frac_{CNST(T)}$ = fraction of animal manure N available for application to managed soils used for construction for each livestock species/category *T*, dimensionless

$Frac_{AM,Rice}$ = fraction of animal manure N applied to managed soils which is applied to flooded rice, dimensionless

$Frac_{RET}$ = fraction of feed intake N that is retained by the animal in body mass or livestock products for each livestock species/category *T*, dimensionless

Annex 10.B Data and Explanatory Text for Development of New Parameters in the *2019 Refinement*

10B.1 Raw data used to compile Annex 10A.1 enteric fermentation Tier 1 emission factors, volatile solids and nitrogen excretion for cattle and buffalo

A database was compiled from peer-reviewed articles, scientific and statistical reports found via a comprehensive literature search in google scholar (https://scholar.google.com) and Elsevier (www.sciencedirect.com) web search engines.

All raw data collected from literature sources and used as a basis by the IPCC authors to refine the final values presented in Tables 10A.1–10A.4 are available in the supplemental data supplied with this Chapter, maintained on the IPCC document website, there identified as Supplemental Information Chapter 10, Volume IV, *2019 Refinement*.

Since agricultural production systems of certain countries may be transitioning from low productivity local subsistence systems to higher productivity systems, the IPCC expert team of the *2019 Refinement* aimed to collect from a variety of literature sources published to date and report the final data differentiated by production system and performance parameters on cattle (dairy and non-dairy) and buffaloes for each world region.

It should be noted that the IPCC expert team assumed that such regions as North America, Western and Eastern Europe, and Oceania may be defined as regions where only high-production systems are in practice. However, Latin America, Asia, Africa, Middle East and Indian subcontinent experience transition period from low productivity local subsistence systems to higher productivity systems, hence, data on performance parameters and feeding situations of cattle and buffaloes reared in the two production systems were recorded by the IPCC expert team.

Moreover, the IPCC expert team of the *2019 Refinement* updated regional representation in Tables 10A.1–10A.4. The *2006 IPCC Guidelines* contain data aggregated performance parameters and enteric fermentation emission factors (EFs) for Africa and Middle East, however, values of nitrogen excretion rate (Nex) were presented separately for these regions, i.e. for Africa and Middle East. Hence, the IPCC expert team improved consistency in the reporting, and the team collected raw data and conducted the estimation of enteric fermentation EFs, Volatile solids (VS) and Nex rates for Africa and Middle East, separately, for the both productivity systems.

In addition, the IPCC expert team updated the representation of non-dairy cattle and buffalo sub-categories. Namely, the *2006 IPCC Guidelines* contain data on performance parameters, diets and feeding situations, and corresponding EFs, VS and Nex for three main sub-categories of non-dairy cattle (i.e., mature females, mature males and young), the 2019 *Refinement* contains data and corresponding EFs, VS and Nex for four main sub-categories: mature females, mature males, replacement and growing animals, and calves.

The majority of values determining performance parameters, diets and feeding situations in different regions of the world were updated by the IPCC expert team in the *2019 Refinement*. Namely:

To develop region-average performance parameters, diets and feeding situations of dairy and non-dairy cattle for *North America*, 12 peer-reviewed publications were examined by the IPCC expert team (Appuhamy *et al*. 2016; Basarab *et al*. 2005; Capper 2011; Dong *et al*. 2014; Jayasundara *et al*. 2016; Legesse *et al*. 2016; Mulliniks *et al*. 2017; Niu *et al*. 2018; Ominski *et al*. 2007; Sheppard *et al*. 2015; Stackhouse-Lawson *et al*. 2012; Waldrip *et al*. 2013). Final values relied on the expert judgement and consensus of the authoring team.

To update performance parameters, diets and feeding situation of dairy and non-dairy cattle reared in *Western Europe*, 7 peer-reviewed publications were examined by the IPCC expert team (Bannink *et al*. 2011; *Bannink et al*. 2016; FAO 2017; Gerrits *et al*. 2014; Hammond *et al*. 2016; Huuskonen 2017; Spek *et al*. 2013). Data determining diets and feeding situations for dairy and non-dairy cattle of Western Europe were updated; all performance parameters, with exception of milk yield per head of dairy cow, were carried over from the *2006 IPCC Guidelines*.

To deliver the regional-average final value on performance parameters, diets and feeding situation of dairy and non-dairy cattle of *Oceania*, 10 data sources were examined by the IPCC expert team (studies and datasets of statistical offices) were examined by the IPCC expert team (Australian Government Department of Climate Change 2006; Dairy Technical Working Group 2015; Fick 2016; Pickering & Wear 2013; Statistics NZ 2018a; Australian Bureau of Agricultural and Resource Economics and Sciences 2018; Dairy Australia 2018; Dairy NZ & LIC 2018; Statistics NZ 2018b). The final values (reported in Table 10A.1 and Table 10A.2) were refined based

on data collected for Australia and New Zealand. Hence, the IPCC expert team encourages small Pacific Island nations to use enteric fermentation EFs, VS and Nex rates developed for Asian region, as productivity systems are more similar.

Overall, 35 data sources (scientific publications and statistical datasets) were examined by the IPCC expert team to obtain raw data on performance parameters, diets and feeding situations required to develop region-average final values for dairy and non-dairy cattle reared in *Eastern Europe* (Amerkhanov *et al*. 2016; Azaubaeva 2008; Bakharev 2012; Dunin *et al*. 2011; FAOSTAT 2017; Furaeva 2013; Gayirbegov & Mandjiev 2013; Golubkov 2015; Golubkov *et al*. 2015; Goncharova & Kibkalo 2011; Goncharova *et al*. 2009; Gren 2013; Gubaidullin *et al*. 2011; Haysanov 2011; Ilichev *et al*. 2011; IPCC 2006; Kalnickij & Haritonov 2008; Kostenko & Pyrozhenko 2012; Leontev *et al*. 2013; Levakhin *et al*. 2011; Litovchenko 2012; Mamaev *et al*. 2017; Nekrasov *et al*. 2013; Nosyreva Yu & Tokareva 2014; Pracht 2013; RUSSTAT 2016; Samorukov *et al*. 2013a; Samorukov *et al*. 2013b; Sharkaev & Kochetkov 2012; Sharkaeva 2012; Sharkaeva 2013; Sheveleva & Bakharev 2013; Shevkhuzhev *et al*. 2015; Tekeev & Chomaev 2011; Zadnepryanskiy & Zakirko 2012). Since Russian Federation, Ukraine and Belarus have the largest herd among other Eastern European countries (FAOSTAT 2017), the IPCC expert team focused mainly on the analysis of cattle management practice of these countries. Initial data for other Eastern European countries were taken from GLEAM model (FAO 2017). To make adjustment regarding the region-average final values reported in Table 10A.1 and Table 10A.2, the IPCC expert team considered the contribution of each country to the total dairy and non-dairy cattle population of Eastern Europe and corresponding parameters.

Raw data on cattle performance parameters, diets and feeding situations were distinguished between two production systems (i.e. low and high) of *Latin America* and collected by the IPCC expert team respectively. In total, 52 publications were examined by the IPCC expert team (Albarrán-Portillo *et al*. 2015; Albertini *et al*. 2012; Amaral *et al*. 2005; Ancco 2015; Ministerio de Ganadería 2017; Barajas Merchan *et al*. 2017; Barrantes 2000; Bartl *et al*. 2009; IPCC 2006; IBGE 2017; Becoña 2012; Ítavo *et al*. 2014; Cândido *et al*. 2015; Cardoso *et al*. 2017b; Castro *et al*. 2012; Chavez 2010; Ciudad de México Financiera Rural 2009; Cunha *et al*. 2016; Euclides & Medeiros 2003; FAO 2017; Huhn *et al*. 1982; Ítavo *et al*. 2014; Kolling *et al*. 2018; Lima *et al*. 2018; Machado Filho *et al*. 2014; Mariani *et al*. 2009; Mata e Silva *et al*. 2017; McManus *et al*. 2011; Medeiros *et al*. 2010; Modernel *et al*. 2013; Oliveira *et al*. 2014; Pajuelo Montalvo 2003; Pajuelo Montalvo 2008; Peres *et al*. 2012; Primavesi *et al*. 2004; Queiroz *et al*. 2011; Quispe *et al*. 2016; Reis 1998; Restle *et al*. 2003; Ribeiro *et al*. 2016; Rodriguez 2018; Rojas & Gómez 2005; Rosa *et al*. 2001; Ruiz & Sandoval 2014; Santos *et al*. 2011; Sgroi 2017; Silva *et al*. 2017; Simões *et al*. 2009; Teixeira *et al*. 2013; Teodoro & Madalena 2002; Teodoro & Madalena 2005; Verruma & Salgado 1994). Moreover, to clarify some parameters, the IPCC expert team conducted interviews with lead researchers of Latin America, namely: Sebastián Galbusera (Argentina); Dr. Pablo Soca, Faculty of Agronomy (Uruguay); Santiago Fariña, Dirceto of the Dairy Redearch Progmaram. National Institute of Agricultural Research (Uruguay); Dr. Laura Astigarraga, Faculty of Agronomy (Uruguay); Dr. Luiz Gustavo Ribeiro Pereira (Embrapa Dairy Cattle, Brazil); Dr. Pablo Soca, Faculty of Agronomy (Brazil). It should be noted that these above-listed publications were sources for initial data mostly for non-dairy cattle reared in Brazil, Uruguay, Peru and Argentina, and for dairy cattle husbandry practice applied in Brazil. However, initial data on performance parameters, diets and feeding situations applied for dairy cattle of other countries of Latin America were obtained from GLEAM model (FAO 2017). To adjust the final values recorded in Table 10A.1 and Table 10A.3, the dairy and non-dairy cattle population kept in each country of Latin America was taken into consideration by the IPCC expert team.

Performance parameters, diet and feeding situation of dairy and non-dairy cattle of the whole *Asian region* for low- and high-productivity systems were refined based on detailed data obtained from 50 publications (Alejandrino *et al*. 1999; Zi *et al*. 2003; Sutarno 2015; Hieu Vu *et al*. 2016; Widiawati *et al*. 2016; Gunawan & Jakaria 2011; Lapitan *et al*. 2008; Ramírez-Restrepo *et al*. 2017; Martojo 2012; Philippines Statistics Authority 2017; Moran 2012; Thanh 2014; Ichinohe *et al*. 2014; Dinh 2007; Department of Veterinary Services 2013; Panandam & Raymond 2005; Lam 2011; Gioi *et al*. 2012; Ariff *et al*. 2015; Waldron *et al*. 2015; Putra *et al*. 2015; Garcia *et al*. 2006; Zhai *et al*. 2006; FAO *et al*. 2014; Gerber *et al*. 2011; Xie *et al*. 2016; Cui *et al*. 2014; Yang *et al*. 2013; Xue *et al*. 2014; Dong *et al*. 2015; Zi *et al*. 2003; Huai *et al*. 1993; Ma *et al*. 2007; Ma *et al*. 2012; Wattiaux *et al*. 2002; Zhou 1998; Beldman *et al*. 2014; Xie *et al*. 2012b; Qiao *et al*. 2013; Dong *et al*. 2017; Han *et al*. 2016; Wang *et al*. 2014; Taneja 1999; FAO 2003; Wang *et al*. 2017; MAAR 2013; Hu & Zhang 2003; Gao *et al*. 2011; Cheng 1984; Gao *et al*. 2013). Raw data were obtained from the literature sources to determine parameters corresponding to low- and high-producing systems. Performance parameters of dairy and non-dairy cattle and their feeding systems were investigated for the following countries: China, Indonesia, Malaysia, Philippines and Vietnam. Moreover, the data of GLEAM model (FAO 2017) were used in a greater degree. A contribution of each country to the total cattle population of Asian region was considered by the IPCC expert team to adjust final values reported in Table 10A.1 and Table 10A.3.

Data on performance parameters, diets and feeding situations of dairy cattle reared in low- and high-productivity systems of *African region* were directly obtained from GLEAM model (FAO 2017). The model contains a compherensive dataset for the both types of productivity system applied in Kenya, Ethiopia, Uganda, Tanzania.

Moreover, performance parameters, diet and feeding situation of non-dairy cattle reared in the both productivity systems of African region were obtained as results of the analysis of 101 scientific articles and statistical reports (Abdel Rahman 2007; Abdelhadi & Babiker 2009; Abera 2016; Abraha *et al*. 2009; Addisu *et al*. 2010; Adebambo 2001; Adesina 2012; Ageeb & Hillers 1991; Ahamefule *et al*. 2007; Ahmed & Zubeir 2013; Ahmed Hassan 2010; Alemayehu *et al*. 2013; Ali *et al*. 2015; Alsiddig *et al*. 2010; Asimwe *et al*. 2015; Bashir & El Zubeir 2013; Bayemi *et al*. 2005; Behnke & Osman 2012; Blench 1999; Central Statistical Agency 2017; Chabo *et al*. 2003; Corbet *et al*. 2006; Dekeba *et al*. 2006; Du Toit *et al*. 2013; Edea *et al*. 2013; Elrshied & Ishag 2015; Engida *et al*. 2015; Essien 2003; Ethiopia F.D.R. 2011; FAO 2017; FAO & IAEA 2011; FAOSTAT 2017; Farmer & Mbwika 2012; Gebre Mariam *et al*. 2013; Goopy *et al*. 2018; Groeneveld *et al*. 1998; Gwaza & Momoh 2016; Haile *et al*. 2011; Halala 2015; Haren & Idris 2015; Ilatsia *et al*. 2011; International Livestock Centre for Africa 1977; Ismail *et al*. 2014; Kahi *et al*. 2006; Kanai & Zagi 2013; Kashoma *et al*. 2011; Kouazounde *et al*. 2015; Kubkomawa 2017; Kurwijila & Bennett 2011; Lukuyu *et al*. 2012; Lukuyu *et al*. 2016; Mai *et al*. 2012; Mandefro *et al*. 2017; Mapiye *et al*. 2011; Masama *et al*. 2003; Mekonnen *et al*. 2012; Ministry of Livestock and Fisheries Development of Tanzania 2014; Ministry of Livestock and Fisheries Development of Tanzania 2015; Mlote 2013; Mpofu 1996; Msanga *et al*. 2012; Muhuyi *et al*. 1999; Muriuki 2011; Musa *et al*. 2011; Mwambene *et al*. 2012; Mwambene *et al*. 2014; Mwanyumba *et al*. 2015; Myburgh *et al*. 2012; Nell 2006; Nell *et al*. 2014; Nouala *et al*. 2003; Nweze *et al*. 2012; Olorunnisomo 2013; Onono *et al*. 2013; Osman 1985; Pico 2004; Rakwadi *et al*. 2016; Raphaka 2008; Rege 1999; Rewe *et al*. 2006; Said *et al*. 2003; Salako 2014; Scholtz & Theunissen 2010; Shirima *et al*. 2016; Shittu *et al*. 2008; Siegmund-Schultze *et al*. 2012; Statistics Botswana 2016; Stein *et al*. 2009; Strous 2010; Strydom 2008; Strydom *et al*. 2000; Strydom *et al*. 2008; Tefera 2013; Tegegne *et al*. 2013; Temoso *et al*. 2016; Tesfa *et al*. 2016; Theunissen *et al*. 2013; Wurzinger *et al*. 2006; Young *et al*. 2005; Yousif & El- Moula 2006; Zerabruk & Vangen 2005). In addition to a rich dataset developed for low- and high-productivity systems, total population of non-dairy cattle of African region and contribution of the non-dairy population reared in each African country to the total (FAOSTAT (2017) was taken into consideration by the IPCC expert team to determine the final values on performance parameters, diet and feeding situation representative for the whole African region.

Overall, 24 publications were examined by the IPCC expert team to obtain raw data on performance parameters, diets and feeding situations of dairy and non-dairy cattle reared in low- and high-productivity systems of *Middle East* (Akbaş *et al*. 2006; Turkish Statistical Institute 2017; Karakok 2007; CBAT 2017; Chashnidel *et al*. 2007; da Cunha *et al*. 2010; Sadeghi-Sefidmazgi *et al*. 2012; FAO *et al*. 2014; Fatahnia *et al*. 2010; Gerber *et al*. 2011; IPCC 2006; Kamalzadeh *et al*. 2008; Kara *et al*. 2014; Karakok 2007; Koçyiğit *et al*. 2014; MFAL 2011; Sadeghi-Sefidmazgi *et al*. 2012; Statistical Centre of Iran 2011; Tasdemir *et al*. 2011; Ula 2016; USDA 2015; *Ustuner et al*. 2016; Özlütürk *et al*. 2006; Yalcin *et al*. 2017; Yilmaz *et al*. 2012). Due to an extend of contribution to the total dairy and non-dairy cattle population of Middle East, the focus of the IPCC expert team was made to investigate dairy and non-dairy cattle management practice applied in Turkey and Iran. The raw data obtained from literature sources for these two countries were adjusted to be a basis to evaluate the final values on performance parameters, diets and feeding situations representative for low- and high-productivity systems of the whole Middle East region.

Raw data on performance parameters, diets and feeding situations of low- and high-productivity systems applied for dairy and non-dairy cattle in *Indian subcontinent* were derived as a result of the analysis of 47 publications (Ahmad *et al*. 2004; Ahmad *et al*. 2013; Birthal & Parthasarathy Rao 2002; Boro *et al*. 2016; Bradfield & Ismail 2012; Chowdhry 2007; da Cunha *et al*. 2010; Department of Animal Husbandry 2013; Deshetti *et al*. 2016; Dhingra *et al*. 2017; FAO 2017; FAO *et al*. 2014; Garg *et al*. 2013; Gerber *et al*. 2011; IPCC 2006; Jabbar *et al*. 2009; Kayastha *et al*. 2008; Kenyanjui *et al*. 2009; Khan 2011; Khan *et al*. 2008; Khan *et al*. 2009; Khan *et al*. 2016; Landes *et al*. 2017; Mahakur *et al*. 2017a; Mahakur *et al*. 2017b; Manoj 2009; Moaeen-ud-Din & Bilal 2017; Nahar *et al*. 2016; National Bureau of Animal Genetic Resources 2017; Pathak *et al*. 2013; Patra 2012; Rahman *et al*. 2012; Rahman *et al*. 2015; Roy *et al*. 2016; Saha *et al*. 2004; Saha *et al*. 2012; Sambhaji 2013; Sarkar *et al*. 2006; Sharma *et al*. 2014; Singhal *et al*. 2005; Sirohi *et al*. 2012; Sodhi *et al*. 2007; Sontakke *et al*. 2014; Thombre *et al*. 2015; Tomar & Sharma 2002; Yadava 2009; Yasothai 2014). Taking into consideration, the largest contribution of cattle population of India, Pakistan and Bangladesh to the total dairy and non-dairy cattle population of the region, the main focus of the IPCC expert team was to collect and investigate low-productivity and high-productivity cattle farming of these countries. The final values reported in Table 10A.1 and Table 10A.3 were refined by the IPCC expert team based on consensus and were used to conduct estimations of enteric fermentation EFs, VS and Nex rates for dairy and non-dairy cattle in low- and high-productivity systems of Indian subcontinent.

Data to complete calculations of enteric fermentation emission factors, VS and nitrogen excretion rates for buffaloes were significantly updated in the *2019 Refinement* in comparison with the information reported in the *2006 IPCC Guidelines*. Namely, the *2006 IPCC Guidelines* report the initial data employed and corresponding EFs for two main regions: Indian subcontinent and Other regions. The IPCC expert team of the *2019 Refinement* extended regional representation and collected data for the same regions, which were applied to present EFs of cattle. Hence, data on buffalo performance parameters, diets and feeding situation for Western Europe, Eastern Europe, Latin America, Asia, Africa and Middle East were developed and reported in addition to presented dataset developed for Indian subcontinent. North America and Oceania were omitted from the reporting as according to

the data presented in (FAOSTAT 2017), the regions do not have any buffalo husbandry practice. Moreover, region-average final values on performance parameters, diets and feeding situations were reported for four buffalo subcategories for all regions: mature males, mature females, growing and replacing animals and calves. The only exception was made for Indian subcontinent, where the final values were presented for five subcategories: breeding mature males, working mature males, mature females, growing and replacing animals and calves.

The IPCC expert team has decided not to distinguish performance parameter values, diets and feeding situation between low productivity and high-productivity systems implemented in buffalo husbandry across the world regions as it was conducted for dairy and non-dairy cattle, but to collect and report region-average values.

Overall, eight peer-reviewed publications were examined by the IPCC expert team to deliver performance parameters, diets and feeding situation of buffaloes kept in *Western Europe* (Borghese 2013; Condor *et al*. 2008; FAO 2005; FAO 2017; Gonzalez Gonzalez 2011; IPCC 2006; Neglia *et al*. 2014; Sabia *et al*. 2014; Zicarelli *et al*. 2007). Since Italy is a main contributor to the total buffalo population of Western Europe (FAOSTAT 2017), the buffalo husbandry practice of Italy was considered to be a representative for the whole Western Europe. However, data on buffalo performance parameters of Germany and Greece were also taken into consideration to adjust final values reported in Table 10A.4. The calculation of enteric fermentation EFs, VS and Nex rates were conducted based on Tier 2 method of the *2019 Refinement*.

To deliver data on performance parameters, diet characterisation and feeding situation of buffaloes of *Eastern Europe*, the focus in the research completed by the IPCC expert team was mainly made on investigation of buffalo husbandry implemented in Bulgaria and Romania. In total, 11 publications (i.e. case studies and statistical reports) were examined to complete a dataset needed to compute enteric fermentation EFs, VS and Nex rates (*Atanasov et al*. 2012; Borghese 2013; Dimov & Tzankova 2003; FAO 2005; FAOSTAT 2017; IPCC 2006; MZH 2016; MZH 2017; Nikolov 2011; Peeva *et al*. 2011; Peeva *et al*. 2013; Tzankova & Dimov 2003).

To develop a dataset on performance parameters, diets and feeding situation representing buffalo husbandry practice of *Latin America*, overall 25 studies were examined by the IPCC expert team (Andrade & Garcia 2005; Andrighetto *et al*. 2003; Andrighetto *et al*. 2003; Bailone *et al*. 2017; Cardoso *et al*. 1997; Cardoso *et al*. 2017a; Coelho *et al*. 2004; Damé *et al*. 2010; dos Santos *et al*. 2016; Gonçalves 2008; Jorge 2005; Jorge *et al*. 2002; Lima *et al*. 2014; Macedo *et al*. 2001; Maeda *et al*. 2007; Oliveira *et al*. 2009; Rassi *et al*. 2009; Rezende *et al*. 2017; Rodrigues *et al*. 2001; Sales *et al*. 2018; Santos *et al*. 2014; Zeoula *et al*. 2014; Tonhati *et al*. 2000; Tonhati *et al*. 2009; Verruma & Salgado 1994). Moreover, the IPCC expert team organized interviews with top researchers in this area to specify the findings and to cover lacking information from the scientific publications (Cristiana Andrighetto (UNESP-Dracena); Dr. José Ribamar Felipe Marques (Embrapa Amazônia Oriental)). In general, the final values recorded in Table 10A.4 for Latin America represent mainly characteristics of buffalo herd of Brazil, as the investigation of buffalo performance parameters reared in other countries of Latin America was not conducted by the IPCC expert team.

Overall, 42 publications (case studies and statistical reports) were examined by the IPCC expert team to derive raw data on buffalo performance parameters, diets and feeding situation of *Asian region* (Abd El-Salam & El-Shibiny 2011; Batosarnma 2006; Berthouly 2008; Carabao situation report 2017; Chang & Huang 2003; Cruz 2007; Cruz 2010; Cruz 2012; Das *et al*. 2004; Deb *et al*. 2016; Djaja 2011; Djajanegara & Diwyanto 2002; FAO 2003; FAO 2017; Flores *et al*. 2007; Han *et al*. 2007; Huai & Jun 1995; Kusnadi & Praharani 2009; Lambertz *et al*. 2014; Li *et al*. 2018a; Loculan 2002; Meyer *et al*. 2000; Mingala *et al*. 2017; Nanda & Nakao 2003; Nha *et al*. 2008; Phomsouvanh 2002; Prabowo 2012; Premasundera 2002; Qin *et al*. 2013; Qingkun *et al*. 2002; Riedel *et al*. 2012; Sanh 2007; Sivarajasingam 1987; Skunmun *et al*. 2002; Somapala 2002; Suryanto *et al*. 2002; Taneja 1999; Tuyen 2009; Van Sanh 2007; Wanapat & Rowlinson 2007; Yang *et al*. 2007; Yang *et al*. 2013a). The detailed analysis of buffalo husbandry practice applied in China, Indonesia, Laos, Philippines, Sri Lanka, Thailand and Vietnam was conducted to underlay for adjustment, based on consensus of the authoring team, of the final values of Table 10A.4.

According to the data reported (FAOSTAT 2017), only Egypt has population of domesticated buffaloes among other African counties. Hence, to deliver data on performance parameters, diets and feeding situation employed to compute enteric fermentation EFs, VS and Nex rates for buffaloes reared in *African region*, 22 publications determining Egyptian buffalo husbandry practice was examined by the IPCC expert team (Abd-Allah *et al*. 2015; Ali *et al*. 2009; Asheeri & Amal 2012; Ashour *et al*. 2007; Habeeb *et al*. 2016; FAO 2005; FAO *et al*. 2014; FAOSTAT 2017; Gerber *et al*. 2011; Habeeb *et al*. 2016; Hassan & Abdel-Raheem 2013; Ibrahim 2012; Ibrahim 2012; IPCC 2006; Khattab *et al*. 2011; Marai *et al*. 2001; Marai *et al*. 2009; Morsy *et al*. 2016; Presicce 2011; Radwan 2016; Shahin *et al*. 2010; Soliman 2009; WAAP 2007). Data on buffalo for other African countries were omitted from the analysis, the final values reported in Table 10A.4 and used in the calculations are relied on the expert judgement and consensus of the authoring team.

The analysis of 27 publications (case studies and statistical reports) resulted in evaluation of the region-average final values on performance parameters, diets and feeding situation of buffaloes husbandry for *Middle East* (Azary

et al. 2007; Turkish Statistical Institute 2017; Çelikeloğlu *et al*. 2015; Chashnidel *et al*. 2007; DAD-IS 2017; Dezfuli 2010; Dezfuli *et al*. 2011; FAO 2017; FAO *et al*. 2014; FAOSTAT 2017; Gerber *et al*. 2011; GLEAM FAO 2017; Hossein-zadeh *et al*. 2012; IPCC 2006; Işik & Gül 2016; Jaayid *et al*. 2011; Mahmoudzadeh & Fazaeli 2009; Mahmoudzadeh *et al*. 2007; Manafiazar *et al*. 2007; Naserian & Saremi 2007; Porter *et al*. 2016; Şekerden 2013; Soysal 2013; Soysal *et al*. 2005; Tariq *et al*. 2013; Turkish Statistical Institute 2017; Yavuz & Zulauf 2004). Due to the availability and representation of publications, the focus of the IPCC expert team was mostly made on buffaloes reared in Tukey and Iran, the data collected for these countries were considered as a basis to made adjustment regarding region-average final values for Middle East reported in Table 10A.4.

To deliver initial data required to calculate enteric fermentation EFs, VS and Nex rates for buffaloes reared in *Indian subcontintent*, 37 publications (case studies and statistical reports) were examined by the IPCC expert team (Afzal *et al*. 2009; AGRI-IS 2017; Anitha *et al*. 2011; Anjum *et al*. 2012a; Anjum *et al*. 2012b; Basra & Nisa 2003; Breeding survey book 2013; Dahiya & Singh 2013; Dhingra *et al*. 2017; FAO 2017; FAO *et al*. 2014; FAOSTAT 2017; FICCI 2014; Gami *et al*. 2017; Garg *et al*. 2018; Gerber *et al*. 2011; Gupta *et al*. 2016; IPCC 2006; Jabbar *et al*. 2009; Jha *et al*. 2011; Khan *et al*. 2008; Khan *et al*. 2010; Khare & Baghel 2010; Kumar & Dass 2006; Kumar *et al*. 2011; Pathak 2005; Patra 2012; Prusty *et al*. 2016; Ranjhan 2007; Shahzad *et al*. 2011; Shekhar *et al*. 2010; Singal 2001; Singh 2002; Singh *et al*. 2012; Singh *et al*. 2015; Singh *et al*. 2017; Tariq *et al*. 2013; Tauqir *et al*. 2011). Data on performance parameters, diets and feeding situation of different breeds of buffaloes in India and Pakistan were adjusted to make the expert decision on the final values reported in Table 10A.4 and to conduct the calculations.

10B.2 Estimation of Cattle/Buffalo CH_4 conversion factors (Y_m)

Dairy Y_ms were developed considering summary statistics from the database consisting of results from 3,353 cows used in Niu *et al*. (2018) (Table 10B.1(New)) as well as data synthesis presented in the articles of Appuhamy *et al.* (2016), Hellwing *et al.* (2016) and Jayasundera *et al.* (2016). It was noted by the IPCC panel that these studies were not representative of global dairy systems and for that reason simple means developed through statistical analyses were deemed not to be reliable. Final values relied on the expert judgement and consensus of the authoring team. The summary statistics from Niu *et al.* (2018) are presented below (Table 10B.1), dividing that large data set into high, medium and low levels of milk productivity.

In the case of all productivity systems, clear differences were identified between the North American and the European feeding and production systems. The strongest contrasting factor was the proportion of neutral detergent fibre (NDF) in the diets of the two regions. Based on these summary statistics the Y_m is clearly driven by the relationship with NDF within the two regional production categories (Figure 10B.1).

To provide additional guidance for the selection of the methane conversion rates, NDF thresholds were established (Table 10B.1). For the highest production categories based on the North American and European statistics a low NDF <35 percent DMI and a high NDF >35 percent DMI categories were developed with values equivalent to 5.7 and 6.0 percent GEI respectively.

In the case of the values for the mid-range productivity, the value of 6.3 was determined assuming that NDF values were greater than 37 percent DMI as the values for medium and low producing animals from North America could not be considered to be representative of low production and lower quality diets. For countries that can clearly demonstrate that the NDF of their feed has been greater than 37 percent DMI, it is recommended to use the high production value that corresponds to the NDF content of the feed.

For low-productivity, the unweighted mean value of 6.5 from the European and North American data, consistent with the *2006 IPCC Guidelines* was selected. The panel did not consider that there was reliable data to modify the value from the *2006 IPCC Guidelines* value considering the very wide variety of diets that could be occurring globally for low productivity dairy cattle. However, it is proposed in the text that if dairy cattle are fed mainly on low quality forages countries are recommended to use the non dairy forage diet Y_m of 7.0.

Figure 10B.1 (New) **Relationships between mean and median neutral detergent fibre (NDF) and methane conversion rate (Y_m) from summary statistics of Niu *et al.* (2018).**

37	**6.18**	**6.18**
38	**6.40**	**6.43**
39	6.62	6.68
40	6.84	6.93

In the case of beef cattle, a total of 113 measurements were compiled from 35 studies. Studies were divided by their dominant diet type into three categories, high forage diets, mixed diets (mixed forage and concentrate) and feedlot diets. Summary statistics were compiled and group averages are reported. Due to the variability in the data, values were rounded based on expert judgement. An overall average was developed for the feedlot and non-feedlot diets. Non feedlot diets were differentiated between dominantly forage based diets and mixed concentrate diets.

There is important variability in the results of studies that attempt to develop relationships between feed quality and methane yield. Nonetheless, numerous empirical and biochemical modelling studies demonstrate both the statistical significance and the biochemical processes that relate reductions in methane production with the introduction of concentrates to ruminant diets (Mills *et al.* 2001; Mills *et al.* 2003; Ellis *et al.* 2006; Ellis *et al.* 2007; Ellis *et al.* 2009; Ellis *et al.* 2010; Alemu *et al.* 2011; Bannink *et al.* 2011; Ellis *et al.* 2014; Escobar-Bahamondes *et al.* 2016; Kebreab *et al.* 2016). For this reason, methane conversion rates are produced from a summary of low, medium and high dietary forage proportions. Raw data used in the development of these values are published in the IPCC TFI website.

TABLE 10B.3 (NEW)
SUMMARY OF DATA COMPILED FOR THE COMPILATION OF Y_M VALUES FOR CATTLE AND BUFFALO

Category	Measurement method	Average Body Weight (kg)	Methane yield (g/kg DMI)	SD (±)	Y_m (% GEI)	SD (±)	n
High forage	Chambers (24), SF_6 (30), Micro-meteorological (2)	451	23.0	4.6	7.2[1]	1.5	56

10B.3 Estimation of Default Emission Factor(s) based on Goat Tier 2 parameters

A database was compiled from peer-reviewed articles that studied in-vivo methane (CH_4) production from goat enteric fermentation and N excretion. These studies were identified through a comprehensive literature search performed in Google scholar and ResearchGate and from sources that carried out review work such as a recent study attempting to derive statistical models for prediction of enteric CH_4 from goats (Patra & Lalhriatpuii 2016) and a New Zealand technical report for CH_4 and N excretion rates for goats (Lassey 2012). Data were directly extracted from the individual studies identified. Authors were contacted in order to fill in gaps of information from the studies.

Overall, 63 publications were obtained from a varied sample of countries and 18 different goat breeds (Aguilera *et al*. 1990; Prieto *et al*. 1990; Shibata *et al*. 1992; Haque *et al*. 1997; AFRC 1998; Haque *et al*. 1998; Islam *et al*. 2000; Islam *et al*. 2001; Rapetti *et al*. 2002; Puchala *et al*. 2005; Rapetti *et al*. 2005; Tovar-Luna *et al*. 2007b; Tovar-Luna *et al*. 2007c; Tovar-Luna *et al*. 2007a; Animut *et al*. 2008; Bhatta *et al*. 2008; Haque *et al*. 2008; Vermorel *et al*. 2008; Li *et al*. 2010; López *et al*. 2010a; López *et al*. 2010b; Tovar-Luna *et al*. 2010b; Tovar-Luna *et al*. 2010a; Gerber *et al*. 2011; López *et al*. 2011; Tovar-Luna *et al*. 2011; Abecia *et al*. 2012; Jeong *et al*. 2012; Lassey 2012; López *et al*. 2012; Mitsumori *et al*. 2012; Puchala *et al*. 2012a; Puchala *et al*. 2012b; Romero-Huelva *et al*. 2012; Yang *et al*. 2012; Bhatta *et al*. 2013; Chethan *et al*. 2013; López & Fernández 2013; Martínez-Fernández *et al*. 2013; Miri *et al*. 2013; López *et al*. 2014; Martínez-Fernández *et al*. 2014; Nielsen *et al*. 2014; Romero-Huelva & Molina-Alcaide 2014; Ibáñez *et al*. 2015a; Ibáñez *et al*. 2015b; Lu *et al*. 2015; Wang & Xue 2015; Arif *et al*. 2016; Castro-Lima *et al*. 2016; Criscioni & Fernández 2016; Lu *et al*. 2016; Patra & Lalhriatpuii 2016; Wang *et al*. 2016a; Wang *et al*. 2016b; Arco-Pérez *et al*. 2017; Barbosa *et al*. 2017; Keli *et al*. 2017; Kumar *et al*. 2017; Na *et al*. 2017; Romero-Huelva *et al*. 2017; Tovar-Luna *et al*. 2017; Azlan *et al*. 2018; Fernández *et al*. 2018; Li *et al*. 2018b; Na *et al*. 2018a; Na *et al*. 2018b; Puchala *et al*. 2018).

Although there was a total of 290 treatment means, treatments that were using substances with antimethanogenic properties were excluded before analysis. The minimum prerequisite for a study to be included in the data set was that Y_m values (or gross energy and CH_4 output energy) were reported.

Information on feed and diet characteristics, feed intake, breed, animal type, digestibility, and rumen were collected in the final data set. Table 10B.4 shows the mean and the range of some of the diet and animal variables for the different studies. Values were quite heterogeneous. For example, dry matter intake ranged between 0.14 and 2.51 kg DM intake/day animal (0.93 on average).

The concentrations of crude protein (CP), neutral detergent fibre (NDF) and starch were within the range of 6-26 percent (mean value of 15 percent), 18-74 percent (mean value of 42 percent) and 1-42 percent (mean value of 19 percent), respectively.

Methane production was expressed as grams per day, liters per day, megajoules per day, or as a proportion of GE or DE; therefore, the following factors were used in converting units: 1 g = 1.40 L =55.5 kJ; 1 L = 0.716 g = 39.54 kJ.

TABLE 10B.4 (NEW)
MEAN, MEDIAN, MAXIMUM, MINIMUM AND QUARTILE 1 AND 3 (Q1 AND Q3) VALUES FOR A SELECTION FEED DIET COMPOSITION, FEED INTAKE, BODY WEIGHT AND MILK PRODUCTIVITY

	Digestibility (%)					Feed intake			Body weight	Milk yield
	DM	OM	N	NDF	GE	DM (kg/day)	GE (MJ/day)	DE (MJ/day)	kg/animal	(kg/day animal)
Mean	68%	69%	72%	54%	71%	0.94	18.77	12.18	39.82	1.90
Median	69%	71%	73%	53%	72%	0.78	15.20	9.44	40.05	1.59
Max	83%	91%	84%	82%	83%	2.59	46.68	29.90	64.00	3.69
Min	49%	40%	44%	18%	52%	0.14	4.64	6.02	14.53	0.81
Q1	64%	65%	67%	46%	67%	0.62	11.80	8.44	33.45	1.31
Q3	74%	76%	78%	60%	76%	1.14	26.12	11.09	47.55	2.28

The CH_4 emissions also varied greatly in the dataset. Table 10B.5 shows the methane emissions expressed in different units and metrics.

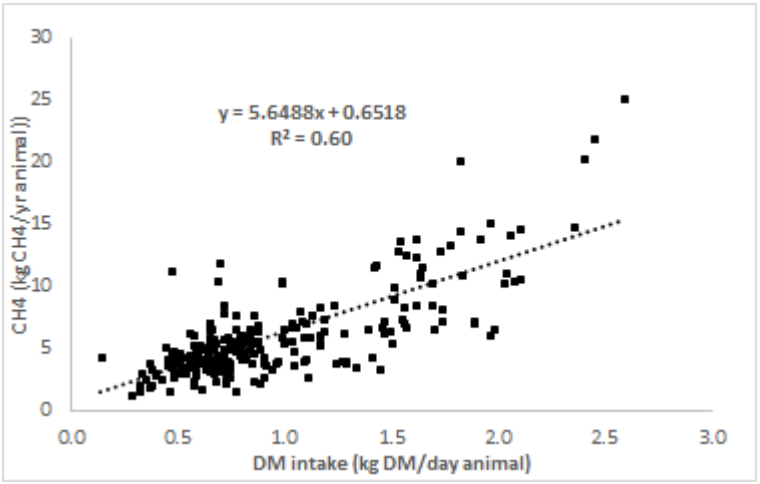
TABLE 10B.5 (NEW)
MEAN, MEDIAN, MAXIMUM, MINIMUM AND QUARTILE 1 AND 3 (Q1 AND Q3) VALUES FOR CH_4 PRODUCTION RESULTS REFERRED AS A PROPORTION OF GROSS ENERGY INTAKE (CH_4 CONVERSION FACTOR: Y_M), DAY^{-1}, KG DM $INTAKE^{-1}$, KG OF MILK $PRODUCED^{-1}$ AND KG OF BODY $WEIGHT^{-1}$

	CH_4				
	Y_m	***MJ/day***	***MJ/kg DM***	***MJ/kg milk***	***J/kg BW***
Mean value	5.3%	0.9	1.0	0.8	23.1
Median	5.3%	0.8	1.0	0.8	20.5
Max	10.3%	3.8	4.7	1.7	73.6
Min	1.2%	0.2	0.3	0.2	5.3
Q1	4.3%	0.6	0.8	0.6	15.8
Q3	6.3%	1.0	1.2	1.1	27.4

The average methane emission was 16.2 g CH_4/animal day, 18.3 g CH_4/kg DM intake, 0.42 g CH_4/ kg BW (*data not shown*). Average/median methane conversion factor (Y_m) was 5.3 percent, which is in the range of the recent value obtained by the study by Patra & Lalhriatpuii (2016), which included 42 studies.

We analyzed the relationship between methane output and diet type (e.g. diet digestibility, percent forage use) but there were no any clear statistical relationships between diet type and enteric methane output (*data not shown*). In general increased body weight and milk yield resulted in greater CH_4 output but body weight and milk yield did not show any statistical relationship with Y_m (*data not shown*).
Methane output per animal was positively correlated with dry matter (Fig 10B.2) and gross energy (Fig 10B.3) intake (R^2=0.60; P<0.00001).

Figure 10B.2 (New) Annual enteric methane output per animal expressed in mass in relation to daily dry matter (DM) intake.



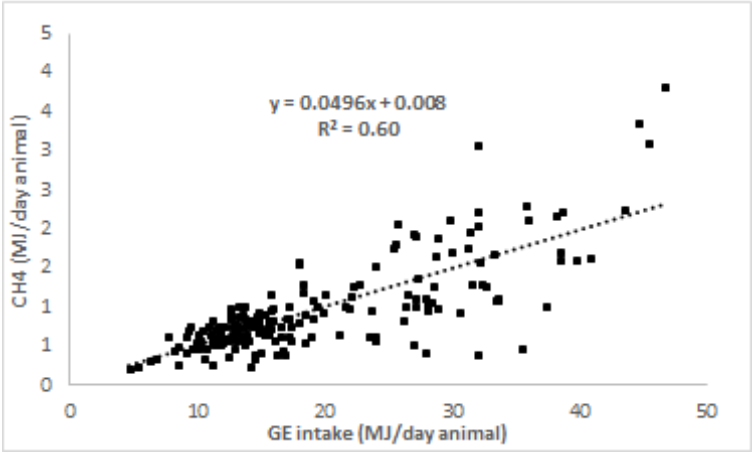


Figure 10B.3 (New) Daily enteric methane output per animal expressed in energy in relation to daily gross energy (GE) intake.

In order to develop Tier 1 EF for enteric CH_4 from goats for both low and high production systems the following steps were followed:

- Average goat weight (LW) for high and low production systems were estimated using global world information from Gerber *et al*. (2013). For high and low production systems it was estimated average weight values of 50 kg and 28 kg, respectively.
- Daily dry matter intake per animal was estimated as a function of animal weight using the equation from AFRC (1998).
- Using the equation from Fig 10B.2 we obtained kg CH_4/animal yr as a function of the previously estimated value of daily dry matter intake.

EF for Tier 1 resulted in 8.7 and 4.9 kg CH_4/head yr for high and low production systems, respectively. These values are both lower than those estimated in Vermorel *et al.* (2008) from French systems (11.9 kg CH_4/head yr^{-1}) and that for high production systems is similar to that proposed by Lassey (2012) for New Zealand goat herd.

Considering the data analysed, a Y_m of 5.5 percent has been chosen. No clear evidence was found to develop Y_m factors separately as a function of diet quality or production system.

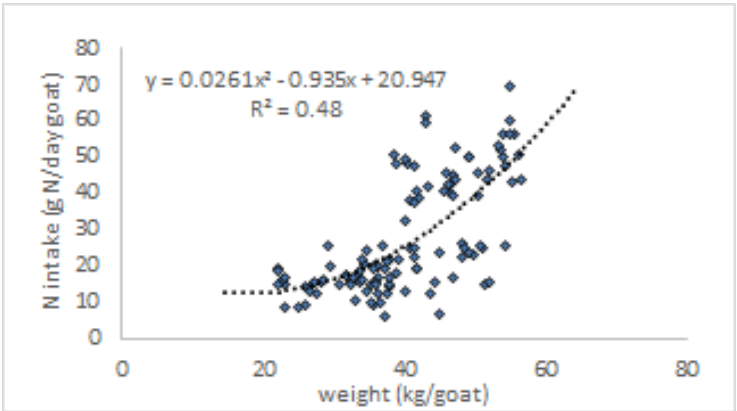
In order to develop default values for N excretion rates (for Table 10.19) the following steps were followed:

Average goat weight (LW) for each global region were estimated using global world information from GLEAM FAO.

Daily N intake per animal and day was estimated as a function of average goat weight using the relationship developed from this database relating goat weight and N intake (Fig 10B.4) (R^2=0.48; P<0.00001).

Daily N excretion rate was subsequently calculated using the relationship also found using this database relating daily N intake and daily N excretion (Fig 10B.5) (R^2=0.89; P<0.00001) and transforming values to excretion rates espressed as kg N $(1000 \text{ kg animal mass})^{-1}$) day^{-1}.

Figure 10B.4 (New) Daily N intake per animal expressed in relation to animal weight.



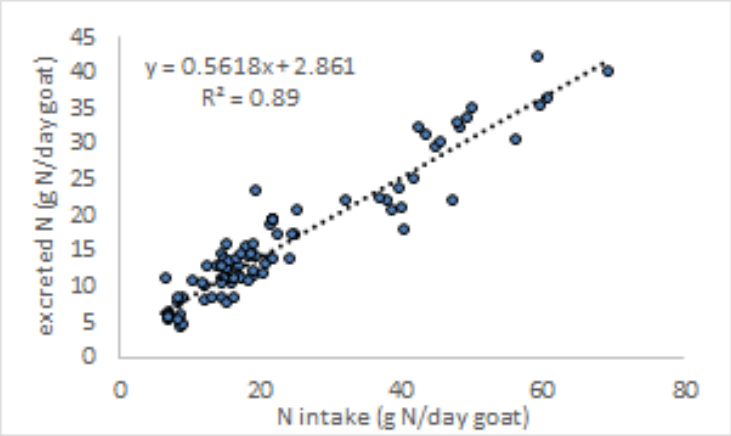


Figure 10B.5 (New) **Daily N excretion output per animal expressed in relation to daily N intake.**

In order to develop default values for volatile solids (VS) excretion rates (for Table 10.14A) we calculated daily VS excretion from goats for each world region according to equation 10.24. Gross energy intake was derived based on DM intake using the conversion factor 18.45 MJ/kg DM. We assumed that digestibility of the feed was 50 and 60 percent for developing and developed countries, respectively. The ash content of the feed was assumed to be 8 percent. We assumed the animal weights for each region based on information from FAO work: GLEAM FAO.

10B.4 Feed intake estimates using a simplified Tier 2 method

Prediction of DMI for cattle based on body weight and estimated dietary net energy concentration (NE_{ma}) or digestible energy values (DE percent):

Several studies have shown that dry matter intake (DMI) is highly and positively related to methane emissions. In some cases it has been reported that up to 92 percent of the variability in enteric methane emissions could be explained by DMI alone (Charmley *et al*. 2016). Most models developed to predict enteric methane emissions usually include either DMI or some form of feed intake. There are a number of models already developed with the objective of predicting DMI and these could be used in conjunction with emission factors to estimate enteric methane emissions in a Tier 2 approach. Appuhamy *et al*. (2016) evaluated 40 prediction equations using data that included measured DMI and feed quality attributes from North America, Europe and Australia/New Zealand. The best performing models in each region were then re-evaluated using calculated DMI and compared with estimates that used measured DMI. They evaluated several DMI prediction equations including the Cornell Net Carbohydrate and Protein System (CNCPS, Fox *et al*. 1992) as modified by Arnerdal (2005), National Research Council (NRC 2001) (developed based on North America cows), Lindgren *et al*. (2001) and Arnerdal (2005) (developed using data from cows in Europe), and Vazquez and Smith (2000) model (developed from Australia/New Zealand data). Appuhamy *et al*. (2016) reported that models using estimated DMI predicted enteric methane emissions just as good as the measured data and concluded that enteric methane emissions from dairy cows can be predicted successfully with estimated DMI, particularly using the modified CNCPS model. Appuhamy *et al*. (2018) further evaluated the comprehensive (IPCC-CMP) and simplified (IPCC-SMP) IPCC models (IPCC 2006) to predict DMI as well as the modified CNCPS and NRC (2001) models to predict DMI using an independent data. The modified CNCPS relying on BW and fat corrected milk yield (Eq. 1) more accurately predicted DMI (RMSPE = 14.1 percent) than NRC (RMSPE = 19.4 percent), IPCC-SMP (RMSPE = 16.9 percent), and IPCC-CMP (RMSPE = 23.4 percent). Overall, the results demonstrated that DMI of dairy cows can be predicted successfully using information such as milk yield, milk fat content, and body weight (BW) that are routinely available in dairy farms.

$$\text{DMI (kg/d)} = 0.0185 * \text{BW (kg)} + 0.305 * \text{fat corrected milk (kg/d)} \quad \text{Eq [1]}$$

A simplified approach can also be used to estimate DMI of beef cattle, updated based on the most recent methodologies as described by NASEM (2017). For growing and finishing cattle, equations are:

Calves

$$\text{DMI (kg/d)} = (BW^{0.75} * (0.2435 * NE_{mf} - 0.0466 * NE_{mf}^2 - 0.1128)) / NE_{mf} \quad \text{Eq. [2]}$$

Yearlings

$$\text{DMI (kg/d)} = (BW^{0.75} * (0.2435 * NE_{mf} - 0.0466 * NE_{mf}^2 - 0.0869)) / NE_{mf} \quad \text{Eq. [3]}$$

Feedlot cattle (high grain diets)

Steers: $\text{DMI (kg/d)} = 3.830 + 0.0143 * BW * 0.96$ Eq. [4]

Heifers: $\text{DMI (kg/d)} = 3.184 + 0.01536 * BW * 0.96$ Eq. [5]

Where: BW = body weight (kg), NE_{mf} = Mcal/kg feed DM Eq. [6]

Mature Cows

Forage type	Digestibility	Forage DMI Capacity (kg/day), % of BW (kg)	
		Non-lactating	Lactating
Low quality	<52	1.8	2.2
Average quality	52-59	2.2	2.5
High quality	>59	2.5	2.7

10B.5 Basis for Changes to MCF Calculations for Liquid/Slurry

The following briefly summarizes the *2006 IPCC Guidelines* approach and improvements included in the current approach.

2006 IPCC Guidelines Model for Liquid/Slurry:

The *2006 IPCC Guidelines* MCF for liquid slurry was based on the following relationship:

MCF = *f*

where *f* was calculated with the following temperature-dependent Arrhenius function, derived from Mangino *et al*. (2001), which is based on Safley & Westerman (1990):

$f = EXP[(Ea\times(T_2-T_1))/(R\times T_2\times T_1)]$

where,

f is a dimensionless fraction (0 to 1). Originally, Safley & Westerman (1990) used *f* to design an anaerobic digestion system at a lower temperature (T_2) based on known performance of a digester at a warmer temperature (T_1).

Ea is the activation energy. Originally, Safley and Westerman used Ea = 15175 cal/mol, based on an earlier study. Mangino *et al*. (2001) continued to use 15175 cal/mol.

T_2 is the variable temperature (K). Defined by Safley & Westerman (1990) as the unknown anaerobic digester temperature. Mangino *et al*. (2001) defined T_2 as the monthly temperature of the anaerobic lagoon (assuming equality with monthly average air temperature). The *2006 IPCC Guidelines* defined T_2 as the annual average temperature of a region.

T_1 is the reference temperature (K). Defined by Safley & Westerman (1990) as 30 °C (303.16 K). Mangino *et al*. (2001) and the *2006 IPCC Guidelines* use the same value.

R is the gas constant 1.987 cal k^{-1} mol^{-1}.

The reasons for modification of MCF, though the Methane conversion factor (MCF) remains an uncertain parameter.

First and foremost, in the *2006 IPCC Guidelines*, the MCF parameter violates a first-principle of inventory development: comparability. The use of an annual average temperature to calculate MCF systematically underestimates the annual MCF due to the mathematical principle known as Jensen's Inequality which applies to non-linear functions such as the Arrhenius equation (VanderZaag *et al*. 2018). Using this mathematical principle it can be shown that for a 1-month retention time, the annual average MCF calculated based on monthly temperature will always exceed the MCF calculated from the annual average temperature. Therefore, the *2006 IPCC Guidelines* MCF values are underestimates, and the level of underestimation is greatest for countries with large seasonal temperature extremes.

The model in the *2006 IPCC Guidelines* also used a management and design practices (MDP) factor which reduced the mass of VS entering the manure storage or lagoon. Since VS cannot simply vanish, there needs to be justification for altering the VS loading rate. In the modified method, the MCF calculation used an MDP = 1.0, which means we are assuming the VS Excretion rates are correct, and that VS Excreted enters the liquid manure storage. MDP factors may be used in specific cases such as when solid-liquid separation systems are used, whereby VS is removed from the liquid system and transferred to a solid system. However in most cases the use of MDP factor is indicative of an inaccurate B0 or VS input into the manure storage system.

For the sake of completeness, it is worth pointing out that the quantity of VS entering liquid storage could be greater than VS excreted (implied MDP >1.0). For instance, the use of straw bedding results in additional VS entering the liquid storage. Another example is waste milk (from treated cows, or from cleaning milking systems) on dairy farms which adds VS to the storage. Secondly, it is well known that the retention time of liquid manure in storage is a critical parameter in determining MCF, and the *2006 IPCC Guidelines* state "both temperature and retention time play an important role in the calculation of MCF". However, the *2006 IPCC Guidelines* calculations of MCF (Table 1), give very little focus to retention time. Previous *Good Practice Guidance and Uncertainty Management in National Greenhouse Gas Inventories (GPG2000)* recommended that future MCFs be modelled accounting for the storage period (Zeeman & Gerbens 2000). Furthermore, the work of Safley & Westerman (1990) showed that the same amount of VS destruction can be achieved by longer retention time at lower temperature compared with shorter retention time at higher temperature. Furthermore the suggestion to use formula 1 for batch-fed storage/digesters that is currently in *2006 IPCC Guidelines* would not result in a value that is comparable to the default annual temperature values, because this equation would inherently require inclusion of retention time.

Recent year-round field studies in climates where the annual average air temperature was <10°C have reported MCFs in the range of 0.61 (Wightman & Woodbury 2016) , ≥0.57 (Balde *et al*. 2016a) at liquid/slurry dairy manure storages, and greater for anaerobic lagoons (Leytem *et al*. 2017). Controlled studies at or around 20°C without added inoculum reported MCF of 55 percent over 165 d (VanderZaag *et al*. 2010) and 32 percent over 150-d (Masse *et al*. 2008). Another study showed the MCF increased non-linearly with the duration of storage (Le Riche *et al*. 2016). Previous IPCC Guidance reported an MCF of 39 percent, 45 percent, and 72 percent for liquid/slurry for Cool, Temperate, and Warm climates, respectively (Zeeman & Gerbens 2000). They also stated that liquid/slurry storage tanks were considered to have ≥6 month retention time. Therefore, the interaction between retention time and temperature has long been recognized, but the calculation of MCFs has not been fully transparent about how this important interaction has been handled (or how it should be handled by practitioners) and therefore has made comparability with measurements challenging.

Thirdly, the single temperature time step given in the IPCC guidelines suggests a level of certainty that is simply not supported by the experimental results, considering the approach being used.

TABLE 10B.6 *2006 IPCC GUIDELINES* TABLE OF MCF VALUES FOR LIQUID/SLURRY (TABLE 10.17)

TABLE 10.17
MCF VALUES BY TEMPERATURE FOR MANURE MANAGEMENT SYSTEMS

System[a]		MCFs by average annual temperature (°C)																			Source and comments
		Cool					Temperate											Warm			
		≤ 10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	≥ 28	
Liquid/Slurry	With natural crust cover	10%	11%	13%	14%	15%	17%	18%	20%	22%	24%	26%	29%	31%	34%	37%	41%	44%	48%	50%	Judgement of IPCC Expert Group in combination with Mangino *et al.* (2001) and Sommer (2000). The estimated reduction due to the crust cover (40%) is an annual average value based on a limited data set and can be highly variable dependent on temperature, rainfall, and composition. When slurry tanks are used as fed-batch storage/digesters, MCF should be calculated according to Formula 1.
	Without natural crust cover	17%	19%	20%	22%	25%	27%	29%	32%	35%	39%	42%	46%	50%	55%	60%	65%	71%	78%	80%	Judgement of IPCC Expert Group in combination with Mangino *et al.* (2001). When slurry tanks are used as fed-batch storage/digesters, MCF should be calculated according to Formula 1.

Proposed Changes:

The proposed change is to use a spreadsheet model to calculate MCF using monthly temperature in each IPCC climate region, and for a specific liquid manure retention time (e.g. the table below). Therefore, this approach produces MCF values that account for both temperature and retention time, while leaving the users to decide which retention time is appropriate for their manure management systems. The spreadsheet model *<Vol4_Ch10_MCF_Calculation-Spreadsheet>* for calculation of country-specific MCFs is available at *https://www.ipcc-nggip.iges.or.jp/public/2019rf/pdf/4_Volume4/Vol4_Ch10_%20MCF_Calculation-Spreadsheet.xlsx*.

TABLE 10B.7 (NEW)
MCFS CALCULATED FOR EACH RETENTION TIME AND CLIMATE (SELECTED IPCC CLIMATE REGIONS SHOWN)

RETENTION TIME	Tropical Montane	Tropical[1] Wet	Tropical[1] Moist	Tropical[1] Dry	Warm Temperate Moist	Warm Temperate Dry	Cool Temperate Moist	Cool Temperate Dry
1 Month	0.25	0.38	0.36	0.42	0.13	0.15	0.06	0.08

[1] Note that an upper limit MCF of 80% has been imposed for consistency with the anaerobic lagoon MCFs at high temperatures and long retention times

Changes in liquid/slurry MCF, compared to the 2006 IPCC Guidelines are summarized below:

#1 – Timestep:

Monthly temperature (proposed) instead of annual average temperature (IPCC 2006)

Methane emissions are non-linearly related to temperature, therefore Jensen's inequality states that the use of the average temperature will lead to systematic underestimation. As a result, monthly average air temperature is proposed for the calculation of MCF, rather than annual average temperature. Therefore, it is proposed that MCF for liquid/slurry be calculated using the Mangino *et al*. (2001) spreadsheet model, with the regional climate data from the IPCC defined climate regions. Additional details below.

#2 – Retention Time:

Several retention times (proposed) instead of 1-month implied retention time (IPCC 2006)

Retention time is a crucial parameter determining the extent of methane emissions and the quantity of VS in storage at any given time, therefore affecting the MCF. The *2006 IPCC Guidelines* used a 1-month retention time for all liquid/slurry systems by using MCF = *f*, based on an annual average temperature. Using a 1-month retention time is unrealistic, since the majority of liquid/slurry storages are meant for storage over several months or more. Therefore, it is proposed to calculate MCF based on five retention times: 1 month, 3 months, 4 months, 6 months, and 12 months.

Proposed "*good practice*" in the case of countries that do not have information on retention times is to use the six month retention time.

#3 – Activation Energy (Ea):

Updated Ea value (19347 cal/mol proposed) instead of 15175 cal/mol (IPCC 2006)

Recent research from Petersen *et al*. (2016) and Elsgaard *et al*. (2016) propose a new Ea value of 81 kJ/mol = 19347 cal/mol. It is proposed to use this updated value.

#4 – Reference Temperature (T_1):

Updated T1 value (308.16 proposed) instead of 303.16 K (IPCC 2006)

The value of T_1 used by *2006 IPCC Guidelines* and Mangino *et al*. (2001) is directly taken from Safley & Westerman (1990). The original intent of Safley and Westerman was comparing performance of a known and unknown anaerobic digester performance. In Mangino *et al*. (2001) and the *2006 IPCC Guidelines* the value of T1 defines the temperature at which *f* = 1.0, therefore T1 defines the temperature at which the B_0 will be reached in one month. There is considerable literature on laboratory methods for incubating manure to measure methane potential (e.g. BMP, B_0) and it is customary for the temperature of these incubations to be ca. 35°C, rather than 30°C. With a temperature of 35°C it would be reasonable to expect the B_0 to nearly be reached in 30 days (i.e. one month) (e.g. Owen *et al*. 1979; Pham *et al*. 2013). Therefore, it is proposed to change T_1 to 308.16 K (=35 + 273.16).

#5 – Manure Temperature (T_2):

Manure temperature lagging behind T_{air} (proposed) instead of equal T_{air} (IPCC 2006)

Most of the time, manure temperature does not equal air temperature. The temperature of liquid manure tends to lag behind air temperature. While models for manure temperature do exist (Rennie *et al*. 2017) this is too complex for the general guidelines. As a pragmatic alternative, a 1-month lag is proposed, i.e., set $T_2 = T_{air}$ from the previous month. It has also been shown (Rennie *et al*. 2018) that manure storages which are emptied once per year at the end of the growing season before winter stay cooler than air temperature during the summer. Therefore, only in the case of once per year emptying (i.e. 12 month retention time), a downward temperature shift of 3°C has also been applied.

#6 – VS carryover after emptying:

After manure is removed, 5 percent remains (proposed), instead of complete emptying (IPCC 2006)

It has been shown in several studies that farms do not completely empty liquid/slurry storages due to the practical challenge of doing so at the farm-scale (Balde *et al*. 2016b). Therefore, it is proposed that 5 percent of VS is retained in storage after emptying, rather than 0 percent (i.e. completely clean) assumption implied in the *2006 IPCC Guidelines* calculations. It is noteworthy that the IPCC 2000 *Good Practice* Guide (Zeeman & Gerbens 2000) mention approximately 15 percent of the manure storage cannot be emptied.

10B.6 Revision of methane from dung deposited onto pasture range and paddocks (Table 10.17)

Dataset

Cai *et al*. (2017) included 26 data, however some of these were omitted due to incomplete information to allow an estimation of methane conversion factor (MCF) and/or emission factors on the basis of volatile solids (VS) content. Therefore, the number of values retained was 20. Our review of the literature identified a further 25 suitable values (Carran *et al*. 2003; Saggar *et al*. 2003; Sherlock *et al*. 2003b; Sherlock *et al*. 2003a; Kelly *et al*. 2016), resulting in a total of 45 data values spanning six countries (Table 10B.8). Data were available for dairy cattle (25), beef cattle (9), sheep (8) and yaks (3). Data was assessed for suitability, in terms of length of study, sufficient replication and inclusion of key manure characteristics to allow estimation of the emission factors (g CH_4/kg VS; Table 10B.9) and MCF (percent; Table 10.17). Some studies also presented emissions on the basis of mass of CH_4 emitted per unit of faecal dry matter (FDM). Therefore, we have also supplied emission factors using these units (g CH_4/kg FDM) for countries with access to total FDM (Table 10B.9).

TABLE 10B.8 (NEW)
REGIONAL DISTRIBUTION OF DATA USED TO DERIVE MCF AND METHANE EF FROM EXCRETION VOLITILE SOLIDS DATA ON PRP

Country	Cattle	Sheep	Total
Australia	13		13
Brazil	4		4
China	3	2	5
Japan	5		5
New Zealand	6	6	12
UK	6		6
Total	**37**	**8**	**45**

Emission factors

Methane conversion factors (MCF) and emission factors were estimated for both cattle and sheep, where yaks were grouped with cattle (Table 10B.9). For estimating MCFs and emission factors based on VS content, ash content of dung is required. We estimated dung ash content to be 17.9 percent for pasture-fed sheep, beef cattle and dairy cattle (Fries *et al*. 1982; Karn 1991; Waghorn *et al*. 1999; Andueza *et al*. 2017). Data from a UK study (Defra, 2014) suggested that the IPCC B_0 values were appropriate for cattle, we therefore assumed the IPCC values for sheep were also reasonable estimates. For yaks, we used the IPCC default B_0 value for buffalo (0.100).

There was no significant difference in values for cattle and sheep regardless of the method of representing methane emissions ($P > 0.05$). For the refinement of the *2006 IPCC Guidelines* we therefore suggest an aggregated value is used. We also explored the possibility of disaggregating EF values by climatic zones, however the limited size of the dataset did not support this. Therefore, an aggregated value regardless of temperature is suggested for the refinement.

When adopting a Tier 2 approach, the MCF must be used in conjunction with a single B_0 value of 0.19 m^3 CH_4 kg^{-1} of VS excreted to ensure consistency with the Tier 1 emission factor provided in Table 10.14.

TABLE 10B.9 (NEW)
METHANE CONVERSION FACTOR (MCF) AND METHANE EMISSION FACTORS (PER KG FAECAL DRY MATTER (FDM)) AND VOLATILE SOLIDS (VS) FOR CATTLE AND SHEEP

Livestock species	MCF (%) Average, (Std Dev)	EF (g CH_4/kg FDM) Average, (Std Dev)	EF (g CH_4/kg VS) Average, (Std Dev)
Cattle	0.46 (0.38)	0.49 (0.42)	0.59 (0.51)
Sheep	0.52 (0.40)	0.53 (0.42)	0.65 (0.51)
Average	**0.47 (0.38)**	**0.50 (0.42)**	**0.60 (0.51)**

10B.7 Estimation of default values for MCFs, EFs for direct N_2O emissions, NH_3 and N_2 volatilized as well as NO_3 leached from solid storage and composting systems

Methodologies

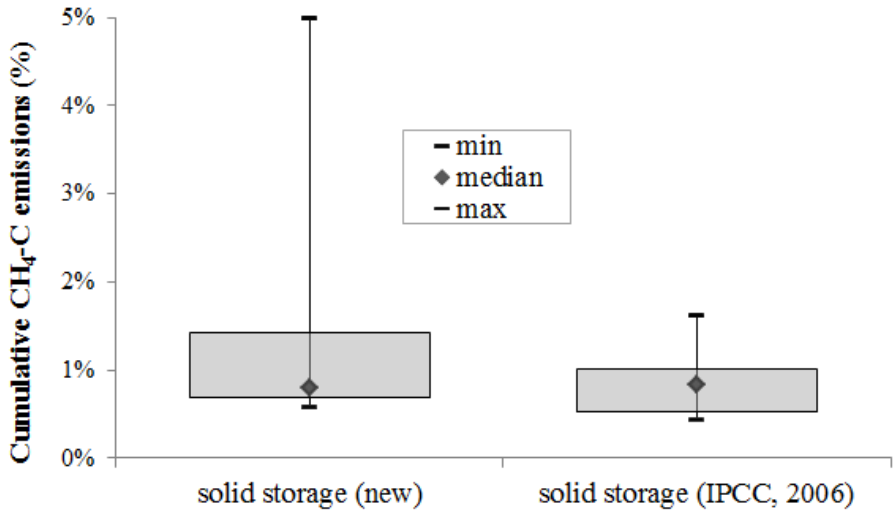
The estimation of updated MCF values, EF for direct N_2O emissions and NO_3 leaching and N_2 from both (i) solid storage and (i) two composting systems (static pile and passive windrow) are based on an extensive meta-analysis of 50 peer-reviewed research articles involving 304 observations and published in open access by Pardo *et al*. (2015). In this study it was quantified the response of GHG emissions, NH_3 emissions, and total N losses to different solid waste management strategies (conventional solid storage, turned composting, forced aerated composting, covering, compacting, addition/substitution of bulking agents and the use of additives).

For solid storage, new treatments have been proposed to be incorporated in the *2019 Refinement*: covering/compacted (both treatments had similar effects on GHG emissions), addition/substitution of bulking agents and the use of additives. In the *2006 IPCC Guidelines for National GHG inventories* default emission factors for solid storage were based on expert IPCC judgement and a single study (Amon *et al*. 2001). In Pardo *et al*. (2015) the estimation of MCF values and EF for direct N_2O emissions from solid storage (without treatment) is based on data from 30 studies at the farm level.

For the new treatments, MCF values and EFs for direct N_2O emissions have been based on:

- 9 studies for compacting and covering;
- 11 studies for addition/substitution of bulking agents;
- 6 studies for use of additives.

For the rest of the management systems, MCF values and EF for direct N_2O emissions have been based on:



- 22 studies for solid storage;
- 6 studies for composting-static piles (Forced aeration);
- 11 studies for composting-Passive windrow (infrequent turning).

Based on the *2006 IPCC Guidelines* climate zone classification two factors were defined: Temperature, which involved two categories (i) Warm temperate and (ii) Cool temperate; and annual rainfall rate, including (i) Dry, (ii) Moist and (iii) Wet conditions.

CH_4 MCF

For the absolute CH_4-C emission values, Pardo *et al*. (2015) used untreated solid storage as a reference system. They compared estimated percent C lost as CH_4 using the *2006 IPCC Guidelines* method (IPCC 2006 MCF) with the values obtained at the different studies (Figure 10B.6).

Figure 10B.6 (New) Comparison between ranges of CH_4-C emissions observed in collected studies in Pardo *et al.* (2015) (new) with estimations for the same studies according to the *2006 IPCC Guidelines* methodology. Figure adapted from Pardo *et al.* (2015).

For untreated solid storage systems Pardo *et al*. (2015) showed that overall values were within the *2006 IPCC Guidelines* range for CH_4 emissions (Figure 10B.6) and confirmed that the differences between cold and temperate conditions were in agreement with those indicated by the *2006 IPCC Guidelines* not shown here, Figure S3b in Pardo *et al*. (2015). There were not enough studies under warm conditions and therefore, the assumption is to keep the same values indicated by the *2006 IPCC Guidelines*.

Values for new solid storage treatments and composting (static pile and passive windrow) are estimated using the reference value from the untreated solid storage system and the relative differences observed in Pardo *et al*. (2015).

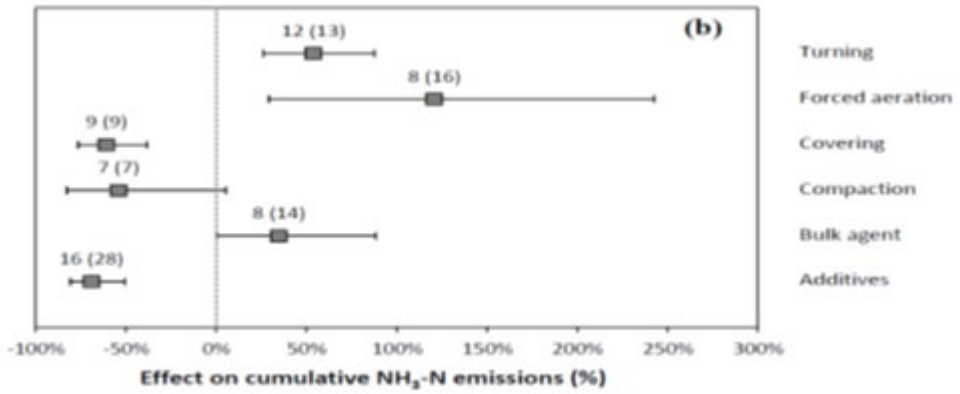
For the new treatments, covering or compacted solid storage resulted in emissions in the same range as in solid storage not shown here, Figure 2b in Pardo *et al*. (2015) and estimated reduction of 75 percent and 50 percent was observed due to bulking agent addition and additives, respectively not shown here, Figure 2b in Pardo *et al*. (2015). The differences amongst climatic zones were assumed to be in the same proportion as that found for untreated solid storage systems.

Both composted static piles and static windrows were estimated to produce 50 percent of the CH_4 emitted from solid storage not shown here, Figure 2b in Pardo *et al*. (2015), which results in consistently greater values than those indicated by the *2006 IPCC Guidelines*. As a difference to the *2006 IPCC Guidelines*, CH_4 emissions were found to be temperature dependent for both composting systems (*2006 IPCC Guidelines* did not indicate temperature differences for static piles).

N_2O EF3 (Table 10.21)

According to the data examined in Pardo *et al*. (2015), there was no evidence to assume a lower EF for solid storage systems (0.005 kg N_2O–N kg^{-1} N excreted) than for passive windrow composting (0.01 kg N_2O–N kg−1N excreted). In fact, an EF of 0.5 percent (0.005kg N_2O-N kg initial N^{-1}) and 1 percent (0.01kg N_2O-N kg initial N^{-1}) were found for composting-passive windrow and solid storage, respectively.

Composting static pile, in contrast to the *2006 IPCC Guidelines*, was found to emit greater N_2O emissions than passive windrows (not shown here, Fig. 3a in Pardo *et al*. 2015).



For the different treatments of solid storage, whereas Pardo *et al*. (2015) found no different effect on N_2O after compaction or covering, for both the addition of bulking agents or additives, a reduction of about 50 percent compared with conventional solid storage was observed not shown here, Figure 2a in Pardo *et al*. (2015).

NH_3 losses

For solid storage and composting relative values compared to solid storage reflect results obtained from meta-analysis by Pardo *et al*. (2015) (Fig 10B.7). Ammonia and NO_x default values in Table 10.22 for conventional solid manure storage and other systems defined both in IPCC Guidelines and EMEP/EEA (2016) have been taken from current EMEP/EEA air pollutant emission inventory guidebook 2016. EFs from EMEP/EEA (2016) values, which are expressed per TAN excreted and for each of the phases of the manure management, have been re-

calculated to be expressed as a funtion of total N excreted considering the mass balance flow between the different manure management phases prior to manure application (housing, yards and storage). For other categories not present in EMEP/CORINAIR (2016), first for stages prior to storage, we have estimated percent N lost using default EMEP/CORINAIR EFs for conventional manure storage and assuming no N_2O or N_2 losses, and subsequently, during storage, we used the relative effect between solid storage and the alternative solid storage categories (e.g. composting) (Fig 10B.7) as the basis to estimate NH_3+NO_x EF during storage.

Figure 10B.7 (New) Effect on cumulative NH_3-N emissions of different solid storage and composting methods compared with conventional solid storage. Figure adapted from Pardo *et al.* (2015)

NO_3 leaching and N_2 losses

Nitrate leaching/run-off has been estimated from the database from Pardo *et al*. (2015). For solid storage and composting some of the studies included measurements of N leaching (15), some of which estimated N_2 from the total N balance, but only one included measurements of N_2 (Moral *et al*. 2012). As a median value about 3 percent is estimated to be lost as NO_3 leaching/run-off (range: 0-38 percent). This value is subject to large uncertainty. In fact these trials may not represent common practices where the efficiency of collection of excreta N is much lower and can lead to as great as 50 percent losses (e.g. Lekasi *et al*. 2001; Rufino *et al*. 2007). Nitrogen (N_2) losses, have only been, to our knowledge, measured by Moral *et al*. (2012) (12 percent) and even though they could be estimated as a result of an N balance from trials where all N flows except N_2 have been measured, the results are very uncertain (0-55 percent). For N_2, an estimated median value of 12 percent was found; coinciding with the measured value by Moral *et al*. (2012). Systems that do not percolate but are subject to large water input will have greater N_2 losses and lower NO_3 leaching-runoff. The opposite effect will be expected with rainy areas with no containment and large possibilities for run-off/leaching. Values must be considered with large caution.

A further summary review was carried out to identify run-off/leaching values from dry lots and manure pack. As observed in the *2006 IPCC Guidelines* runoff and leaching values varied greatly citing ranges of 3 to 6 percent of N excreted (Eghball & Power 1994) or 5 to 19 percent (Bierman *et al*. 1999). In humid environments losses can be significant reaching 22-25 percent (Uusi-Kämppä 2002). However, uncovered holding and feeding pens without runoff containment tend to be in drier climates simply due to challenges in moisture control in more humid environments. Furthermore, considerable numbers of cattle are raised in drier climates and as a result considerably more studies exist looking at runoff from feedlots and drylots. Likewise recent attempts have been made to attempt to model these losses to the environment (Kizil *et al*. 2006; Williams et al. 2006). These studies tend to place the range of runoff loss between 1 percent and roughly 7 (Kizil *et al*. 2006; Erickson & Klopfenstein 2010; Vadas & Powell 2013). It is proposed the value of 3.5 percent with an uncertain range of 0 to 7 percent be considered as a default leaching factor for open, uncovered, uncontained drylots and bedded pack to provide a Tier 1 estimate of the fraction of N excreted lost to the environment.

Inventory compilers must be careful to consider that this refers to N lost to the environment surrounding the pens or leached into the soil. If runoff is captured and returned to agricultural fields these losses must not be considered. In humid environments, in cases where manure is left exposed to rainfall, inventory compilers should consider the use of the upper bounds of the leaching fraction and furthermore to consider the development of a country specific leaching fraction.

Review of the effect of slurry store solid covers and natural crust on emissions of CH_4 and N_2O

The review found 18 papers dealing with the impact of solid covers or natural crusts on CH_4 and/or N_2O emissions from slurry stores. 11 of them were suitable to be included here to deduce emission factors (Amon *et al*. 2006; Clemens *et al*. 2006; Guarino *et al*. 2006; Amon *et al*. 2007; VanderZaag *et al*. 2008; VanderZaag *et al*. 2009; Aguerre *et al*. 2012; Nielsen *et al*. 2013; Hou *et al*. 2015; Matulaitis *et al*. 2015; Misselbrook *et al*. 2016).

For CH_4 emissions from Liquid/Slurry, the *2006 IPCC Guidelines* state that by judgement of the IPCC Expert Group, a reduction of 40 percent due to crust cover may be applied when a thick, dry, crust is present. The new review carried our within the *2019 Refinement* confirms this judgement (VanderZaag *et al*. 2008; Aguerre *et al*. 2012; Nielsen *et al*. 2013). A solid cover reduces CH_4 emissions by 25 to 50 percent (range: 0 to 90 percent) (Amon *et al*. 2006; Clemens *et al*. 2006; Guarino *et al*. 2006; Amon *et al*. 2007; VanderZaag *et al*. 2008; VanderZaag *et al*. 2009; Hou *et al*. 2015; Matulaitis *et al*. 2015; Misselbrook *et al*. 2016).

For N_2O emissions from Liquid/Slurry with natural crust cover a detailed literature review carried out during the *2019 Refinement* revealed only very few new datasets on the measurement of N_2O emissions from manure stores and the influence of crusting. These datasets agree that N_2O emissions increase when a crust is formed, but do not give concrete numbers on the level of increase (VanderZaag *et al*. 2008; Aguerre *et al*. 2012).

For N_2O emissions from Liquid/Slurry with a cover a detailed literature review carried out during the *2019 Refinement* revealed only few new datasets on the measurement of N_2O emissions from manure stores. These datasets encompass a large range from a 50 percent reduction to a 100 percent increase in N_2O emissions when slurry stores are covered. The *2019 Refinement* therefore suggest to use the emission factor of crust cover (Amon *et al*. 2006; Clemens *et al*. 2006; Guarino *et al*. 2006; Amon *et al*. 2007; VanderZaag *et al*. 2009; Hou *et al*. 2015; Misselbrook *et al*. 2016).

GREENHOUSE GAS PROTOCOL

FAQ

1. What are scope 3 emissions?

The GHG Protocol Corporate Standard classifies a company's GHG emissions into three 'scopes'. Scope 1 emissions are direct emissions from owned or controlled sources. Scope 2 emissions are indirect emissions from the generation of purchased energy. Scope 3 emissions are all indirect emissions (not included in scope 2) that occur in the value chain of the reporting company, including both upstream and downstream emissions.

2. What are product life cycle emissions?

Product life cycle emissions are all the emissions associated with the production and use of a specific product, from cradle to grave, including emissions from raw materials, manufacture, transport, storage, sale, use and disposal.

3. What is the main difference between the two standards?

The GHG Protocol Corporate Value Chain (Scope 3) Standard and GHG Protocol Product Standard both take a value chain or life cycle approach to GHG accounting. The Corporate Value Chain (Scope 3) Standard accounts for emissions at the corporate level, while the Product Standard accounts for emissions at the individual product level. The Corporate Value Chain (Scope 3) Standard helps companies identify GHG reduction opportunities, track performance, and engage suppliers at a corporate level, while the Product Standard helps a company meet the same objectives at a product level. Together with the GHG Protocol Corporate Standard, the three standards provide a comprehensive approach to value chain GHG measurement and management.

4. Why are value chain emissions important?

Most of the largest companies in the world now account and report on the emissions from their direct operations (scopes 1 and 2). The new standards close the GHG gap: businesses can now act on the full range of corporate value chain and product emissions as well.

Emissions along the value chain often represent a company's biggest greenhouse gas impacts, which means companies have been missing out on significant opportunities for improvement. For example, road tester Kraft Foods found that value chain emissions comprise more than 90 percent of the company's total emissions. Developing a full GHG emissions inventory – incorporating corporate-level scope 1, scope 2, and scope 3 emissions – enables companies to understand their full value chain emissions and to focus their efforts on the greatest GHG reduction opportunities.

5. Why should businesses care?

Businesses have found that developing corporate value chain (scope 3) and product GHG inventories delivers a positive return on investment. The new standards help companies to:

- Identify and understand risks and opportunities associated with value chain emissions;
- Identify GHG reduction opportunities, set reduction targets and track performance;
- Engage suppliers and other value chain partners in GHG management and sustainability;
- Enhance stakeholder information and corporate reputation through public reporting.

Through these activities, companies can reduce emissions and costs to meet strategic business objectives.

6. Why do the standards only account for GHG emissions and not other environmental impacts? Can the standards be used for other impacts (e.g. water)?

The GHG Protocol standards address GHG emissions. GHG emissions are a great starting point for businesses because of the data availability, their correlation with energy use, and often their correlation with other environmental impacts. The general accounting methodology of both standards can be adapted by businesses to account for other impacts.

7. Should the standards be used to compare products or companies?

In the future, industries will be able to build off the Product Standard to develop industry specific product rules to give them the ability to compare products. For now, the main benefits are to identify hot spots in a product life cycle and efficiently concentrate resources.

The Product Standard provides some guidance on how companies with a goal for comparison can use and/or develop product rules in conjunction with the standard. Product rules offer more specification for a given product category than the general standard can provide.

The Corporate Value Chain (Scope 3) Standard is designed to enable comparisons of a company's GHG emissions over time. It is not designed to support comparisons between companies based on their scope 3 emissions. Differences in reported emissions may be a result of differences in inventory methodology, company size or structure. Additional measures are necessary to enable valid comparisons across companies, such as consistency in methodology, consistency in data used to calculate the inventory, and reporting of intensity ratios or performance metrics. Additional consistency can be provided through GHG reporting programs or sector-specific guidance.

8. How will the standards help drive global emissions reductions?

Businesses can't manage what they can't measure. Because climate change is a complex and global problem, decisions about how to reduce emissions need to be based on facts rather than assumptions.

The new standards provide an essential foundation for strategic thinking about reducing emissions. They allow businesses to identify the biggest "hot spots" in their value chains – the activities that generate the most emissions. This insight allows businesses to focus on achieving the most meaningful reductions, not only from within their operations, but across global value chains. If the standards are successful, product and value chain GHG measurement will become standard business practice and companies all around the globe will have the information they need to effectively reduce emissions.

9. Are the new standards compulsary?

Use of the new standards is voluntary. In the future, governments and programs may decide to use the

standards or some version of the standards when creating mandatory programs or regulations.

10. Why is having one consistent global standard important?

Climate change is a global problem and businesses operate in a global environment. Value chains – and the risks and opportunities associated with GHG emissions – span national borders. Businesses operating in a global economy need a single, consistent, harmonized approach. Since the new standards take a value chain approach to emissions measurement and management that crosses national borders, the need for a global standard is even more important.

11. How were the standards developed?

The standards development process is a defining feature of the GHG Protocol. The GHG Protocol follows a broad and inclusive multi-stakeholder process to develop greenhouse gas accounting and reporting standards with participation from businesses, government agencies, NGOs, and academic institutions from around the world.

In 2008, WRI and WBCSD launched a three-year process to develop the new standards. A 25-member Steering Committee of experts provided strategic direction throughout the process. The first drafts of the standards were developed in 2009 by Technical Working Groups consisting of over 207 members (representing diverse industries, government agencies, academic institutions, and non-profit organizations worldwide). In 2010, 60 companies from a variety of industry sectors road-tested the standards and provided feedback on their practicality and usability. Members of a Stakeholder Advisory Group (consisting of more than 2,300 participants) provided feedback on each draft of the standards.

12. Which companies road-tested the standards?

The following companies road-tested one or both of the standards:

- 3M
- Abengoa
- Acer
- Airbus
- AkzoNobel
- Alcoa
- Amcor Ltd.
- Anvil Knitwear
- Autodesk, Inc.
- Baosteel Group Corporation
- BASF

Scope 3 GHG Inventory Guidance

List of Terms

- **GHG** – *Greenhouse Gas; any gas that contributes to the greenhouse effect and climate change by absorbing infrared radiation. There are seven greenhouse gases accounted for by the GHG Protocol: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), sulfur hexafluoride (SF_6), nitrogen trifluoride (NF_3), hydrofluorocarbons (HFCs), and perfluorocarbons (PFCs).*
- **SBT** – *Science Based Target; greenhouse gas reduction target adopted by companies to achieve the level of decarbonization necessary to keep global temperatures from rising above 2 degrees Celsius compared to preindustrial temperatures. In October 2019, the ambition requirements for SBTs increased to "well below 2 degrees."*
- **CDP** – *Formerly the Carbon Disclosure Project; a global platform that collects and publicly displays environmental performance data from companies, cities, states and regions to inform investor and shareholder decision-making.*
- **Reporting Processor** – *The dairy cooperative, manufacturing company, or processing company utilizing this guidance tool in preparation to publicly disclose its greenhouse gas emissions inventory.*
- **CNG** – *Compressed natural gas; methane stored at high pressure.*
- **LNG** – *Liquefied natural gas; a cooled mixture of methane and ethane.*
- **LPG** – *Liquefied petroleum gas; flammable hydrocarbon gases including propane and butane.*
- **CO_2e** – *Carbon dioxide equivalent; a standardized unit used to normalize and report emissions of greenhouse gases.*
- **GWP** – *Global Warming Potential; a relative measure of the potential of a specific GHG to absorb infrared radiation and influence climate change. GWP values are used to calculate the carbon dioxide equivalent of a GHG, with CO_2 being the benchmark (GWP = 1) and other GHGs having values many times greater than CO_2 (e.g., GWP of methane = 28).*
- **Emission Factor** – *The emission rate of a greenhouse gas for a given source.*
- **Activity Data** – *Data related to the magnitude of emissions from various anthropogenic activities.*
- **Scope 1 Emissions** – *Direct emissions from owned or controlled sources.*
- **Scope 2 Emissions** – *Indirect emissions from the generation of purchased energy.*
- **Scope 3 Emissions** – *All indirect emissions (not included in Scope 2) that occur in the value chain of the reporting company, including both upstream and downstream emissions.*
- **GHG Protocol** – *A standards organization developed by the World Resources Institute (WRI) that establishes comprehensive global standardized frameworks to measure and manage greenhouse gas (GHG) emissions from private and public sector operations, value chains and mitigation actions.*
- **Environmentally Extended Input-Output Databases** – *Based on national economic and environmental statistics. These databases have advantages over process databases in that they cover the complete economy, eliminating the need for cut-offs in life cycle assessment.*

Scope 3 GHG Inventory Guidance

Introduction to this Tool

Within the last few years, global realization of the necessity to implement climate change mitigation strategies has become paramount. As a result, organizations such as the Science Based Targets Initiative have mobilized in an effort to engage companies to set climate goals on par with those of the 2015 Paris Climate Agreement—keeping global temperatures from rising more than two degrees Celsius. Furthermore, the Science Based Targets Initiative introduced more ambitious climate targets in October 2019, targeting global temperature stabilization to 1.5 degrees.

Many large dairy purchasing companies have already set or have pledged to set a Science Based Target (hereafter "SBT"). For these companies to meet their SBTs, they require a comprehensive account of their supply chain GHG emissions each year to track progress over time. Therefore, large consumer-facing companies such as these increasingly expect their suppliers to collect and externally disclose their GHG emissions data.

Scope 3 Emissions in U.S. Dairy

Similar to many other industries, the majority of GHG emissions in U.S. dairy arise from supply chain activities upstream of the dairy processors or cooperatives. More specifically, over half of the industry's GHG emissions are generated on the dairy farm as a result of feed production, manure management, and enteric processes. From both dairy retailers' and processors' perspectives, upstream on-farm emissions, along with other processes such as transportation, are considered Scope 3 indirect emissions. As a result, this guidance places particular importance on upstream Scope 3 GHG accounting, although guidance on both upstream and downstream Scope 3 GHG emissions is included to be as comprehensive as possible and account for all 15 Scope 3 GHG categories identified by the GHG Protocol. (Figure 1.0 below)

Although guidance on all 15 Scope 3 categories is included in this resource, the categories determined to emit the most GHGs in the U.S. dairy supply chain comprise the main component of this document. The categories that are considered insignificant and/or non-integral to composing a dairy processors Scope 3 GHG inventory are appended at the end of the document. These categories are deemed insignificant because the basis for determining their associated emissions is not significant in the U.S. dairy value chain. For the purposes of this guidance, insignificant Scope 3 categories in U.S. dairy either do not contain a large quantity of emissions and/or are not feasible to account for due to lack of relevant data, resources and/or time.

However, a caveat to this rule is that the relative importance of individual Scope 3 categories may vary depending on the composition of the reporting processor's supply chain. If possible, reporting processors should attempt to account for emissions from all Scope 3 categories. Furthermore, the reporting processor should not exclude any Scope 3 category that is expected to contribute significantly to their total Scope 3 emissions. However, if resources and time are limited, this guidance recommends taking inventory of emissions from the Scope 3 categories in the main component of this document first, followed by emissions from the categories in the Appendix section. Table 1.0, page 3, differentiates between significant and insignificant Scope 3 categories in the U.S. dairy value chain.

(Figure 1.0) Differentiating between upstream and downstream in the U.S. dairy value chain from dairy processing perspective

In addition, reporting processors may refer to the "Setting the Scope 3 Boundary" section of this guidance, located on page 7.

Defining Scope 3 Indirect Emissions

The Greenhouse Gas Protocol defines Scope 3 emissions as "all indirect emissions (not included in Scope 2) that occur in the value chain of the reporting company, including both upstream and downstream emissions."[1] Since on-farm emissions are both dairy buyers' and dairy processors' Scope 3 emissions and they comprise such a large proportion of U.S. dairy's total GHG inventory, and it is imperative that said emissions are accurately accounted for and quantified.

Additionally, the GHG Protocol is launching the Land Sector and Removals Guidance to explain how companies should account for and report emissions and removals from land management and land use change, building on the Scope 3 Standard. The Innovation Center plans to release dairy-specific guidance based on the Land Sector and Removals Guidance as an addendum to this document in 2025.

Purpose

This guidance document is intended to assist U.S. dairy cooperatives and processing companies to accurately account for and calculate their Scope 3 GHG emissions. It is intended to coincide with the Innovation Center for U.S. Dairy's Scope 1 & 2 GHG Inventory Guidance. Therefore, cooperatives and

Differentiating Between Significant/Feasible and Insignificant/Unfeasible Scope 3 Categories in U.S. Dairy	
Significant Scope 3 Categories	Insignificant Scope 3 Categories
Purchased Goods and Services	Business Travel
Capital Goods (unless processor does not purchase operational equipment in reporting year)	Employee Commuting
Fuel and Energy Related Activities	Processing of Sold Products
Upstream Transportation and Distribution	Use of Sold Products
Waste Generated in Operations	End of Life Treatment of Sold Products
Upstream Leased Assets (unless processor does not have large portfolio of leased assets as a lessee)	Investments
Downstream Transportation and Distribution	Franchises
Downstream Leased Assets (unless processor does not have large portfolio of leased assets as a lessor)	

(Table 1.0) Differentiating between significant and insignificant Scope 3 categories in U.S. dairy based on emissions quantities and feasibility of accounting

U.S. Dairy Industry Supply Chain GHG Emissions Categorization – Processing Point of View	
Supply Chain Stage	GHG Emissions Scope
Feed Production	Scope 3 (Possible Scopes 1, 2 for cooperatives)
Milk Production	Scope 3 (Possible Scopes 1, 2 for cooperatives)
Milk Transport	Scope 3 (Scopes 1, 2 if processor or cooperative owns/controls fleet)
Processing	Scopes 1, 2
Packaging	Scopes 1, 2
Distribution	Scope 3 (Scopes 1, 2 if processor or cooperative owns/controls fleet)
Retail	Scope 3
Consumer	Scope 3

(Table 1.1) Differentiating between Scope 1, 2 and 3 emissions from U.S. dairy cooperatives and processors' perspectives

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

processors that utilize this guidance document should ensure they implement the same organizational boundary for Scope 1, 2 and 3. The Greenhouse Gas Protocol does not permit reporting companies to vary their organizational boundary for each Scope. For more guidance on setting organizational boundaries, refer to the Inventory Management Plan chapter of The Innovation Center's Scope 1 & 2 GHG Inventory Guidance.

For the purposes of credibility and consistency, this document is primarily based on the Greenhouse Gas Protocol's Corporate Value Chain (Scope 3) Accounting and Reporting Standard, as well as the Greenhouse Gas Protocol's Technical Guidance for Calculating Scope 3 Emissions.

This guidance document coincides with the FARM (Farmers Ensuring Responsible Management) Environmental Stewardship program (below). Managed by the National Milk Producers Federation, FARM obtains relevant on-farm data to quantify Scope 3 GHG emissions from Purchased Goods and Services, U.S. dairy's largest Scope 3 emissions category.

FARM Environmental Stewardship (FARM ES) is a farm-level environmental assessment and customer assurance program that provides a comprehensive estimate of GHG emissions on dairy farms. Powered by the Ruminant Farm Systems (RuFaS) model, the program provides tools and resources for farmers to measure and improve their footprint, and data can be aggregated by dairy cooperatives and processors for reporting emissions to dairy buyers.

Additional resources are referenced throughout the document that provide useful information and data relevant to certain necessary calculations.

Although this guidance document is designed to equip reporting processors with the tools and resources necessary to compose their own Scope 3 inventory, Scope 3 GHG accounting is an onerous task. If the reporting entity has sufficient financial resources, it is recommended that a consultant be hired for the first year of conducting a Scope 3 inventory. This ensures professional and expert GHG accounting and sets a baseline standard for the company to model going forward.

If possible, the consultant should compose a consolidated list of resources used in the Scope 3 accounting exercise, so that the reporting processor may utilize them in future reporting years. The consultant's expertise, in combination with this accounting guidance resource, should combine to serve reporting processors with a strong foundation of Scope 3 GHG support.

The FARM (Farmers Assuring Responsible Management) Environmental Stewardship Program

Farmers are the original environmental stewards. The Farmers Assuring Responsible Management (FARM) Environmental Stewardship (ES) program helps tell that story for dairy farmers.

Launched in 2017, FARM ES is a farm-level environmental assessment and customer assurance program. The core FARM ES evaluation provides a comprehensive estimate of greenhouse gas emissions on dairy farms powered by the Ruminant Farm Systems (RuFaS) model. The program provides tools and resources for farmers to measure and improve their footprint. Data can be aggregated by dairy cooperatives and processors for reporting emissions to dairy buyers.

The Conservation Practice Questionnaire (CPQ) is an optional add-on to the FARM Environmental Stewardship evaluation that addresses field and dairy-level conservation activities to capture a more holistic sustainability story.

The program website offers a variety of tools and resources that explain the program, support continuous improvement efforts and give information on the model methodology.

Steps to Create a Scope 3 Inventory

This section provides background information on the overall process of developing a Scope 3 GHG inventory. It includes the chronological steps processors should use to sufficiently account for their Scope 3 emissions.

Developing an accurate and representative Scope 3 inventory can be an arduous task. It contains significantly more categories than Scopes 1 and 2; therefore, it is recommended that the reporting dairy processor or cooperative thoroughly reviews and understands the steps involved in accounting and reporting a Scope 3 inventory.

A chronological list of the steps involved in creating a sufficient Scope 3 inventory is presented in Figure 2.0. More detailed descriptions of what each step entails are included below. Several of the steps have specific requirements that must be met according to the GHG Protocol Corporate Value Chain (Scope 3) Standard.

(Figure 2.0) A chronological roadmap of the steps reporting processors should take when conducting a Scope 3 GHG inventory

Defining Business Goals

Before reporting processors begin measuring their Scope 3 emissions, it is important to identify which business goal(s) to pursue by taking an inventory. By clearly understanding and defining business goals at the start of the Scope 3 accounting and reporting process, reporting processors can better allocate limited resources for developing the most effective operational boundary possible. This saves time and money. For more information on operational boundaries, consult the Inventory Management Plan chapter of the Scope 1 and 2 GHG Inventory Guidance.

Furthermore, identifying which business goals to achieve can potentially offer economic incentives for dairy stakeholders throughout the supply chain. Not only is measuring and managing GHG emissions the right thing to do, it often makes financial sense.

A more detailed breakdown of common business goals (from the GHG Protocol Corporate Value Chain Accounting and Reporting Standard) that reporting companies identify and pursue by taking a Scope 3 GHG inventory is depicted in Table 2.0 on page 6.

All of these business goals outlined by the GHG Protocol are germane to reporting processors in U.S. dairy. However, it is up to the reporting processor to identify which business goals it intends to pursue. Often, large dairy purchasing companies may expect reporting processors to collect and disclose their GHG inventories, which is categorized under the "Enhance stakeholder information and corporate reputation through public reporting" goal (page 6, Table 2.0). While this should be a priority, reporting processors can incentivize Scope 3 GHG accounting and measurement by pursuing business goals that may help identify cost-saving opportunities or operational hotspots for GHG emissions.

This guidance therefore recommends that reporting processors pursue business goals that accommodate customer requests and goals that are mutually beneficial. All four goals listed (page 6) are relevant to U.S. dairy. Marketplace expectations, however, should be prioritized in scenarios where reporting processors lack adequate time or dedicated resources to developing a Scope 3 inventory.

Reviewing Accounting and Reporting Principles

Much like the GHG Protocol Corporate Standard, on which the Scope 1 & 2 GHG Inventory Guidance is based, the GHG Protocol Corporate Value Chain Accounting and Reporting Standard requires that reporting processors' Scope 3 inventories "represent a faithful, true, and fair account" of their emissions.[2] Reporting processors should ensure that they abide by all five principles outlined below: (page 6, Table 2.1)

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

GHG Protocol Corporate Value Chain Business Goal Table	
Business Goal	Details
Identify and understand risks and opportunities associated with value chain emissions	• Identify GHG-related risks in the value chain • Identify new market opportunities • Inform investment and procurement decisions
Identify GHG reduction opportunities, set reduction targets, and track performance	• Identify GHG "hot spots" and prioritize reduction efforts across the value chain • Set Scope 3 GHG reduction targets • Quantify and report GHG performance over time
Engage value chain partners in GHG management	• Partner with suppliers, customers, and other companies in the value chain to achieve GHG reductions • Expand GHG accountability, transparency, and management in the supply chain • Enable greater transparency on companies' efforts to engage suppliers • Reduce energy use, costs, and risks in the supply chain and avoid future costs related to energy and emissions • Reduce costs through improved supply chain efficiency and reduction of material, resource and energy use
Enhance stakeholder information and corporate reputation through public reporting	• Improve corporate reputation and accountability through public disclosure • Meet needs of stakeholders (e.g., investors, customers, civil society, governments), enhance stakeholder reputation, and improve stakeholder relationships through public disclosure of GHG emissions, progress toward GHG targets, and demonstration of environmental stewardship • Participate in government- and NGO-led GHG reporting and management programs to disclose GHG-related information

(Table 2.0) Common business goals identified & pursued by reporting companies when conducting a Scope 3 inventory

GHG Inventory Accounting and Reporting Principles	
Principle	Description
Relevance	GHG inventory reflects company's GHG emissions, and allows external and internal entities to use data for making decisions
Completeness	All GHG emissions sources within the inventory boundary are accounted for and reported; if exclusions are made, a detailed disclosure is included in their place
Consistency	Methodologies are the same across different scopes and categories of emissions to ensure robust performance tracking over time
Transparency	All assumptions and references to associated calculation methodologies/data sources are clearly and openly disclosed
Accuracy	Ensure GHG calculations are correct and reduce uncertainty as much as possible*

(Table 2.1) Accounting and reporting principles that reporting processors should abide by when composing a comprehensive GHG inventory

NOTE: * More information on accounting for uncertainty in Scope 3 quantification can be found in Appendix B of the GHG Protocol Corporate Value Chain Accounting and Reporting Standard. In addition, the World Resources Institute provides an Uncertainty Calculation Excel Tool with an accompanying Uncertainty Guidance Document.

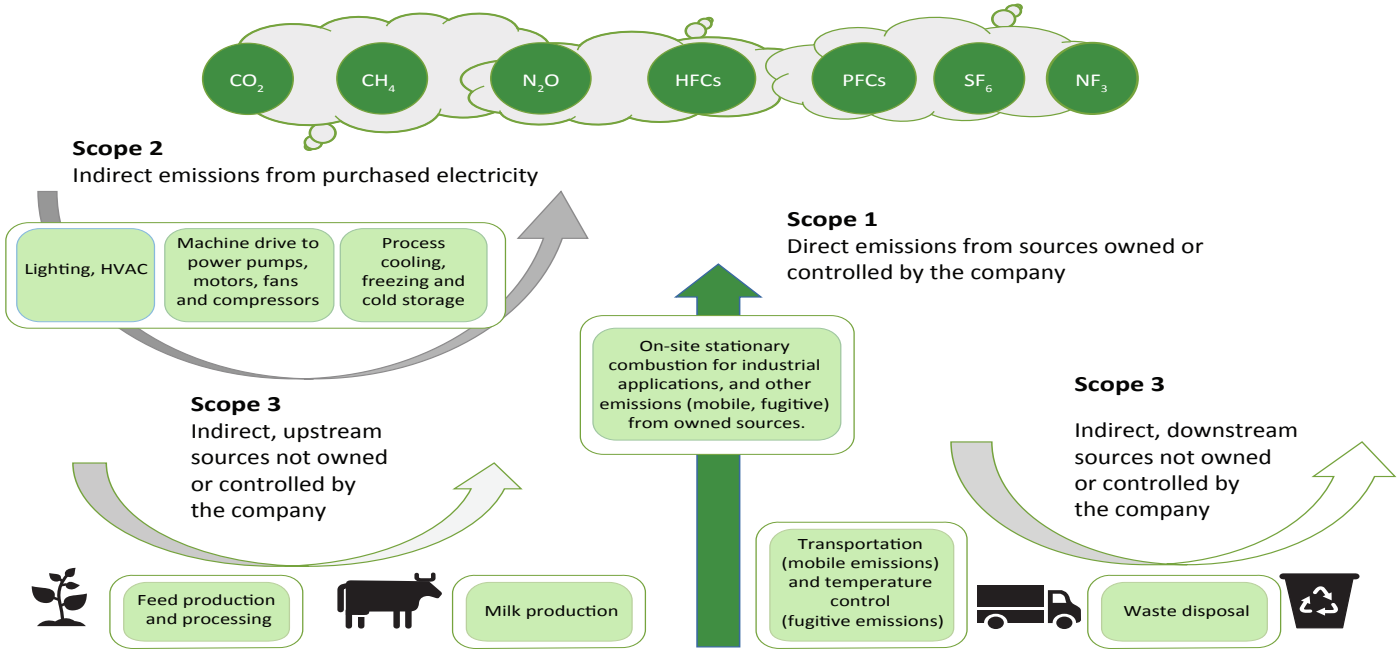
Scope 3 GHG Inventory Guidance

Identifying Relevant Scope 3 Activities

Given the limited resources that most organizations have to manage their Scope 3 GHG emissions, it is imperative that the relevancy of sources be determined. Identification of the relevant Scope 3 categories is a critical step that can be dependent on several factors including:

- The size of the Scope 3 category (its contribution to the reporting processor's total GHG emissions)
- The importance of the Scope 3 category to key stakeholder groups (is the information being requested)
- The ability of the reporting processor to reduce the Scope 3 emissions from certain categories

Depending on the reporting processor's consolidation approach, certain categories of Scope 3 emissions may be accounted for in its Scope 1 and/or 2 inventories. Furthermore, the reporting processor may voluntarily exclude certain Scope 3 categories from its inventory so long as a justified and transparent explanation is included in its place.



Each Scope 3 category has a minimum required boundary that all reporting processors must adhere to. These minimum boundaries are available in chapter five of the Corporate Value Chain Accounting and Reporting Standard.

Setting the Scope 3 Boundary

Reporting processors should include all Scope 3 GHG emissions from each category to the extent feasible. Oftentimes, reporting processors may not be able to procure necessary data from various emission sources in their supply chain. As stated, reporting processors may include a transparent and justified explanation as a substitute. However, if certain Scope 3 categories in the dairy supply chain are significant sources of emissions, such as Purchased Goods and Services, reporting processors should report emissions data in this category. The GHG Protocol Corporate Value Chain Accounting and Reporting Standard Table 6.1 outlines the criteria that reporting entities should use to determine if each Scope 3 category is significant.

Several Scope 3 categories may not apply to the reporting processor. For example, smaller processors may not own franchises or have investments. In this case, it is permissible to either report zero emissions for these categories or simply state that the category is not applicable.

To ensure reporting processors account for all GHG emission sources, they should map their value chain in order to identify all relevant categories of their Scope 3 inventory. The map should include a list of dairy farmers and the milk volumes purchased from each farm.

(Figure 2.1) Common Scope 1, 2 and 3 emission sources in the dairy processing industry

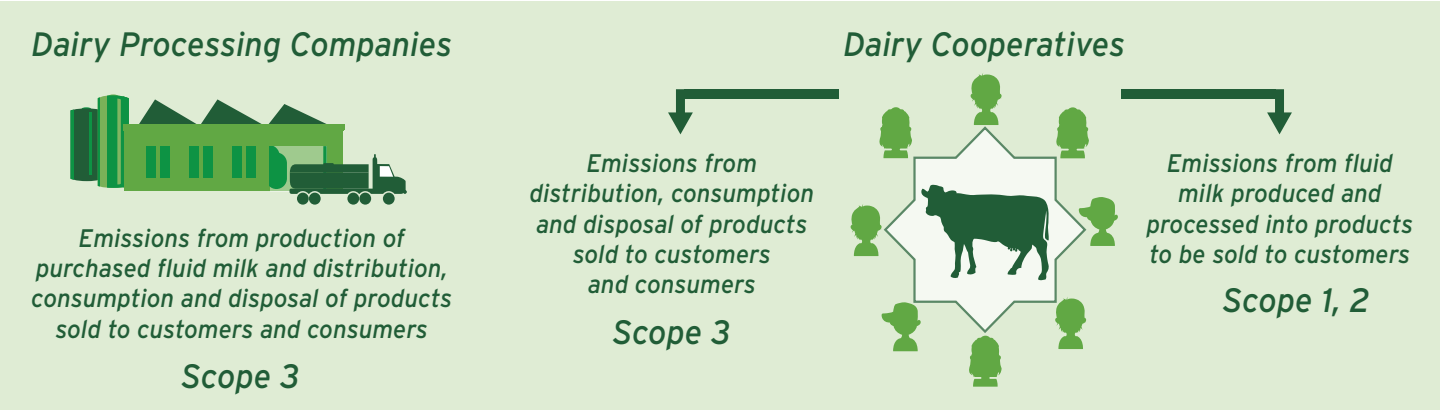
© 2024 Innovation Center for U.S. Dairy. All rights reserved.

This value chain map can be achieved by contacting suppliers and obtaining relevant on-farm data relative to GHG emissions categories. The FARM Environmental Stewardship Program (discussed in more detail in Scope 3: Purchased Goods and Services, (page 11) is particularly useful for obtaining this data. In addition, the reporting processor should procure a list of the types and quantities of the different dairy products it sells.

For the Scope 3 categories that do apply to reporting processors, abiding by this guidance will ensure that the minimum boundary of GHG emissions are accounted for. However, reporting processors may consult Table 5.4 of the GHG Protocol Corporate Value Chain Accounting and Reporting Standard for more details.

To account for changing supply chain partners over time, reporting processors should select a fixed starting date to encompass all Scope 3 emissions over the reporting year. For example, one option is to sync the reporting of Scope 3 accounting at the start of the processor's fiscal year. This is a processor decision. Regardless of the fixed starting date, the Scope 3 boundary should account for the company's emissions over one full year (i.e., January 1 through December 31).

When utilizing this guidance resource, reporting processors should select their start date and account for emissions from that date until the same date the following year. Reporting processors may find it easiest to set their fixed starting date for the reporting year at the outset of the accounting exercise.



Collecting Data

Scope 1 and Scope 2 data are often much easier to collect as opposed to Scope 3. This is due to the greater amount of external engagement reporting processors must do in order to procure the information necessary to complete a Scope 3 inventory. As a result, the GHG Protocol Corporate Value Chain Standard recommends prioritizing data collection efforts that are likely to contribute most significantly to the reporting processor's Scope 3 GHG emissions.

In the dairy industry, the largest proportion of GHG emissions arise from on-farm activities such as enteric emissions, feed production and manure management. From the reporting processor's perspective, these emissions would be categorized in the Scope 3: Purchased Goods and Services section since these on-farm practices are directly related to producing raw milk that ultimately ends up at processing plants. Many dairy cooperatives process significant portions of the fluid milk they produce; therefore, this is a crucial differentiation to note when composing a Scope 3 inventory. Figure 2.2 clearly depicts which scopes of GHG emissions apply to different dairy processing business scenarios.

As for the other categories, relative proportions of Scope 3 GHG emissions are subjective to each individual reporting processor. For example, some reporting processors, which manufacture a wide variety of dairy products, have more processing facilities than others and, as a result, have a larger quantity of capital goods, waste, and/or distribution networks. To determine their Scope 3 priorities, they may conduct a Scope 3 screening to estimate which categories contribute most significantly to their overall inventory.

The GHG Protocol outlines other methods of prioritizing data collection. This guidance, however, strongly recommends conducting a Scope 3 screening and prioritization based on the magnitude of requests from larger consumer-facing companies seeking granular data from processors' activities.

(Figure 2.2) Differentiating GHG emissions between dairy processing companies and dairy cooperatives

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

In its calculations, Scope 3 uses the same emission factor approach as Scopes 1 and 2. The emission factors, however, are different and could come from an Environmentally-Extended Input Output (EEIO) life cycle database to account for all phases of the emissions' lifetime. (See page 1, List of Terms)

When possible, reporting processors should collect primary data, which is sourced from specific activities throughout their own value chain. However, this may not be possible as certain companies upstream and/or downstream in the value chain may not be able to supply the reporting processor with primary data. In this case, reporting processors may use secondary data, which is less specific, but gives an industry-average estimation of the GHG emissions from specific activities based on magnitude. Refer to the GHG Protocol Corporate Value Chain Accounting and Reporting Standard (Table 7.3) for additional guidance and explanation on primary and secondary data.

Allocating Emissions

In many instances, reporting processors may receive a certain proportion of suppliers' fluid milk, as farms may sell their milk to numerous customers. Additionally, reporting processors often distribute their dairy products to different customers and retailers.

This dynamic receiving and distributing setup in the dairy processing industry makes allocation necessary. Allocation is the process of partitioning the emissions from various categories based on the quantity or amount of goods or products purchased/sold. According to the GHG Protocol Corporate Value Chain Standard, there are two scenarios where allocation is necessary. (See Table 2.2)

The GHG Protocol strongly urges reporting entities to avoid allocation whenever possible. This is because allocating emissions adds uncertainty to calculations. Allocation is avoided by collecting granular data. The best approaches to collect granular data are:

- Obtain GHG data from value chain companies on dairy products purchased or sold specifically
- Sub-meter energy use and other activity data where possible
- Use engineering models to estimate emissions from each produced dairy product

For reporting processors that must allocate emissions for certain Scope 3 categories, additional guidance and examples are provided in Chapter 8 of the Corporate Value Chain Accounting and Reporting Standard. Specifically, reporting processors may find Table 8.2 particularly useful to determine if allocation is necessary, as this graphic depicts examples of the data necessary. (Table 8.2 shows examples of data need and the allocation method to use.)

Setting a Target and Tracking Emissions Over Time

Reporting processors may choose to set a Scope 3 reduction target and track emissions reductions over time. In the U.S. dairy industry, large consumer-facing dairy purchasing companies, most likely, will be interested in setting targets and tracking emissions over time. This is due to the fact that these companies are larger than the majority of dairy processing companies and therefore, have a much larger Scope 3 GHG footprint. Also, while the majority of dairy processing companies are privately owned, many dairy buyers are publicly traded and face increased shareholder requirements for public, non-financial disclosure of topics such as GHG emissions.

Allocation Scenarios in Dairy Processing

Allocation Scenario	Example
One facility/activity/vehicle/production line/business unit produces multiple outputs	The same dairy processing plant produces milk and cheese
Emissions are only quantified for an entire facility/activity/vehicle/production line/business unit, rather than fractionally	A dairy customer only purchases yogurt from a processing company that manufactures milk, cheese, yogurt and whey OR A processor purchases only a subset of a given supplier's milk

(Table 2.2) Common allocation scenarios and examples in U.S. dairy

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

As mentioned in the introduction, the primary purpose of this guidance is to assist dairy processors in accurately measuring their Scope 3 GHG emissions to accommodate the needs and requests of larger dairy purchasers. The Science Based Targets Initiative (SBTi) requires companies to set Scope 3 targets whenever Scope 3 emissions represent greater than 40 percent of total emissions (Scope 1 + Scope 2 + Scope 3 emissions combined). Additionally, SBTi requires businesses with SBTs in land-intensive sectors, such as dairy, to set forest, land and agriculture (FLAG) targets — a near-term and long-term target related to land-based emissions reductions and removals. Large dairy customers, such as supermarkets, are increasingly requesting suppliers to set SBTs as part of the customers' own SBT commitments. Therefore, reporting processors may consult Chapter 9 of the Corporate Value Chain Accounting and Reporting Standard for information regarding GHG reduction target setting and tracking over time.

Verifying/Assuring Emissions

Similar to setting targets and tracking progress, assurance is optional in the Scope 3 inventory process as well. However, when feasible, reporting processors should attempt to verify their Scope 3 inventory. Doing this will increase both the processing company's and other stakeholders confidence that the Scope 3 inventory abides by the GHG Protocol reporting principles of completeness, accuracy, consistency, transparency and relevance.

The two most common forms of assurance are first-party assurance and third-party assurance. First-party assurance involves people from within the reporting processing company who were not directly a part of measuring and quantifying the Scope 3 inventory. Third-party assurance involves people from an external organization who were not a part of composing the Scope 3 inventory, nor who are affiliated with the reporting entity.

If the reporting processor decides to conduct an assurance process of its Scope 3 inventory, this guidance recommends utilizing a third-party verifier. This ensures more independence from the reporting company, mitigating any bias or conflict of interest that may arise from a first-party audit. Chapter 10 of the GHG Protocol Corporate Value Chain Accounting and Reporting Standard contains guidance on how to properly conduct the assurance process.

Reporting Emissions

This guidance strongly recommends that reporting processors publicly disclose their comprehensive GHG inventory through the CDP (formerly Carbon Disclosure Project) Climate Change Questionnaire.

The CDP is a globally-recognized nonprofit organization that collects and externally displays environmental performance data from companies, cities, states and regions so that investors and purchasers may make informed decisions and identify sustainability strategies. The CDP has three questionnaires — Forestry, Water and Climate Change — that various reporting organizations may utilize to disclose their environmental metrics. The Climate Change Questionnaire collects information related to GHG emissions specifically and represents a credible and renowned platform by which dairy processors may effectively report their Scope 1, 2 and 3 GHG inventory.

The Climate Change Questionnaire includes an array of both qualitative and quantitative questions. The quantitative questions request GHG metrics that are specific to the reporting entity. Many of the qualitative questions, however, request information that pertains to the U.S. dairy industry as a whole. As a result, reporting processors may consult the CDP Climate Change Questionnaire Response Guidance to guide their CDP Climate Change responses and/or to familiarize themselves with the types of responses that are sufficiently detailed for the CDP questionnaire.

As for the quantitative CDP Climate Change questions, the GHG inventory information collected and calculated in the U.S. dairy processing Scope 1, 2 and 3 accounting and reporting guidance literature is sufficient. This guidance literature abides by the GHG Protocol Corporate Standard and/or Corporate Value Chain Standard, identified by the CDP as a robust and acceptable protocol by which to account for and calculate GHG emissions.

Chapter 11 of the GHG Protocol Corporate Value Chain Accounting and Reporting Standard includes more detailed information on the required and optional GHG information a reporting processor must and may include in its GHG inventory disclosure.

Scope 3: Purchased Goods and Services

Chapter at a Glance

- Defining Purchased Goods and Services
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance

This section provides guidance on how to identify and account for Scope 3 indirect GHG emissions from dairy processors' purchased goods and services upstream in the value chain.

1

Defining Purchased Goods and Services: The Purchased Goods and Services Scope 3 category captures "cradle-to-gate" GHG emissions from all products purchased by the reporting processor in the reporting year. In other words, any and all GHG emissions created from producing products and/or services up to when they leave the farm are accounted for under the Purchased Goods and Services category. This excludes any emissions from sources owned or controlled by the processor (for example farm operations owned by the cooperative organization).[2] Therefore, Scope 3: Purchased Goods and Services captures the GHG emissions associated with the on-farm production of raw milk that the reporting processor purchases (a purchased good). GHG emissions from the Purchased Goods and Services category account for roughly three quarters of the industry's total emissions; therefore, accurate and detailed accounting and reporting procedures for this category are paramount.

Dairy processors may also purchase an array of other goods and/or services necessary to further process fluid milk into products like cheese and yogurt. Although it is beyond the scope of this guidance document, the Scope 3 GHG emissions from Purchased Goods and Services for products other than fluid milk also must be calculated in order to produce a complete summary of GHG emissions from this category.

2

Identifying Sources: Raw milk generally comprises the largest portion of goods purchased from dairy suppliers, and the on-farm processes necessary to produce raw milk are the largest contributor of dairy supply chain GHG emissions. A more detailed breakdown of the dairy production processes and the main GHG emissions associated with each process are included below:

GHG Emissions Associated with On-Farm Milk Production Processes

Process	GHG Emissions Generated
Nitrogen fertilizer production	CO_2
Manure and chemical crop fertilizer application	N_2O
Manure/urine deposition on pasture crops	N_2O
Energy consumption in field operations, drying and processing of feed crops and fodder	CO_2
Crop processing into by-products and concentrates	CO_2
Feed transport from production site to feeding site	CO_2
Enteric fermentation from ruminant cows	CH_4
Direct and indirect emissions from manure storage	CH_4 and N_2O

(Table 3.0) Processes involved in producing raw milk upstream from the processing phase of the dairy value chain and their associated GHG emissions

continued on next page

Scope 3: Purchased Goods and Services

2

As mentioned above, the U.S. dairy industry's largest source of GHG emissions comes from the farm. More specifically, a comprehensive life cycle assessment for fluid milk[7] conducted by the Innovation Center for U.S. Dairy found that GHG emissions in the U.S. dairy industry are divided into proportions identified in Table 3.1.

U.S. Dairy Industry Fluid Milk GHG Emissions Allocation	
Fluid Milk Production Process	Approximate GHG Emissions
Enteric Emissions	26%
Manure Management	25%
Feed Production	20%
Refrigeration and Packaging	9%
Distribution, Retail and Consumer	20%

(Table 3.1) Approximate source allocation of U.S. dairy GHG emissions according to comprehensive fluid milk LCA

Enteric emissions, manure management and feed production alone comprise over 70 percent of the entire industry's GHG emissions. From a reporting processor's perspective, these areas are considered Scope 3: Purchased Goods and Services. Accurately accounting for and quantifying emissions from this category is an extremely important component of a reporting processor's Scope 3 inventory. An updated U.S. dairy cradle-to-processing gate life cycle assessment (202 baseline) is currently being conducted, and updated GHG emissions allocations will be published in 2025.

NOTE: GHG emissions from conversion of land for crop growing (land use change) should also be reported. However, these emissions should be reported in a special "Biogenic Carbon" category that is not included in Scope 1, 2, or 3, but rather as a separate category (see GHG Protocol's Land Sector and Removals Guidance).

3

Collecting Activity Data: In order to account for and quantify Scope 3: Purchased Goods and Services, this guidance recommends using the Supplier-Specific method, which entails collecting farm level data from each milk supplier. This method is designed to collect more granular data from value chain emissions because it captures specific information associated with each purchased good or service.

4

Data Collection Guidance: This guidance recommends utilizing the FARM Environmental Stewardship program, managed by the National Milk Producers Federation. This on-farm evaluation collects data on milk production, herd size, energy, crop and feed production and manure management through a limited set of questions. The tool allows dairy cooperatives and processors to obtain accurate and specific data necessary to generate a scientifically robust estimate of Scope 3 GHG emissions from the production of raw milk, while reducing the burden on farmers. Collecting and then aggregating accurate farm-level data associated with all of the processes involved in producing raw milk will reflect a comprehensive Scope 3: Purchased Goods and Services inventory associated with dairy processors' purchased raw milk.

If the reporting cooperative or processor is a large company that sources from many different farms, the FARM Environmental Stewardship module has a sampling protocol that is based on the "stratified random sampling" concept. It takes a number of factors into account to generate an on-farm GHG footprint that is applicable and representative of the entire reporting processor's supplier footprint. This eliminates the need for larger reporting processors to obtain supplier-specific data from all of its farms, which may pose a significant logistical and financial burden.

NOTE: Data collection guidance for Purchased Goods and Services is based on the FARM Environmental Stewardship module. FARM ES calculations are based on a whole-farm model that simulates dairy farm production and environmental impact. For details on the model's methodologies and scope, visit the FARM website.

Scope 3: Capital Goods

Chapter at a Glance

- Defining Capital Goods
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from the production of capital goods procured by the reporting processor in the reporting time frame.

1

Defining Capital Goods: The Greenhouse Gas Protocol defines capital goods as "final products that have an extended life and are used by the company to manufacture a product, provide a service, or sell, store, and deliver merchandise."[1] This category captures emissions associated with the production and manufacturing of capital goods used in the reporting processor's direct operations. The only Scope 3: Capital Goods emissions that need be accounted for are from newly purchased and/or acquired capital goods in the reporting year. Capital goods previously owned before the reporting year should not be included in this section.

2

Identifying Sources: Common capital goods that dairy processors use to produce retail-ready milk and other dairy products are listed below. The arrow represents the chronology associated with dairy processing from raw milk receiving through producing retail-ready milk.

Common Capital Goods in U.S. Dairy Processing	
Processing Stage	Capital Good
Raw Milk Inflow	Holding Tanks
	Filters
	Separators
	Standardizers
Pasteurization	Boilers
	Combustion Turbines
	Process Heaters
	Cooling Equipment
Homogenization	Homogenizers
Finishing and Packaging	Automated Fillers
	Cold Storage Tanks
	Forklifts and Other Off-Road Equipment
Other	Air Conditioning Equipment

Chronological Process

(Table 4.0) Common capital goods in U.S. dairy processing to be accounted for in Scope 3: Capital Goods

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Capital Goods

3

Collecting Activity Data: Dairy processing is rather infrastructure-heavy throughout the processing phase, demanding an array of machines and equipment to transform the raw milk brought in from the farm into consumer-ready products. Therefore, emissions from capital goods may be a significant source of Scope 3 emissions in the value chain. In order to collect robust product-level data on each capital good, the GHG Protocol recommends using the Supplier-Specific method. However, it may be often difficult for reporting processors to consult each and every capital good supplier for GHG inventory data specific to each piece of equipment. Therefore, this guidance recommends using the Hybrid method, which is a balance between acquiring capital good supplier-specific activity data when available and using industry average data to fill in gaps. For each capital good, the reporting processor should try to obtain as much of the following information as possible:

Supplier-Specific Methodology for Capital Goods Activity Data	
Capital Good Supplier Activity Data Category	Activity Data to Collect
Fuel and Electricity Information	Capital good suppliers allocated Scope 1 and 2 data (see Chapter 8 of the GHG Protocol Scope 3 Standard and the Innovation Center's Scope 1 and 2 GHG Inventory Guidance for additional guidance)
Raw Material Information	Mass/volume of material inputs, mass/volume of fuel inputs, distance from origin of raw material inputs to capital good manufacturer
Waste Information	Capital good suppliers waste output quantities in capital good manufacturing

(Table 4.1) Activity data to be collected on capital goods using the Supplier-Specific method. This methodology should be used first to obtain all relevant information available from the reporting processor's capital goods suppliers. Then, secondary data may be used to fill in remaining gaps.

4

Data Collection Guidance: Similar to Scope 3: Purchased Goods and Services, reporting processors may consult several internal resources as a means of procuring primary activity data from their capital goods suppliers. These resources include:

- Internal data systems
- Publicly available GHG reports detailing emissions from sourcing and manufacturing capital goods
- User manuals

Capital goods, which may not have readily available supplier-specific data, may have to use secondary emission factors to fill the gaps where primary activity data is not included. It is important to note that if the reporting processor uses secondary emission factors, it must disaggregate and then overwrite them with supplier-specific data. For example, if the reporting processor collects supplier-specific data only on Scope 1, Scope 2 and waste, all other emissions associated with said capital goods must be estimated using secondary data. Specific equations necessary for factoring in disaggregation of secondary emission factors are included in the Calculation Approach section.

Relevant emission factors can be found in the following sources:

- GHG Protocol website
- Supplier-developed emission factors (if the capital good supplier conducted an LCA study on its products)
- Life cycle databases
- Industry associations
- Government or multilateral agencies

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Capital Goods

5

Calculation Approach: Reporting processors may use the equation (below) as a baseline calculation to quantify GHG emissions from capital goods. The equation assumes that the reporting processor's capital good supplier(s) only have supplier-specific data on Scope 1, Scope 2 and waste emissions, and all other GHG emissions data associated with the production of said capital good must be accounted for using secondary data.

Equation for All Capital Goods Purchased

Σ Allocated Scope 1 and Scope 2 Emissions of Capital Good Supplier (kg CO_2e)

PLUS (+)

Σ Mass of Waste Generated from Capital Good Production (kg) **X** Waste Activity Emission Factor (kg CO_2e/kg)

PLUS (+)

Σ Quantity of Capital Good (kg, units, $) **X** Capital Good Emission Factor (Excluding Scope 1, Scope 2 and Waste Emissions Generated by Producer) (kg CO_2e/kg or unit or $)

If the reporting processor is able to procure 100 percent of the supplier-specific data, leaving no need for gaps to be filled in with secondary data, the following equation should be used.

Equation for All Capital Goods Purchased

Σ Allocated Scope 1 and Scope 2 Emissions of Capital Good Supplier (kg CO_2e)

PLUS (+)

Σ Mass or Quantity of Material Inputs for Capital Good Production (kg) **X** Cradle-to-Gate Emission Factor for Material (kg CO_2e)

PLUS (+)

Σ Transport Distance of Material Inputs to Capital Good Supplier (km) **X** Mass or Volume of Material Input (tons or TEUs) **X** Cradle-to-Gate Emission Factor for Capital Good Delivery Vehicle Type (kg CO_2e/ton or TEU/km)

PLUS (+)

Σ Mass of Waste Generated from Capital Good Production (kg) **X** Waste Activity Emission Factor (kg CO_2e/kg)

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Fuel and Energy Related Activities

Chapter at a Glance

- Defining Fuel and Energy
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from the production of fuel and energy that the reporting processor purchases.

1

Defining Fuel and Energy Related Activities: This category accounts for emissions from purchased fuels and electricity much like Scope 1 and 2. However, the key difference is that the reporting processor's Scope 3 GHG emissions from purchased fuel and electricity comprise those emissions arising from the extraction, production and transportation of the fuel and electricity that it purchases, not the consumption. For example, if a reporting processor consumes 100 kWh of fuel, and 200 kWh of electricity in the reporting year, then its Scope 3: Fuel and Energy Related Activities inventory would be the GHG emissions associated with extracting, producing and distributing that quantity of fuel and electricity over a given distance to the reporting processor (end consumer). Therefore, it is important for the reporting processor to use emission factors that exclude GHG emissions from combustion in their calculations.

2

Identifying Sources: Table 5.0 (below) gives a more detailed depiction of the upstream fuel and electricity production activities relevant to reporting processors:

Scope 3 Fuel and Energy Related Emissions Sources

Emission Source	Description	Example
Purchased Fuels	Extraction, production and transportation of fuels	Coal mining, gasoline refining, biofuel production, natural gas distribution
Purchased Energy	Extraction, production and transportation of fuels used to produce electricity, steam, heating, and cooling	Coal mining, fuel refining, natural gas extraction
Transmission & Distribution Losses	Fuel and/or electricity that escapes either in generation at the plant, or in transmission to the reporting processor	Electricity loss through the transmission line due to resistance

(Table 5.0) Upstream fuel and energy production processes that represent Scope 3 sources to dairy processors

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Fuel and Energy Related Activities

3

Collecting Activity Data: Quantifying a wholly representative Scope 3: Fuel and Energy Related Activities inventory requires several equations, each demanding different activity data and different emission factors. The appropriate activity data that corresponds to each emission source is included in Table 5.1 (below).

Relevant Activity Data and Emission Factors for Scope 3: Fuel and Energy Related Activities

Emission Source	Activity Data Needed	Emission Factor Needed
Purchased Fuels	Type and amount of all fuels directly consumed	Fuel provider-specific – for extraction, production and transportation per unit of fuel consumed at processing facility, by fuel type and region
Purchased Energy	Quantities of electricity, steam, heating and cooling purchased (sub-divided by supplier, or grid region)	Utility-specific – for extraction, production and transportation of fuels consumed by processing facility per MWh of electricity/ steam/heat/cooling generated Available in eGRID2016 Datafile (XLSX) EPA eGRID sub-region emission factor database
Transmission & Distribution Losses	Electricity, steam, heating and cooling per unit of consumption; divided by grid region	Utility-specific – transmission & distribution loss rate, specific to grid where processing facility's energy is generated and consumed Available in EPA eGRID sub-region emission factor database

(Table 5.1) Activity data and emission factors to be collected to compose a full account of Scope 3: Fuel and Energy Related Activities inventory

4

Data Collection Guidance: For Purchased Fuels: Reporting processors may reference a number of resources to obtain this activity data, such as:

- Reporting processor's own Scope 1 inventory
- Fuel suppliers

Emission factor resources (if necessary):

- Life cycle databases, available on the GHG Protocol website
- EPA eGRID database

For Purchased Electricity: This category requires that the reporting processor disaggregate the total quantity of electricity, steam, heat or cooling purchased by either supplier, or grid region. Resources for this data are as follows:

- Reporting processor's own Scope 2 inventory
- Government agency energy management departments
- Energy suppliers/generators

continued on next page

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Fuel and Energy Related Activities

4

Emission factor resources:

- Supplier-developed emission factors
- Life cycle databases, available on the GHG Protocol website
- EPA eGRID database

For Transmission & Distribution (T&D) Losses: This category requires that the reporting processor apply the percentage of transmission and distribution losses to the total quantity of electricity, steam, heat, or cooling purchased. Resources for this data are as follows:

- Reporting processor's own Scope 2 inventory
- Resources for transmission and distribution loss percentages
- EPA eGRID database

5

Calculation Approach: This guidance recommends using the Supplier-Specific method for all three emission sources within this category. This method involves collecting fuel, electricity and T&D loss rates data specifically from the reporting processor's suppliers. The corresponding equations for each emission source are included below.

Once the reporting processor has accounted for GHG emissions from all three sources in this category, the individual source totals may be aggregated to quantify the complete Scope 3: Fuel and Energy Related Activities inventory.

Equation for For Purchased Fuels

Σ (Fuel Consumed (kWh, m^3, etc.) **X** Upstream Fuel Emission Factor (kg CO_2e/kWh, m^3, etc..))
Where: Upstream Fuel Emission Factor **=** Life Cycle Emission Factor **-** Combustion Emission Factor

Equation For Purchased Electricity

Σ (Electricity Consumed (kWh) **X** Upstream Electricity Emission Factor (kg CO_2e/kWh))

PLUS (+)

(Steam Consumed (kWh) **X** Upstream Steam Emission Factor (kg CO_2e/kWh))

PLUS (+)

(Heat Consumed (kWh) **X** Upstream Heat Emission Factor (kg CO_2e/kWh))

PLUS (+)

(Cooling Consumed (kWh) **X** Upstream Cooling Emission Factor (kg CO_2e/kWh))
Where: Upstream Emission Elec./Steam/Heat/Cooling Emission Factor **=** Life Cycle Emission Factor **-** Combustion Emission Factor **-** Transmission & Distribution Losses

NOTE: The ∑ in this equation represents summing across either electricity suppliers or regions.

Scope 3: Upstream Transportation and Distribution

Chapter at a Glance

- Defining Transportation and Distribution
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

*This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from transportation and distribution of products purchased by the reporting processor from its Tier 1 suppliers.**

TIP: *Tier 1 suppliers refer to the farms where the reporting processor has a purchase order for goods and services.

1

Defining Upstream Transportation and Distribution: Upstream transportation and distribution refers to the transportation and distribution services that the reporting processor purchases over the reporting period. Any transportation and distribution service not purchased by the reporting processor is classified as downstream transportation and distribution. Therefore, if the reporting processor hires an external company owning its own fleet of delivery trucks to distribute the processor's products, the GHG emissions from those trucks would constitute the reporting processor's Scope 3: Upstream Transportation and Distribution emissions. However, if the reporting processor does not purchase the transportation and distribution service, the resultant GHG emissions would be accounted for in Scope 3: Downstream Transportation and Distribution.

Furthermore, if the reporting processor's Tier 1 supplier purchases from a supplier as well (the reporting processor's Tier 2 supplier), emissions from the transportation and distribution between the Tier 1 and 2 suppliers are accounted for in Scope 3: Purchased Goods and Services.

2

Identifying Sources: Much like the Scope 1: Mobile Combustion Emissions guidance, accounting for Scope 3: Upstream Transportation and Distribution emissions sources involves identifying the mobile emission sources in the reporting processor's value chain that are owned and/or operated by other companies.

Common Mobile Emission Sources in U.S. Dairy Transportation and Distribution

Common Scope 3 Mobile Combustion Sources		Common Fuels Used
On-Road Vehicles	Combination trucks and fluid milk trucks	Diesel fuel, gasoline, biodiesel
Non-Road Vehicles (Mobile Machinery)	Forklifts and non-road equipment	Diesel fuel, gasoline, propane
	Construction equipment	Diesel fuel

(Table 6.0) Common Scope 3 mobile emission sources and accompanying fuels used in the dairy value chain

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Upstream Transportation and Distribution

3

Collecting Activity Data: Again, like Scope 1: Mobile Combustion Emissions, key activity data is needed to calculate Scope 3: Upstream Transportation and Distribution emissions. Fuel use data or distance-traveled data can both be used for calculating Scope 3: Upstream Transportation and Distribution GHG emissions. If the distance-traveled approach is used, some additional information on the vehicle characteristics is required.

Activity Data for Mobile Emission Calculations	
Data Type	Common Fuels Used
Vehicle Characteristics	Type and model year
Distance Traveled	Miles, kilometers
Fuel Type	Gasoline, diesel, fuel oil, CNG, LNG, LPG
Fuel Amount	Gallon, liter, barrel, cubic foot, cubic meter

(Table 6.1) Activity data to be collected for each mobile combustion emissions source not owned or operated by the reporting processor

4

Data Collection Guidance: Sources for activity data necessary to calculate Scope 3: Upstream Transportation and Distribution data include:

- Aggregated fuel receipts from suppliers
- Purchase records from suppliers
- Internal transport management systems[3]

5

Calculation Approach: Use the GHG Protocol Mobile Combustion GHG Emissions Calculation Tool as in the Scope 1: Mobile Combustion Emissions guidance. Ensure that "Scope 3" is selected under the "Scope" column in the "Activity Data" tab. This tool developed by the GHG Protocol, has the appropriate emissions factors built in. It automatically calculates Scope 3 emissions from transportation and distribution so long as the appropriate activity data is included.

If the reporting processor chooses to use an alternate method of calculating Scope 3: Upstream Transportation and Distribution emissions, data sources for appropriate emission factors include[5]:

- Transportation carriers
- Government agencies (i.e., EPA, IPCC)
- The Climate Registry
- GHG Protocol website
- Industry associations

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Waste Generated in Operations

Chapter at a Glance

- Defining Operations
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from disposal and treatment of waste generated by the reporting processor.

1

Defining Waste Generation in Operations: This Scope 3 category specifically captures emissions generated from the handling and disposal of waste generated in the reporting processor's owned and/or operated facilities. It is important to note that CO_2 emissions from biomass materials are reported outside of the scopes in a separate memo item. Since much of dairy processing waste is generated from biomass materials, reporting processors should account for CO_2 emissions from waste in an appended memo. However, CH_4 (methane) and N_2O (nitrous oxide) emissions are still accounted for in the scopes for this category. Furthermore, this category accounts for all future emissions deriving from the reporting processor's waste in the reporting year.

U.S. dairy processing generally yields little solid waste, making this a rather insignificant Scope 3 source for reporting processors. However, the American dairy processing industry does generate significant quantities of wastewater that produce GHG emissions when treated and/or disposed of.[4] Undoubtedly, reporting processors will produce varying quantities of wastewater depending on the number of processing facilities and the type of dairy products produced.

2

Identifying Sources: Table 7.0 identifies key procedures in the dairy processing industry that produce waste. Depending on the dairy products produced by the reporting processor, these waste sources may or may not apply. Reporting processors should consult the table based on products produced.

Source: UNFAO

Typical U.S. Dairy Processes that Produce Waste

Dairy Process	Waste Source	Waste Type
Milk Receiving	Storage tank washing, pipeline washing and sanitizing	Wastewater
Whole Milk Processing	Cleaning operations between product changes	Wastewater
Cheese/Whey/Curd Processing	Whey production, wash water, curd particles	Wastewater
Butter/Ghee Processing	Butter washing	Wastewater
Milk Powder Processing	Cleaning, fine dust emission from drying	Wastewater
Condensed Milk/Cream/Khoa Processing	Coagulated milk, fine cheese curd particles	Wastewater
Wastewater Purification	Resulting sludge after purification	Solid Waste

(Table 7.0) Waste-producing processes typical of the U.S. dairy industry's processing activities

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Waste Generated in Operations

3

Collecting Activity Data: This guidance recommends using the Waste-Type-Specific method to account for and calculate GHG emissions from the reporting processor's third-party handled waste. This entails differentiating between waste types and the disposal method for each waste type. Reporting processors should collect the following:

- Waste produced per quantity of product (i.e., m^3 of wastewater per gallon of fat and protein corrected milk)
- Different waste types associated with dairy processing
- Waste treatment applied to each waste type (i.e., landfill, wastewater treatment, recycling)

4

Data Collection Guidance: Third-party waste handlers often charge companies based on method of waste disposal, so this is a relatively easy way for reporting processors to identify waste disposal methods that apply. Waste management bills often contain this specific information. Furthermore, appropriate emission factors necessary for calculating operation-derived waste can be found in a variety of databases, including:

- IPCC Guidelines
- Life cycle databases
- Industry associations

If a third-party waste handler does not charge based on waste disposal method, this guidance recommends using the Average-Data method. It involves using average emission factors for each disposal method (i.e., landfill) and multiplying these emission factors by quantities of each waste type.

5

Calculation Approach: Reporting processors may use the calculation equation below to account for Scope 3: Waste Generated in Operations.

Once the reporting processor applies this equation for each waste type, simply aggregating the CO_2e for each waste type will yield the total GHG emissions from waste management. Alternatively, reporting processors may utilize the U.S. EPA's Waste emission factors in the Emission Factors Hub to quantify emission in this category.

Equation for Waste Generated in Operations
Σ (Waste Produced (tons or m^3) **X** Specific Emission Factor for Waste Type (kg CO_2e/ton or m^3))

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Upstream Leased Assets

Chapter at a Glance

- Defining Leased Assets
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from sources the reporting processor leases upstream in its supply chain.

1

Defining Upstream Leased Assets: If the reporting processor does not own all of its processing facilities and/or equipment, but rather leases them, the associated GHG emissions from these assets may be accounted for in this category depending on the GHG inventory consolidation approach utilized.

If the reporting processor has adopted the Operational Control approach, GHG emissions from operation of leased facilities/equipment are considered under Scope 1 and Scope 2, despite not being owned by the reporting entity. However, if another consolidation approach has been implemented, the Scope 3 emissions in this category include the Scope 1 and 2 emissions of the reporting processor's lessor(s).

2

Identifying Sources: GHG emission sources from leased assets can be calculated as detailed in the methodology for Scope 1 and 2 inventories. By aggregating Scope 1 and 2 emissions from all leased assets (buildings, equipment etc.), the reporting processor can clearly define its Scope 3: Upstream Lease Assets inventory.

GHG Emission Sources from Leased Assets		
Leased Asset	Emissions	Scope
Processing Facilities/Office Space	Fuel consumed, refrigerant leaked, process emissions	Scope 1
	Electricity consumed, steam consumed, heat consumed, cooling consumed	Scope 2
Equipment/Machines	Fuel consumed	Scope 1
	Electricity consumed	Scope 2

(Table 8.0) GHG emission sources from leased assets

3

Collecting Activity Data: This guidance recommends using the Asset-Specific method, outlined by the GHG Protocol Corporate Value Chain Standard. This method involves obtaining data specific to each and every asset that the reporting processor leases. For each leased asset, the reporting processor should collect activity data outlined in Table 8.0. If the reporting processor is unable to obtain the fuel and energy data associated with each leased asset, other methods of accounting for Scope 3: Upstream Leased Assets emissions can be found in the GHG Protocol Technical Guidance for Calculating Scope 3 Emissions.

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Upstream Leased Assets

4

Data Collection Guidance: Much like Scope 1 and 2 accounting, the necessary activity data for this category can be collected via many different methods:

- Utility bills
- Purchase records
- Meter readings
- Internal IT systems

Appropriate emission factors are available from an array of different sources as well, such as:

- The EPA GHG Emissions Factors Hub
- Life cycle databases
- Other government agencies such as the IPCC, and Climate Registry
- Industry associations
- Company-developed factors if applicable

5

Calculation Approach: The following equation represents the appropriate methodology for calculating Scope 3: Upstream Leased Assets using the Asset-Specific method:

Calculating Scope 3: Upstream Leased Assets using the Asset-Specific Method

Scope 1 Emissions from Upstream Leased Assets

(Fuel Consumed **X** Fuel Emission Factor (kg CO_2e/fuel unit)) **+** (Refrigerant Leakage (kg) **X** Refrigerant Emission Factor (kg CO_2e/kg))

PLUS (+)

Scope 2 Emissions from Upstream Leased Assets

(Electricity, Steam, Heating, Cooling Consumed (kWh)) **X** (Electricity, Steam, Heating, Cooling Emission Factor (kg CO_2e/kWh))

EQUALS (=)

Scope 3 Emissions from Upstream Leased Assets

Scope 3: Upstream Leased Assets Inventory **=** Σ Scope 3 Emissions from All Upstream Leased Assets

Reporting processors may use the GHG Emissions from Purchased Electricity, GHG Emissions from Stationary Combustion, and Refrigeration and Air-Conditioning Equipment Excel tools as resources to assist in quantifying emissions in this category. They all have built-in GHG Protocol emission factors in order to streamline GHG emissions from fuel, electricity, steam, heat, cooling and refrigeration.

If the reporting processor only leases a section or portion of the facility, and the facility lacks sub-metering infrastructure, then energy consumption may be allocated using an estimation based on the share of space the reporting processor leases (based on floor space). This may be calculated using the following equation:

Equation for Section or Portion Leases

(Reporting Processor's Used Space (m^2) **/** (Building's Total Area (m^2) **X** Building Occupancy Rate) **X** Total Building Energy Use (kWh)

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Downstream Transportation and Distribution

Chapter at a Glance

- Defining Transportation and Distribution
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from transportation and distribution of sold products not owned or operated by the reporting facility.

1

Defining Downstream Transportation and Distribution: Downstream Transportation and Distribution refers to the transportation and distribution services that the reporting processor does not purchase over the reporting period. Any transportation and distribution service purchased by the reporting processor is classified as Upstream Transportation and Distribution. Therefore, if the reporting processor receives or sells a product from/to another company that pays for all transportation and distribution needs, the GHG emissions from said transportation and distribution would constitute the reporting processor's Scope 3: Downstream Transportation and Distribution emissions.

Furthermore, emissions resulting from storage of the milk downstream from the reporting processor are accounted for in this category. For example, GHG emissions arising from leaking refrigerants, as well as fuel and/or electricity used to refrigerate the sold milk in the distribution trucks, are included in this category.

Differentiating Between Upstream and Downstream Transportation and Distribution in U.S. Dairy

Scenario	Entity	
	Reporting Processor	Retailer
If reporting processor does not pay for transportation of dairy products to retailer	Scope 3: Downstream Transportation and Distribution	Scope 3: Upstream Transportation and Distribution
If reporting processor does pay for transportation of dairy products to retailer	Scope 3: Upstream Transportation and Distribution	Scope 1 & 2 Or Scope 3: Downstream Transportation and Distribution

(Table 9.0) Differentiation of transportation and distribution of dairy throughout the U.S. dairy value chain

2

Identifying Sources: Much like the Scope 1: Mobile Combustion Emissions guidance, accounting for Scope 3: Downstream Transportation and Distribution emissions sources involves identifying the mobile emission sources in the reporting processor's value chain that are owned and/or operated by other companies.

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

continued on next page

Scope 3: Downstream Transportation and Distribution

2

Downstream Transportation and Distribution Emission Sources		
Downstream Activity	Infrastructure	Emission Source
On-Road Vehicles	Combination trucks and fluid milk trucks	Diesel fuel, gasoline, biodiesel
	In-truck refrigeration	Leaking refrigerants
Warehouses and Distribution Centers	Refrigeration	Purchased electricity, leaking refrigerants
Retail Facilities	Refrigeration	Purchased electricity, leaking refrigerants

(Table 9.1) Activity data to be collected for each mobile combustion emissions source not owned or operated by the reporting processor

3

Collecting Activity Data: Again, like Scope 1: Mobile Combustion Emissions, key activity data is needed to calculate Scope 3: Downstream Transportation and Distribution emissions. Use the Distance-Based method to quantify downstream transportation emissions, which requires the following activity data:

Activity Data for Mobile Emission Calculations	
Data Type	Information Needed
Vehicle Characteristics	Type and model year
Distance Traveled	Miles, kilometers
Fuel Type	Gasoline, diesel, fuel oil, CNG, LNG, LPG
Fuel Amount	Gallon, liter, barrel, cubic foot, cubic meter

(Table 9.2) Activity data to be collected for each mobile combustion emissions source not owned or operated by the reporting processor

Activity Data for Refrigerant Leakage	
Data Type	Information Needed
Type of Equipment	In-truck refrigeration, warehouse refrigeration, retail refrigeration
Refrigerant Used	HFC type, PFC type
Annual Leakage Rate	Percent
Total Refrigerant Charge	Pounds

(Table 9.3) Activity data to be collected for each refrigeration source not owned or operated by the reporting processor

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Downstream Transportation and Distribution

4

Data Collection Guidance: Sources for activity data necessary to calculate Scope 3: Downstream Transportation and Distribution data include:

- Aggregated fuel receipts from customers
- Purchase records from customers
- Internal transport management systems[3]
- Retailer equipment records
- Third-party transportation fleet records
- Life cycle databases

5

Calculation Approach: Use the GHG Protocol Mobile Combustion GHG Emissions Calculation Tool as in the Scope 1: Mobile Emissions guidance. However, this time ensure that "Scope 3" is selected under the "Scope" column in the "Activity Data" tab. This tool, developed by the GHG Protocol, has the appropriate emission factors built in. It automatically calculates Scope 3 emissions from transportation and distribution so long as the appropriate activity data is input.

To calculate emissions from refrigeration throughout the downstream value chain, reporting processors may utilize the GHG Protocol Refrigeration and Air-Conditioning Equipment calculation tool. It has built-in emissions factors for calculating refrigerant emissions and offers a variety of methods with instructions.

If the reporting processor chooses to use an alternate method of calculating Scope 3 upstream transportation and distribution emissions, data sources for appropriate emission factors include[5]:

- Transportation carriers
- Government agencies (i.e., EPA, IPCC)
- The Climate Registry
- GHG Protocol website
- Industry associations

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Downstream Leased Assets

Chapter at a Glance

- Defining Leased Assets
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from owned assets that the reporting company leases to other parties.

1

Defining Downstream Leased Assets: This category accounts for emissions from leased assets that the reporting processor owns and rents to other companies. Although uncommon in the dairy processing industry, there may be occasions where a cooperative or large processing company leases one or several of its facilities and/or equipment to other companies. Contrary to Scope 3: Upstream Leased Assets, the reporting processor is the lessor in this category, which captures GHG emissions from any and all facilities, or equipment that are generated by the lessee.

Similar to Scope 3: Upstream Leased Assets, GHG emissions from owned, but not operated assets may be considered under Scope 1 or Scope 2 for the lessor, depending on the reporting processor's consolidation approach. Furthermore, this category of GHG emissions mirrors Scope 3: Upstream Leased Assets in that the leasing company's Scope 1 and 2 GHG emissions associated with the asset(s) are equivalent to the Scope 3: Downstream Leased Assets for the reporting processor.

2

Identifying Sources: By aggregating leasing companies' Scope 1 and 2 emissions from all reporting processor-owned assets (buildings, equipment etc.), the reporting processor can clearly define its Scope 3: Upstream Lease Assets inventory.

GHG Emission Sources from Leased Assets		
Leased Asset	Emissions	Scope
Processing Facilities/Office Space	Fuel consumed, refrigerant leaked, process emissions	Scope 1
	Electricity consumed, steam consumed, heat consumed, cooling consumed	Scope 2
Equipment/Machines	Fuel consumed	Scope 1
	Electricity consumed	Scope 2

(Table 10.0) GHG emission sources from leased assets

3

Collecting Activity Data: This guidance recommends using the Asset-Specific method, outlined by the GHG Protocol Corporate Value Chain Standard. This method involves obtaining data that is specific to each and every asset that the reporting processor is the lessor to. For each asset, the reporting processor should collect activity data outlined in Table 10.0. If the reporting processor is unable to obtain the fuel and energy data associated with each asset, other methods of accounting for Scope 3: Downstream Leased Assets emissions can be found in the GHG Protocol Technical Guidance for Calculating Scope 3 Emissions.

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Downstream Leased Assets

4

Data Collection Guidance: Much like Scope 1 and 2 accounting, the necessary activity data for this category can be collected via many different methods:

- Utility bills
- Purchase records
- Meter readings
- Internal IT systems

Appropriate emission factors are available from an array of different sources as well, such as:

- The EPA GHG Emissions Factors Hub
- Life cycle databases
- Other government agencies such as the IPCC, and Climate Registry
- Industry associations
- Company-developed factors if applicable

5

Calculation Approach: The following equation represents the appropriate methodology for calculating Scope 3: Downstream Leased Assets using the Asset-Specific method. It is the same methodology for Scope 3: Upstream Leased Assets:

Calculating Scope 3: Downstream Leased Assets using the Asset-Specific Method

Scope 1 Emissions from Upstream Leased Asset

(Fuel Consumed **X** Fuel Emission Factor (kg CO_2e/fuel unit)) **+** (Refrigerant Leakage (kg) **X** Refrigerant Emission Factor (kg CO_2e/kg))

PLUS (+)

Scope 2 Emissions from Upstream Leased Asset

(Electricity, Steam, Heating, Cooling Consumed (kWh)) **X** (Electricity, Steam, Heating, Cooling Emission Factor (kg CO_2e/kWh))

EQUALS (=)

Scope 3 Emissions from Upstream Leased Asset

Scope 3: Upstream Leased Assets Inventory **=** Σ Scope 3 Emissions from All Upstream Leased Assets

Reporting processors may use the GHG Emissions from Purchased Electricity, GHG Emissions from Stationary Combustion and Refrigeration and Air-Conditioning Equipment Excel tools as resources to assist in quantifying emissions in this category. They have built-in GHG Protocol emission factors to streamline GHG emissions from fuel, electricity, steam, heat, cooling and refrigeration.

If the leasing company only leases a section or portion of the facility, and the facility lacks sub-metering infrastructure, then energy consumption may be allocated using an estimation based on the share of space the company leases (based on floor space). This may be calculated using the following equation:

Equation for Section or Portion Leases

Leasing Company's Used Space (m^2) **/** (Building's Total Area (m^2) **X** Building Occupancy Rate) **X** Total Building Energy Use (kWh)

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Appendix: This category is not a priority in the U.S. dairy value chain, but is recommended for a comprehensive Scope 3 inventory.

Scope 3: Business Travel

Chapter at a Glance

- Defining Business Travel
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from business-related travel.

While this section is not a priority in U.S. dairy GHG accounting, reporting processors should include it to compose the most comprehensive Scope 3 inventory (account for prioritized sections first).

1

Defining Business Travel: Business-related travel emissions are considered Scope 3 indirect emissions if the method of transportation used by the traveling employee is not owned and/or operated by the reporting processor. If the vehicle used by the traveling employee is owned by the reporting processor, emissions from said vehicle would be accounted for under Scope 1 (if powered by fuel) or Scope 2 (if powered by electricity). Emissions from leased vehicles operated by the reporting processor are considered Scope 3, but are accounted for in Scope 3: Upstream Leased Assets. Emissions from employee commuting are accounted for in Scope 3: Employee Commuting.

Differentiating Mobile Emission Sources and Scopes		
Emitting Transportation Activity	Category	Scope
Operation of owned/controlled vehicles	Fuel/electricity consumption	Scope 1, Scope 2
Business travel in unowned/non-processor operated vehicles	Business travel	Scope 3
Transportation to and from work in unowned/non-processor operated vehicles	Employee commuting	Scope 3
Transportation in leased vehicles operated by reporting processor	Upstream leased assets	Scope 3

(Table 11.0) Differentiation of transportation-related emission sources

2

Identifying Sources: Identifying sources of emissions from business travel simply involves keeping track of any and all business trips via air, rail, bus, automobile (i.e., rental cars), or other travel methods. Reporting processors may also include emissions from hotel stays in this category. Although optional, including this information may give a more accurate and robust account of Scope 3 emissions from business travel. Hotel emissions are quantified using emission factors specific to hotel type (i.e., kg CO_2 per hotel night).

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Business Travel

3

Collecting Activity Data: The GHG Protocol Scope 3 Calculation Guidance recommends using the Distance-Based method for calculating business travel-related emissions for reporting entities not significantly impacted by business travel as a contributor to overall Scope 3 inventory. This method requires keeping track of the distance traveled and transportation method used for all business trips in the reporting year. If activity data is not available for calculating emissions using the Distance-Based method, reporting processors may employ the Spend-Based method, which involves a different set of emission factors called secondary (EEIO) emission factors. By determining the total amount spent on business travel in the reporting year, the reporting processor may calculate emissions using these secondary emission factors. However, the GHG Protocol recommends using the Distance-Based method when possible.

Activity Data for Business Travel Emissions Calculations	
Data Type	Information Needed
Mode of Transport	Road, Rail, Water, Aircraft
Vehicle Characteristics	Type and Class
Distance Traveled	Miles, Kilometers
Passengers	Number of passengers traveling

(Table 11.1) Relevant activity data to collect for Scope 3: Business Travel accounting

4

Data Collection Guidance: Sources of activity data necessary to calculate Scope 3: Business Travel emissions include:

- Distance tracking reports through a travel agency or other travel providers
- Distance tracking through internal expense and reimbursement systems
- Annual employee surveys
- Emissions data obtained through travel providers

5

Calculation Approach: Use the GHG Protocol's Mobile Combustion GHG Emissions Calculation Tool, which has built-in emission factors for various transportation methods, and will automatically calculate CO_2, CH_4 and N_2O emissions data from the reporting processor's input activity data. It is important to select "Scope 3" under the "Scope" column in the "Activity Data" tab. If a reporting processor wishes to utilize a calculation resource other than the GHG Protocol's Mobile Combustion GHG Emissions Calculation Tool, the U.S. EPA Climate Leaders GHG Inventory Protocol, "Optional Emissions from Commuting, Business Travel and Product Transport"[5] may be consulted.

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Appendix: This category is not a priority in the U.S. dairy value chain, but is recommended for a comprehensive Scope 3 inventory.

Scope 3: Employee Commuting

Chapter at a Glance

- Employee Commuting
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from employee commuting.

While this section is not a priority in U.S. dairy GHG accounting, reporting processors should include it to compose the most comprehensive Scope 3 inventory (account for prioritized sections first).

1

Defining Employee Commuting: This Scope 3 category captures all GHG emissions generated from the reporting processor's employee base traveling to and from work at the processing and/or manufacturing facilities and corporate offices.

Differentiating Mobile Emission Sources and Scopes		
Emitting Transportation Activity	Category	Scope
Operation of owned/controlled vehicles	Fuel/electricity consumption	Scope 1, Scope 2
Business travel in unowned/non-processor operated vehicles	Business travel	Scope 3
Transportation to and from work in unowned/non-processor operated vehicles	Employee commuting	Scope 3
Transportation in leased vehicles operated by reporting processor	Upstream leased assets	Scope 3

(Table 12.0) Differentiation of transportation-related emission sources

2

Identify Sources: Depending on region, access to public transportation and processing facility location, employees may utilize a diverse array of transportation methods to commute to and from work. Therefore, employee commuting emissions may arise from sources such as automobile, bus, rail, air and subway. Reporting processors may also include emissions arising from employees working remotely in this category, although this is optional.

3

Collecting Activity Data: Commuting employees may contribute significantly to the Scope 3 inventory depending on company size. The GHG Protocol Scope 3 Corporate Value Chain Standard recommends using the Fuel-Based method, which requires collecting data on the amount of fuel consumed through employee commuting. Data on the types and quantities/cost of various fuels consumed for all employees at all processing facilities may be difficult to collect. If so, the reporting processor may utilize the Distance-Based method, as in Scope 3: Business Travel, to accurately quantify emissions from employee commuting.

For Fuel-Based activity data and calculation methodology, use the Scope 3: Upstream Transportation and Distribution. The reporting processor may refer to this category if using the Fuel-Based approach. If the Distance-Based method is used, apply the methodology for Scope 3: Business Travel.

continued on next page

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Employee Commuting

3

Activity Data for Employee Commuting Emissions Calculations	
Data Type	Information Needed
Mode of Transport	Road, Rail, Water, Aircraft
Vehicle Characteristics	Type and Class
Distance Traveled	Miles, Kilometers
Passengers	Number of passengers traveling via each method

(Table 12.1) Relevant activity data to collect for Scope 3: Employee Commuting accounting

4

Data Collection Guidance: The reporting processor may distribute a survey or questionnaire to collect data on commuting habits. The survey should include the questions in Table 12.2 (below).

Employee Commuting Survey Questions	
Survey Question	Applicable Metrics
How far do employees travel to and from work? (OR calculate distance from employee residence to processing facility)	Miles per day
How many days do employees commute per week?	Days per week
How many weeks do employees work per year?	Weeks per year
How many days per week do employees use different transportation methods?	Days per week for each transportation method
If there is a car-pooling initiative among the company – • What's the proportion of employees carpooling? • What is the average carpooling occupancy per vehicle?	Percentage of employees who carpool and/or average persons per vehicle
If applicable – what is the energy used from employees who work remotely?	kWh

(Table 12.2) Survey questions that are useful for collecting Scope 3: Employee Commuting data

5

Calculation Approach: Use the GHG Protocol's Mobile Combustion GHG Emissions Calculation Tool, which has built-in emission factors for various transportation methods. It will automatically calculate CO_2, CH_4 and N_2O emissions data from the reporting processor's input activity data. This tool may be used to calculate Scope 3 emissions from employee commuting using both the Fuel-Based method and the Distance-Based method. It is important that the reporting processor ensures "Scope 3" is selected under the "Scope" column in the "Activity Data" tab.

Once the reporting processor has obtained emissions for every employee at each processing facility, the reporting processor may simply aggregate commuting emissions from all company-owned or operated facilities to determine its total Scope 3: Employee Commuting footprint.

If a reporting processor wishes to utilize a calculation resource other than the GHG Protocol's Mobile Combustion GHG Emissions Calculation Tool, the U.S. EPA Climate Leaders GHG Inventory Protocol, "Optional Emissions from Commuting, Business Travel and Product Transport"[5] may be consulted.

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Appendix: This category is not a priority in the U.S. dairy value chain, but is recommended for a comprehensive Scope 3 inventory.

Scope 3: Processing of Sold Products

Chapter at a Glance

- Defining Sold Products
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from processing of sold intermediate products by other processors further down the supply chain.

While this section is not a priority in U.S. dairy GHG accounting, reporting processors should include it to compose the most comprehensive Scope 3 inventory (account for prioritized sections first).

1

Defining Processing of Sold Products: Certain reporting processors may distribute their milk to other processors to be used for products such as ice cream, cheese, yogurt, etc. These products are considered intermediate products in dairy. The GHG Protocol defines intermediate products as those that "require further processing, transformation, or inclusion in another product before use, and therefore result in emissions from processing subsequent to sale by the reporting company and before use by the end consumer."[2] The reporting processor's Scope 3: Processing of Sold Products emissions are equivalent to other processors' Scope 1 and 2 emissions down their supply chain.

2

Identifying Sources: Intermediate dairy processing mainly creates GHG emissions from fuel and electricity used at processing facilities, as well as from waste generated from said processing. However, collecting primary data on emissions from these sources can often be difficult and unrealistic, especially if the reporting processor distributes to a large quantity of intermediate processors. Therefore, reporting processors should use the Average-Data method to estimate emissions from sold intermediate product-derived GHG emissions.

3

Collecting Activity Data: Using the Average-Data method entails collecting information on the downstream intermediate processing activities in the reporting processor's supply chain in order to select and apply the relevant industry-average emission factors.

Average Data Method – Processing of Sold Products	
Activity Data Categories	Information Needed
Intermediate processing activities	Coagulation, acidification, cutting, washing, draining, freezing, packaging, homogenizing, etc.
Allocation information	Mass, economic value

(Table 13.0) Activity data necessary to utilize the Average-Data method for quantifying Scope 3: Processing of Sold Products in the downstream supply chain

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Processing of Sold Products

4

Data Collection Guidance: Reporting processors may refer to purchasing records, internal data systems, and industry-average data from associations or databases to accurately identify the mass of dairy products sold to its intermediate suppliers.

Once the reporting processor has collected relevant information on the processes involved in further processing for every sold product, it should seek the appropriate emission factors that coincide with each process. Reporting processors may consult a variety of resources that publish robust emission factors relevant to intermediate product processing activities. Some of these resources include:

- U.S.-specific GHG emission analysis for fluid milk processing plants[4]
- Life cycle databases
- The GHG Protocol website
- Companies or manufacturers
- Industry associations
- Environmental organizations such as the EPA, IPCC, or the Climate Registry

From here, quantifying emissions from Scope 3: Processing of Sold Products is calculated by the equation below:

Intermediate Process Emissions
Mass of sold milk to intermediate processor **X** Emission factor for processing activity (kg CO_2e/kg FPCM)

The reporting processor should execute this calculation for every shipment of milk that endures a different intermediate process, making sure to apply the correct emission factor for each intermediate process and factoring in the correct mass of milk that undergoes said processes. Once done, the reporting processor may aggregate emissions from all intermediate processes germane to its downstream supply chain to arrive at its total Scope 3: Processing of Sold Products footprint.

Scope 3: Processing of Sold Products Emissions
((Intermediate Process 1 Emissions) (kg CO_2e **+** (Intermediate Process 2 Emissions) (kg CO_2e) **+** .....)

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Appendix: This category is not a priority in the U.S. dairy value chain, but is recommended for a comprehensive Scope 3 inventory.

Scope 3: Use of Sold Products

Chapter at a Glance

- Defining Sold Products
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from the use and consumption phase of sold milk and other dairy products by end consumers.

While this section is not a priority in U.S. dairy GHG accounting, reporting processors should include it to compose the most comprehensive Scope 3 inventory (account for prioritized sections first).

1

Defining Use of Sold Products: For U.S. dairy, the use of sold products is relatively easy to define, as fluid milk does not directly produce GHG emissions in its use phase. The GHG Protocol's Corporate Value Chain Standard requires that direct-use phase emissions are accounted for in this category, while indirect-use phase emissions are optional to report.

2

Identifying Sources: For fluid milk specifically, indirect-use phase emissions come from refrigerating the milk in the consumers' homes or businesses between point-of-purchase and complete consumption. Additionally, other dairy products such as cheese may produce indirect-use phase emissions if they are cooked, which demands fuel and/or electricity.

Measuring indirect-use phase emissions is often difficult. For this category, follow and adopt the methodology in Table 14.0.

GHG Emission Sources from Dairy Use Phase

Use Phase Activity	Emissions Source
Refrigeration	Electricity Consumption
	Refrigerant Leakage
Cooking	Fuel Consumption
	Electricity Consumption

(Table 14.0) Common emissions sources from the use of dairy products by the end consumer

3

Collecting Activity Data: The reporting processor should first create and/or obtain a typical use-phase profile based on the average lifetime that the dairy product is in the "use" phase and implement relevant emission factors.

Use Phase Activity Data Collection Guideline

Indirect Emissions Activity Data Category	Activity Data
Use Scenarios	Cooking (Roasting, Boiling, Microwaving, Frying)
Fuel Consumed	LNG, LPG, CNG, Propane (in therms, cubic feet, cubic meters)
Electricity Consumed	kWh
Refrigerant Leakage	HFCs, PFCs (in kg CO_2e)

(Table 14.1) Activity data to be collected to calculate indirect-use phase emissions from consumption of dairy

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Use of Sold Products

4

Data Collection Guidance: Developing a typical use-phase profile involves identifying the use phase scenarios (shown in table 14.1) for each product the reporting processor sells, and creating a weighted average based on each use scenario, length of use and quantity sold. Reporting processors may consult a variety of resources to obtain this information, such as:

- Industry recognized benchmark testing specifications
- Product category rules
- Previous emissions studies
- Consumer studies

5

Calculation Approach: Reporting processors can quantify their Scope 3: Use of Sold Products footprint using the calculation on page 39.

The calculation represents how to account for and quantify use phase emissions from dairy. For fluid milk, the only necessary equations to be included in the calculations are the Refrigerant Leakage and Refrigerator equations. If the reporting processor sells dairy products that are often cooked, such as cheese, all the equations may need to be utilized in order to quantify an accurate and fully-encompassing account of Scope 3: Use of Sold Products inventory. Calculate emissions from each equation for each product sold, then aggregate all emissions from each equation to arrive at a total Scope 3: Use of Sold Products account.

Reporting processors may consult a variety of resources that publish robust emission factors relevant to stationary combustion and refrigerating activities. Some of these resources include:

- Life cycle databases
- The GHG Protocol
- Companies or manufacturers
- Industry associations
- Environmental organizations such as the EPA, IPCC, or the Climate Registry

For the reporting processor's convenience, the GHG Protocol Stationary Combustion Excel Tool with relevant emission factors for various fuels and electricity is linked. Furthermore, the GHG Protocol Refrigerant Emissions Calculation Excel Tool is linked.

Appendix: This category is not a priority in the U.S. dairy value chain, but is recommended for a comprehensive Scope 3 inventory.

Scope 3: End-of-Life Treatment of Sold Products

Chapter at a Glance

- Defining End-of-Life
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from the end-of-life waste disposal and treatment of sold dairy products by the reporting processor.

While this section is not a priority in U.S. dairy GHG accounting, reporting processors should include it to compose the most comprehensive Scope 3 inventory (account for prioritized sections first).

1

Defining End-of-Life Treatment of Sold Products: This category captures GHG emissions associated with waste, much like Scope 3: Waste Generated in Operations. However, the key difference in this category is that it accounts for GHG emissions deriving from end-of-life waste disposal and treatment of dairy products sold by the reporting processor (in the reporting period). Like Scope 3: Waste Generated in Operations, this category accounts for emissions from biomass materials, and therefore CO_2 emissions must be accounted for outside any of the three scopes in a separate memo item. Methane and nitrous oxide emissions, however, are still accounted for within the scopes for this category. Rather than using the sheer volume of waste produced during dairy processing to quantify emissions, reporting processors should use the mass of product sold (including packaging).

Obtaining accurate and quality data on the proportions and distribution of waste management activities associated with sold products is often difficult for reporting processors. This category requires the reporting processor to disclose assumptions on its sold product lifetimes, as well as waste treatment methods.

2

Identifying Sources: Almost all dairy products sold on the U.S. market are packaged in recyclable materials. Recycling's emission factor is 0.0 kg CO_2e/kg since all the material re-enters the supply stream. Therefore, reporting processors should try to formulate the most accurate assumptions on what quantities of its sold products and/or packaging material do not actually get recycled but rather go to landfill, or incineration. In addition, dairy products are consumable, so waste from dairy processors in this category is likely to be much lower than the actual mass of products and packaging sold. As a result, reporting processors should consult industry average data on the proportion of sold products that get wasted (not consumed, and/or recycled).

Source: Journal of Food and Dairy Technology

Common Packaging Methods in U.S. Dairy

Packaging Material	Dairy Products	Recyclable?
Plastic Based	Fluid milk, butter, cheese, ghee, whipped cream	Most
Glass Based	Fluid milk, ghee	Yes
Paper Based	Fluid milk, ice cream	Yes
Metal Based	Cheese spread, milk powder, ghee, whipped cream	Yes
Flexible Film Based	Cheese	In specific markets

(Table 15.0) Common U.S. dairy packaging materials and their recyclability[6]

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: End-of-Life Treatment of Sold Products

3

Collecting Activity Data: As mentioned above, reporting processors should use the mass of product sold in the reporting year to quantify emissions in this category. Furthermore, reporting processors should collect information on the distribution of their sold products in different waste management methods.

Activity Data Needed for Calculating Scope 3: End-of-Life Treatment of Sold Products	
Activity Data	Examples
Mass of sold dairy products (including packaging of individual consumable products, and packaging used to transport individual products)	Plastic milk cartons, cardboard boxes, glass jugs, paperboard milk cartons, metal cans, cellophane wrapping
Proportion of sold materials in different waste streams	% recycled, % landfilled, % incinerated

(Table 15.1) Relevant activity data necessary for Scope 3: End-of-Life Treatment of Sold Products accounting

4

Data Collection Guidance: Although collecting accurate data on dairy waste streams after products are sold may be difficult, many resources exist to assist with this procedure. Several are included below:

- Specific government directives on waste treatment (for the U.S.: Facts and Figures about Materials, Waste and Recycling)[6]
- Industry associations that have conducted research into consumer disposal habits (if applicable)
- Average data on waste treatment from reporting processor's point-of-sale through end-of-life treatment

5

Calculation Approach: Much like Scope 3: Waste Generated in Operations, this category employs the Waste-Type-Specific method to calculate GHG emissions from the reporting processor's sold products and packaging. The appropriate equation is included below for reference. Reporting processors should ensure that they use an accurate and robust emission factor for each waste treatment method applicable to their supply chain. Resources such as the EPA's Documentation for Greenhouse Gas Emission and Energy Factors Used in the Waste Reduction Model include emission factor data for this category's emission calculations.

Scope 3: End-of-Life Treatment of Sold Products Footprint

Mass of Sold Products and Packaging (kg) **X** % Recycled Waste **X** Recycling Emission Factor (kg CO_2e/kg)

PLUS (+)

Mass of Sold Products and Packaging (kg) **X** % Landfilled Waste **X** Landfill Emission Factor (kg CO_2e/kg)

PLUS (+)

Mass of Sold Products and Packaging (kg) **X** % of Incinerated Waste **X** Incineration Emission Factor (kg CO_2e/kg)

Appendix: This category is not a priority in the U.S. dairy value chain, but is recommended for a comprehensive Scope 3 inventory.

Scope 3: Franchises

Chapter at a Glance

- Defining Franchises
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from the operation of franchises down the reporting processor's value chain.

While this section is not a priority in U.S. dairy GHG accounting, reporting processors should include it to compose the most comprehensive Scope 3 inventory (account for prioritized sections first).

1

Defining Franchises: Franchises, although a very common business model, are not often implemented in the U.S. dairy processing industry. However, on the off-chance that a reporting processor owns a franchise network, this category accounts for the GHG emissions generated from the operation of said franchise(s). The GHG Protocol Corporate Value Chain Accounting and Reporting Standard defines franchises as businesses "operating under a license to sell or distribute another company's goods or services within a certain location."[1] The Scope 1 and Scope 2 GHG emissions from these franchise locations that sell or distribute a reporting processor's dairy products are equivalent to the Scope 3 emissions accounted for in this category.

2

Identifying Sources: As briefly described above, Scope 3 GHG emission sources in this category arise from the operation of franchises downstream from the reporting processor. Collecting and accounting for Scope 1 and 2 GHG emissions at each and every franchise location will translate into a comprehensive Scope 3: Franchises inventory.

3

Collecting Activity Data: This guidance recommends using the Franchise-Specific method for collecting activity data, which requires the reporting processor to collect Scope 1 and 2 data specific to each and every franchise operating under its label. If franchisees have conducted a Scope 1 and 2 inventory, then simply applying the inventory to this category accomplishes this data collection strategy. However, if no such inventory exists, reporting processors should aim to collect activity data similar to the Scope 1 and 2 data collected in the Scope 3: Upstream/Downstream Leased Assets categories.

If the reporting processor is unable to obtain the fuel and energy data associated with each franchise, other methods of accounting for Scope 3: Franchises emissions can be found in the GHG Protocol Technical Guidance for Calculating Scope 3 Emissions.

Table 16.0 (below) includes applicable activity data.

GHG Emission Sources from Franchises	
Emission Source	Scope
Fuel consumed, refrigerant leaked, process emissions	Scope 1
Electricity consumed, steam consumed, heat consumed, cooling consumed	Scope 2

(Table 16.0) Scope 1 and 2 GHG emission sources from franchises

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

Scope 3: Franchises

4

Data Collection Guidance: Much like Scope 1 and 2 accounting, the necessary activity data for this category can be collected via many different methods:

- Utility bills
- Purchase records
- Meter readings
- Internal IT systems

Appropriate emission factors are available from an array of different sources as well, such as:

- The EPA GHG Emissions Factors Hub
- Life cycle databases
- Other government agencies such as the IPCC, and Climate Registry
- Industry associations
- Company-developed factors if applicable

5

Calculation Approach: The following equation represents the appropriate methodology for calculating Scope 3: Franchises using the Franchise-Specific method and is the same methodology for Scope 3: Upstream/ Downstream Leased Assets:

Calculating Scope 3: Franchises Using the Franchise-Specific Method

Scope 1 Emissions from Franchise

(Fuel Consumed **X** Fuel Emission Factor (kg CO_2e/fuel unit)) **+** (Refrigerant Leakage (kg) **X** Refrigerant Emission Factor (kg CO_2e/kg))

PLUS (+)

Scope 2 Emissions from Franchise

(Electricity, Steam, Heating, Cooling Consumed (kWh)) **X** (Electricity, Steam, Heating, Cooling Emission Factor (kg CO_2e/kWh))

EQUALS (=)

Scope 3 Emissions from Franchise

Scope 3: Franchises Inventory **=** Σ Scope 3 Emissions from All Franchises

Reporting processors may use the GHG Emissions from Purchased Electricity, GHG Emissions from Stationary Combustion, and Refrigeration and Air-Conditioning Equipment Excel tools as resources to assist in quantifying emissions in this category. They have built-in GHG Protocol emission factors to streamline GHG emissions from fuel, electricity, steam, heat, cooling and refrigeration.

If the franchise company only operates in a section or portion of the facility, and the facility lacks sub-metering infrastructure, then energy consumption may be allocated using an estimation based on the share of space the company leases (based on floor space). This may be calculated using the following equation:

Equation for Section or Portion Operation

Franchise-Used Space (m^2) **/** (Building's Total Area (m^2) **X** Building Occupancy Rate) **X** Total Building Energy Use (kWh)

© 2024 Innovation Center for U.S. Dairy. All rights reserved.

Appendix: This category is not a priority in the U.S. dairy value chain, but is recommended for a comprehensive Scope 3 inventory.

Scope 3: Investments

Chapter at a Glance

- Defining Investments
- Identifying Sources
- Collecting Activity Data
- Data Collection Guidance
- Calculation Approach

This section provides guidance on how to account for and calculate Scope 3 indirect GHG emissions from the reporting processor's investments in the reporting period.

While this section is not a priority in U.S. dairy GHG accounting, reporting processors should include it to compose the most comprehensive Scope 3 inventory (account for prioritized sections first).

1

Defining Investments: This category mainly applies to financial institutions and profit-driven investment companies. However, Scope 3: Investments may apply to a dairy processor/cooperative if it has joint financial control of another company, and/or directly influences subsidiaries and associate companies. Again, depending on the reporting processor's organizational boundary, GHG emissions may be accounted for in Scope 1 or 2. More specifically, if the reporting processor uses the equity share approach in its IMP, the GHG emissions from investments would then be equivalent to the share of investment it has in the investee under Scope 1 and 2. However, if using a control approach, emissions are categorized in Scope 3, as the reporting processor does not operate the investment company.

In this regard, the Scope 1 and 2 emissions from each and every investee operation are equivalent to the reporting processor's Scope 3: Investment emissions.

2

Identifying Sources: As briefly described above, Scope 3 GHG emission sources in this category arise from investee operations downstream from the reporting processor. Collecting and accounting for Scope 1 and 2 GHG emissions at each and every investee operation will translate into a comprehensive Scope 3: Investments inventory.

3

Collecting Activity Data: This guidance recommends using the Investment-Specific method for collecting activity data, which requires the reporting processor to collect Scope 1 and 2 data specific to each and every investee operation/company. If investee companies have conducted a Scope 1 and 2 inventory, then simply applying the inventory to this category accomplishes the data collection strategy. However, if no such inventory exists, reporting processors should apply the Average-Data method to fill in the gaps. This involves applying revenue data from the investee company, and combining it with Environmental Extended Input-Output data (from applicable life cycle databases, such as those listed on the GHG Protocol website) to estimate Scope 1 and 2 emissions.

For both methods, reporting processors should account for their proportion of emissions from the investee company based on their share of investment. For example, if a reporting processor has a 30 percent share of equity in a company, then the correct allocation of emissions from this investee company would equal its Scope 1 and 2 emissions multiplied by 0.30. Table 17.0 (page 45) includes applicable activity data.

 © 2024 Innovation Center for U.S. Dairy. All rights reserved.

continued on next page

Scope 3: Investments

3

GHG Emission Sources from Investments	
Emission Source	Scope
Fuel consumed, refrigerant leaked, process emissions	Scope 1
Electricity consumed, steam consumed, heat consumed, cooling consumed	Scope 2

(Table 17.0) Scope 1 and 2 GHG emission sources from Investments

4

Data Collection Guidance: In addition to the appropriate EEIO data for estimating average emissions, reporting processors should consult their financial records, and/or GHG inventory reports of investee companies for the Investment-Specific method, if they exist.

If the reporting processor is able to obtain relevant GHG inventories from investee companies, no emission factors should be necessary, as the investee companies have already calculated their Scope 1 and Scope 2 inventories.

However, if the Average-Data method is employed, the reporting processor should disaggregate the EEIO emission factor, similar to Scope 3: Capital Goods. This allows for the reporting processor to account for only Scope 1 and 2 GHG emissions from the investee company, as opposed to all three scopes. This disaggregation process can often be arduous and, potentially, impossible. If so, the reporting processor may use the full EEIO factor as long as this information is transparently disclosed.

5

Calculation Approach: If utilizing the Investment-Specific method, the reporting processor's Scope 3: Investments inventory from this approach is simply the aggregate of all the investee company's Scope 1 and 2 inventories multiplied by its equity share in each company.

Investment-Specific Method

Scope 3: Investments Inventory = Σ (Scope 1 and 2 Inventories of Investee Company X % Equity Share)

If utilizing the Average-Data method, the reporting processor's Scope 3: Investments inventory from this approach is the investee company's revenue multiplied by the corresponding emission factor for its sector. The quantity is then multiplied by the equity share in the investee company. Sum across all investee companies that employ this method to find the aggregated Scope 3: Investments inventory via the Average-Data method.

Average-Data Method

Scope 3: Investments Inventory = Σ ((Investee Company Revenue ($) X Investee Sector Emission Factor (kg CO_2e/$ Rev.)) X Equity Share (%))

About the Innovation Center for U.S. Dairy®

The Innovation Center for U.S. Dairy® is a forum that brings together the dairy community to address the changing needs and expectations of consumers through a framework of shared best practices and accountability. Initiated in 2008 by dairy farmers through the dairy checkoff, we collaborate on efforts that are important both to us and our valued customers — in areas like animal care, food safety, nutrition and health, the environment and community contributions.

Visit USDairy.com for more information about the Innovation Center for U.S. Dairy.

1. Introduction

1.1 GOAL AND OBJECTIVES

The wider context for this study is to ensure that benchmarking of livestock supply chains is based on internationally recognized and harmonized methodology and datasets. The overall goal of this assessment is to develop a robust life cycle inventory (LCI) and emission intensity database. Specific objectives were to establish a global database of emission intensities for major feed crops disaggregated by production practices and country as well as provide a consolidated database of life cycle inventories to support continued benchmarking of livestock supply chains.

1.2 SCOPE OF THE STUDY

The main focus is on the quantification of greenhouse gas emissions arising from the **cultivation phase** in crop production. The study focuses on 5 main crops: **maize, wheat, barley, cassava and soybean**. The assessment covers the major GHG emissions: CO_2, N_2O and CH_4 and includes all major processes from raw material production through to on-farm cultivation to the field-gate. In addition, the analysis incorporates carbon stock changes associated with land-use change. Results from this analysis are presented in a database which provides information on the life cycle inventory per crop and the emission intensities associated with the cultivation of the crop. Users are able to query the database to access aggregate information on emission intensities per crop disaggregated by production system and country.

1.3 INTENDED APPLICATION

Emissions attributed to feed production are required to compute any life cycle assessment (LCA) of livestock supply chains. There is however no global dataset on emissions related to feed ingredients available to the practitioners and available data is generally of limited geographical relevance. This database is intended to support benchmarking and evaluation of livestock supply chains.

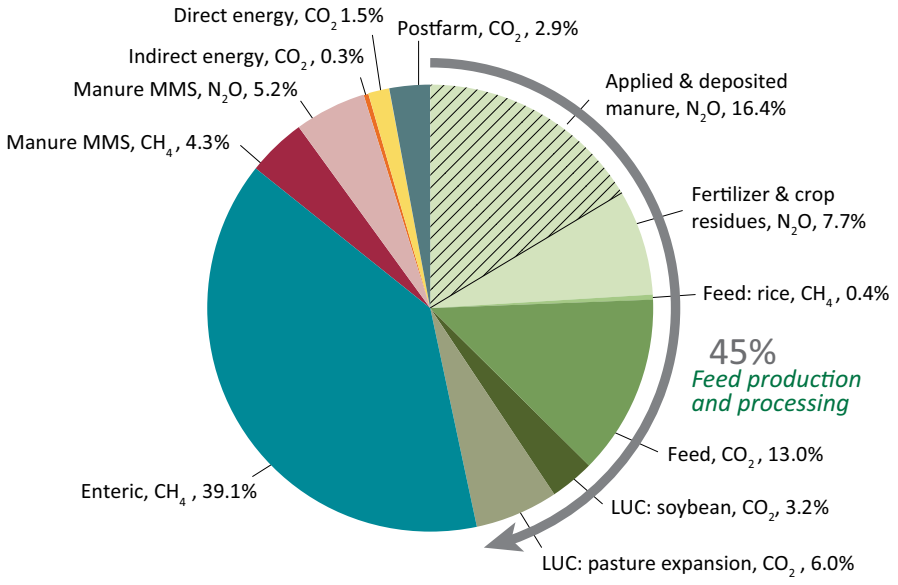
1.4 OUTLINE OF THE REPORT

This report presents the information on the background to the study, the approach and methodology applied. It also presents and discusses the results from the analysis of GHG emissions. An accompanying document "*A life cycle inventory for wheat, maize, barley, soybean and cassava*" provides more detailed information on the life cycle inventory (LCI).

Section 2 and 3 of this report presents a brief overview of the global feed sector and crop production practices, respectively. Section 4 provides an overview of the approach and methodology applied in the assessment of GHG emissions for the five crops. This information is supplemented by an accompanying document that presents background information on the life cycle inventories of the crops. Section 5 and 6 presents an initial discussion on uncertainty and key challenges and future work that will be undertaken.

2. The Global Feed Sector

The future for farming and agriculture holds many challenges, not least the continued efforts to optimize resource use and reduce greenhouse gas (GHG) emissions. This needs to be set against the urgent and growing need to improve productivity to meet the anticipated requirements to provide more food, feed and fuel, for a growing global population. These challenges are and will increasingly be influenced by the availability and price of resources as well as by policies set to meet carbon emissions targets and other sustainability requirements.



The animal feed industry plays an important role in the global supply of food, enabling production of animal protein throughout the world. Feed is the largest and most important component to ensuring safe, abundant and affordable supply of animal protein. At the same time, producing feed for livestock production is resource demanding: it occupies one-third of the world's ice-free surface and consumes 8% of global human water use, mainly for the irrigation of feed crops (FAO, 2006). The area dedicated to feed-crop production represents 33 percent of total arable land.

Feed production demands high energy inputs and chemicals, land and water resources — all of which are becoming increasingly scarce. Resource scarcity, on-going global warming and frequent and drastic climatic vagaries, increased competition for resources (land, energy, water and nutrients), coupled with increasing resource prices will further pose a greater challenge to the sustainability of food and feed production systems. Similarly, Increase in the use of food crops for animal feeds and for biofuel production could have serious implications for food security.

In 2005, the livestock sector consumed 6.3 billion tons of feed biomass. Feed use differs considerably depending on the region, livestock production systems and species; most feed-grain (69 percent) is fed to pigs and poultry in regions where industrial, intensive systems dominate production (W. Europe, North America, East Asia, and Central and South America). The rest is used for dairy production in mixed systems globally and for feedlot operations, notably in North America, Western Europe and Central and South America. A preliminary assessment identified maize, wheat, barley, soybean and cassava as major crops utilized for animal feed.

Globally, feed production, processing and transport contributed about 3.2 Gt CO_2 eq.; accounting for about 45 percent of the sector's emissions (Figure 1, Gerber *et al.*, 2013). The main source of GHG emissions in most livestock supply chains is feed production (de Vries and de Boer, 2010). Dominant GHGs emitted during feed production include carbon dioxide and nitrous oxide and to a lesser extent, methane (Duxbury, 1994; Herrero *et al.*, 2009).

Figure 1
Contribution of feed production
and processing to GHG emissions from livestock

Source: GLEAM, 2013

Cropping systems belong to complex production systems due to their dependence on environmental conditions that are variable in time (e.g. within a year, from year to year) and in space (e.g. varies by country, region, local site conditions). In addition, the correlation between inputs (such as fertilizers, pesticides, etc.) to outputs (of harvested crop, gaseous field emissions, leachate, etc.) is complex and often non-linear in nature. Because of the high contribution of feed production to GHG emissions and the large variability in production systems, a robust and sound assessment of emissions is important.

3. Crop Management Practices

Maximizing productive output in crop production has been achieved through the use of heavy farm equipment and machinery powered by fossil fuel, intensive tillage, high-yielding crop varieties, irrigation, manufactured inputs, and ever increasing capital intensity. Changing land-use practices, technological advancement and varietal improvement have enabled world grain harvests to double from 1.2 to 2.5 billion tonnes per year between 1970 and 2010 (FAOSTAT, 2015). Average world cereal yields increased from 1602 kg/ha to 3034 kg/ha over the same period (FAOSTAT, 2015) while there has also been a 233% increase in global fertilizer use from 31.8 to 105.9 Mt/yr, and a 73% increase in the irrigated cropland area (FAOSTAT, 2015).

It is now recognized that these enormous gains in agricultural production and productivity are often accompanied by localized negative effects on the natural resource base such as land degradation, salinization of irrigated areas, over-extraction of groundwater, the build-up of pest resistance and the erosion of biodiversity. Agriculture also has negative global environmental impacts through, for example, deforestation, emissions of greenhouse gases and nitrate pollution of water bodies.

Crops are grown under a wide range of production systems. Crop production, encompasses a series of processes ranging from land preparation through planting to the produce/product reaching the farm-gate. Sections below provide brief description of activities in cropping systems.

TILLAGE PRACTICES

Tillage is a fundamental practice in agricultural management. It can be defined as a method of 'working' the soil either physically, chemically, mechanically or biologically to create suitable conditions for seedling germination, establishment and growth (FAO, 2011). Tillage involves preparing soil for planting or seeding by ploughing, cultivating or otherwise turning it. Tillage loosens and aerates the soil, which allows for the deeper penetration of roots. It controls weeds and mixes organic matter, fertilizer and manure with the soil.

Generally, there are two types of tillage systems i.e. **conventional, and conservation tillage system**.

A *conventional tillage practice* refers to use of a mouldboard or animal drawn plough to incorporate residue into the soil by extensive tillage. It is two types i.e. mechanized, and traditional systems. Traditional tillage system is mainly practiced in many developing regions and is carried out by manual labour using native tools e.g., the hoe or cutlass. In mechanized system, mechanical soil manipulation is done by ploughing through one or more harrowing. Conventional tillage embraces not only primary cultivation practices, based on ploughing or soil inversion, but also secondary operations directed at land preparation and sowing or planting. Typically, this involves ploughing (soil inversion), followed by one or two harrowing events to produce a suitable layer for plant establishment, as well as the removal of most of the plant residues derived from the previous crop. Once crops are planted, a cultivator is used, often several times, to keep the weeds down (Abdulla *et al.* 2013).

Thus, in the process the soil was tilled repeatedly at great cost in terms of time and energy.

Conservation tillage systems, in contrast, are primarily based on reducing soil disturbance by restricting any land preparation activities to a shallow depth and eliminating soil inversion, while conserving and managing crop residues (Cunningham *et al.*, 2004). Globally, conservation tillage is practiced on approximately 144 million hectares, predominantly in North and South America (FAO Conservation Tillage database, 2015). Globally, different conservation tillage systems have been developed and they include: non-inversion tillage, eco-tillage, minimum tillage, mulch tillage, reduced tillage, zone tillage or no-tillage. Conservation tillage aims to leave at least 30% of the previous crop residues remaining on the soil surface, whereas conventional tillage leaves less than 15%.

The cultivation of soils through ploughing is the most energy demanding process in the production of arable crops. The diesel fuel used contributes directly to CO_2 emissions along with that used in the manufacture of the machinery. Tillage also has a major influence on soil C emissions and is one of the principal agronomic activities thought to reduce soil organic carbon (SOC) stocks. For this reason, conservation tillage is becoming increasingly attractive to farmers because clearly reduces production cost relative to conventional tillage.

Seeding/sowing in both conventional and conservation tillage, seeding/sowing involves direct seeding into crop residue or directly in the soil**.** Seeding or sowing may be done mechanically or manually.

CROP NUTRITION

This involves the use of mineral or organic substances, natural or manufactured, that are applied to soil or irrigation water to supply plants with nutrients and supply elements that are essential for plant growth. Nitrogen (N), phosphorus (P), and potassium (K) are the primary major nutrients required for plant growth and are the main components of most fertilizers which are consumed in relatively large amounts. The use of fertilizer has been essential for crop production; mineral and organic fertilizers are applied to balance the gap between the nutrients required for optimal crop development and the nutrients supplied by the soil and by available organic sources (Bentrup, 2009). These chemicals are energy intensive to produce, create vast amounts of waste, and contribute to greenhouse gas emissions.

PLANT PROTECTION

Crop protection which includes the use of herbicides, insecticides, fungicides, as well as biotechnology products, helps control weed species, harmful insects and numerous plant diseases that afflict crops. The term pesticide is commonly used to refer to elements used in plant protection and covers a wide range of compounds including insecticides, fungicides, herbicides, rodenticides, molluscicides, nematicides, plant growth regulators and others. In the process of development of agriculture, pesticides have become an important tool as a plant protection agent for boosting food production. Improvements in the control of weedy competitors of crops and crop diseases can significantly increase yields. Pesticides are almost entirely produced from crude petroleum or natural gas products (West and Marland, 2002). Emissions from pesticides are therefore related to the energy input both from the material used as feedstock and the direct

energy inputs. Carbon dioxide emissions from production of pesticides consist of emissions from the manufacture the active ingredient, from the formulation of the active ingredients and those from packaging, transportation, and application of the pesticide formulation.

WEED MANAGEMENT

The occurrence of weeds in agricultural crops leads to substantial yield reductions causing economic losses all over the world. Weed management can be based on a combination of mechanical and chemical practices. Higher weeds generally occur where reduced tillage is practiced. This is because in traditional plough cultivation (conventional tillage) weed seeds are buried and often decay. As a result, conservation tillage systems generally rely more heavily on chemical weed control than conventional tillage systems.

IRRIGATION

Irrigation makes agriculture possible in areas previously unsuitable for intensive crop production. In large areas of the world irrigation significantly increases agricultural production, and many countries have significant fractions of irrigated cropland. About 20% of total arable cropland is under irrigation, producing about 40% of the global harvest (Sauer *et al.*, 2010). Yet, irrigation is a very carbon intensive practice. Sloggett (1979; 1992) estimated that 23% of the on-farm energy use for crop production in the US was for on-farm pumping. The energy required to pump water depends on numerous factors including total dynamic head (based on water lift, pipe friction, and system pressure), the water flow rate and the pumping system efficiency (Whiffen, 1991). The energy use depends on the water table depth or the lift height.

HARVESTING

Harvesting is the process of removal of entire plants or economic parts after crop maturity. The economic product may be grain, seed leaf, root or entire plant. The remaining portion of the stem that is left on the field after harvest is known as stubble. Crops maybe harvested by machine or by hand depending on the level of mechanization and the type of crop. Harvesting emissions are generated by different operations: crop handling by the harvest machine, loading of the harvested crop into trailers or trucks, and transport by trailers or trucks in the field.

4. Methodology

4.1 LIFE CYCLE ASSESSMENT (LCA) METHODOLOGY

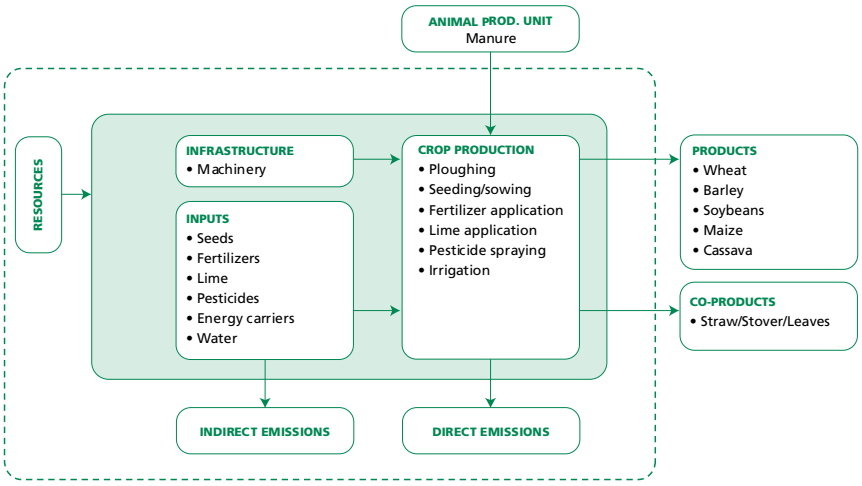
Life Cycle Assessment (LCA) is an approach for the integrated assessment of environmental impacts along a life cycle of a product (Guinee *et al.*, 2002). Such an assessment may involve a wide range of environmental impacts such as climate change, eutrophication, acidification, etc.

In this study, the focus is on the assessment of the contribution of major feed crops to climate change. This study uses the LCA methodology described in the LEAP Feed Guidelines: "Environmental performance of animal feeds supply chains".

In this chapter, the methodology used for estimating the total emissions and emission intensities of GHGs resulting from cropping activities is described.

4.2 FUNCTIONAL UNIT

The functional unit in crop cultivation is 1 kg of dry matter (DM) product at harvest. For this study, the functional unit is taken as:



- 1 kg of wheat,
- 1 kg of maize,
- 1 kg of soybean,
- 1 kg of barley,
- 1 kg of cassava.

4.3 SYSTEM BOUNDARY

The system boundary defines the processes and input/output components that have been taken into account in the life cycle study. For this study, the system boundary extends from the extraction of raw materials, through the production and transport of inputs, to field cultivation and harvest of one kg of DM product (Figure 2).

Figure 2

Schematic representation of the system boundary considered in this assessment

Process included within the system boundary

The system defined in this life cycle study includes impacts associated with:

- The extraction, production and transport to the farm of fuel, fertilizers, agrochemicals (pesticides and lime) used in crop cultivation.
- Energy use on the farm for field operations/cultivation activities.
- Indirect/embedded energy in the production and maintenance of machinery and equipment.
- Soil emissions associated with the application of N fertilizers, agricultural lime and manure.
- Emissions from crop residue management.
- Emissions related to land use change.

Process excluded from the system boundary

A number of processes are excluded:

- Production of seed and young plant material due to lack of reliable data.
- The system excludes drying after harvesting due to the lack of reliable data on a global scale.
- Burning of crop residues.
- All processes in the production chain beyond the farm-gate.

Summary of assumptions and considerations

The estimation of GHG emissions from the 5 crops is based on several assumptions or considerations, some of which are suggested by the studies reviewed.

- Emissions associated with irrigation (pumping of water) were calculated only for groundwater. Energy used for on-farm surface water collection and distribution is assumed to be negligible (wang *et al.*, 2014; Daccache *et al.*, 2014; West and Marland, 2002).
- Crops were assumed to grow in monoculture due to insufficient data for determining typical crop rotation practices at a global scale.
- Seeding rates were assumed to be similar across the different tillage intensities (i.e. conventional, reduced and no-till) even though a few studies (Frye, 1984) noted that no-till crops may require up to 20% more seed to produce the same yield using conventional tillage.
- Countries for which the assessment is done for conservation tillage include: USA, Argentina, Paraguay, Brazil, Australia, Canada, Europe 27 and Kazakhstan. These countries represent 90 percent of the global land area under conservation tillage. Other countries with areas under conservation tillage where excluded from the assessment due to lack of sufficient data and the small area under conservation tillage. The rest of the countries were considered to practice conventional tillage only.

4.4 ALLOCATION OF GHG EMISSIONS

Agricultural production usually results in the generation of by-products or co-products, especially if farms have on-site product processing facilities. In addition, certain agricultural activities will contribute to multiple streams of products (and their co/by-products), especially on mixed farms. For instance, fertilizer application will support not only crop growth, but also livestock production, if some of the primary output (the crop) is used as livestock feed.

Allocation is the process of partitioning GHG emissions data from a farm to the different product streams from that farm. Crop production systems are multi-functional and generate multiple products. Typically, several different products and outputs are produced for different purposes and therefore, inputs and emissions need to be allocated between the various products.

This assessment was undertaken with the main objective of improving benchmarking of livestock supply chains by providing data to support such efforts. For this reason, no allocation between outputs is undertaken in this case. This should facilitate LCA practitioners interested in conducting their own assessment to do so in a transparent manner. LCA Practitioners should however refer to the LEAP Guidelines on Feed for rules on allocation between various outputs.

4.5 EMISSIONS FROM THE CULTIVATION OF CROPS

Crop production contributes to the emission of GHGs through disturbance of soil and vegetation carbon pools (e.g., ploughing/tillage and management of crop residues) and the emissions of other GHGs, but also through field or farm operations. (e.g., emissions from energy sources needed for tillage practices or in the application of organic amendments and chemicals).

A number of inputs are used for crop production e.g. fertilizers, pesticides, lime, water and fossil fuel energy. The production, formulation, storage, distribution of these inputs and their application with mechanized equipment lead to combustion of fossil fuel and use of energy from alternate sources, which also emits CO_2 and other greenhouse gases (GHGs) into the atmosphere. Fossil fuel CO_2 emissions on croplands are estimated to be responsible for 0.4-0.6 Gt CO_2 eq. per year in 2010 from agricultural use in machinery, such as tractors, irrigation pumps, etc. (AR5 IPCC, 2014). Emissions from energy use associated with crop production may be grouped into primary and secondary sources. Primary sources of emissions (direct) are either due to on-farm mobile operations (e.g., tillage, sowing, fertilization, harvesting and transport) or stationary operations (e.g., pumping water). Secondary sources of emissions (indirect) comprise of emissions from manufacturing, packaging and storage of synthetic fertilizers and pesticides and the production and maintenance of equipment, etc. The production of N fertilizer alone was estimated to release 410 Tg CO_2 eq. per year, which is equivalent to 0.8% of the global GHG emissions (Bentrup, 2009). Other inputs such as pesticides, phosphate and potassium fertilizers are not considered to produce GHG emissions during their use/application during the crop production phase.

Agricultural soils represent a very large, and growing global source of nitrous oxide. A major direct source of nitrous oxide from agricultural soils is from fertilizer use. Emissions from synthetic fertilizers grew at an average rate of 3.9% per year from 1961 to 2010, with absolute values increasing more than 9-fold, from 0.07 to 0.68 Gt CO_2 eq. per year (Tubiello *et al.*, 2013). Widespread increase in the use of nitrogen based fertilizers has been driven by the need for greater crop yields, and by more intensive farming practices. Similarly, the widespread and often poorly controlled use of animal manure as fertilizer can lead to substantial emissions of nitrous oxide from agricultural soils. Additional nitrous oxide arises from agricultural soils through crop residue management and the process of nitrogen fixation. Indirect agricultural sources of nitrous oxide remain poorly defined in most cases due to the high variability. There are several ways in which such indirect emissions occur.

The most important of these is nitrous oxide emission arising from volatilization, nitrogen leaching and run-off from agricultural soils.

A change in land use causes a change in carbon stocks aboveground and belowground. According to IPCC (2014), land use and changes in land use, principally those associated with deforestation and expansion of agricultural production for food, contribute about 9 – 11 % of total anthropogenic greenhouse gas emission (approximately 4.3 – 5.5 $GtCO_2$ eq. /year). Land-use change (LUC) occurs when land is converted to the production of crop from other uses or states, including non-feedstock agricultural lands, forests, and grasslands. This type of LUC is sometimes called direct LUC.

***Modelling Framework*:**

The emissions were calculated using the Global Livestock Environmental Assessment Model (GLEAM). GLEAM is a modelling framework that simulates the interaction of activities and processes involved in livestock production and the environment. The model is developed to assess livestock's impacts, adaptation and mitigation options at (sub)national, regional and global scale. GLEAM differentiates key stages along livestock supply chains such as feed production, processing and transport; on-farm herd management, animal feeding and manure management; and animal products processing and transport. The model captures the specific impacts of each stage, offering a comprehensive and disaggregated picture of livestock supply chains impacts and valuable information for intervention.

Subsequent sections present the methodology used in the estimation of GHG emissions.

4.6 CARBON DIOXIDE EMISSIONS FROM CROP PRODUCTION

Four sources discussed below relate to production of inputs, while the other 4 to management practices. Each of these is discussed in the subsequent sub-section.

4.6.1 CO_2 emissions from the production of energy for crop production

Use of energy (fossil fuels and electricity) in agriculture results in CO_2 emissions from the combustion, and there are additional emissions associated with production and delivery of fuels to the farm. This section deals with the latter category of emissions. In crop production, three main types of fuels for farm operations are used: diesel oil, natural gas, and electricity. Diesel oil is related to crop production activities and the operation of farm machinery used for various cropping activities. Natural gas and electricity are used more for other farm operations such as such as ground water abstraction, machine maintenance and crop drying. Carbon dioxide emissions attributable to electricity consumption are based on the fuels used in power generation and for each region, an emission factor reflecting the mean generation mix was estimated from the International Energy Agency (IEA) database. Emission factors for electricity generation applied in this assessment are provided in the life cycle inventory document.

4.6.2 CO_2 emissions from the production of synthetic fertilizer and lime

Greenhouse gas emissions associated with fertilizer production vary according to different processing technologies and energy sources (Wood and Cowie, 2004; Cherubini, 2010). This analysis includes emissions from three primary nutrients (N, P and K)

plus agricultural lime ($CaCO_3$). CO_2 emissions during the production of these inputs result from the energy required for production and transport. CO_2 emissions due to fertilizer application are dealt with separately in later calculations of energy use associated with the operation of farm machinery (Section 4.6.6). Nitrous oxide emissions arising from fertilizer application are dealt with separately in Section 3.6 of this report.

To calculate indirect emissions from the production and transportation of fertilizers and agricultural lime, average emission factors were taken from Kool *et al.* (2012) and multiplied by the national average application rate taken from IFA and FAOSTAT databases. Emission factors coefficients applied are provided in the life cycle inventory document.

Emissions were calculated as:

$$\textbf{Application rate} * \textbf{EF}_{\text{synthetic fertilizer}}$$

Where:

Application rate: synthetic fertilizer/ lime application rate per hectare, kg/ha

EF synthetic fertilizer: emission factor for production of synthetic fertilizer, (Kg CO_2 eq. /kg synthetic fertilizer)

Where no specific information on the application of agricultural lime was available, no estimates were made.

4.6.3 CO_2 emissions from production of pesticides

In order to control weeds, pests and diseases, farmers apply chemicals such as herbicides, fungicides, and insecticides to crops. GHG emissions are released during the manufacture of pesticides, which includes the formulation, packaging and transportation. Pesticides are input as the active ingredient application rate (kg a.i. per hectare). Estimation of emissions associated with pesticides is complex; energy consumption in pesticide production will depend on the composition and the manufacturing processes employed. There is also a wide range of energy used in producing different pesticides and significant changes over the years in the pesticide ingredients used.

Equivalent C emissions for pesticides were calculated using the EFs of 25.5 Kg CO_2 eq. /kg a.i. derived from Audley *et al.* (2009). Where data on the amount of active substance of pesticides applied, CO_2 eq. emissions were calculated by multiplying the EFs by the amount of active substance.

Emissions from the production of pesticides are derived as follows:

$$\textbf{Application rate} * \textbf{EF}_{\text{pesticides}}$$

Where:

Application rate: application rate of pesticides, kg a.i./ha

EF pesticides: emission factor for production of pesticides, Kg CO_2 eq. /kg a.i.

4.6.4 CO_2 emissions from the production, amortisation and maintenance of farm machinery and equipment

Greenhouse gas emissions from the use of machinery and equipment for crop production can be categorised into direct and indirect emissions. The direct emissions

are caused by the burning of fossil fuel during field operations and the indirect emissions arise from the manufacture of farm machinery, amortization and maintenance of the machines. This section presents the approach used for the estimation of indirect emissions.

Data on the machinery and equipment, used in each cropping system, degree of mechanization in each country per crop was gathered from literature. This data is presented in Annex 5 of the life cycle inventory document and are based on different data sources. Emissions caused by the manufacture, amortisation and maintenance of machinery were calculated using the approach to assess the indirect energy use from Nemecek and Kagi (2007).

4.6.5 CO_2 emissions from land use change

Soils are an important part of the carbon cycle and changes in soil carbon can influence GHG emissions. GHG emissions can result from soil carbon losses, caused by land use changes (LUC). Emissions from land use change were calculated for direct land use change for the approach 'weighted average' and 'worst-case scenario' based on the approach from PAS 2050-1:2012 as recommended in the LEAP Feed Guidelines. This approach is not crop-specific: the impacts from land use change are allocated to all crops, which increased in area harvested in a specific country, dependent on their respective share of area increase. According to PAS2050, these emissions are distributed over a time period of 20 years (1990-2010).

The approach uses statistical data from FAOSTAT for crop yields, harvested area of crops and area of forest and grassland, from FAO's global forest resource assessment for carbon stocks (in case former land use is unknown) (FAO 2010), and values of soil organic carbon stock and stock change factors (IPCC 2006). Changes in soil organic carbon stock are taken into account with that methodology. The emissions are reported separately as required by the LEAP guidelines. Emission factors are provided in Annex 6 of the LCI document.

4.6.6 CO_2 emissions from on-farm machinery use for field operations

Agricultural machinery can be employed in a number of field activities such as soil management, fertilization, harvesting, irrigation, etc. in this study, direct energy is only calculated for tractors, harvesters and irrigation. Other equipment is usually used in combination with tractors and consequently no direct energy emissions were estimated for these. On-farm emissions associated with the use of fossil fuel use for field operations will vary by cropping practice, scale of production, level of mechanization, type of machinery used and frequency of activity.

An extensive literature review was undertaken to collect information on the type and number of times the field operation is performed, the machinery used and the fuel consumption for each activity. Emission intensity estimates also takes into account the cropping system (conventional versus conservation tillage) as described in Section 2 of this document. The information is presented in Annex 5 of the accompanying document on life cycle inventory.

To estimate direct energy use and emissions from the use of machinery, the following equations based on Nemecek and Kagi (2007) were used:

(1) Diesel-use (a,b) kg/ha = frequency (a) * operation time (a) * MFC (a,b) * density (diesel)

Where:
Frequency (a) = the frequency of the activity a in the growing season
Operation time = the time required to do the activity a on one hectare (hour/ha)
MFC (a,b) = Mean Fuel Consumption, the characteristic fuel consumption for activity a with tractor b (liters/hour)
Density (diesel) = the density of diesel (kg per liter)

(2) Energy-use (mj/ha) = Diesel-use (kg/ha) * MJdiesel (mj/kg)

Where:
MJdiesel = energy density diesel (mj/kg)

(3) Emissions (Kg CO_2/ha) = Energy-use (mj/ha) * CO_2dieselMJ (kg CO_2/MJ diesel)

Where:
CO_2dieselMJ = the direct and indirect GHG emissions per MJ of diesel (in g/MJ)

4.6.7 CO_2 emissions from the abstraction of ground water for irrigation

CO_2 emissions from irrigation were calculated based on the energy required for abstraction (pumping) and water application. Irrigation is a primary consumer of energy on farms particularly when pumping is required, so any changes to the irrigation method used can be expected to change on-farm energy consumption. The direct energy inputs are primarily used to operate farm machinery and pumps, while indirect energy inputs refer to energy that is used to produce equipment and other goods and services that are used on-farm. Where groundwater is used, more energy is required for pumping. The energy required for pumping depends on the crop water requirement, total head, flow rate and system efficiency.

The operational processes involving energy for irrigation are abstraction and application of water. However, many factors within each process influence energy intensity. Energy use varies with the source of water (groundwater, surface water and water stored in reservoirs), the distance and lift over which water is transported before application, and the application method (in the case of pressurized systems). In addition, the intensity of water use in irrigated agriculture is a critical factor determining the amount of water and thereby the energy required for irrigation. Pumping water is the most energy-demanding process (Wang *et al.*, 2012; Lal, 2004).

CO_2 emissions from irrigation were calculated based on the energy needed for abstraction (pumping) and water application. The energy used for abstraction is a function of water source. In this study, the energy required to abstract water from a surface source was assumed to be negligible; only energy (lift) for groundwater abstraction was included. This assumes that water is conveyed to the farm by gravity and not pressurized, but it is recognized that the water source is not always in close proximity to a farm.

Energy for abstraction of water was calculated by apply a basic theoretical physical relationship, which prescribes the energy required to lift 1 m^3 of water (with a density 1000 kg m^3) up 1 m at 100% efficiency is 0.0027 kWh (see equation below), Rothausen and Conway 2011).

The following assumptions and data sources were used in the calculation of emissions from abstraction of ground water:

- Average country lift values were based on the groundwater table depth model (WTD) (Fan and Miguez-Macho, 2013) and the Global Map of Irrigated Areas (GMIA) (2013).
- The efficiency was found to range between 11% -30% for electric pumps and 40% to 67% for electricity pumps.
- Mass of water from groundwater used for irrigation (m3/year) on national base was derived from Siebert *et al.* (2010).

The GHG emissions are equal to the energy consumption multiplied by its emission factor.

$$\textbf{Energy (kWh)} = \frac{\textbf{9.8 m s}^{-2}\ \textbf{x Lift (m) x Mass (kg)}}{\textbf{3.6 x 10}^{6}\ \textbf{x Efficiency (\%)}}$$

Where:
Energy = energy use for calculated for abstraction of water from shallow and deep wells.

The energy source used also determines the quantity of CO_2 emitted for each kWh of energy produced. The estimated CO_2 emissions emitted from a diesel engine to produce 1 kWh of energy are equivalent to 0.32021 kg (Wang *et al.*, 2012).

For electric motors, the energy to CO_2 conversion factor depends on the energy source from which the electricity is produced. For each country, the International Energy Agency (IEA 2015) has calculated the energy to CO_2 conversion factor using the total CO_2 emissions from fossil fuels consumed for electricity generation divided by the outputs of electricity generated from fossil fuels, nuclear, hydro, geothermal, solar, wind, ocean and biofuels. These conversion factors for both diesel and electric engines were used here to estimate the total volume of CO_2 emitted by irrigation pumping.

4.6.8 CO_2 emissions from application of agricultural lime

Agricultural lime is commonly used in the management of croplands and grasslands to decrease soil acidity. Lime is often applied in the form of crushed limestone ($CaCO_3$) or crushed dolomite ($CaMg(CO_3)_2$). Adding carbonates to soils in the form of lime or dolomite leads to CO_2 emissions as the carbonate limes dissolve and release bicarbonate ($2HCO_3$), which evolves into CO_2 and water (H_2O). CO_2 emissions from the dissolution of carbonate rock discussed here do not include emissions from the fossil fuels used to crush, deliver, and spread the crushed rock on agricultural fields. Direct emissions from lime application were calculated according to IPCC (2006) using an emission factor (EF) for limestone of 0.396 kg CO_2/kg limestone.

4.7 NITROUS OXIDE EMISSIONS FROM SOILS

In most soils, an increase in available nitrogen enhances nitrification and denitrification rates, which then increases the production of N_2O, along with indirect emissions from leaching and volatilization. The main sources of N_2O included in the methodology for estimating N_2O emissions from soils include:

- Synthetic nitrogen fertilizers
- Organic nitrogen applied as fertilizers e.g. animal manure
- Nitrogen in crop residues

Many fertilizers contain nitrogen, a part of which is released into the atmosphere as nitrous oxide. In the assessment, nitrous oxide emissions from cultivation of crops were calculated according to the Tier 1 methodology of IPCC (2006). The method includes a direct contribution from N_2O produced from added N in the soil system and an indirect contribution of N_2O produced from N that escapes the cropping system via leaching and volatilization. Tier 1 is the basic method, designed to use readily-available national statistics (also known as activity data) in combination with default EFs and additional parameters that are provided. This approach is straightforward and transparent. The default EFs are derived from very large datasets and hence give an accurate representation of 'average' emissions at the global scale. However, a Tier 1 methodology is less accurate in representing the effects that regional or local variations in management and/or environment within a given source category may have on GHG emissions from soils and on the effects of implementing GHG mitigation methods.

Direct N_2O emission in the IPCC (2006) methodology is calculated from the empirical assumption that 1% of the added nitrogen in soil system is emitted as N_2O. To calculate the amount of added nitrogen, the IPCC methodology includes the amount of fertilizer N applied and a contribution from aboveground and below-ground crop residues:

$$\mathbf{N_2O\ (direct) = (FSN + FON + FCR) \times EFN \times 44/28\ (kg\ N_2O/ha),}$$

Where:
FSN = Amount of synthetic fertilizer applied (kg N/ha)
FON = Amount of annual manure applied (kg N/ha)
FCR = Amount of N crop residues above ground and below-ground (kg N/ha)
EFN = IPCC emission factor for added nitrogen (0.01 kg N_2O-N/kg N)

The quantity of crop residues left after harvesting was calculated based on the crop yield, less any residue removed as the co-product. Estimates for the amount of N in crop residues were calculated according to IPCC equation 11.6 (IPCC, 2006).

Indirect nitrous oxide emissions are calculated from the nitrogen lost by leaching and volatilization. To calculate the contribution of N_2O from the amount of leached N, the IPCC (2006) emission factor of 0.0075 kg N_2O-N/kg N was applied. Nitrogen lost through volatilization of ammonia was assumed to be 10% of the mineral and organic fertilizers applied (IPCC, 2006). To calculate the contribution of N_2O from the amount of volatilized NH_3 the IPCC (2006) emission factor of 0.01 kg N_2O-N/kg NH3-N was applied.

Indirect nitrous oxide emissions (kg N_2O/ha) were calculated as:

$$\mathbf{N_2O\ (indirect) = (FL \times EFL + FA \times EFD) \times 44/28}$$

Where:
FL = Amount of nitrogen lost through leaching (kg N/ha)
EFL = IPCC emission factor for leached nitrogen (0.0075 kg N_2O-N/ha)
FA = Amount of ammonia emitted from fertilizer application
EFD = IPCC emission factor for volatilization and re-deposition (0.01 kg N_2O-N/kg NH_3-N)

5. Challenges and future work

This study was based on the guidance developed under the framework of the LEAP Partnership and is a first attempt to provide a global life cycle inventory dataset that can be used to assess feed supply chains. The study has also highlighted numerous challenges and gaps particularly related to data availability to support benchmarking of livestock supply chains.

A number of issues standout:

- To account for the diversity of agricultural management at the global scale it is crucial to include regional differences in crop varieties and sub-national variability of management practices, e.g. sequential cropping and crop rotations, which are relevant for soil nutrient dynamics, should be included for future model improvements.
- Spatial variability of input use e.g. fertilizer use is important. For example, in this simulation, we apply only one fertilization rate at national level although fertilizer application varies spatially and by crop.
- Better descriptions of current production practices and improving data particularly for developing and emerging regions is key to understanding the impact of the projected demand for livestock products in these regions. A better understanding of input use is an imperative to improving the system.

Short-term developments for future versions of the LEAP database and its content can be classified in the following areas:

- incorporation of data related to changes in soil carbon stocks
- improvements in the estimation of N_2O emissions
- inclusion of information on uncertainty
- improvements in the database system
- improvements in data supply and data query

An extension of the content of the LEAP database and the building up of international collaboration in LCI data collection and supply are key activities for the future.

Long term recommendations for future assessments should be based around two major aspects: improving data quality and increasing the database coverage in terms of crops covered and environmental impacts. An LCA analysis is dependent upon the quality of the data used to construct it. This first assessment has identified areas where improved data quality will allow a more accurate description of GHG emissions. In particular, nitrous oxide emissions that make up a considerable proportion of total on-farm GHG emissions may be more accurately assessed using manufacturing specific emission factors for nitrogen fertilizer and site specific emission factors for nitrogen dependent field emissions. Data quality would be further improved with accurate quantitative data and its allocation amongst operational processes.

The end point for this study was the field gate; a future study should focus on extension of the assessed system boundary. Many feed materials used in the livestock chain are by-products of processes beyond the farm-gate; an expanded assessment would provide an indication on how much this affects the carbon footprint of animal feed products.

One of the strengths of an LCA analysis is the identification of inefficiencies and potential 'hotspots' for optimization. It is envisioned that future LCA work, taking into account the above considerations will allow the discussion of possible efficient production strategies that could be utilized to lower GHG emissions from feed production.

Our Sustainability Efforts

We are redefining dairy and food production through our unwavering commitment to environmental stewardship

Our Sustainability Vision

Grounded in a full life cycle approach, our sustainability program integrates best-in-class practices that reduce greenhouse gas emissions, conserve water, and close resource loops, setting a new standard for the industry.

We envision a holistic dairy and food manufacturing ecosystem that thrives in harmony with nature, one where every product reflects our respec

Across our dairies, processing facilities, and extended supply chain, we commit to innovating in resource conservation, renewable energy, and regenerative practices.

By partnering closely with suppliers who share our values, we deliver wholesome, natural products while safeguarding our shared environment for generations to come.

Sustainability Policy

Our **Environmental Sustainability Policy** applies across every facet of our operation, from our dairies and processing facilities to distribution and supplier partnerships, reflecting our commitment to responsible **resource management** and **environmental stewardship**.

Anchored by the core principles of **Compliance & Integrity**, **Continuous Improvement**, and **Collaboration & Transparency**, the policy details our three key commitments:

Dairy Sense: Keeping the Dairy Right Sized

Regardless of the dairy's herd size, there is one key theme that applies to everyone, a land base that matches the number of cows and heifers in the herd.

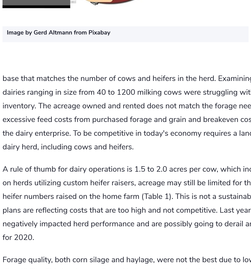

Image by Gerd Altmann from Pixabay

March 2020

Production Perspective

Dairy operations need to be "custom-tailored" to the resources available, as there is no cookie-cutter approach to managing the business. However, regardless of the dairy's herd size, there is one key theme that applies to everyone: a land base that matches the number of cows and heifers in the herd. Examining cash flows from 2019, dairies ranging in size from 40 to 1200 milking cows were struggling with inadequate forage inventory. The acreage owned and rented does not match the forage needs of the herd. The result is excessive feed costs from purchased forage and grain and breakeven costs exceeding $22.00/cwt for the dairy enterprise. To be competitive in today's economy requires a land base right-sized for the dairy herd, including cows and heifers.

A rule of thumb for dairy operations is 1.5 to 2.0 acres per cow, which includes the youngstock. Even on herds utilizing custom heifer raisers, acreage may still be limited for the cows and the reduced heifer numbers raised on the home farm (Table 1). This is not a sustainable model, and the cash flow plans are reflecting costs that are too high and not competitive. Last year in 2019, several challenges negatively impacted herd performance and are possibly going to derail any chance of improvement for 2020.

Forage quality, both corn silage and haylage, were not the best due to lower than ideal fiber digestibility. This has been reflected in lower milk production than expected and as a result lower milk income. Due to rainfall at undesirable times last spring, quantity of small grain silage was compromised, and corn was planted very late. Even though most farms are utilizing double cropping as a forage source, the yields were extremely low. The tonnage for small grain silage on an as-fed basis ranged from 2 to 10 tons/acre. Farms that are doing a good job typically are in the 6 to 8 tons/acre range. The farms with extremely low tonnage have extremely high unit costs. In most cases, the small grain silage was harvested late, and quality was not ideal for lactating cows.

Another common thread observed in herds of all sizes relates to heifer numbers. With the popularity of sexed semen and the low prices for cattle, more heifers are staying on the farm. This is turning into a liability because they require feed, which is draining the limited inventory. When evaluating heifer rations for the cash flow plans, it is no coincidence forages needed are not matching the forages purchased. Heifers are being short-changed due to cash flow issues.

Drilling down further, age at first calving is being extended beyond the recommended 24 months. The percentage of first-lactation animals is getting close to 50 percent of the milking herd, when the range should be around 38 to 40 percent. First-lactation animals do not perform to the level of mature cows and are another liability to the herd because of reduced milk income.

Profitability relies on having a solid foundation from which to build. Emphasis is usually on forage quality, which is important, but quantity is probably the more significant factor in many situations. Relying on purchased forage and grain to compensate for inadequate or inefficient home-raised feed production is a formula for disaster. This, coupled with a large heifer inventory, is putting a strain on the whole farm system. The best way to determine severity of the problem is to do an intensive cash flow assessment, including numbers from both the financial and production side of the operation. Now is the time to determine the best course of action to take advantage of an improved milk price for 2020.

Table 1. Animal units compared to acreage harvested for crops (owned and rented land) for an Amish producer.

Animal	Number	Bodyweight, lbs.	Animal unit[1]
Milk cows	44	1300	44.0
Dry cows	7	1350	7.3
Calves < 6 months	5	250	1.0
Heifers 7 to 12 months	5	600	2.3
Heifers >12 months	10	900	6.9
Horses/mules	12	1100	10.0
Total animal units			71.5

Total animal units: 71.5
Total harvestable acres: 57.0
Acres per animal: 1.25[2]

Note: A custom heifer raiser is used for some of the replacement animals.

[1]The milking herd average bodyweight is considered the standard bodyweight of 1.0. Example: dry cow bodyweight of 1350 divided by 1300 equals 1.038 times 7 dry cows equals 7.3 animal units.

[2]Recommended acres per animal is 1.5 to 2.0.

Action Plan for Evaluating the Whole Farm System

Goal – Complete a cash flow plan for the whole farm

Step 1: Using Penn State Extension's Excel spreadsheet, complete a year-end analysis for 2019 on both a cash and accrual basis.

Step 2: Compile income for the dairy and other sources, including crop sales or other farm income (custom work, hogs, birds, etc.).

Step 3: Compile expenses for the dairy, crops, feed, overheads, family living, and loan payments, including principal and interest.

Step 4: Include accounts payable. The usual areas are feed, seed, fertilizer, and vet expenses.

Step 5: Work with the appropriate consultants to discuss the farm's breakeven cost, comparing the whole farm to the dairy and crop enterprises.

Feeding management and characteristics of rations for high-producing dairy cows in freestall herds

M. I. Endres[1] and L. A. Espejo
Department of Animal Science, University of Minnesota, St. Paul 55108

ABSTRACT

The objectives of this cross-sectional observational study were to 1) describe the feeding management and characteristics of rations for high-producing Holstein cows housed in freestall barns in Minnesota, 2) evaluate ration change over time, and 3) investigate herd-level risk factors for ration change. Each of 50 randomly selected freestall dairy herds was visited once during the study. Samples of TMR were collected from the high-production group feed bunk to represent the initial ration as delivered to the cows, 3 additional samples were collected every 2 to 3 h after feed delivery, and the accumulated orts were cleaned out of the feed bunk. Feeding management practices and TMR formulation were also collected at the time of visit. Seventy percent of herds fed once daily, 22% fed twice daily, and 8% fed 3 times daily. Frequency of feed push-up was 5.4 ± 2.3 times daily. Linear feed bunk space per cow was 0.45 ± 0.11 m. Sixty-two percent of the farms had 3-row pens and 38% had 2-row pens. Linear feed bunk space per cow was greater in 2-row pens (0.56 m/cow) than in 3-row pens (0.39 m/cow). Post and rail was the most common type of feed barrier; it was used by 60% of the herds. Headlocks were used by 28% of the herds, combination of post and rail with headlocks was used by 8%, and diagonal bars were used by 4%. Water trough linear space was 4.6 ± 2.1 cm/cow. Estimated dry matter intake was 24.3 kg/cow per day. The forage content of the formulated ration was 52% of the ration DM, and corn silage was the most commonly used forage. The NDF content of the analyzed ration was greater than the NDF content of the formulated ration (30.6 and 29.8%, respectively). In contrast, the CP content was lower (17.5 and 17.9%, respectively). Some feeding management practices (e.g., feeding frequency) were associated with ration NDF content change over time. This association may be minimized by implementing ration and management changes.

Key words: feeding management, ration characteristic, particle size

INTRODUCTION

In recent decades, there has been a trend for housing dairy cows in freestall barns instead of tiestall barns in the upper Midwest to improve labor efficiency in dairy operations. With this change, cows are no longer fed individually; instead, they are fed as a group with a TMR, where forages and concentrates are mixed together. Feeding a TMR allows producers to incorporate all the required ingredients into a single ration to meet cows' nutritional requirements and optimize herd milk production. However, feeding cows as groups is more challenging because they can potentially sort the feed and individual preferences can lead to cows eating different diets. In addition, social interactions among cows at the feed bunk can affect individual cows' intake.

Several management and environmental factors have been shown to affect feeding behavior of dairy cows. Increasing feed bunk space per cow resulted in a reduction in displacements of subordinate cows by dominant cows while they were eating (Olofsson, 1999; DeVries et al., 2004). In addition, type and design of the feed barrier was shown to influence aggressive behavior between cows while they were eating (Huzzey et al., 2006). Similarly, water consumption is an important factor influencing milk production. Water intake could be affected by available space per cow at the water trough (Castle and Thomas, 1975). An assessment of feeding management practices used in Minnesota freestall herds has not been conducted in recent history.

Ration physical and chemical characteristics are important factors in meeting the nutritional requirements of high-producing dairy cows (NRC, 2001). Those characteristics have not been evaluated in a large data set of Minnesota freestall herds. The Penn State Forage and TMR Particle Separator is a field tool that can be used to describe physical characteristics of rations. An additional sieve measuring 1.18 mm was added recently (Kononoff et al., 2003); it allows for more accurate estimation of the average TMR particle size distribution.

Selective consumption or sorting of the TMR has been reported (Leonardi and Armentano, 2003; DeVries

et al., 2007). Observation of the feeding behavior and analysis of the orts revealed that cows typically sort against long particles (Leonardi and Armentano, 2003; DeVries et al., 2007), which could reduce the intake of physically effective NDF and increase the intake of the finer nonstructural carbohydrate fraction. This situation could affect the normal function of the rumen and increase the risk of SARA and displaced abomasum, result in fluctuations in feed intake, alter the immune function, increase the incidence of foot lesions, depress milk fat, and reduce rumination activity (Martin, 2000; Leonardi and Armentano, 2003). Recent studies have investigated sorting activity of cows housed in a freestall facility (DeVries et al., 2007; Leonardi and Armentano, 2007). Measuring feed sorting behavior in commercial herds is difficult, but better documenting changes to the ration in a large number of freestall facilities can be of interest and point to potential feed sorting activity.

The objectives of this observational study were to 1) document feeding management and characteristics of rations provided to high-producing Holstein cows housed in freestall barns in Minnesota; 2) evaluate ration NDF content change over time; and 3) investigate herd-level risk factors for ration NDF content change over time.

MATERIALS AND METHODS

On-Farm Data Collection

This cross-sectional observational study was performed in 50 freestall dairy farms in Minnesota between June and October 2004. Dairy farms were selected randomly from a list of herds having more than 150 cows situated within a geographical area where most of the dairy farms in Minnesota are located (central and southeast Minnesota). The list was obtained from the Minnesota Department of Agriculture (St. Paul). Herd owners were contacted by phone and asked about their willingness to participate in the study. The only criterion for enrollment was that cows were housed in freestall barns. All farms had Holstein cows as the predominant breed, but this was not a criterion for selection. Observation was focused on the high-production group. High-production group size was 117 ± 51 (mean ± SD) cows. Therefore, results from this study would represent the population of cows in the high-production group housed in freestall dairy farms with a herd size ≥150 cows.

Each farm was visited once during the study. Logistical limitations and the goal of visiting all herds during the same season did not allow for more than 1 visit per farm. On each farm, samples of the TMR were collected from 6 to 10 areas along the feed bunk of the high-production group pen and mixed together in a 5-gallon bucket to obtain a representative sample of the TMR along the feed bunk. Special care was taken to ensure that each grab sample of the TMR represented the remaining feed in the feed bunk in each sampled area. This process was repeated 5 times during the day as follows: sample 1 represented the initial TMR collected immediately after it was delivered; samples 2, 3, and 4 represented samples taken every 2 to 3 h after sample 1 (delivery time); and sample 5 was taken from the accumulated orts cleaned out of the bunk by the feed manager. We were unable to collect ration weights for delivered feed and orts. Most producers indicated feeding for a maximum of 5% orts (as fed), with some targeting 2 to 3%.

At every sampling time, an evaluation of the particle size distribution of the TMR was performed by the same person using the 3-sieve (19-, 8- and 1.18-mm) Penn State Forage and TMR Particle Size Separator and the methodology described by Kononoff et al. (2003). The procedure was performed in triplicate for each sampling time and the weight of the mass retained on each screen and the bottom pan was recorded in every replicate.

In addition, at each sampling time a representative subsample of the TMR was taken and kept frozen (−20°C) for the analysis of CP and NDF using standard methods. Samples were dried in a 60°C forced-air oven and ground in a Wiley mill (Swedesboro, NJ) to pass through a 1-mm screen. Final DM was determined by drying samples at 105°C for 8 h (AOAC, 1995). Samples were analyzed for NDF using the Ankom200 fiber system (Ankom Technology Corporation, Fairport, NY). Sodium sulfite and heat-stable α-amylase were included in the neutral detergent extraction, and heat-stable α-amylase was also added during the first 2 rinses (Hintz et al., 1996). Samples were analyzed for CP using a TrueSpec Protein Nitrogen Analyzer (Leco Corporation, St. Joseph, MI; AOAC, 1995).

Information on feeding frequency, frequency of feed push-up, and number of cows in the pen was obtained from the herd manager. The linear length of the feed bunk and water troughs was measured during the farm visit. A copy of the TMR formulation used for the high-production group at the time of visit was also obtained and used to determine the type and amount of forage in the ration, to describe the nutrient composition of the formulated diet, and to compare the nutrient formulation for CP and NDF with laboratory results. Milk production data were summarized from the nearest DHIA test date to the time of visit as management level milk (**MLM**) for each group on each farm. Management level milk adjusts the daily milk yield for 150 DIM, 3.5% fat, and 3.0% true protein. Milk fat and milk protein were reported as percentages.

Statistical Analysis

Descriptive statistics was used to characterize the distribution of the variables in the study using the MEANS and FREQ procedures of SAS (SAS Institute Inc., Cary, NC). *t*-Test was used to determine differences in the mean linear feed bunk space per cow between 2-row and 3-row pens. *t*-Test was also used to determine differences between DM, CP, and NDF of the formulated ration and the analyzed ration. These *t*-tests were performed using the MEANS procedure of SAS (SAS Institute Inc.). Differences were declared at $P < 0.05$.

Exploratory data analysis was performed using the GPLOT and UNIVARIATE procedures of SAS (SAS Institute Inc.). Mixed models were used to evaluate chemical (DM, NDF, and CP) changes of the ration across the 5 samples. Farms were included in these models as a random effect, and least squares means of the 5 samples were computed and compared using Bonferroni test for multiple comparisons. A random-effect mixed model was used to analyze the association of NDF content (percentage) over time (dependent variable) and the possible associated factors (explanatory variables), using farm as a random effect. Following the evaluation of the models using Akaike's and Bayesian information criteria, the final model that better fit the data included a random intercept and slope (time) by farm with an unstructured working correlation matrix within farm. The models were selected using the MIXED procedure of SAS (SAS Institute Inc.).

The following were initially used as explanatory variables: time after feed delivery when the sample was taken (hours); feed delivery frequency (grouped in 2 categories: 1 = once daily; 2 = twice or more daily); feed push-up frequency (grouped in 2 categories: 1 = 5 times or fewer daily; 2 = 6 times or more daily); feed bunk barrier design (grouped in 2 categories: 1 = predominantly headlock; 2 = predominantly post and rail); percentage of hay in the ration (DM basis); feed bunk space per cow (meters); and initial TMR DM content (percentge). Interactions between initial NDF content and percentage of hay in the ration and between initial NDF content and initial TMR DM content were also considered in the model. Stepwise backward elimination was used to remove nonsignificant terms from the model. The threshold value to keep a term in the model was $P \leq 0.05$. Model assumptions were evaluated using residual plots. The model was also used to calculate the BLUP for the random effects of the farm. Once the BLUP were ordered from highest to lowest, management and production characteristics were calculated for the 50th, 25th, and 10th percentiles.

RESULTS AND DISCUSSION

Feeding Management Practices

Seventy percent of herds fed once daily, 22% fed twice daily, and 8% fed 3 times daily. The frequency of feed push-up was 5.4 ± 2.3 times daily (range = 3–12 times daily). It was expected that farms that fed their cows only once daily would have higher frequency of feed push-up throughout the day; however, a single regression analysis showed that feed delivery frequency was not associated with feed push-up frequency. Some might expect that pushing up feed will increase feeding activity. However, DeVries et al. (2003) did not find differences in feeding activity when 2 extra push-ups were implemented during the late evening and early morning hours in a freestall herd fed twice daily. They concluded that fresh feed delivery and the milking process were more important in stimulating the feeding activity of dairy cows. In another study, DeVries and von Keyserlingk (2005) concluded that the feed delivery effect was more important than the milking effect. However, it is essential to push up feed to the cows various times during the day to provide them access to the feed because they tend to toss feed forward and no longer within reach when they eat at a feed bunk.

The linear feed bunk space per cow was 0.45 ± 0.11 m (range = 0.21–0.75 m). DeVries et al. (2004) showed that an increase in linear feed bunk space per cow reduced aggressive behavior among cows and improved feeding time, especially of more subordinate cows. Similarly, Olofsson (1999) reported that an increase in the level of competition at the feed bunk by increasing the number of cows per feeding station (4 times) resulted in an increase in the frequency of displacements from the bunk for subordinate cows. Additionally, the exposure to higher levels of competition at the feed bunk increased their consumption rate, reduced their time spent eating, and increased their time spent standing. The American Society of Agricultural Engineers recommended that linear feed bunk space per cow should be no less than 0.60 m (ASAE, 2001). In the current study, 92% of the high-production groups had less than the recommended feed bunk space, which indicates some level of overstocking in the pens as it relates to feeding space.

The linear feed bunk space per cow in freestall barns is a function of the number of cows in the pen and the length of the feed bunk, which is related to the pen configuration (2-row or 3-row). We found that 62% of the farms had 3-row pens and 38% had 2-row pens. The average linear feed bunk space per cow was greater ($P < 0.01$) in 2-row pens (0.56 ± 0.09 m/cow) than

Table 1. Characteristics of the TMR provided to high-producing Holstein cows in 50 freestall herds in Minnesota

Ca, % of DM	0.96	0.09	0.94	1.11
P, % of DM	0.43	0.04	0.36	0.52
NE_L, Mcal/kg of DM	1.71	0.42	1.63	1.83

[a,b]Means within a column and item with different superscripts differ ($P < 0.01$).

[1]Values for analyzed DM (%), analyzed NDF (%), and analyzed CP (% of DM) are laboratory results of samples collected immediately after feed delivery. Values for all other items are obtained from the formulated ration for the high-production group.

in 3-row pens (0.39 ± 0.08 m/cow). However, in both cases, the mean linear space per cow was less than 0.74 m for a 2-row pen and 0.46 m for a 3-row pen when the pen was stocked at 1 cow per stall (Mentink and Cook, 2006), indicating some level of overstocking. Mentink and Cook (2006) also reported a significant difference in feed bunk space between 2-row and 3-row pens (0.58 m and 0.42 m, respectively) in a field study with 10 dairy herds in Wisconsin.

Post and rail was the most common type of feed barrier; it was used by 60% of the herds. Headlocks were used by 28% of the herds, combination of post and rail with headlocks was used by 8%, and diagonal bars were used by 4%. Huzzey et al. (2006) showed that headlocks reduced aggressive behaviors between cows at the feed bunk, especially for more subordinate cows, compared with post and rail barriers. We speculate that producers preferred post and rail barriers for economic reasons.

The throat height at the feed bunk was 51.4 ± 8.8 cm (measure taken from the pen) and the feed table depth was 39.1 ± 7.0 cm (measure taken from the feed lane). Therefore, the feed bunk was 12.4 ± 8.2 cm higher than the pen. Observation of cows fed in feed troughs at different heights indicated that they prefer to eat from feed troughs placed at floor level with their heads down at the natural pasture position (Albright, 1993) or slightly (10 cm) above this level (ASAE, 2001). The position of head down reduced the feed tossing behavior and waste in comparison with elevated feed bunks (28 cm height on the bottom of the trough and 76 cm height on the top; Albright, 1993). Neck rail height was 122.9 ± 9.1 cm (including all types of feed barrier design), which was basically the recommendation (122.0 cm) for adult cows (ASAE, 2001). The opening between the curb and the neck rail on the feed lane was 71.5 ± 7.4 cm. All these measurements seemed appropriate for cows housed in freestall barns.

Water was provided mainly in water troughs with a linear space of 4.6 ± 2.1 cm/cow (range = 2.0–11.3 cm/cow). Behavioral studies have indicated that the recommended water trough space for milking cows should be from 3.2 to 5.3 cm/cow depending on the DM content of the ration (Castle and Thomas, 1975).

Ration Characteristics and Milk Production

All farms fed their high-production group a TMR. The ration formulation for the high-production group was obtained from 49 of the 50 farms that participated in this study. All rations were formulated to meet the nutrient requirements of lactating dairy cows (NRC, 2001). On average, rations were formulated for 40 kg of daily milk production and 625 kg of BW. Table 1 summarizes ration characteristics, including nutrient concentrations.

The estimated ration DMI was 24.3 kg/cow per day. The forage content of the formulated ration was 52% of the ration DM. Corn silage was the source of forage most commonly used in the formulation of the TMR, and only 1 farm did not include it in the ration formulation for the high-production group. The percentage of corn silage was 25.4 ± 7.9% of the ration DM and

[1]Measured with the Penn State Forage and TMR Particle Separator (Kononoff et al., 2003). Values shown in percentage of the material as fed retained on the sieve.

48.7 ± 14.2% of the total forage DM. The second most commonly used source of forage was alfalfa haylage, which was included in 47 of the rations at 22.6 ± 8.3% of the TMR and 43.4 ± 14.9 of the total forage. Hay was included in 31 of the rations at 6.9 ± 3.6% of the TMR and 13.4 ± 6.9% of the total forage. Straw was used in 7 rations at 0.74 ± 0.44% of the TMR and 1.4 ± 0.78% of the total forage. Additionally, 3 farms used other sources of forage such as barley silage (2) or sweet corn silage (1) at 3.4 ± 1.4% of the TMR and 6.9 ± 3.9% of the total forage.

Results of the laboratory analysis of the initial samples of TMR (sample 1) from the 50 farms are shown in Table 1. The estimated DM of the formulated ration was similar to the DM measured in the initial ration; however, the estimated NDF and CP of the formulated ration were different than the analyzed values. The NDF content of the analyzed ration was greater than the estimated NDF content of the formulated ration ($P < 0.01$); in contrast, the CP content of the analyzed ration was lower than the estimated CP of the formulated ration ($P < 0.01$). Because both NDF and CP contents of the rations were greater than the minimum recommended for high-producing dairy cows (25% NDF and 14.1% CP, assuming a perfect balance between RUP and RDP; NRC, 2001) and the difference between formulated and analyzed values was very small, it appears that these statistical differences would not represent biological differences and would have no effect on the cows' health or performance. Factors that could account for these small differences include sampling discrepancies and day-to-day variation in TMR mixing.

Daily milk production (MLM) for the 50 high-production groups was 39.9 ± 5.6 kg/d. Milk fat percentage was 3.51 ± 0.36 and milk protein percentage was 2.90 ± 0.2 (Table 2). Rations were formulated for 40 kg of milk/day and the average production indicated that this goal was reached for the average farm.

Heinrichs and Kononoff (2002) recommended that between 2 and 8% of the weight of the TMR (as fed basis) should be retained on the upper sieve (particles larger than 19 mm) of the Penn State Particle Separator. No rations in this study were below the lower recommended limit of 2%, whereas 52% of them were above the upper recommended limit of 8%; however, 84% of the rations were below 15% (Table 3). A high proportion of larger particles in the TMR would not necessarily represent a risk for normal rumen activity. However, increasing the proportion of larger particles in the ration could potentially lead to more sorting by the cows (Martin, 2000; Shaver, 2002).

The analysis of distribution of smaller particles showed that the percentage of farms with TMR particle size not meeting the recommendation (30–50%) for particles between 19 and 8 mm and between 8 and 1.18 mm was 22 and 24%, respectively. All rations included the recommended proportion for particles <1.18 mm (<20%).

We observed basically no change in the percentage material retained on the second sieve (>8 mm) of the Penn State Separator over time (Figure 1). Other sieves, especially the top sieve (>19 mm), had a noticeable change from the initial TMR to the orts. It appears that cows were less likely to select for or against particles between 19 and 8 mm. These results substantiate the recommendation by Kononoff et al. (2003) for less than 8% on the top sieve but 30 to 50% on the second sieve.

Ration Change Over Time

We observed an increase ($P < 0.01$) in NDF content and a decrease ($P < 0.01$) in CP and DM content over time (Table 4). The NDF content least squares means increased 6.75 percentage units from the initial ration to the orts ($P < 0.01$). In contrast, the least squares means of the CP content decreased 1.52 percentage units from the initial ration to the orts ($P < 0.01$). Some cows could be consuming a ration lower in NDF and higher in starch, which could lead to ruminal acidosis.

Studies have reported sorting of TMR against longer particles in favor of shorter particles in group-housed cattle. In the current observational study, complete data were not available to demonstrate that cows were indeed sorting the TMR. However, sorting activity against long particles could be a likely explanation for the changes in TMR NDF content. DeVries et al. (2007) used the Penn State Separator to investigate whether the amount of forage in the TMR of cows housed in a

Feeding frequency, times/d			
1 vs. 2 or 3	1.59	0.75	0.018

freestall barn would affect feed sorting behavior and found that cows sorted against long particles in both diets (62.3 or 50.7% forage), but cows fed the lower forage diet had greater feed sorting activity. Martin (2000) evaluated change in the particle size distribution of the TMR in a freestall herd and found changes in the mass retained by the top screen and the bottom pan of the Penn State Particle Separator 23.5 h after feed delivery. The mass retained on the top screen increased 6.3-fold, whereas the mass on the bottom pan decreased 3.0-fold. Leonardi and Armentano (2007) found that cows housed in a freestall facility sorted their rations against longer particles, favoring finer particles. The intake of the longest particles, expressed as a percentage of the predicted intake, was 63.3%. Sorting was also evaluated when the same cows were housed in a tiestall barn. Their intake of the longest particles was 73.2% when fed individually, indicating that cows can sort even more when housed in a group.

Risk Factors for Ration NDF Content Change Over Time

Feed push-up frequency, percentage of hay in the ration, feed bunk barrier design, feed bunk space per cow, and all interaction effects were excluded from the statistical model because of lack of significance. Visual evaluation of the residual plots and the distribution of the random intercept and slopes did not indicate violations of the model assumptions. The presence of a few outlier observations did not change the main findings of the study; therefore, outliers were retained.

The analysis of the other risk factors showed that time after feed delivery ($P < 0.01$) and feeding frequency ($P < 0.05$) were associated with greater changes in NDF content over time. In contrast, initial TMR DM content ($P < 0.05$) was associated with lower NDF content change (Table 5).

Greater initial DM content (drier TMR) was associated with lower NDF content change over time. An increase of 1 percentage unit in DM content was associated with a reduction of 0.17 percentage units in NDF. The magnitude of the association was low and probably not biologically significant. In addition, there might be a confounding factor with drier rations in this data set having a greater percentage of dry hay. Leonardi et al. (2005) reported that adding water to the TMR decreased its DM content and reduced the sorting for shorter particles. It is suggested that drier TMR are more susceptible to being sorted because their particles are less likely attached to each other and the movement of the tongue and nose of the cows could then easily separate the ration by particle size.

The feed barrier design (headlocks or post and rail) was not associated with particle size change over time. Huzzey et al. (2006) found that headlocks reduced the aggression between cows at the feed bunk and concluded that the physical separation provided by headlocks could be used to reduce the competition for feed bunk space, thus possibly decreasing sorting activity. The data collected from this study did not allow us to reach that conclusion because sorting behavior could not be accurately measured.

Martin (2000) and Shaver (2002) recommended adding less dry hay to the ration to reduce the feed sorting activity of cows. We found that the hay content of the TMR was not associated with ration particle size

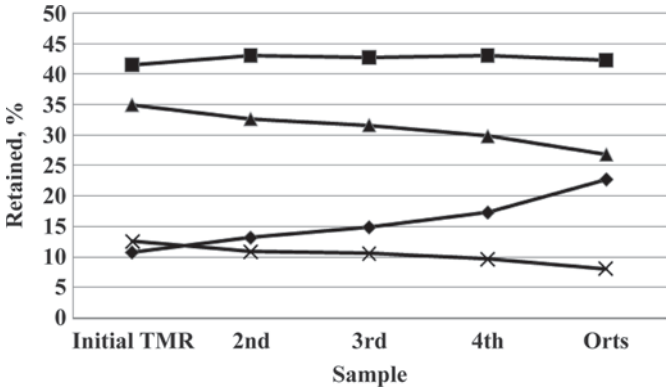

Figure 1. Average percentage of material retained on each sieve of the Penn State Forage and TMR Particle Size Separator over time [top (▲; >19 mm), second (■; >8 mm), third (♦; >1.18 mm), and bottom (×; <1.18 mm) pans] for 50 freestall herds in Minnesota. Samples represent the initial TMR collected at feed delivery; the second, third, and fourth samples collected every 2 to 3 h after feed delivery; and the orts.

change over time; however, the use of hay as a source of forage was not very common in the rations evaluated. Hay inclusion ranged from 0 to 16% of the TMR, with an average of 4.4%. Martin (2000) and Shaver (2002) also recommended an increase in the frequency of fresh feed delivery and push-up to reduce the sorting of the TMR because pushing-up can result in some mixing of the feed. In the current study, the frequency of feed delivery was associated with NDF content change; herds that fed cows once daily had greater change than herds feeding 2 or 3 times daily.

Percentile Distribution for Rate of Change of NDF Content Over Time

The groups of cows on each farm were ranked based on the rate of change of the TMR NDF content over time by percentile distribution (Table 6) using the BLUP for the random effect of farm. Groups with a greater rate of NDF content change had greater proportions of longer particle material in the ration, greater percentage of forage in the ration, and lower milk production ($P < 0.05$) compared with groups that had a lower rate of change of NDF content over time.

Groups with higher rates of NDF change over time had lower daily milk yield. Cows in the top 50th percentile of high-production groups with greater rates of change in particle size produced approximately 3 kg/d less milk (adjusted for components and DIM) than cows in the 50th percentile for lower rates of change. It is possible that herds with less change in the TMR NDF content over time were herds with better overall management, which could result in better animal performance. Additionally, this observation could be confounded with feeding diets containing greater proportion of forage, and, therefore, relatively less milk production per cow. Milk composition (percentages of fat and protein) was similar among percentiles.

CONCLUSIONS

Information collected in this observational study indicated that the majority of freestall dairy farms in Minnesota fed cows once daily in 3-row pens with post and rail feed barriers, and provided 0.45 m of feed bunk space per cow. The main forage used in the ration was corn silage, and rations had adequate concentrations of NDF and CP. We could not measure feed sorting behavior because of the methodology used. However, we observed that ration NDF content increased over time. This chemical change in the TMR could potentially be detrimental to certain cows. Some feeding management practices and TMR characteristics were associated with the particle size change over time. Therefore this effect may be minimized by implementing management changes (e.g., increasing feeding frequency to twice daily).

This was an ecological type of study; therefore, the observations and conclusions based on groups of cows could not be extrapolated to an individual-cow level. Another limitation of this type of observational study was its inability to demonstrate a cause–effect relationship between the TMR NDF content change and the hypothetical risk factors. Controlled studies with groups of cows are needed to establish the causality relationship of these associations as well as a more in-depth analysis of the factors that affect particle size change and feed sorting behavior of cows.

ACKNOWLEDGMENTS

We thank the 50 dairy producers who allowed us to visit their operations and collect data. We also thank Lynn Eberly (University of Minnesota, School of Public Health, Minneapolis) for her expert advice on statistical modeling of the data and Gerald Steuernagel (AgriTech Analytics, Visalia, CA) for providing the equations to calculate MLM.

Regional carbon footprint analysis of dairy feeds for milk production in the USA

Felix Adom · Ashley Maes · Charles Workman · Zara Clayton-Nierderman · Greg Thoma · David Shonnard

Received: 18 March 2011 / Accepted: 22 January 2012 / Published online: 22 February 2012
© Springer-Verlag 2012

Abstract
Purpose A greenhouse gas emissions analysis (carbon footprint) was conducted for cultivation, harvesting, and production of common dairy feeds used for the production of dairy milk in the USA. The goal was to determine the carbon footprint (grams CO_2 equivalents (gCO_2e)/kg of dry feed) in the USA on a regional basis, identify key inputs, and make recommendations for emissions reduction.
Methods Commonly used dairy feeds in the USA, such as soybeans, alfalfa, corn, and others, were identified based on a recent literature review and information from dairy farm surveys. The following input data for the cultivation and harvesting of dairy feeds were collected for five US regions: crop production data, energy input, soil amendments, and crop protection chemicals. Life cycle inventory input data were mainly collected from the US Department of Agriculture National Agricultural Statistical Service on a state-by-state basis as well as from state extension services forage crop budget estimates. In addition to consulting other life cycle assessment studies and published articles and reports, this cradle-to-farm gate carbon footprint analysis was conducted using the Ecoinvent™ unit processes in SimaPro version 7.1© (PRé Consultants 2009).
Results The final carbon footprint results (gCO_2e/kg of dry dairy feed) varied regionally depending on a number of factors such as lime and fertilizer application rates. The average national US carbon footprint results of the main feeds were: corn grain (390), corn silage (200), dried distillers grains with solubles (910 dry mill, 670 wet mill), oats (850), soybeans (390), soybean meal (410), winter wheat (430), alfalfa hay (170), and forage mix (160).
Conclusions and recommendations The southeast dairy region generally showed a relatively high level of carbon footprint for most feeds, and this is attributable to the higher application rates of both synthetic fertilizers and lime. The highest contributor to carbon footprint for most regions (apart from soybeans and soybean meal) was due to the application of inorganic nitrogen fertilizer. Efficient transfer of knowledge to farmers with regards to fertilizer best management practices such as precision application of farm nutrients may contribute significantly to reducing regional crop carbon footprints.

1 Introduction

The issue of environmental sustainability has become a prominent factor in decision-making for industries in

addressing environmental challenges, such as global climate change. The United States (US) dairy industry inaugurated a study to analyze greenhouse gas (GHG) emissions from milk production in the USA. The US dairy milk supply chain can be divided into the following major stages: (a) feed production, (b) milk production, (c) milk delivery to processor, (d) processing, (e) packaging, (f) distribution, (g) retail activities, (h) milk consumption, and (i) disposal. In a comprehensive report, within which this article is a part, each stage was analyzed independently and combined to provide the carbon footprint for the dairy supply chain (Thoma et al. 2012). This article here focuses on the production of dairy feed in the USA using sources of data at the level of individual states and then aggregates that information into five dairy regions.

While there have been a number of life cycle assessment (LCA) studies on crops in Europe, there have been relatively few in the USA. The Ecoinvent™ (PRé Consultants 2009) database contains many food and forage crop inventory profiles, but these are from European data sources. Hayashi et al. (2006) reviewed the progress of LCA studies in Europe for areas like renewable energy, animal production, and horticulture. In the USA, there were several LCA studies conducted on single crops such as switchgrass, soybeans, and corn associated with bioenergy product analyses, including studies by Kim et al. (2009 a, b), Spatari et al. (2005), Landis et al. (2007), Shapouri et al. (2002), Sheehan et al. (1998), Pradhan et al. (2009), and Rotz et al. (2010). A review of this literature indicated that no previous LCAs considered a large number of crops and dairy feeds, and therefore, our study fills an important gap in the USA with respect to updated analyses for agricultural crops and other dairy feeds.

2 Life cycle assessment methodology

2.1 Dairy feeds, goal, and scope

In this study, ISO protocols were followed and all GHG emissions were expressed as equivalent emissions of carbon dioxide (CO_2e.). Commonly used feeds for US dairy production were identified based on a recent literature source (Mowrey and Spain 1999) and information obtained from a nationwide dairy producer survey regarding the composition of dairy feeds (and other related topics) (Thoma et al. 2012—see Appendix A of Electronic Supplementary Material). Over 5,000 surveys were sent to dairy farmers through their Co-ops from January to May 2009 and a second mailing was conducted in June 2009. Of those surveyed, 531 responded. The main relevancy of this survey to this carbon footprint study was the identification of commonly used dairy feeds in the USA. Responses from the dairy farmer survey and the collection of other crop data were organized on the basis of five regions as shown in Fig. 1. The definition of dairy milk production regions was done through consultation with dairy experts (Thoma et al. 2012). The basis for selection of these regions was a combination of production practices and climatic conditions. There are over 130 distinct dairy feedstuffs included in the results of that survey.

Goal The main goal of this study was to determine the carbon footprint from the cultivation and harvesting of US dairy feeds on a basis of 1 kg of feed harvested or produced in units of grams CO_2 equivalents (gCO_2e)/kg of dry feed. An additional goal was to identify dairy feed inputs with the highest environmental impact to serve as a source of information for improvement in production and as a benchmark against which progress can be measured in the dairy industry.

Scope The scope was a cradle-to-farm gate analysis. In this article, we report on grain, forage crops, and other coproducts [e.g., dried distillers grains with soluble (DDGS) and soybean meal) for which inventory data were available from US government and university extension sources. In this study, we did not consider all of the 130 or so dairy feeds identified in the survey by Thoma et al. (2012). Table 1 shows the three major categories of dairy feeds considered in this study, including grain crops, forage crops, and coproducts. This study includes application of inorganic fertilizers, effects of crop residues, manure application, crop protection chemicals, and energy inputs required for cultivation and harvesting. According to a study by Landis et al. (2007), seed production comprised less than 1% of GHG emissions for corn and soybean. This result was generalized for all dairy feeds analyzed in this study by assuming all

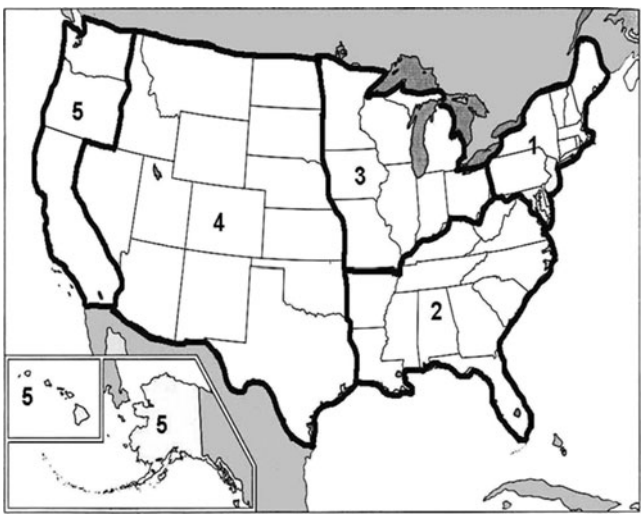

Fig. 1 Dairy production regions used for this study

Table 1 Dairy feeds analyzed in this study

Grain crops	Forage crops	Coproducts
	Alfalfa hay (16%)	
Oats (14%)	Alfalfa silage (16%)	
Soybean (13%)	Forage mix (16%)	DDGS, dry mill (10%)
Corn silage (65%)	Grain mix (15%)	DDGS, wet mill (60%)
Corn grain (15.5%)	Grass hay (16%)	Soybean meal (11%)
Winter wheat (13.5%)	Grass pasture (16%)	
	Grass silage (16%)	

Shown in parenthesis are the percentage moisture content for all feed analyzed in this study (NDSU 2011)

associated inputs for seed production were below cutoff criteria, and hence were excluded. Also, the scope of this carbon footprint analysis does not include incidental effects such as emissions from employee travel to or from the farm. Infrastructure elements, such as construction of buildings and farm equipment, were also excluded.

2.2 Functional unit

The functional unit for this carbon footprint study was 1 kg of dairy feed (grains, forage crops, and other coproducts) harvested or processed on dry matter basis.

2.3 Geographical boundaries

The geographical context of this carbon footprint study is the USA for dairy feeds grown and produced in the USA.

2.4 Allocation procedure

Most dairy feeds produced no coproducts, but for certain feeds, it was not possible to avoid allocation. For those feeds, allocations based on market value were used, as shown in Table 2. Section 3.1 explains the basis for allocation of nitrogen (N) inputs to corn and corn silage. Sections 3.1.1 and 3.1.2 explain in more detail the economic allocation to soybean oil and meal as well as wet and dried distillers grains with solubles. Five-year average commodity cost data from Illinois were used for economic allocation of soybean oil and meal, which was assumed to be representative of the national commodity market (USDA-IL 2010). Also, mass allocation based on a 5-year average yield provided by the National Oilseeds Processing Association was used for testing scenario cases, while economic allocation was adopted as the base case. Economic and mass allocation values for dried distillers grains with solubles from the thesis by Kodera (2007) were used in this study.

Table 2 Summary of allocation ratios and types used in this study

Coproduct	Economic allocation	Mass allocation
Soybean oil/meal/hulls	56.7:41.2:2.1	19.4:74:6.6[a]
DDGS dry/ethanol	30:70	52:48
DDGS wet/ethanol	24:76	51:49
Dairy feed/corn		Causal allocation
Corn/corn silage[b]		
Region 1		59:41
Region 2		91:9
Region 3		96:4
Region 4		95:5
Region 5		No data
		Causal relationship based on crop nitrogen requirements determined from reported yield

[a] CGB (2010)

[b] The large differences between regions are primarily determined by the relative production of each crop. More silage is grown in region 1 compared to corn grain than the other regions, and therefore, the allocation of shared inputs is not nearly equal

2.5 Inputs versus inventory data and possible limitations

Inputs such as fertilizer and fuel used for each crop production system were obtained from US government sources and the US literature. Inventory data underlying those inputs are largely from the Ecoinvent™ database (PRé Consultants 2009), which mostly represents European production. This presents a possible limitation to this study. However, European inventory data, while not geographically relevant, are technologically relevant for the inputs used in this US study because both US and European production uses modern technology. In addition, inventory data for many study inputs are simply not available yet based on US production.

3 Life cycle inventory analysis

A life cycle diagram describing the key inputs for each crop production system is shown in Fig. 2. The major inputs included: inorganic and organic fertilizer application on the farm, agrochemicals used to control pests, and farm energy use. Lime application on the farm was considered for some of the crops where data were available as well as effects of crop residues on direct and indirect nitrous oxide (N_2O) emissions. Energy use included gasoline, diesel, liquefied petroleum gas (LPG), natural gas, and electricity. GHG emissions for this analysis include: carbon dioxide (CO_2), methane (CH_4), N_2O, solvents, and refrigerants. Solvents and refrigerants were not directly included as

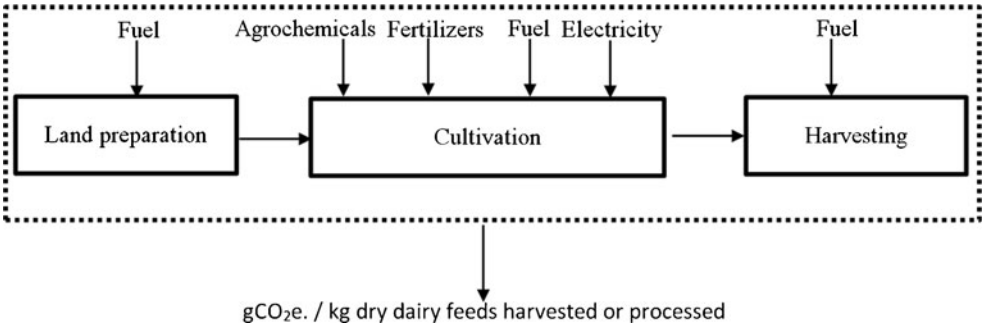

Fig. 2 Life cycle diagram for the cultivation and harvesting of dairy feed crops. *Dotted lines* represent the system boundary considered in this carbon footprint analysis

system inputs, rather these were incorporated by the use of Ecoinvent™ ecoprofiles (PRé Consultants 2009) for the various crop inputs. N_2O emissions from nitrogen fertilizer application for the degradation of crop residues and manure application were accounted for using IPCC (2006) guidelines for national GHG inventories (tier 1).

3.1 Production inputs and inventory for grains: corn, oats, soybeans, and winter wheat

Every year, the US Department of Agriculture (USDA) National Agricultural Statistical Service (NASS) conducts hundreds of farm surveys on cropping practice, chemical use, farm costs, and income. It is usually structured in a three-phase annual survey with specific goals. Phase I screens various farms for commodities and for potential inclusion in phases II and III, and this is done usually on a state-by-state basis. Phase II collects data on chemicals, fertilizer, and pesticides and has only one collection mode—personal interviews via-face-to-face contact. Phase III focuses on detailed economic information about the agricultural operation and the operator's household. Response rate from farmers has been highest for phase II with an average response rate of 80% from 2002 to 2006 and an average sample size of 5,465 according to the National Research Council (2008).

Table 3 summarizes the major crop databases and sources of the dairy grain crops. The USDA NASS databases were the primary source of crop production data for this study. Specific data obtained on a state-by-state basis included area harvested, yield, and total production. Average values for the harvested acres, yield, and production over the 5-year production period (2004–2008) were calculated and used. Annual crop production data for soybean, oats, wheat, corn grain, and silage for the 5-year period were obtained from the crop production summary reports from USDA NASS (2009a, 2007a). Appendix B of the Electronic Supplementary Material shows the computational spreadsheets of the major crops discussed here.

MacDonald et al. (2009) established that about 5% of US cropland receives animal manure, with corn land receiving over half of this applied manure. The percentage of planted acres receiving manure (manure share) was highest for corn and oats, being 11.6% and 9%, respectively. For all other grain crops, this area percentage for manure was approximately 1% or less. Therefore, we assume that only corn and oats receive manure as a fertilizer supplement. Dairy production regions needing supplementation with manure were identified by estimating the growth nitrogen requirements to meet crop production yields and comparing these with reported inorganic nitrogen inputs from the USDA NASS databases. The following sections explain in more details how the manure inputs were determined.

Corn Combined corn and silage input data for fertilizer and chemical application rates were obtained for states in regions 1, 2, 3, and 4, but no data were reported for region

Table 3 Crop databases and data sources for dairy grains

Summary of crop inventory and data source	
Soybean and soybean meal	Data sources
Area harvested/production data	USDA NASS (2009a, 2007a)
Fertilizer and agrochemical inputs	USDA NASS (2007b)
Lime input	Pradhan et al. (2009)
Energy inputs	Sheehan et al. (1998)
Oats	
Area harvested/production data	USDA NASS (2009a, 2007a)

	Wang (2001)
	Kodera (2007)
	Kim and Dale (2002)

5. USDA NASS database reported separate productivity data for corn grain and silage. Agrochemical chemical input data such as inorganic fertilizers and herbicides were reported for combined corn and silage land area. Productivity data indicated that region 5 contributed less than 1% toward the total corn production in the USA. MacDonald et al. (2009) in their report on manure usage for fertilizer estimated that 408 million kg of manure nitrogen was applied to corn grain and silage in the USA in 2007. The USDA NASS data for nitrogen application rates do not include manure contributions. In addition, the reported inorganic N application rates do not meet known crop requirements of approximately 0.54 kg N/bushel (bu) for corn grain and 5.19 kg N/mt for silage as defined by numerous crop production budgets (NDSU 1992). The amount of manure N required to reach the crop requirement was determined on a state-by-state basis using this equation: manure N = corn N growth requirement − synthetic N fertilizer application − residual N following rotation with soybeans. Using crop budgets for a corn–soybean rotation, it was estimated that approximately 23 kg N/ac was supplied in soybean residue (MSU 2010). The organic N from manure was applied in a manner to force the total N per crop to match the growth requirements mentioned above. Using a causal allocation based on the crop nitrogen requirements for both grain and silage, other crop inputs were allocated. Table 2 shows the allocation ratios used in this model for the various dairy production regions. Using this method, the total manure nitrogen applied to corn was approximately matched to the reported annual application rate of 408 million kg within a 4% margin. Specific inputs (e.g., lime) for the various crops are further explained in subsequent sections.

Soybeans In the case of soybeans, the USDA NASS (2009a, 2007a, b) had data such as quantity of inorganic fertilizer used, area harvested, crop productivity, chemical use, and other information for states in regions 2, 3, and 4. Soybean energy inputs and lime application rate data were obtained from Sheehan et al. (1998) and Pradhan et al. (2009), respectively. Inorganic nitrogen input data from USDA NASS (2007b) were included, while manure inputs were not because MacDonald et al. (2009) reported a manure share of approximately 1% of acres for soybean. Section 3.1.1 provides the sources of inventory data for the soybean meal–oil. The average of the carbon footprint in regions 2, 3, and 4 was used to represent regions 1 and 5 for which there were no data available.

Oats The primary source of data for fertilizer and chemical inputs for oats was from USDA NASS (2006). However, no input data (e.g., inorganic fertilizer and crop protection chemical) were reported for the states in region 2, and this is due to its relatively low oats productivity (5% of oats production). Due to the unavailability of input data for lime application for oat-producing states, the national average lime application rate for soybeans was assumed for the oats analysis (extension documents validated this estimate). Based on the N requirement recommendation of 0.5 kg N/bu and 40 kg N/ac (Beegle 1997), NASS reported inorganic N input data for dairy production regions 1 and 3 were low, requiring supplementation with manure. The reported inorganic N input data for regions 4 and 5 were sufficient to meet N requirement of oats. An estimated 20 kg N/ac of additional N from manure meets the reported yields, and this was applied to regions 1 and 3 on a state-by-state basis. This method does not take into account any nitrogen credit from prior rotation unlike in the case of manure GHG impact estimation for corn. Section 3.5 provides the details on energy inputs. Finally, due to lack of data for region 2, the inventory for this region was estimated by averaging regions 1, 3, 4, and 5.

Winter wheat This study focused on winter wheat because it accounts for 70% to 80% of the total wheat produced in the USA (USDA NASS 2009b) as compared to other types like durum and spring wheat. Productivity data were obtained from USDA NASS (2009a, 2007a); however, no data were available for the energy inputs on a state-to-state basis. Energy estimates for the production of wheat in the USA on a per hectare basis was obtained from Piringer and Steinberg (2006) for the wheat analysis. Manure impact was not considered for wheat primarily because it has less than 1% of acres applied with manure (MacDonald et al. 2009).

For all crops, input data for fuel and electricity consumption on the farm for crop production were obtained from the technical literature, state agricultural extension services, the US Department of Energy, the USDA, and other academic institutions (see Table 3). There are three regional interconnection grids in the USA, namely, Eastern Interconnection, Western Interconnection, and the Electric Reliability Council of Texas Interconnection. GHG emission factors (in gCO_2e/kWh) were constructed using Ecoinvent™ unit processes (PRé Consultants 2009) based on regional fuel mixes. Additionally, precombustion emissions and the transmission and distribution losses were included in the emission factor using regional interconnection grid data reported by Deru and Torcellini (2007). Section 3.5 of this article explains in more detail the assumptions and data sources for the specific crops for which energy input data were not available.

3.1.1 Soybean meal–oil–hull allocation

In the soybean meal analysis, additional processes were considered including transporting soybean to the crusher and crushing to recover oil and meal. The impact of

transporting soybean to the crusher was estimated as well as the impact of crushing with the use of data obtained from Sheehan et al. (1998), Pradhan et al. (2009), and Pollak (2010). The crushing and extraction energy required were updated based on a more recent study by Pradhan et al. (2009). Allocation to meal and oil were based on economic value of the coproducts from price data averaged over 2004–2008. The primary data source for prices was from Illinois, but is expected to be representative of the national commodity markets during the time period (USDA-IL 2010). Soybean meal allocation factors are shown in Table 2.

3.1.2 Dried distillers grains with solubles

Articles from the technical literature representing work done by LCA experts with corn ethanol and DDGS were used in this analysis. A thesis by Kodera (2007) performed a review of the effects of allocation method on LCA impacts of corn ethanol production by the dry milling process, for example, mass, energy, and value allocation as well as system expansion. Based on the allocation factor summary in this thesis and a study by Kim and Dale (2002), an allocation of the GHG burdens for corn ethanol production was made to DDGS in our model. As shown in Table 4, allocation factors varied widely and this resulted in some uncertainty for DDGS carbon footprint analysis. The DDGS GHG emissions values in this table were obtained using the allocation factors shown combined with GHG emissions for corn ethanol from three studies (Hill et al. 2006; Wang 2001; Shapouri et al. 2003) and DDGS production data from Hill et al. (2006). Detailed analysis of wet mill and dry mill DDGS can be found in Appendix B-6 of Electronic Supplementary Material.

3.2 Production inputs and inventory for forage crops: alfalfa, alfalfa silage, grass hay, grass pasture, and grass silage

To estimate the inventory for cattle forage production, crop production budgets produced by state agriculture extension specialists were collected and used as the primary source of input data. These budgets estimated the inputs needed to produce alfalfa, grass hay, silage, and pasture. These are not actual production records, but estimates prepared by agricultural extension agents with detailed knowledge of agronomic conditions in specific states. For this analysis, inventory data on fuel, electricity, fertilizers, soil amendments (N, P, K, sulfur, boron, and lime), and crop protection chemicals were used. When only purchase price for inputs was given, price was converted to quantity using information from budgets published on the same year that provided both price and quantity for the inputs in question. Pesticide application rates varied widely, depending on the type of pesticide. For budgets where only estimated pesticide purchase price was provided, available cost data were used to convert to quantities (Schnitkey 2004). MacDonald et al. (2009) reported that 6.9% (manure share) of hay and pasture land received manure as fertilizer. Because the budgets used to create the unit processes for these forage feeds report recommended total organic and inorganic nitrogen application rates together, it was assumed that 6.9% of the fertilizer applied was in the form of manure. In several cases, budgets provided total quantity of fertilizer, but did not specify the percentage breakdown for each. In this case, a ratio of 20:40:40 NPK for alfalfa was chosen, as it is a nitrogen fixer. For grass, we used 50:25:25.

Some budgets included custom costs for contracted services such as tilling, planting, or harvesting rather than providing explicit input estimates for each of these processes. Using figures from MSU Extension (MSU 2010) that showed custom costs per acre and fuel cost per acre for different practices, it was found that 16% of custom costs for tillage went to fuel, 12% to planting, 18% to fertilizers, and 18% of harvesting costs went to fuel. Over a 5-year period, a typical field is tilled and planted once, fertilized five times and harvested twice per year (10×); thus each practice was weighted by these estimated rates, giving tillage and planting a value of 1, fertilizing a value of 5, and harvesting a value of 10. As a result, a weighted average of 18% of custom costs was attributed to the consumption of diesel fuel.

There is a large difference in diesel use for hay, silage, and pasture. Most states provided budgets for hay, but fewer

Table 4 Allocation factors and GHG intensity of DDGS (see Appendix B-6)

	Energy	Mass	Economic	System expansion	References
Allocation factor to ethanol	0.57	0.48	0.70	0.80	Kim and Dale (2002); Kodera (2007)
Allocation factor to DDGS	0.43	0.52	0.30	0.20	
DDGS GHG emissions [kg CO_2e/kg DDGS (dry)]	1.60	2.30	0.91	0.53	
Corn ethanol (kg CO_2e/MJ ethanol)		0.0849			Hill et al. (2006)
		0.07			Wang (2001)
		0.062			Shapouri et al. (2003)

for pasture or silage. Using those few states that provided diesel use data for both (primarily regions 2 and 3), the average difference in diesel used to harvest hay or silage per short ton of crop was calculated. We assumed the dry matter yield was equivalent for pasture, hay, or silage. The only difference was harvesting and hauling. After finding the mean diesel use for hay for each region, we added ~1 gal per dry short ton of crop if harvested as silage and subtracted ~3 gal if kept as pasture.

3.3 Direct/indirect N_2O emissions

The IPCC (2006) tier 1 method was used to calculate direct and indirect N_2O emissions from managed soils for inputs such as synthetic and manure N fertilizer, N in crop residues (above and below ground residues) as well as CO_2 released by lime and urea-containing fertilizer. Direct N_2O release was estimated as 1% of N applied to soil released as N in N_2O. For indirect N_2O emissions, two major pathways were included. The first is the volatilization of N as NH_3 and oxides of N at a rate of 10% of applied N, and redeposition of these gases on water bodies where N_2O–N is emitted at a rate of 1% of the redeposited N. Leaching and runoff is the second pathway with a default leaching factor of 30% of applied N and an emission factor for N_2O–N of 0.75% of leached N. When urea ($CO(NH_2)_2$) is applied, it can be converted to ions like ammonium (NH_4^+) and bicarbonate (HCO_3^-) in the presence of urease enzymes and release CO_2. GHG emission from lime application is dealt with in Section 3.6. In this study, dinitrogen monoxide (N_2O) emissions for manure application is a combination of direct and indirect mechanisms as discussed above (see Appendix C of the Electronic Supplementary Material) including emissions from manure management systems (MMS).

The USDA NASS database does provide N fertilizer input data for crops (see Table 3); however, this database does not indicate the type of nitrogen fertilizer applied to crops. The production of different nitrogen fertilizers results in very different quantities of GHG emissions from their production. Therefore, an average US nitrogen fertilizer production profile was created for this study. Data on fertilizer consumption in the USA from the period of 2004–2007 was obtained and used to create the synthetic N ecoprofile for this analysis (Appendix D-1 and D-2 of Supplementary Documents). One of the N fertilizers, nitrogen solutions, was comprised of urea (35%), ammonium nitrate (40%), and water (25%) (Dyno Nobel Inc, MSDS 2010; Vitosh 1996).

For phosphorus fertilizer, a similar approach as for N fertilizer was taken by basing the mixture of phosphate fertilizers in proportion to their US production (USDA ERS 2009) as reported in Appendix D-3 of the Electronic Supplementary Material. Potassium and sulfur fertilizers as well as lime were treated similarly.

3.4 Crop protection chemicals

Insecticides, herbicides, and fungicides applied on the farm were considered in our analysis. In cases where the ecoprofile of a pesticide was not found in the Ecoinvent™ database in SimaPro 7.1© (PRé Consultants 2009), the chemical class was used. For instance, tebupirimphos which was not directly listed in the Ecoinvent™ database belongs to the organophosphorous class of compounds (PAN Pesticides Database 2009) and this was the ecoprofile used in our model. Rate of crop protection chemical application for soybean and winter wheat were all obtained from USDA NASS (2007b) while that of corn and oats were obtained from USDA NASS (2006). Forage crop protection data were obtained from state extension budgets as mentioned earlier.

3.5 On-farm energy

This analysis accounted for the following energy inputs on the farm: electricity, gasoline, diesel, LPG, and natural gas. Due to the lack of energy input information in the USDA NASS database, other sources were used to fill in the required data for the crop analysis. Energy input data for forage energy were from state extension documents as mentioned previously. Soybean energy input data were obtained from Sheehan et al. (1998) and represented 14 soybean-producing states, which together accounted for about 86% of the soybean produced in the USA. Additionally, energy input data for corn producing states were obtained from Shapouri et al. (2002) and represented about 80% of corn produced in the USA. In the case of oats, data for diesel use were obtained from Dartt and Schwab (2001). Due to lack of data on gasoline consumption for oats cultivation and harvesting, it was assumed that gasoline consumption was equal to one third of diesel consumption, based on diesel and gasoline inputs for other field crops, for example corn and soybeans. To fill data gaps, LPG and electricity inputs for corn and soybean were then averaged on a regional basis and used as an estimate for oats. Energy estimates for production of wheat in the USA on a per hectare basis was obtained from Piringer and Steinberg (2006).

3.6 Lime application

Lime application rates for soybean were obtained from Pradhan et al. (2009). In the case of oats, the national average of lime application rate for soybeans was assumed, which in our study (358 lb lime/acre) falls within the recommended range from two budgets that were obtained from

KSU (2003) and Crozier et al. (2004). Lime application data for corn grain and silage were estimated using a crop production budget (MSU 2010). While data on lime application rate were not available for wheat production, it appeared that lime was seldom used. For example, only 9% of wheat land area has ever been treated with lime based on a 1997 survey by USDA (Heimlich 2003). According to a US Geological Survey (USGS 2007) approximately 10.8 billion and 32 million kg of limestone and quicklime were applied in the US agricultural sector, respectively. As a result, every kilogram of an average US lime comprises 0.997 kg $CaCO_3$ and 0.003 kg of CaO. Final GHG intensity of lime accounts for both the production and its application on the field. Due to the on-farm application of calcium carbonate to acidic soils, CO_2 is released, which was accounted for in this study using the emission factor from the IPCC (2006) (see Section 3.8 for emission factor).

3.7 Crop residue effects on direct/indirect N_2O emissions

In this study, the 2006 IPCC guidelines for national GHG inventories (tier 1) was used to account for the N_2O emissions from the degradation of crop residues above and below ground. The average regional yields for various dairy feeds were converted on a dry weight basis to obtain a kilogram dry crop per harvested area. In addition, other parameters like the N content and weight of dry matter residue above and below ground allowed for the final estimation of kilogram N above and below ground of crop residue per kilogram of crop harvested. Appendix E of the Electronic Supplementary Material shows the detailed analysis of N_2O emissions of crop residues.

3.8 Emission factors for fertilizer, crop protection chemicals, and energy input

The emission factors are shown in Table 5 for the production and use of various fertilizers, lime, and energy inputs. Emission factors for pesticides are listed in the Electronic Supplementary Material (see Appendix F).

3.9 Data quality

The pedigree matrix derived from Frischknecht et al. (2007) was used to assess the quality of data, primarily fertilizer and other N_2O emissions, crop protection chemicals, and

Table 5 Emission factors for farm input: fertilizer, agrochemical, and energy

Farm inputs		Emission factors	Sources
Fertilizer	N	3.871 kg CO_2e/kg N in US mix N fertilizer due to manufacturing of N fertilizer	USDA ERS (2009)[a]
		0.633 kg CO_2e/kg N in US urea in US mix of N fertilizer due to field emissions CO_2	IPCC (2006)
		6.205 kg CO_2e/kg N in US mix of N fertilizer due to direct and indirect N_2O field emissions	Ecoinvent Database (PRé Consultants 2009)
	P	3.028 kg CO_2e/kg P in US mix P fertilizer due to manufacturing of P fertilizer (applied as P)	USDA ERS (2009)
			Ecoinvent Database (PRé Consultants 2009)
	K	0.573 kg CO_2e/kg K in US mix K fertilizer due to manufacturing of K fertilizer	USDA ERS (2009)
			Ecoinvent Database (PRé Consultants 2009)
	S	3.855 kg CO_2e/kg S in fertilizer	Ecoinvent Database (PRé Consultants 2009)
Agrochemicals	Lime	0.0158 kg CO_2e/kg lime due to manufacturing	USGS (2007)[b]
		0.4400 kg CO_2/kg $CaCO_3$ due to application on farm	
Fuel	Gasoline	10.96 kg CO_2e/gal	Deru and Torcellini (2007)
	Diesel	11.89 kg CO_2e/gal

[b] http://minerals.usgs.gov/minerals/pubs/commodity/stone_crushed/myb1-2007-stonc.xls and http://minerals.usgs.gov/minerals/pubs/commodity/lime/myb1-2007-lime.xls

energy inputs. Six characteristics of data quality were included: *reliability*, *completeness*, *temporal correlation*, *geographic correlation*, *further technological correlation*, and *sample size*. This was done by assigning a set of scores from 1 to 5 after a careful analysis of each data source (see Appendix G of Electronic Supplementary Material). Using some basic uncertainty (U_7) factors provided in Table 7.2 of Frischknecht et al. (2007) and assessing the data sources according to the six characteristics mentioned above, the square of geometric standard deviation (SD_{g95}) was calculated using Eq. 1:

Equation 1 For calculating SD_{g95}

$$SD_{g95} = \sigma_g^2 = \exp\sqrt{[\ln(U_1)]^2+[\ln(U_2)]^2+[\ln(U_3)]^2+[\ln(U_4)]^2+[\ln(U_5)]^2+[\ln(U_6)]^2+[\ln(U_7)]^2} \quad (1)$$

where U_1 = uncertainty factor of reliability, U_2 = uncertainty factor of completeness, U_3 = uncertainty factor of temporal correlation, U_4 = uncertainty factor of geographic correlation, U_5 = uncertainty factor of other technological correlation, U_6 = uncertainty factor of sample size, and U_7 = basic uncertainty factor.

By assuming a log-normal distribution of uncertainty, the estimated SD_{g95} was used to calculate an upper and a lower bound of the 95th percentile confidence interval for the various dairy feeds on a national basis (Table 6). The geometric mean (in micrograms) was used to estimate the lower and upper bound (gCO2e/kg feed) using Eqs. 2 and 3 (Frischknecht et al. 2007).

Equations 2 and 3 For calculating the lower and upper bound values of carbon footprint

$$\text{Lowerbound} = \frac{\mu_g}{\sigma^2{}_g} \quad (2)$$

$$\text{Upperbound} = \mu_g \times \sigma^2 g \quad (3)$$

4 Life cycle greenhouse gas impact assessment and interpretation of results

4.1 General assumptions for life cycle impact analysis

In estimating the carbon footprint, the GHG emissions were converted to CO_2 equivalents using global warming potentials (GWP) in the "IPCC 2006 100a" method in SimaPro 7.1© (PRé Consultants 2009); GWP is 1 for CO_2, 298 for N_2O, and 25 for CH_4 (Forster et al. 2007). The effects of other greenhouse gases emitted in minor amounts such as refrigerants, halons, and certain chlorinated solvents were also accounted for.

Table 6 Cradle-to-farm gate carbon footprint results of commonly used feeds by region and on national basis (gCO_2e/kg dry feed)

	Production region							
	1	2	3	4	5	Lower bound	Central bound (geometric mean)[a]	Higher bound
Alfalfa hay	190	270	140	140	150	140	170	210
Alfalfa silage	200	280	150	150	160	150	180	220
Corn grain	360	440	370	440	**400**	270	390	560
Corn silage	160	260	190	220	**210**	140	200	290
DDGS, dry mill	910	910	910	910	910	590	910	1,400
DDGS, wet mill	670	670	670	670	670	430	670	1,400
Forage mix	160	260	140	140	150	130	160	200

Oats	800	**800**	580	1,000	1,140	580	850	1,240
Soybean	**410**	520	330	390	**410**	270	390	580
Soybean meal	460	540	400	430	450	420	460	490
Winter wheat	380	400	510	500	390	300	430	600

For crops with data presented in bold, no data for production was available; the average of results from other regions was adopted

[a] The geometric mean represents the US national greenhouse gas profiles for the various dairy feed with their respective ranges (lower/upper bound) estimated using the square of geometric standard deviation as shown in Eq. 2

4.2 Regional greenhouse gas emissions of dairy feeds

Table 6 summarizes the regional GHG emissions of dairy feeds on a per dry kilogram basis. Careful examination of the table reveals that there is significant variability among the regions for several feeds. Nearly all of the highest values are associated with region 2, and this appears to be driven primarily by greater nitrogen and lime inputs. The exception is the production of oats in region 5, which is nearly double the lowest value. This is as a result of much higher application rates for N reported in California; approximately three times the rates applied in other areas. This is partially offset by larger yields; however, the yield is only 1.5 to 1.7 times that of other regions. Grass has a higher carbon footprint than other forage crops and nearly as high as corn grain. Regional results for each feed analyzed were combined to estimate the national carbon footprint (see Table 6). Overall, processed coproducts like wet mill and dry mill DDGS and soybean meal show higher GHG emissions.

Results in Table 6 can be compared to recent literature values, though some of these studies occurred in different geographic contexts. Landis et al. (2007) modeled the agrosystem material flows for US corn and soybean by employing the greenhouse gases, regulated emissions, and energy use in transportation (GREET) model. The following results were obtained by Landis et al. (2007): 310–680 gCO_2e/kg of dry corn and 120–290 gCO_2e/kg of dry soybean. The carbon footprint results for corn and soybean at the farm stage from GREET (2010) were 290 and 200 gCO_2e/kg of dry crop, respectively. Two separate studies by Kim and Dale (2009a—40 counties in the USA) and Kim et al. (2009b—eight counties in the USA) estimated 360±100 and 540±290 gCO_2e/kg of dry corn grain, respectively, for US corn-producing counties. In our study, the national carbon footprint of corn grain was estimated to be 390 gCO_2e/kg of dry corn grain, with upper and lower bounds of 270 and 560 gCO_2e/kg of dry corn grain. Additionally, a value of 300 gCO_2e was estimated for 1 kg dry corn at field using the United States Life Cycle Inventory database in SimaPro (PRé Consultants 2009). The GHG emissions of 1 kg corn silage at the farm gate for the Swiss production processes using Ecoinvent Database was 190 gCO_2e/kg of dry corn silage, a value close to corn silage for our study in Table 6. A value of 620 gCO_2e/kg dry soybean was obtained from the Denmark LCA food database in SimaPro (Denmark LCA Food 2011 and PRé Consultants 2009). Dalgaard et al. (2008), using the EDIP 97 database (a Danish LCA methodology) in SimaPro (PRé Consultants 2009), analyzed the GWP of 1 kg (dry) of soybean meal to be 721 gCO_2e while Pelletier (2008) in the study of the environmental performance in the US broiler poultry sector estimated 297 gCO_2e. Finally, another European study by Van der Werf et al. (2005) estimated the GHG emissions for the production of 1 kg of wheat and barley to be 375 and 400 gCO_2e/kg of dry crop, respectively, while the Denmark LCA food database (PRé Consultants 2009) estimates 710 and 570 gCO_2e for 1 kg of dry wheat and oats, respectively. Taking into account the differences in modeling tools, study scope, and geographical context for the different studies, results from the literature are generally comparable to those obtained in this study. The following sections will display the results in more detail with regard to the relative importance of specific crop life cycle stages and inputs.

4.2.1 Soybean

Soybean showed a lower carbon footprint than some crops due to lower inorganic nitrogen fertilizer application, and this was largely due to the fact that it is a nitrogen-fixing crop. However, significant contributors to the various regional results are: lime application, gasoline, diesel, and N_2O emissions from soybean residues, as shown in Fig. 3. Together, they contributed about 70–86% of the overall GHG emissions in each productive dairy region. Interesting was the relative impact of lime input on the overall regional footprints. Lime input data for regions 2 and 3 for the soybean-producing states were relatively comprehensive (60% and 100% of states reporting, respectively). For region 4, data for lime application were available for just two states out of the six soybean-producing states. Another probable reason could have been the acidic nature of soils in regions 2 and 3 requiring more lime to increase soil pH for plant growth. Emissions of N_2O from crop residues were large compared to N_2O released from the application of N fertilizers for soybeans, a distinctly different feature compared to other crops. Approximately 65% of GHG emissions from N fertilizers were due to field application, with about 35% from manufacture, as also seen from the data in Table 5. Although it was not exactly clear why the states in the midwest (region 3) used relatively lower amounts of diesel, one possible reason was the effect of the Midwest Clean Initiative Diesel (EPA 2011) which encourages operational changes, technological improvements, and use of cleaner fuels for powering equipment. Finally, using the pedigree matrix, the standard deviation with 95% confidence interval for inorganic fertilizer, crop protection chemicals, and energy inputs was estimated to be 1.51, 1.21, and 1.57, respectively (see Appendix G-11 of the Electronic Supplementary Material).

4.2.2 Oats

The major contributors to the oats carbon footprint in the USA (Fig. 4) were identified to be inorganic nitrogen and phosphate fertilizers, manure, lime application, diesel, and the impact of N_2O emissions from oat residues, which together makes up approximately 72–92% of the overall

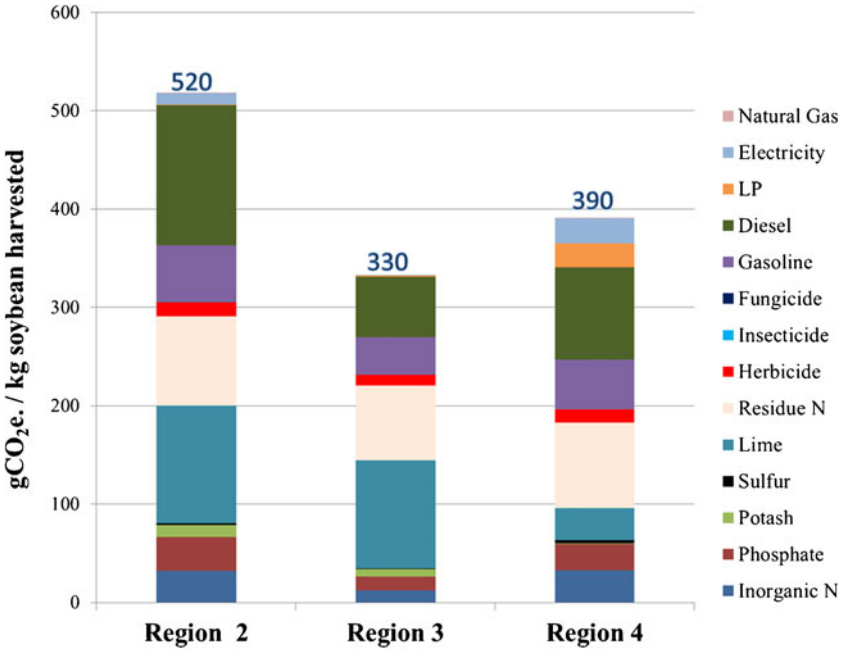

Fig. 3 Carbon footprint profile of soybeans harvested in the USA

footprint in each region. The regional variation in carbon footprint was due to the impact of fertilizer application rate. For example, dairy region 5 shows an unusually high carbon footprint of 1,100 gCO_2e/kg of oats harvested, due to high fertilizer N application. Furthermore, results from California in region 5 may not be representative of the other states in this region. About 65% of inorganic N fertilizer GHG emissions was from field application and 35% was due to manufacture.

The impact of crop residues remains fairly constant across the various regions for oats, contributing about 9% on national average towards the carbon footprints reported. However, the use of manure to supplement inorganic fertilizers in regions 1 and 3 contributed 21% and 26%, respectively, towards the regional footprints. Finally, in the case of oats, the standard deviation with 95% confidence for inorganic fertilizer, chemical protection, and energy inputs was estimated to be 1.51, 1.24, and 1.36, respectively (see Appendix G-11 of the Electronic Supplementary Material).

4.2.3 Corn grain and silage

Inorganic fertilizers, manure, phosphates, lime, diesel as well as the impacts of grain drying and N_2O emissions due to residues contributed approximately 80–90% towards the regional C footprint of corn grain (Fig. 5). In the corn silage analysis in Fig. 6, inorganic fertilizers, manure, phosphates, lime, diesel as well as the impacts of drying and N_2O emissions due to residues contributed about 73–90% towards the corn silage footprint for each dairy region. The

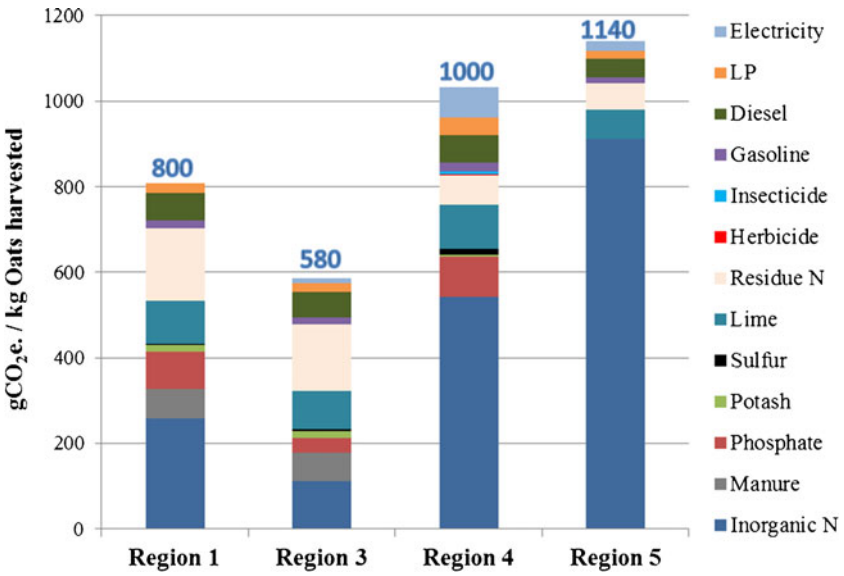

Fig. 4 Carbon footprint profile of oats harvested in the USA

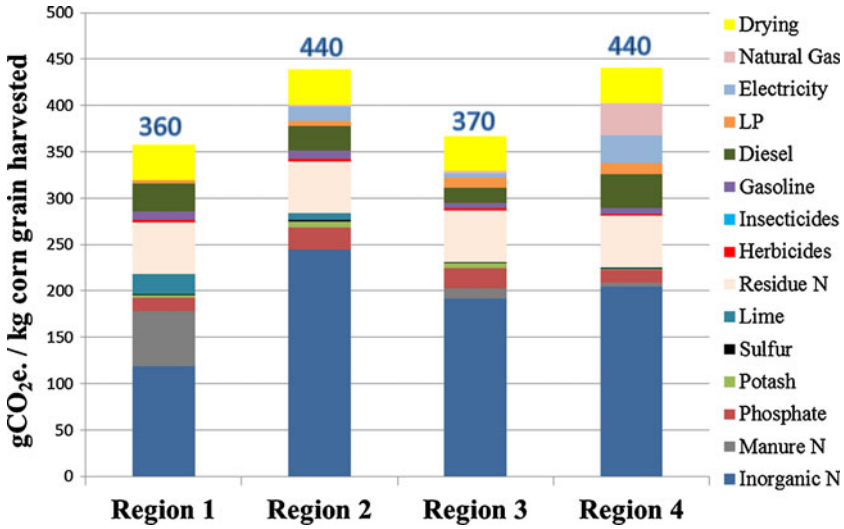

Fig. 5 Carbon footprint profile of corn grain harvested in the USA

contribution of the MMS to the GHG emissions for both crops was small (always <2%). Generally, the GHG emissions for corn grain with respect to the various dairy regions were about two times greater than for the corn silage. The comparatively larger emissions for corn grain compared to silage were mainly due to the allocation method applied from Section 3.1, under "Corn". Figure 5 shows high contributions of inorganic fertilizer from region 2, as this is the reason why additional manure was not added to supplement plant growth in this region. Interestingly, Fig. 6 shows a relatively high contribution for the use of natural gas for region 4 and this was primarily due to extremely high level of energy requirements from corn farms in Texas. In the final analysis, the standard deviation with 95% confidence for fertilizer, chemical protection, and energy inputs was estimated to be 1.51, 1.21, and 1.26, respectively, (see Appendix G-11 of the Electronic Supplementary Material) using the pedigree matrix.

4.2.4 Winter wheat

Regions 3 and 4 showed the highest carbon footprint (Fig. 7), largely due to the high rate of application of inorganic nitrogen fertilizers by farmers. Inorganic nitrogen and phosphate fertilizers, diesel, and the impact of N_2O releases contributed 93–95% of the overall GHG emissions in each dairy region. As in other crops, about 65% of inorganic N fertilizer GHG emissions was from field application and 35% was due to fertilizer manufacture.

On the whole, the carbon footprints for all dairy feed crops analyzed in this study were within the range 160–1140 gCO_2e/kg of dry feed. Various contributions of different farm inputs varied on a regional basis and this was mainly due to the different fertilizer, liming, and energy requirements depending on location, soil properties, and climate.

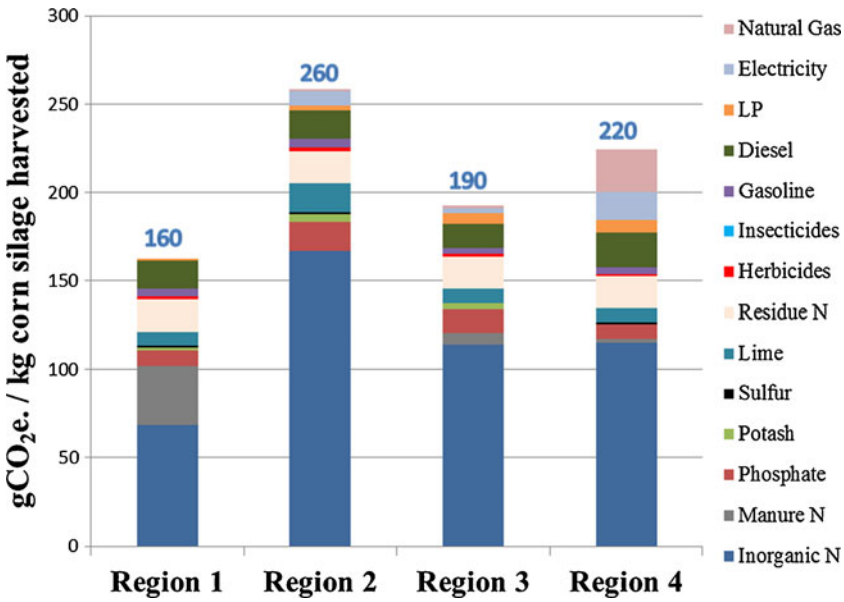

Fig. 6 Carbon footprint profile of corn silage harvested in the USA

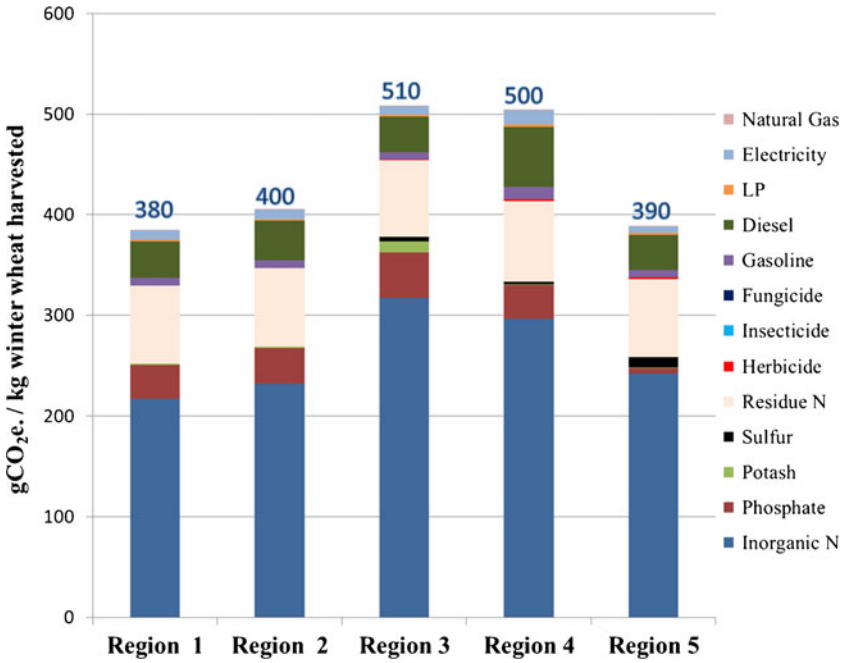

Fig. 7 Carbon footprint profile of winter wheat harvested in the USA

4.2.5 Forage crops: alfalfa hay, alfalfa silage, grass hay, grass pasture, and grass silage

The major contributors towards the regional footprints for both alfalfa hay and silage were identified to be due to crop residue, phosphate, lime, diesel, and electricity. In all regions, these factors contributed between 80% and 90% toward the overall regional footprint. However, impacts due to the application of potash, boron, crop protection chemicals, and use of gasoline were minimal ranging between 4% and 14% toward the carbon footprint for both alfalfa hay and silage. Contributions to carbon (GHG) footprint due to the application of inorganic fertilizer for both alfalfa hay and silage was less than 10% in all dairy production regions for which input data were available, and this low result was not surprising given that alfalfa is a nitrogen-fixing crop.

Grass showed a higher carbon footprint than other forage crops and nearly as high as the corn grain. Grass typically requires less maintenance and inputs, but produces lower yields than many other crops. In addition, there is much higher variability and uncertainty in actual yield than for other commodity crops. Region 2, which has the highest carbon footprint for grass and hay production, also had higher fuel, lime, and nitrogen use based on the available budget information. In all the different types of grass analyzed, inorganic fertilizers were the major contributors ranging from 34% to as high as 90% toward the footprint in the case of grass pasture. Lime contributions were significant for regions 1, 2, and 3, ranging between 13% and 19% for all grasses analyzed, but under 10% for regions 4 and 5. This reflects the acidic nature of soil in regions 1 to 3.

Finally, the standard deviation with 95% confidence for all inputs of alfalfa and grass were both estimated to be 1.22. Emission ranges varied significantly on a regional basis. The ranges reported in gCO_2e/kg dry forage feed were as follows: 140–270 (alfalfa hay), 150–280 (alfalfa silage), 270–470 (grass hay), 220–410 (grass pasture) and 280–410 (grass silage). The GHG emissions of 1 kg grass hay and silage at the farm gate for the Swiss production processes using Ecoinvent™ database (PRé Consultants 2009) were analyzed to be 180 and 220 gCO_2e/kg of dry feed, respectively, and somewhat lower than our results.

5 Conclusions and recommendations

In this carbon footprint study, the main goal was to estimate the GHG emissions from the cultivation and harvesting of dairy feeds on a basis of one dry kilogram of dairy feed harvested or produced (gCO_2e/kg of dry dairy feed). Table 6 shows the cradle-to-farm gate carbon footprint results obtained for all dairy feeds analyzed in this study. There were large differences in GHG emissions among the different dairy crops, with corn silage showing the lowest, while oats and DDGS displayed the highest. This variability was largely driven by fertilizer and energy utilization intensity as shown in Figs. 3, 4, 5, 6, and 7. There was some variability in carbon footprint for any crop from region to region, driven by regional differences in energy and lime use, but this variability was smaller than inter-crop variability.

The highest contributor to carbon footprint was the on-farm application of inorganic N fertilizer except for the leguminous feeds, whereas the fertilizer input categories P,

K, and S accounted for relatively small impacts for all crops. About 65% of inorganic N fertilizer GHG emissions was due to N_2O release upon application, whereas 35% was from fertilizer manufacture. N_2O emission contribution from crop residues was also significant for most crops. With N fertilizer input being the largest contributor to GHG emissions, much effort should be targeted toward lowering emissions associated with their production and use on the farm. Additionally, the efficient transfer of knowledge to farmers with regards to fertilizer best management practices might help reduce emissions on the farm. The use of crop protection chemicals was not so significant however, and energy use impacts varied widely from region to region, likely due to differences in climate, energy conservation programs, and need for crop drying. Finally, on the energy front, there is the need to promote the use of safe and cleaner forms of energy to help reduce climate active GHG emissions associated with the energy input needed by farmers.

This study highlights key crop inputs that are the drivers for emissions of greenhouse gases from the cradle-to-gate cultivation and harvesting for US dairy grain and forage crops. These crop results are equally applicable for uses other than dairy products; for example food production in general and bioenergy. Hopefully, these results will be useful for reducing GHG emissions by guiding efforts to modifying agricultural practices with respect to fertilizer application, use of manure, and energy consumption.

Acknowledgments The authors would like to thank Zachary Bergmann for crop data analysis. This work was funded by the Innovation Center for US Dairy. Parts of this study were subject to an external critical review by a panel of LCA experts. This manuscript was improved by the comments of anonymous reviewers.

Frequently Asked Questions

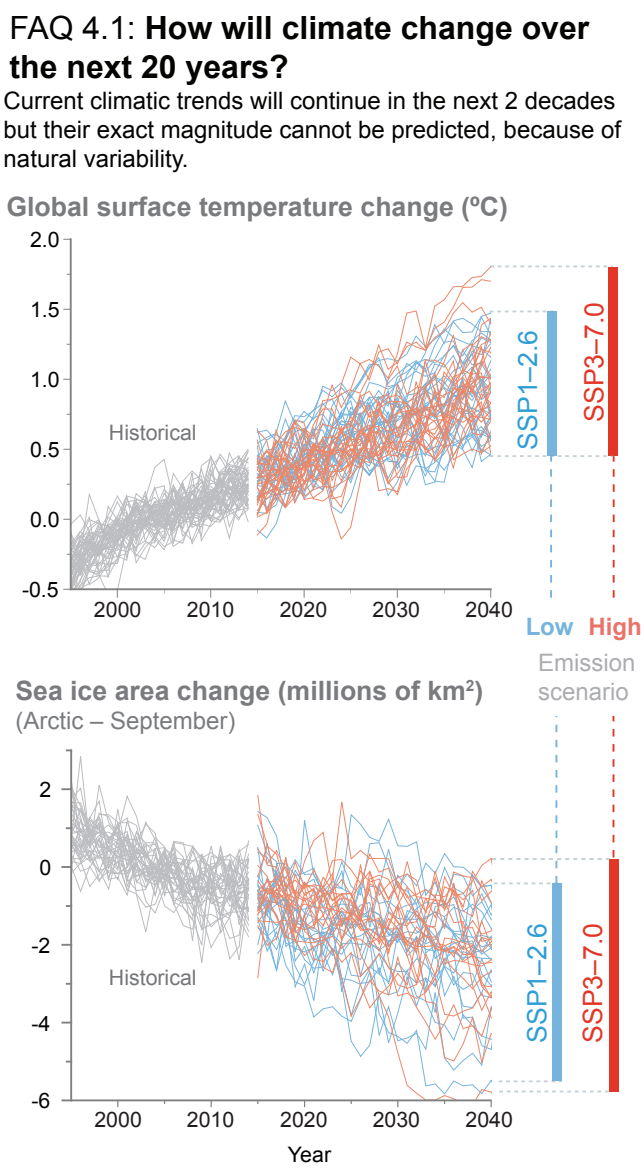
FAQ 4.1 | How Will the Climate Change Over the Next Twenty Years?

The parts of the climate system that have shown clear increasing or decreasing trends in recent decades will continue these trends for at least the next twenty years. Examples include changes in global surface temperature, Arctic sea ice cover, and global average sea level. However, over a period as short as twenty years, these trends are substantially influenced by natural climate variability, which can either amplify or attenuate the trend expected from the further increase in greenhouse gas concentrations.



Twenty years are a long time by human standards but a short time from a climate point of view. Emissions of greenhouse gases will continue over the next twenty years, as assumed in all the scenarios considered in this Report, albeit with varying rates. These emissions will further increase concentrations of greenhouse gases in the atmosphere (see FAQ 4.2), leading to continued trends in global surface warming and other parts of the climate system, including Arctic sea ice and global average sea level (see FAQ 9.2). FAQ 4.1, Figure 1 shows that both global surface temperature rise and the shrinking of sea ice in the Arctic will continue, with little difference between high- and low-emissions scenarios over the next 20 years (that is, between the red and blue lines).

However, these expected trends will be overlain by natural climate variability (see FAQ 3.2). First, a major volcanic eruption might occur, such as the 1991 eruption of Mt. Pinatubo on the Philippines; such an eruption might cause a global surface cooling of a few tenths of a degree Celsius lasting several years. Second, both atmosphere and ocean show variations that occur spontaneously, without any external influence. These variations range from localized weather systems to continent- and ocean-wide patterns and oscillations that change over months, years, or decades. Over a period of twenty years, natural climate variability strongly influences many climate quantities, when compared to the response to the increase in greenhouse gas concentrations from human activities. The effect of natural variability is illustrated by the very different trajectories that individual black, red or blue lines can take in FAQ 4.1, Figure 1. Whether natural variability would amplify or attenuate the human influence cannot generally be predicted out to twenty years into the future. Natural climate variability over the next twenty years thus constitutes an uncertainty that at best can be quantified accurately but that cannot be reduced.

Locally, the effect of natural variability would be much larger still. Simulations (not shown here) indicate that, locally, a cooling trend over the next twenty years cannot be ruled out, even under the high-emissions scenario – at a small number of locations on Earth, but these might lie anywhere. Globally, though, temperatures would rise under all scenarios.

In summary, while the direction of future change is clear for the two important climate quantities shown here – the global surface temperature and the Arctic sea ice area in September – the magnitude of the change is much less clear because of natural variability.

FAQ 4.1 (continued)

FAQ 4.1, Figure 1 | Simulations over the period 1995–2040, encompassing the recent past and the next twenty years, of two important indicators of global climate change. (Top) Global surface temperature, and **(bottom)**, the area of Arctic sea ice in September. Both quantities are shown as deviations from the average over the period 1995–2014. The grey curves are for the historical period ending in 2014; the blue curves represent a low-emissions scenario (SSP1-2.6) and the red curves one high-emissions scenario (SSP3-7.0).

Frequently Asked Questions

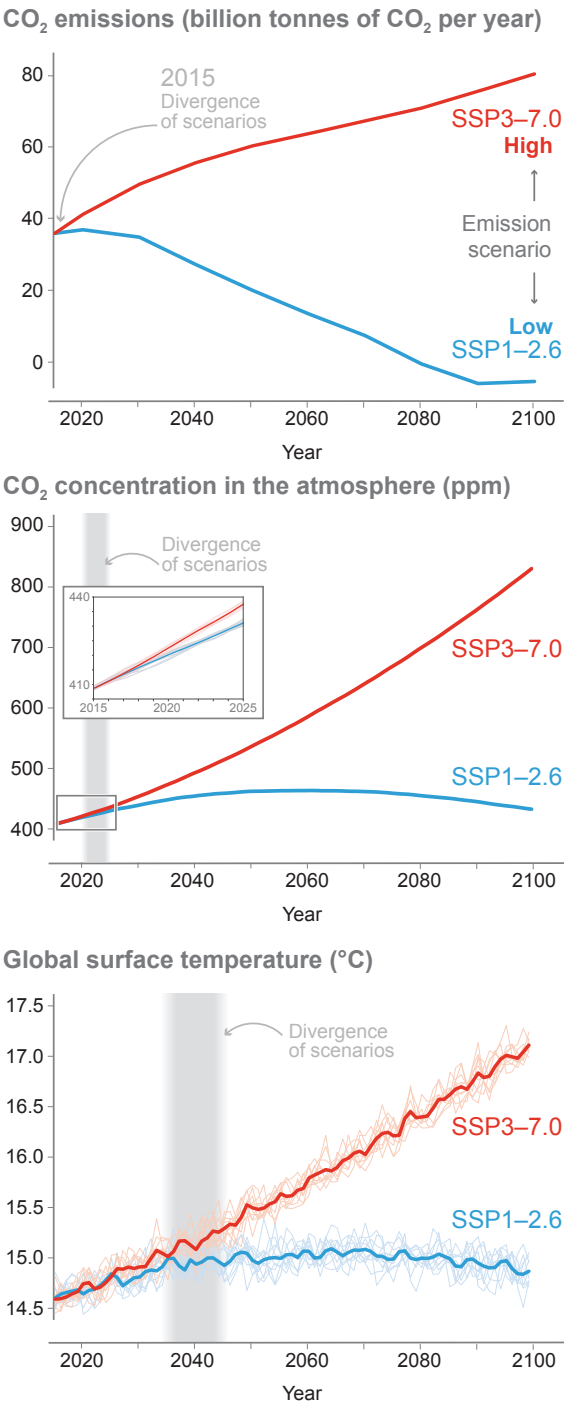
FAQ 4.2 | How Quickly Would We See the Effects of Reducing Carbon Dioxide Emissions?

The effects of substantial reductions in carbon dioxide emissions would not be apparent immediately, and the time required to detect the effects would depend on the scale and pace of emissions reductions. Under the lower-emissions scenarios considered in this Report, the increase in atmospheric carbon dioxide concentrations would slow visibly after about five to ten years, while the slowing down of global surface warming would be detectable after about twenty to thirty years. The effects on regional precipitation trends would only become apparent after several decades.

Reducing emissions of carbon dioxide (CO_2) – the most important greenhouse gas emitted by human activities – would slow down the rate of increase in atmospheric CO_2 concentration. However, concentrations would only begin to decrease when net emissions approach zero, that is, when most or all of the CO_2 emitted into the atmosphere each year is removed by natural and human processes (see FAQ 5.1 and FAQ 5.3). This delay between a peak in emissions and a decrease in concentration is a manifestation of the very long lifetime of CO_2 in the atmosphere; part of the CO_2 emitted by humans remains in the atmosphere for centuries to millennia.

Reducing the rate of increase in CO_2 concentration would slow down global surface warming within a decade. But this reduction in the rate of warming would initially be masked by natural climate variability and might not be detected for a few decades (see FAQ 1.2, FAQ 3.2 and FAQ 4.1). Detecting whether surface warming has indeed slowed down would thus be difficult in the years right after emissions reductions begin.

The time needed to detect the effect of emissions reductions is illustrated by comparing low- and high-emissions scenarios (FAQ 4.2, Figure 1). In the low-emissions scenario (SSP1-2.6), CO_2 emissions level off after 2015 and begin to fall in 2020, while they keep increasing throughout the 21st century in the high-emissions scenario (SSP3-7.0). The uncertainty arising from natural internal variability in the climate system is represented by simulating each scenario ten times with the same climate model but starting from slightly different initial states back in 1850 (thin lines). For each scenario, the differences between individual simulations are caused entirely by simulated natural internal variability. The average of all simulations represents the climate response expected for a given scenario. The climate history that would actually unfold under each scenario would consist of this expected response combined with the contribution from natural internal variability and the contribution from potential future volcanic eruptions (the latter effect is not represented here).



FAQ 4.2, Figure 1 shows that the atmospheric CO_2 concentrations differ noticeably between the two scenarios about five to ten years after the emissions have begun to diverge in year 2015. In contrast, the difference in global surface temperatures between the two scenarios does not become apparent until later – about two to three decades after the emissions histories have begun to diverge in this example. This time would be longer if emissions were reduced more slowly than in the low-emissions scenario illustrated here and shorter in the case of stronger reductions. Detection would take longer for regional quantities and for precipitation changes, which vary more strongly from natural causes. For instance, even in the low-emissions scenario, the effect of reduced CO_2 emissions would not become visible in regional precipitation until late in the 21st century.

In summary, it is only after a few decades of reducing CO_2 emissions that we would clearly see global temperatures starting to stabilize. By contrast, short-term reductions in CO_2 emissions, such as during the COVID-19 pandemic, do not have detectable effects on either CO_2 concentration or global temperature. Only sustained emissions reductions over decades would have a widespread effect across the climate system.

FAQ 4.2 (continued)

FAQ 4.2: **Detecting reduced CO_2 emissions**

Sustained reduction in carbon dioxide (CO_2) emissions would become apparent in atmospheric concentration after 5–10 years and in the temperature after 20–30 years.

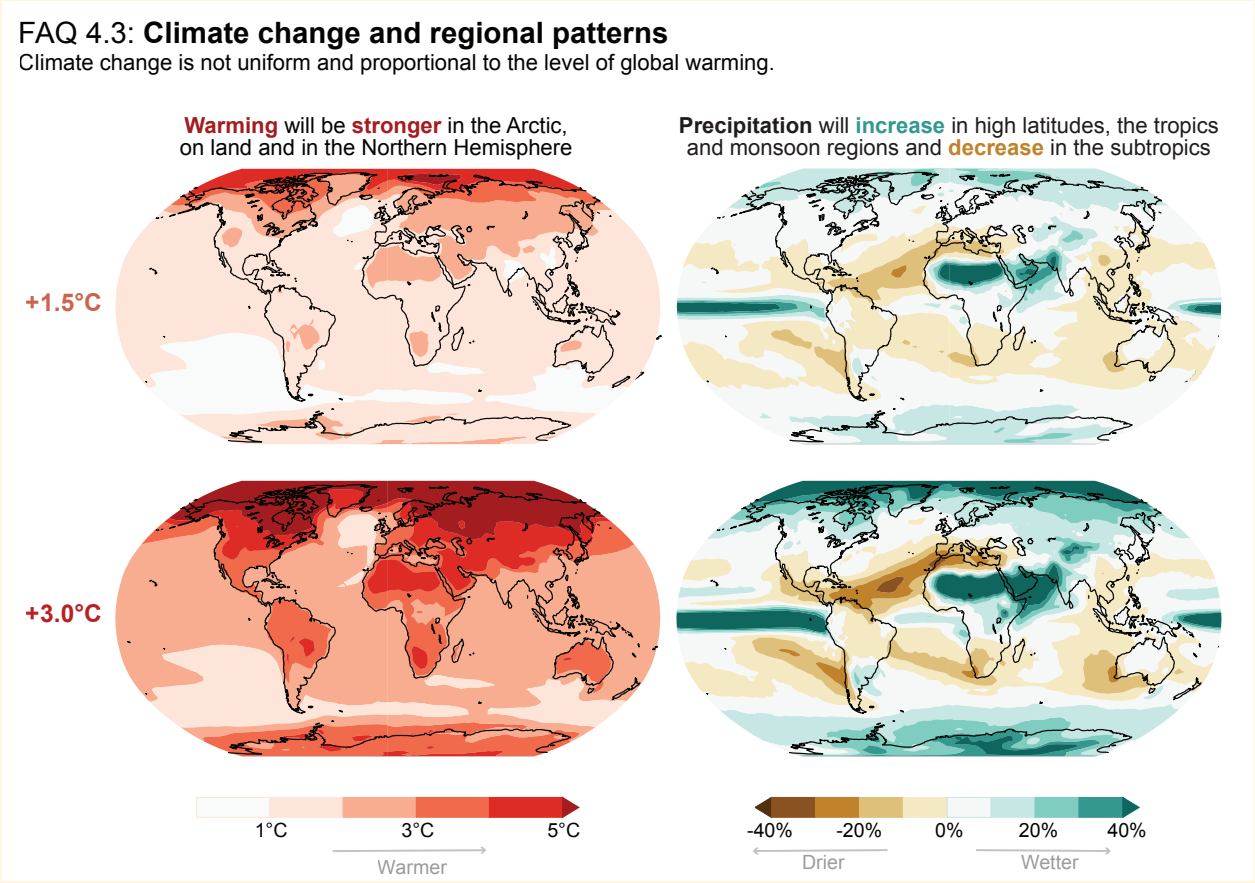
FAQ 4.2, Figure 1 | Observing the benefits of emissions reductions. (Top) Carbon dioxide (CO_2) emissions, **(middle)** CO_2 concentration in the atmosphere and **(bottom)** effect on global surface temperature for two scenarios: a low-emissions scenario (SSP1-2.6, blue) and a high-emissions scenario (SSP3-7.0). In the low-emissions scenario, CO_2 emissions begin to decrease in 2020 whereas they keep increasing throughout the 21st century in the high-emissions scenario. The thick lines are the average of the 10 individual simulations (thin line) for each scenario. Differences between individual simulations reflect natural variability.

FAQ 4.3 | At a Given Level of Global Warming, What Are the Spatial Patterns of Climate Change?

As the planet warms, climate change does not unfold uniformly across the globe, but some patterns of regional change show clear, direct and consistent relationships to increases in global surface temperature. The Arctic warms more than other regions, land areas warm more than the ocean surface, and the Northern Hemisphere more than the Southern Hemisphere. Precipitation increases over high latitudes, tropics and large parts of the monsoon regions, but decreases over the subtropics. For cases like these, we can infer the direction and magnitude of some regional changes – particularly temperature and precipitation changes – for any given level of global warming.

The intensity of climate change will depend on the level of global warming. It is possible to identify certain patterns of regional climate change that occur consistently, but increase in amplitude, across increasing levels of global warming. Such robust spatial patterns of climate change are largely independent of the specific scenario (and pathway in time) that results in a given level of global warming. That is, as long as different scenarios result in the same global warming level, irrespective of the time when this level is attained in each scenario, we can infer the patterns of regional change that would result from this warming. When patterns of changes are robust, regional consequences can be assessed for all levels of global warming, for all future time periods, and for all scenarios. Temperature and precipitation show such robust patterns of changes that are particularly striking.

The high latitudes of the Northern Hemisphere are projected to warm the most, by two to four times the level of global warming – a phenomenon referred to as Arctic amplification (FAQ 4.3, Figure 1, left). Several processes contribute to this high rate of warming, including increases in the absorption of solar radiation due to the loss of reflective sea ice and snow in a warmer world. In the Southern Hemisphere, Antarctica is projected to warm faster than the mid-latitude Southern Ocean, but the Southern Hemisphere high latitudes are projected to warm at a reduced amplitude compared to the level of global warming (FAQ 4.3, Figure 1, left). An important reason for the relatively slower warming of the Southern Hemisphere high latitudes is the upwelling of Antarctic deep waters that drives a large surface heat uptake in the Southern Ocean.



The warming is generally stronger over land than over the ocean, and in the Northern Hemisphere compared to the Southern Hemisphere, and with less warming over the central subpolar North Atlantic and the southernmost Pacific. The differences are the result of several factors, including differences in how land and ocean areas absorb and retain heat, the fact that there is more land area in the Northern Hemisphere than in the Southern Hemisphere, and the influence of ocean circulation. In the Southern Hemisphere, robust patterns of relatively high warming are projected for subtropical South America, southern Africa, and Australia. The relatively strong warming in subtropical southern Africa arises from strong interactions between soil moisture and temperature and from increased solar radiation as a consequence of enhanced subsidence.

Precipitation changes are also proportional to the level of global warming (FAQ 4.3, Figure 1, right), although uncertainties are larger than for the temperature change. In the high latitudes of both the Southern and Northern Hemispheres, increases in precipitation are expected as the planet continues to warm, with larger changes expected at higher levels of global warming (FAQ 4.3, Figure 1, right). The same holds true for the projected precipitation increases over the tropics and large parts of the monsoon regions. General drying is expected over the subtropical regions, particularly over the Mediterranean, southern Africa and parts of Australia, South America, and south-west North America, as well as over the subtropical Atlantic and parts of the subtropical Indian and Pacific Oceans. Increases in precipitation over the tropics and decreases over the subtropics amplify with higher levels of global warming.

Some regions that are already dry and warm, such as southern Africa and the Mediterranean, are expected to become progressively drier and drastically warmer at higher levels of global warming.

In summary, climate change will not affect all the parts of the globe evenly. Rather, distinct regional patterns of temperature and precipitation change can be identified, and these changes are projected to amplify as the level of global warming increases.

FAQ 4.3 (continued)

FAQ 4.3, Figure 1 | Regional changes in temperature (left) and precipitation (right) are proportional to the level of global warming, irrespective of the scenario through which the level of global warming is reached. Surface warming and precipitation change are shown relative to the 1850–1900 climate, and for time periods over which the globally averaged surface warming is 1.5°C **(top)** and 3°C **(bottom)**, respectively. Changes presented here are based on 31 CMIP6 models using the high-emissions scenario SSP3-7.0.

Irreversible climate change due to carbon dioxide emissions

Contributed by Susan Solomon, December 16, 2008 (sent for review November 12, 2008)

The severity of damaging human-induced climate change depends not only on the magnitude of the change but also on the potential for irreversibility. This paper shows that the climate change that takes place due to increases in carbon dioxide concentration is largely irreversible for 1,000 years after emissions stop. Following cessation of emissions, removal of atmospheric carbon dioxide decreases radiative forcing, but is largely compensated by slower loss of heat to the ocean, so that atmospheric temperatures do not drop significantly for at least 1,000 years. Among illustrative irreversible impacts that should be expected if atmospheric carbon dioxide concentrations increase from current levels near 385 parts per million by volume (ppmv) to a peak of 450–600 ppmv over the coming century are irreversible dry-season rainfall reductions in several regions comparable to those of the ''dust bowl'' era and inexorable sea level rise. Thermal expansion of the warming ocean provides a conservative lower limit to irreversible global average sea level rise of at least 0.4–1.0 m if 21st century CO_2 concentrations exceed 600 ppmv and 0.6–1.9 m for peak CO_2 concentrations exceeding ≈1,000 ppmv. Additional contributions from glaciers and ice sheet contributions to future sea level rise are uncertain but may equal or exceed several meters over the next millennium or longer.

dangerous interference | precipitation | sea level rise | warming

Over the 20th century, the atmospheric concentrations of key greenhouse gases increased due to human activities. The stated objective (Article 2) of the United Nations Framework Convention on Climate Change (UNFCCC) is to achieve stabilization of greenhouse gas concentrations in the atmosphere at a low enough level to prevent "dangerous anthropogenic interference with the climate system." Many studies have focused on projections of possible 21st century dangers (1–3). However, the principles (Article 3) of the UNFCCC specifically emphasize "threats of serious or irreversible damage," underscoring the importance of the longer term. While some irreversible climate changes such as ice sheet collapse are possible but highly uncertain (1, 4), others can now be identified with greater confidence, and examples among the latter are presented in this paper. It is not generally appreciated that the atmospheric temperature increases caused by rising carbon dioxide concentrations are not expected to decrease significantly even if carbon emissions were to completely cease (5–7) (see Fig. 1). Future carbon dioxide emissions in the 21st century will hence lead to adverse climate changes on both short and long time scales that would be essentially irreversible (where irreversible is defined here as a time scale exceeding the end of the millennium in year 3000; note that we do not consider geo-engineering measures that might be able to remove gases already in the atmosphere or to introduce active cooling to counteract warming). For the same reason, the physical climate changes that are due to anthropogenic carbon dioxide already in the atmosphere today are expected to be largely irreversible. Such climate changes will lead to a range of damaging impacts in different regions and sectors, some of which occur promptly in association with warming, while others build up under sustained warming because of the time lags of the processes involved. Here we illustrate 2 such aspects of the irreversibly altered world that should be expected. These aspects are among reasons for concern but are not comprehensive; other possible climate impacts include Arctic sea ice retreat, increases in heavy rainfall and flooding, permafrost melt, loss of glaciers and snowpack with attendant changes in water supply, increased intensity of hurricanes, etc. A complete climate impacts review is presented elsewhere (8) and is beyond the scope of this paper. We focus on illustrative adverse and irreversible climate impacts for which 3 criteria are met: (*i*) observed changes are already occurring and there is evidence for anthropogenic contributions to these changes, (*ii*) the phenomenon is based upon physical principles thought to be well understood, and (*iii*) projections are available and are broadly robust across models.

Advances in modeling have led not only to improvements in complex Atmosphere–Ocean General Circulation Models (AOGCMs) for projecting 21st century climate, but also to the implementation of Earth System Models of Intermediate Complexity (EMICs) for millennial time scales. These 2 types of models are used in this paper to show how different peak carbon dioxide concentrations that could be attained in the 21st century are expected to lead to substantial and irreversible decreases in dry-season rainfall in a number of already-dry subtropical areas and lower limits to eventual sea level rise of the order of meters, implying unavoidable inundation of many small islands and low-lying coastal areas.

Results

Longevity of an Atmospheric CO_2 Perturbation. As has long been known, the removal of carbon dioxide from the atmosphere involves multiple processes including rapid exchange with the land biosphere and the surface layer of the ocean through air–sea exchange and much slower penetration to the ocean interior that is dependent upon the buffering effect of ocean chemistry along with vertical transport (9–12). On the time scale of a millennium addressed here, the CO_2 equilibrates largely between the atmosphere and the ocean and, depending on associated increases in acidity and in ocean warming (i.e., an increase in the Revelle or "buffer" factor, see below), typically ≈20% of the added tonnes of CO_2 remain in the atmosphere while ≈80% are mixed into the ocean. Carbon isotope studies provide important observational constraints on these processes and time constants. On multimillenium and longer time scales, geochemical and geological

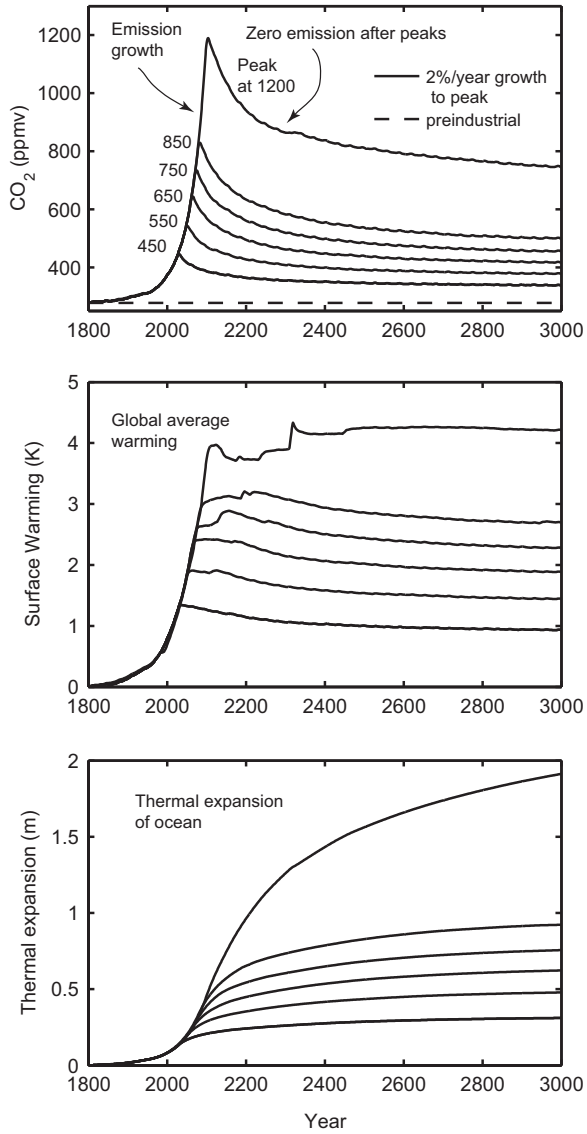

Fig. 1. Carbon dioxide and global mean climate system changes (relative to preindustrial conditions in 1765) from 1 illustrative model, the Bern 2.5CC EMIC, whose results are comparable to the suite of assessed EMICs (5, 7). Climate system responses are shown for a ramp of CO_2 emissions at a rate of 2%/year to peak CO_2 values of 450, 550, 650, 750, 850, and 1200 ppmv, followed by zero emissions. The rate of global fossil fuel CO_2 emission grew at ≈1%/year from 1980 to 2000 and >3%/year in the period from 2000 to 2005 (13). Results have been smoothed using an 11-year running mean. The 31-year variation seen in the carbon dioxide time series is introduced by the climatology used to force the terrestrial biosphere model (15). (*Top*) Falloff of CO_2 concentrations following zero emissions after the peak. (*Middle*) Globally averaged surface warming (degrees Celsius) for these cases (note that this model has an equilibrium climate sensitivity of 3.2 °C for carbon dioxide doubling). Warming over land is expected to be larger than these global averaged values, with the greatest warming expected in the Arctic (5). (*Bottom*) Sea level rise (meters) from thermal expansion only (not including loss of glaciers, ice caps, or ice sheets).

processes could restore atmospheric carbon dioxide to its preindustrial values (10, 11), but are not included here.

Fig. 1 illustrates how the concentrations of carbon dioxide would be expected to fall off through the coming millennium if manmade emissions were to cease immediately following an illustrative future rate of emission increase of 2% per year [comparable to observations over the past decade (ref. 13)] up to peak concentrations of 450, 550, 650, 750, 850, or 1,200 ppmv; similar results were obtained across a range of EMICs that were assessed in the Intergovernmental Panel on Climate Change (IPCC) Fourth Assessment Report (5, 7). This is not intended to be a realistic scenario but rather to represent a test case whose purpose is to probe physical climate system changes. A more gradual reduction of carbon dioxide emission (as is more likely), or a faster or slower adopted rate of emissions in the growth period, would lead to long-term behavior qualitatively similar to that illustrated in Fig. 1 (see also Fig. S1). The example of a sudden cessation of emissions provides an upper bound to how much reversibility is possible, if, for example, unexpectedly damaging climate changes were to be observed.

Carbon dioxide is the only greenhouse gas whose falloff displays multiple rather than single time constants (see Fig. S2). Current emissions of major non-CO_2 greenhouse gases such as methane or nitrous oxide are significant for climate change in the next few decades or century, but these gases do not persist over time in the same way as carbon dioxide (14).

Fig. 1 shows that a quasi-equilibrium amount of CO_2 is expected to be retained in the atmosphere by the end of the millennium that is surprisingly large: typically ≈40% of the peak concentration enhancement over preindustrial values (≈280 ppmv). This can be easily understood on the basis of the observed instantaneous airborne fraction (AF^{peak}) of ≈50% of anthropogenic carbon emissions retained during their buildup in the atmosphere, together with well-established ocean chemistry and physics that require ≈20% of the emitted carbon to remain in the atmosphere on thousand-year timescales [quasi-equilibrium airborne fraction (AF^{equi}), determined largely by the Revelle factor governing the long-term partitioning of carbon between the ocean and atmosphere/biosphere system] (9–11). Assuming given cumulative emissions, EMI, the peak concentration, CO_2^{peak} (increase over the preindustrial value CO_2^0), and the resulting 1,000-year quasi-equilibrium concentration, CO_2^{equi} can be expressed as

$$CO_2^{peak} = CO_2^0 + AF^{peak} \cdot EMI \quad [1]$$

$$CO_2^{equi} = CO_2^0 + AF^{equi} \cdot EMI \quad [2]$$

so that

$$CO_2^{equi} - CO_2^0 = \frac{AF^{equi}}{AF^{peak}} (CO_2^{peak} - CO_2^0). \quad [3]$$

Given an instantaneous airborne fraction (AF^{peak}) of ≈50% during the period of rising CO_2, and a quasi-equilbrium airborne factor (AF^{equi}) of 20%, it follows that the quasi-equilibrium enhancement of CO_2 concentration above its preindustrial value is ≈40% of the peak enhancement. For example, if the CO_2 concentration were to peak at 800 ppmv followed by zero emissions, the quasi-equilibrium CO_2 concentration would still be far above the preindustrial value at ≈500 ppmv. Additional carbon cycle feedbacks could reduce the efficiency of the ocean and biosphere to remove the anthropogenic CO_2 and thereby increase these CO_2 values (15, 16). Further, a longer decay time and increased CO_2 concentrations at year 1000 are expected for large total carbon emissions (17).

Irreversible Climate Change: Atmospheric Warming. Global average temperatures increase while CO_2 is increasing and then remain approximately constant (within ≈ ±0.5 °C) until the end of the millennium despite zero further emissions in all of the test cases shown in Fig. 1. This important result is due to a near balance between the long-term decrease of radiative forcing due to CO_2 concentration decay and reduced cooling through heat loss to the oceans. It arises because long-term carbon dioxide removal

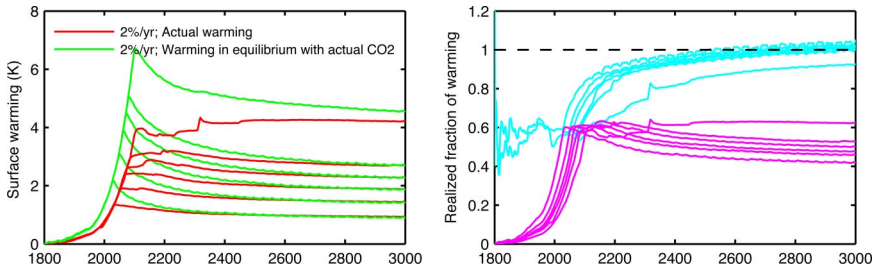

Fig. 2. Comparison between calculated time-dependent surface warming in the Bern2.5CC model and the values that would be expected if temperatures were in equilibrium with respect to the CO_2 enhancements, illustrative of 2%/year emission increases to 450, 550, 650, 750, 850, and 1,200 ppmv as in Fig. 1. (*Left*) The actual and equilibrium temperature changes (based upon the model's climate sensitivity at equilibrium). The cyan lines in *Right* show the ratio of actual and equilibrium temperatures (or realized fraction of the warming for the time-dependent CO_2 concentrations), while the magenta lines show the ratio of actual warming to the equilibrium temperature for the peak CO_2 concentration.

and ocean heat uptake are both dependent on the same physics of deep-ocean mixing. Sea level rise due to thermal expansion accompanies mixing of heat into the ocean long after carbon dioxide emissions have stopped. For larger carbon dioxide concentrations, warming and thermal sea level rise show greater increases and display transient changes that can be very rapid (i.e., the rapid changes in Fig. 1 *Middle*), mainly because of changes in ocean circulation (18). Paleoclimatic evidence suggests that additional contributions from melting of glaciers and ice sheets may be comparable to or greater than thermal expansion (discussed further below), but these are not included in Fig. 1.

Fig. 2 explores how close the modeled temperature changes are to thermal equilibrium with respect to the changing carbon dioxide concentration over time, sometimes called the realized warming fraction (19) (shown for the different peak CO_2 cases). Fig. 2 *Left* shows how the calculated warmings compare to those expected if temperatures were in equilibrium with the carbon dioxide concentrations vs. time, while Fig. 2 *Right* shows the ratio of these calculated time-dependent and equilibrium temperatures. During the period when carbon dioxide is increasing, the realized global warming fraction is ≈50–60% of the equilibrium warming, close to values obtained in other models (5, 19). After emissions cease, the temperature change approaches equilibrium with respect to the slowly decreasing carbon dioxide concentrations (cyan lines in Fig. 2 *Right*). The continuing warming through year 3000 is maintained at ≈40–60% of the equilibrium warming corresponding to the peak CO_2 concentration (magenta lines in Fig. 2 *Right*). Related changes in fast-responding atmospheric climate variables such as precipitation, water vapor, heat waves, cloudiness, etc., are expected to occur largely simultaneously with the temperature changes.

Irreversible Climate Change: Precipitation Changes. Warming is expected to be linked to changes in rainfall (20), which can adversely affect the supply of water for humans, agriculture, and ecosystems. Precipitation is highly variable but long-term rainfall decreases have been observed in some large regions including, e.g., the Mediterranean, southern Africa, and parts of southwestern North America (21–25). Confident projection of future changes remains elusive over many parts of the globe and at small scales. However, well-known physics (the Clausius–Clapeyron law) implies that increased temperature causes increased atmospheric water vapor concentrations, and changes in water vapor transport and the hydrologic cycle can hence be expected (26–28). Further, advances in modeling show that a robust characteristic of anthropogenic climate change is poleward expansion of the Hadley cell and shifting of the pattern of precipitation minus evaporation (*P–E*) and the storm tracks (22, 26), and hence a pattern of drying over much of the already-dry subtropics in a warmer world (≈15°-40° latitude in each hemisphere) (5, 26). Attribution studies suggest that such a drying pattern is already occurring in a manner consistent with models including anthropogenic forcing (23), particularly in the southwestern United States (22) and Mediterranean basin (24, 25).

We use a suite of 22 available AOGCM projections based upon the evaluation in the IPCC 2007 report (5, 29) to characterize precipitation changes. Changes in precipitation are expected (5, 20, 30) to scale approximately linearly with increasing warming (see Fig. S3). The equilibrium relationship between precipitation and temperature may be slightly smaller (by ≈15%) than the transient values, due to changes in the land/ocean thermal contrast (31). On the other hand, the observed 20th century changes follow a similar latitudinal pattern but presently exceed those calculated by AOGCMs (23). Models that include more complex representations of the land surface, soil, and vegetation interactively are likely to display additional feedbacks so that larger precipitation responses are possible.

Here we evaluate the relationship between temperature and precipitation averaged for each month and over a decade at each grid point. One ensemble member is used for each model so that all AOGCMs are equally weighted in the multimodel ensemble; results are nearly identical if all available model ensemble members are used.

Fig. 3 presents a map of the expected dry-season (3 driest consecutive months at each grid point) precipitation trends per degree of global warming. Fig. 3 shows that large uncertainties remain in the projections for many regions (white areas). However, it also shows that there are some subtropical locations on every inhabited continent where dry seasons are expected to become drier in the decadal average by up to 10% per degree of warming. Some of these grid points occur in desert regions that are already very dry, but many occur in currently more temperate and semiarid locations. We find that model results are more robust over land across the available models over wider areas for drying of the dry season than for the annual mean or wet season (see Fig. S4). The *Insets* in Fig. 3 show the monthly mean projected precipitation changes averaged over several large regions as delineated on the map. Increased drying of respective dry seasons is projected by >90% of the models averaged over the indicated regions of southern Europe, northern Africa, southern Africa, and southwestern North America and by >80% of the models for eastern South America and western Australia (see Fig. S3). Although given particular years would show exceptions, the long-term irreversible warming and mean rainfall changes as suggested by Figs. 1 and 3 would have important consequences in many regions. While some relief can be expected in the wet season for some regions (Fig. S4), changes in dry-season precipitation in northern Africa, southern Europe, and western Australia are expected to be near 20% for 2 °C warming, and those of southwestern North America, eastern South America, and southern Africa would be ≈10% for 2 °C of global mean warming. For comparison, the American "dust

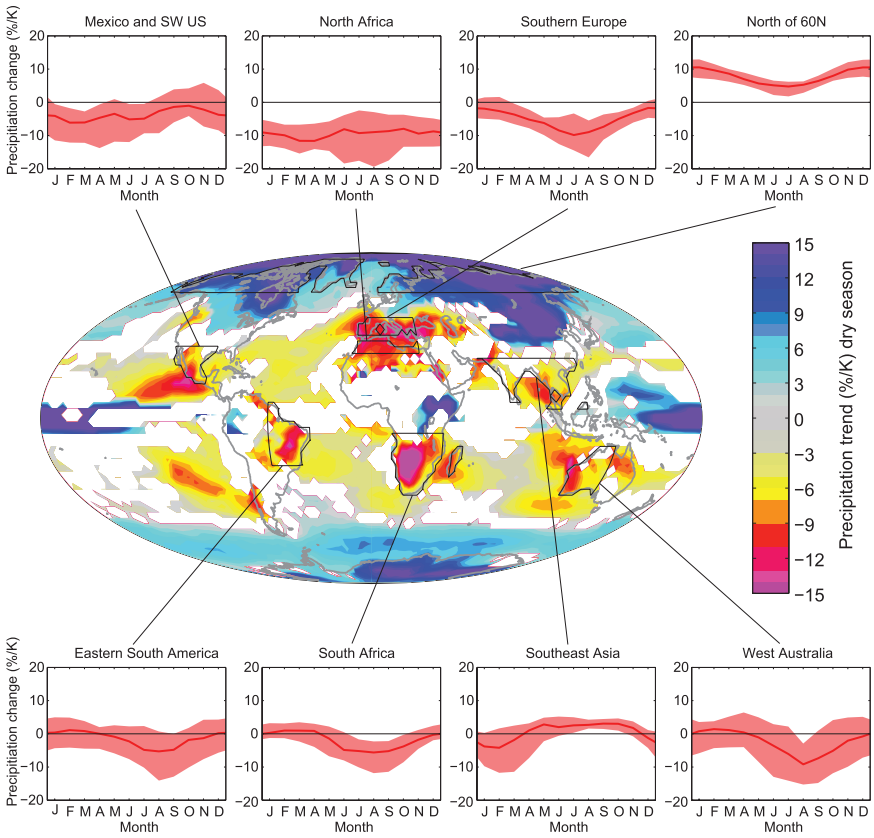

Fig. 3. Expected decadally averaged changes in the global distribution of precipitation per degree of warming (percentage of change in precipitation per degree of warming, relative to 1900–1950 as the baseline period) in the dry season at each grid point, based upon a suite of 22 AOGCMs for a midrange future scenario (A1B, see ref. 5). White is used where fewer than 16 of 22 models agree on the sign of the change. Data are monthly averaged over several broad regions in *Inset* plots. Red lines show the best estimate (median) of the changes in these regions, while the red shading indicates the ± 1-σ likely range (i.e., 2 of 3 chances) across the models.

bowl" was associated with averaged rainfall decreases of ≈10% over ≈10–20 years, similar to major droughts in Europe and western Australia in the 1940s and 1950s (22, 32). The spatial changes in precipitation as shown in Fig. 3 imply greater challenges in the distribution of food and water supplies than those with which the world has had difficulty coping in the past. Such changes occurring not just for a few decades but over centuries are expected to have a range of impacts that differ by region. These include, e.g., human water supplies (25), effects on dry-season wheat and maize agriculture in certain regions of rain-fed farming such as Africa (33, 34), increased fire frequency, ecosystem change, and desertification (24, 35–38).

Fig. 4 *Upper* relates the expected irreversible changes in regional dry-season precipitation shown in Fig. 3 to best estimates of the corresponding peak and long-term CO_2 concentrations. We use 3 °C as the best estimate of climate sensitivity across the suite of AOGCMs for a doubling of carbon dioxide from preindustrial values (5) along with the regional drying values depicted in Fig. 3 and assuming that ≈40% of the carbon dioxide peak concentration is retained after 1000 years. Fig. 4 shows that if carbon dioxide were to peak at levels of ≈450 ppmv, irreversible decreases of ≈8–10% in dry-season precipitation would be expected on average over each of the indicated large regions of southern Europe, western Australia, and northern Africa, while a carbon dioxide peak value near 600 ppmv would be expected to lead to sustained rainfall decreases of ≈13–16% in the dry seasons in these areas; smaller but statistically significant irreversible changes would also be expected for southwestern North America, eastern South America, and Southern Africa.

Irreversible Climate Change: Sea Level Rise. Anthropogenic carbon dioxide will cause irrevocable sea level rise. There are 2 relatively well-understood processes that contribute to this and a third that may be much more important but is also very uncertain. Warming causes the ocean to expand and sea levels to rise as shown in Fig. 1; this has been the dominant source of sea level rise in the past decade at least (39). Loss of land ice also makes important contributions to sea level rise as the world warms. Mountain glaciers in many locations are observed to be retreating due to warming, and this contribution to sea level rise is also relatively well understood. Warming may also lead to large losses of the Greenland and/or Antarctic ice sheets. Additional rapid ice losses from particular parts of the ice sheets of Greenland and Antarctica have recently been observed (40–42). One recent study uses current ice discharge data to suggest ice sheet contributions of up to 1–2 m to sea level rise by 2100 (42), but other studies suggest that changes in winds rather than warming may account for currently observed rapid ice sheet flow (43), rendering quantitative extrapolation into the future uncertain. In addition to rapid ice flow, slow ice sheet mass balance processes are another mechanism for potential large sea level rise. Paleoclimatic data demonstrate large contributions of ice sheet loss to sea level rise (1, 4) but provide limited constraints on the rate of such processes. Some recent studies suggest that ice sheet surface mass balance loss for peak CO_2 concentrations of 400–800 ppmv may be even slower than the removal of manmade carbon dioxide following cessation of emis-

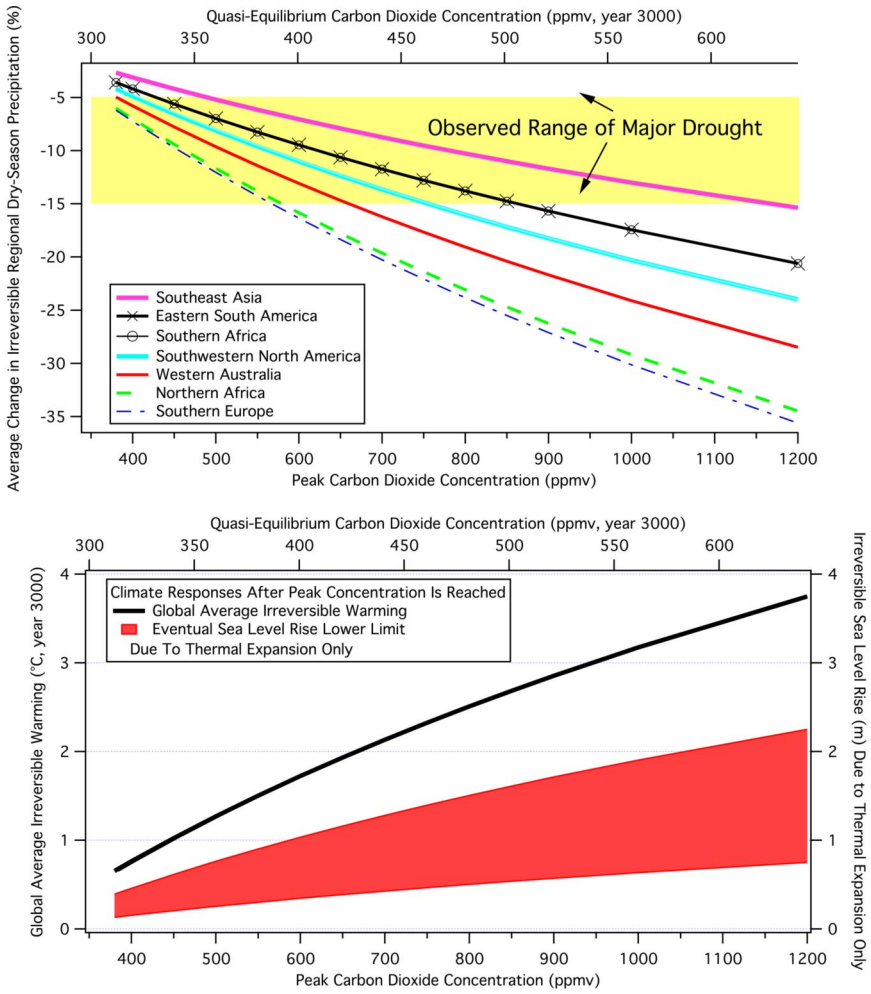

Fig. 4. Illustrative irreversible climate changes as a function of peak carbon dioxide reached. (*Upper*) Best estimate of expected irreversible dry-season precipitation changes for the regions shown in Fig. 3, as a function of the peak carbon dioxide concentration during the 21st century. The quasi-equilibrium CO_2 concentrations shown correspond to 40% remaining in the long term as discussed in the text. The precipitation change per degree is derived for each region as in Fig. 3; see also Fig. S3. The yellow box indicates the range of precipitation change observed during typical major regional droughts such as the ''dust bowl'' in North America (32). (*Lower*) Corresponding irreversible global warming (black line). Also shown is the associated lower limit of irreversible sea level rise (because of thermal expansion only based upon a range of 0.2–0.6 m/°C), from an assessment across available models (5). Smaller values (by ≈30%) for expected warming, precipitation, and thermal sea level rise would be obtained if climate sensitivity is smaller than the best estimate while larger values (by ≈50%) would be expected for the upper end of the estimated likely range of climate sensitivity (49).

sions, so that this loss could contribute less than a meter to irreversible sea level rise even after many thousands of years (44, 45). It is evident that the contribution from the ice sheets could be large in the future, but the dependence upon carbon dioxide levels is extremely uncertain not only over the coming century but also in the millennial time scale.

An assessed range of models suggests that the eventual contribution to sea level rise from thermal expansion of the ocean is expected to be 0.2–0.6 m per degree of global warming (5). Fig. 4 uses this range together with a best estimate for climate sensitivity of 3 °C (5) to estimate lower limits to eventual sea level rise due to thermal expansion alone. Fig. 4 shows that even with zero emissions after reaching a peak concentration, irreversible global average sea level rise of at least 0.4–1.0 m is expected if 21st century CO_2 concentrations exceed 600 ppmv and as much as 1.9 m for a peak CO_2 concentration exceeding ≈1,000 ppmv. Loss of glaciers and small ice caps is relatively well understood and is expected to be largely complete under sustained warming of, for example, 4 °C within ≈500 years (46). For lower values of warming, partial remnants of glaciers might be retained, but this has not been examined in detail for realistic representations of glacier shrinkage and is not quantified here. Complete losses of glaciers and small ice caps have the potential to raise future sea level by ≈0.2–0.7 m (46, 47) in addition to thermal expansion. Further contributions due to partial loss of the great ice sheets of Antarctica and/or Greenland could add several meters or more to these values but for what warming levels and on what time scales are still poorly characterized.

Sea level rise can be expected to affect many coastal regions (48). While sea walls and other adaptation measures might combat some of this sea level rise, Fig. 4 shows that carbon dioxide peak concentrations that could be reached in the future for the conservative lower limit defined by thermal expansion alone can be expected to be associated with substantial irreversible commitments to future changes in the geography of the Earth because many coastal and island features would ultimately become submerged.

Discussion: Some Policy Implications

It is sometimes imagined that slow processes such as climate changes pose small risks, on the basis of the assumption that a choice can always be made to quickly reduce emissions and

Downloaded from https://www.pnas.org by 216.24.173.200 on May 1, 2026 from IP address 216.24.173.200.

thereby reverse any harm within a few years or decades. We have shown that this assumption is incorrect for carbon dioxide emissions, because of the longevity of the atmospheric CO_2 perturbation and ocean warming. Irreversible climate changes due to carbon dioxide emissions have already taken place, and future carbon dioxide emissions would imply further irreversible effects on the planet, with attendant long legacies for choices made by contemporary society. Discount rates used in some estimates of economic trade-offs assume that more efficient climate mitigation can occur in a future richer world, but neglect the irreversibility shown here. Similarly, understanding of irreversibility reveals limitations in trading of greenhouse gases on the basis of 100-year estimated climate changes (global warming potentials, GWPs), because this metric neglects carbon dioxide's unique long-term effects. In this paper we have quantified how societal decisions regarding carbon dioxide concentrations that have already occurred or could occur in the coming century imply irreversible dangers relating to climate change for some illustrative populations and regions. These and other dangers pose substantial challenges to humanity and nature, with a magnitude that is directly linked to the peak level of carbon dioxide reached.

Materials and Methods

The AOGCM simulation data presented in this paper are part of the World Climate Research Program's (WCRP's) Coupled Model Intercomparison Project phase 3 (CMIP3) multimodel data set (29) and are available from the Program for Climate Model Diagnosis and Intercomparison (PCMDI) (www-pcmdi.llnl.gov/ipcc/about_ipcc.php), where further information on the AOGCMs can also be obtained. The EMIC used in this study is the Bern2.5CC EMIC described in refs. 7 and 15; it is compared to other models in refs. 5 and 7. It is a coupled climate–carbon cycle model of intermediate complexity that consists of a zonally averaged dynamic ocean model, a 1-layer atmospheric energy–moisture balance model, and interactive representations of the marine and terrestrial carbon cycles.

ACKNOWLEDGMENTS. We gratefully acknowledge the modeling groups, the Program for Climate Model Diagnosis and Intercomparison, and the World Climate Research Program's Working Group on Coupled Modeling for their roles in making available the Working Group on Coupled Modeling's Coupled Model Intercomparison Project phase 3 multimodel data set. Support of this data set is provided by the Office of Science, U.S. Department of Energy. We also appreciate helpful comments from 3 reviewers.

ABSTRACT

Earth systems may fall into an undesirable system state if 1.5 °C of warming is exceeded. Carbon release from substantial permafrost stocks vulnerable to near-term warming represents a positive climate feedback that may increase the risk of 1.5 °C warming or greater. Methane (CH_4) is a short-lived but powerful greenhouse gas with a global warming potential 28.5 times that of carbon dioxide (CO_2) over a 100 year time span. Because permafrost thaw in the coming centuries is partly determined by the warming in the 21st century, rapid reductions in methane emissions early in the 21st century could have far reaching effects. We use a reduced complexity carbon cycle model and a permafrost feedback module to explore the possibility that accelerating reductions in methane emissions could help avoid long-term warming by limiting permafrost melt. We simulate three extended Representative Concentration Pathway (RCP) emission scenarios (RCP 2.6, 4.5, and 6) through the year 2300 and impose methane mitigation strategies where we reduce CH_4 emissions by 1%, 5% or 10% annually until the long-term scenario emission level is reached. We find that accelerated rates of methane mitigation do not sufficiently alter the global temperature anomaly to prevent or delay a permafrost feedback, nor do they result in meaningful long term reductions in temperatures. We find that the long-term magnitude of methane mitigation (i.e., long-term emission level) and not the rate of reduction, corresponds to long-term temperature change. Further study of methane-climate dynamics is necessary to fully resolve this question.

1. Introduction

There is increasing recognition and concern that multiple intrinsic positive feedbacks in the Earth system may lead to “tipping points” whereby the Earth system state may rapidly transition into a new undesirable one once some threshold of global mean warming is passed. Such feedbacks include ice sheet loss, permafrost melt, Atlantic ocean circulation, and Amazon rainforest dieback (Lenton et al., 2019). Without these feedbacks, previous estimates for “safe warming” ranged between 2-3 °C. With the inclusion of positive, interacting feedbacks, Lenton et al. (2019) concluded that warming must be limited to 1.5 °C. Warming past 1.5 °C may cause runaway feedback effects. Therefore, a full assessment of mitigation pathways to avoid crossing undesirable climate boundaries should explicitly include major feedbacks.

Among the many positive climate feedbacks, permafrost melt and subsequent carbon emissions may have the greatest effect on climate in the coming centuries due to the vast amounts of carbon stored within the permafrost and vulnerability to temperature perturbation (Crichton et al., 2016). Because long-term warming is primarily a function of *cumulative* carbon emissions (Pierrehumbert, 2014; Global, 2022) the concept of the carbon budget was developed. It describes a total cumulative amount of carbon that can be emitted to limit global mean warming (with some degree of confidence) to a given level, e.g. 1.5 °C. Each year, anthropogenic CO_2 emissions take roughly 9 gigatonnes of carbon (GtC) off the budget. In 2019, there was an estimated 136 GtC left in the budget for 1.5 °C, (Lenton et al., 2019; Rogelj et al., 2019) but more recent estimates from 2021 posit that only 120 GtC remain (Friedlingstein et al., 2022).

The permafrost may be the most impactful near-term feedback because of high net carbon content and sensitivity to degradation with increased warming. As temperatures rise, permafrost emissions could rapidly exhaust the carbon budget. As of 2014, it has been estimated that circumpolar permafrost at a depth of 0-3 meters stored 1035 GtC (Hugelius et al., 2014). Several existing studies have estimated permafrost carbon emissions under Representative Concentration Pathway (RCP) emissions scenarios used by the Intergovernmental Panel on Climate Change (IPCC), namely RCP 2.6, RCP 4.5, RCP 6.0, and RCP 8.5, with the number corresponding to the change in radiative forcing the Earth experiences in the year 2100 (e.g., under RCP 8.5, the Earth will experience +8.5 Watts/m^{-2} of radiative forcing). Under RCP 8.5, 33-114 GtC may be released from the permafrost by 2100, contributing to an additional warming of 0.04-0.23 °C (Schneider Von Deimling et al., 2012), and by 2300, half the vulnerable permafrost carbon stock could be released. While the RCP 8.5 is a high-end scenario, there is still a great deal of uncertainty regarding permafrost carbon stocks, thawing processes, and subsequent microbial decomposition to CO_2 and CH_4, as well as other potential feedbacks (Schneider Von Deimling et al., 2012). Another study found that the permafrost feedback effect reduces the carbon budget for avoiding 2 °C warming by 100 GtC (Gasser et al., 2018), accounting for roughly 24% of the remaining carbon budget (Friedlingstein et al., 2022). Therefore, permafrost feedback is the primary positive climate feedback we examine in this paper.

Methane is a powerful greenhouse gas and is responsible for about 1.19 W/m^{-2} of radiative forcing since 1750. Given that warming is a function of multiple anthropogenic greenhouse gas emissions, mitigating methane emissions will play an important role in avoiding the climate boundary (Dreyfus et al., 2022; Rogelj et al., 2014; Harmsen et al., 2020; Xu and Ramanathan, 2017; Christensen et al., 2019). However, multiple authors have argued that methane mitigation is not a substitute for immediate decarbonization and will not "buy us time" as we work towards net-zero carbon (Pierrehumbert, 2014; Rogelj et al., 2014; Bowerman et al., 2013; Myhre et al., 2011). These conclusions hinge on the fundamentally different climate effects of short-lived and long-lived greenhouse gases.

Because near term climate forcers like methane have relatively short atmospheric lifetimes, the annual emissions *rate* of these substances is far more relevant than cumulative emissions over time (Pierrehumbert, 2014): There is no long-term "methane budget". We are concerned with net cumulative emissions of CO_2 because it is a long-lived millennial gas, where in contrast, methane oxidizes to CO_2 in the presence of hydroxyl radicals (OH), and has a perturbation lifetime of approximately 12.4 years (IPCC, 2023). Therefore, mitigation efforts should make their focus limiting annual methane emissions rather than limiting a net cumulative amount.

How to best plan methane mitigation in the coming years remains an open question. Although there is uncertainty regarding how much, there is general agreement that some warming can be avoided in this century by implementing methane mitigation plans (Smith and Mizrahi, 2013; Dreyfus et al., 2022), with methane mitigation especially valuable for limiting near term warming rates and magnitude by mid-century (Ocko et al., 2021). However, McKeough (2022) concluded that mitigation could be postponed to as late as 2050-2080 with limited impact on the temperature anomaly at 2100 (McKeough, 2022). Nevertheless, methane mitigation is understudied in relation to its long-term effects (past 2100), especially in relation to positive climate feedbacks. That is, because feedbacks such as permafrost may be sensitive to near-term temperature changes that are strongly influenced by methane emissions rates early in the twenty-first century, rapid methane mitigation could be a higher priority than previously realized.

We address the question of the rate of methane mitigation: Is there any benefit to an accelerated emissions reduction plan in the presence of a permafrost carbon feedback? We are interested in the possibility that the mitigation of methane could prevent some release of CO_2, as well as CH_4, from the permafrost, and therefore mitigate long-term warming. Because methane has considerable short term temperature effects and can strongly influence the short-term rate of warming, it warrants examination in relation to the permafrost feedback.

We use a reduced complexity model that represents the most relevant Earth systems to understand the dynamics between reducing annual CH_4 emissions and long term temperature changes from CO_2 and CH_4, as well as nitrous oxide (N_2O), due to its interaction with methane. Radiative forcing attributable to our three greenhouse gases is described with IPCC formulas, and the associated temperature change is determined by a two-box ocean layer heat transfer model from Pierrehumbert (2014). We develop a simplified carbon cycle model based on Glotter et al. (2014) and Hartin et al. (2016, 2015) that describes flux between three terrestrial biota compartments and two ocean compartments. Increased carbon uptake due to CO_2 fertilization and CO_2 buffering with acidification are included. We model permafrost decomposition via a linear decrease in permafrost extent with rise in temperature and subsequent release of emissions as exponential decay. This is based on the model of Kessler (2017), where permafrost carbon mobilization to a labile carbon pool increases linearly with temperature. Carbon in this labile pool is then emitted to the atmosphere as a mix of CO_2 and CH_4 according to exponential dynamics with an e-folding time of about 70 years. These simplified representations of Earth systems describe the relationship of emissions to temperature perturbation. Finally, we drive the model using RCP CO_2 emission time-series while varying rates of methane mitigation to determine the impact on long term temperature.

2. Methods

We use a reduced complexity climate model implemented as a system of coupled first order differential equations. These equations model the carbon cycle with carbon fluxes between atmospheric, terrestrial, and ocean layers, along with ocean carbonate chemistry. We use a simple two-box temperature response model to calculate the effects of radiative forcing from CO_2, N_2O, and CH_4 on surface temperature. We include a two-part linear permafrost feedback using a differential equation that responds to increases of the global mean temperature. The temperature and carbon cycle model can be driven either by imposed atmospheric GHG concentrations (when driving the model with historical data) or with GHG emissions (and resulting modeled concentrations) when projecting the model forward.

2.1. The carbon cycle

2.1.1. Terrestrial carbon stores

The terrestrial carbon stores included in our model are the vegetation, detritus and soil. Together, these have a significant interaction with atmospheric carbon. We use a differential equation to describe each major box, where C_V is the carbon of the vegetation layer, C_D is the carbon in the detritus layer, and C_S is the carbon in the soil layer. Each box (Equations (1), (2), (3)) has a source term representing net primary productivity (NPP), where autotrophs store some of amount of carbon. Each layer has loss and source terms to describe the transfer of carbon from one layer to another. The vegetation box's loss term represents the transfer of carbon to the detritus ($C_V f_{vd}$) and soil ($C_V f_{vs}$) layers. The detritus box's loss term describes the carbon transfer to the soil layer ($C_D f_{ds}$). The soil and detritus boxes have loss terms for heterotrophic respiration (RH), where microbial activity releases carbon into the atmosphere. Finally, each layer has a term representing losses of carbon due to land use change (F_{LC}).

We use formulas from Hartin et al. (2015) given by

$$\frac{dC_V}{dt} = NPP f_{nv} - C_V(f_{vd} + f_{vs}) - F_{LC} f_{lv}\,, \tag{1}$$

$$\frac{dC_D}{dt} = NPP f_{nd} + C_V f_{vd} - C_D f_{ds} - RH_{det} - F_{LC} f_{ld}\,, \tag{2}$$

$$\frac{dC_S}{dt} = NPPf_{ns} + C_V f_{vs} + C_D f_{ds} - RH_{soil} - F_{LC} f_{ls} \,. \tag{3}$$

Any land use change alters the CO_2 content of the terrestrial stores. If land is deforested, each layer releases carbon into the atmosphere. If x GtC are released due to land use change, a certain proportion of those emissions comes from each of the different layer represented by the portions f_{lv}, f_{ld}, and f_{ls} (Table 1).

Heterotrophic respiration (RH) from the detritus and soil layers feeds into the atmosphere. RH is a function of the current carbon content of the respective strata and the respiration factor Q_{10} which is the factor by which respiration increases for a 10 degree increase in temperature. For soil and detritus, we use a ten-year average of global mean temperature perturbation divided by ten. A running average is used to represent the slow change in temperature from the surface of the Earth to the lower layers of soil.

Net primary productivity (NPP) is a function of current atmospheric carbon levels compared to pre-industrial carbon levels in ppm scaled by the carbon fertilization parameter, β. The value for β varies depending on the region (Hartin et al., 2016), but we use a single value to represent the whole earth system. The total NPP is subtracted from our atmospheric carbon, reflecting the carbon uptake by all terrestrial sinks, and is added to terrestrial stores by a factor f_{nv}, f_{nd}, f_{ns} (Table 1). Therefore, we determine NPP and RH by

$$\mathrm{NPP}(t) = \mathrm{NPP}_0 \times f(C_{atm}, \beta) \tag{4}$$

$$f(C_{atm}, \beta) = 1 + \beta \times log\left(\frac{C_{atm}}{C_0}\right) \tag{5}$$

$$\mathrm{RH}_{s,d}(t) = C_{s,d} \times f_{rs,rd} \times Q_{10}^{T(t)/10}. \tag{6}$$

2.1.2. Oceanic carbon stores

Ocean carbon flows and buffering chemistry are modeled using the Bolin and Erikson Adjusted Model (BEAM) (Glotter et al., 2014), where CO_2 cycles between the atmosphere, upper ocean, and lower ocean.

We represent the carbon in the atmosphere, upper ocean, and lower ocean boxes as C_A, C_U, and C_L respectively. Important parameters include δ_d and δ_a, where δ_d represents the ratio of the moles of the lower (deep) ocean to the moles of the upper ocean. Then, δ_a is the ratio of moles between the atmosphere and the upper ocean. Given the ocean is approximately 500 times the size of the atmosphere, we set δ_d to 50 and solve for δ_a using known values for atmospheric and ocean moles. We use k_a for the turnover time for the upper ocean, k_d for the turnover time for the deep ocean, and k_H for Henry's constant. Lastly, the anthropogenic emissions stream $E(t)$ is added directly to C_A.

To model the carbon chemistry of the ocean, we look at the dynamics of how atmospheric carbon is absorbed into the different ocean layers. The loss of carbon in the atmosphere to the upper ocean is represented by $-k_a C_A$, and its flux back into the atmosphere is described with the expression $k_a \frac{k_H}{\delta_a} C_U$. Carbon flux in the upper ocean is described with the same expressions with opposite signs. Additionally, there is an exchange between the upper and lower ocean given by $-k_d C_U + \frac{k_d}{\delta_d} C_L$. These flows can be represented by the equations (Glotter et al., 2014)

$$\frac{dC_A}{dt} = -k_a C_A + k_a \frac{k_H}{\delta_a} C_U + E(t) \,, \tag{7}$$

$$\frac{dC_U}{dt} = k_a C_A - k_a \frac{k_H}{\delta_a} C_U - k_d C_U + \frac{k_d}{\delta_d} C_L \,, \tag{8}$$

$$\frac{dC_L}{dt} = k_d C_U - \frac{k_d}{\delta_d} C_L \,. \tag{9}$$

However, this does not completely model the dynamics between the ocean and the atmosphere. We must take into account the dynamic ocean chemistry as atmospheric CO_2 is dissolved in saltwater into the forms of bicarbonate (HCO_3^-) and carbonate (CO_3^{2-}). The dissociation of carbon into its compounds occurs with dissociation constants k_1 and k_2 (see Table 1). This dynamic equilibrium is represented by (Glotter et al., 2014)

$$CO_2 + H_2O \overset{k_1}{\rightleftharpoons} HCO_3^- + H^+ \overset{k_2}{\rightleftharpoons} CO_3^{2-} + 2H^+, \text{ where} \tag{10}$$

$$k_1 = \frac{[HCO_3^-][H^+]}{[CO_2(aq)]} \text{ and } k_2 = \frac{[CO_3^{2-}][H^+]}{[HCO_3^-]} \,. \tag{11}$$

Because CO_2 is a weak acid that reduces the ocean's capacity to absorb additional carbon dioxide, we must determine what the ocean's carbon storage capacity is at a given time. We use Λ as this "carbon storage factor", representing the ratio of the equilibrium of total dissolved inorganic carbon to CO_2 (aq). Because we have the dissociation constants k_1 and k_2, Λ also can be described as a function of hydrogen ion concentrations at a given time, and we get the following (Glotter et al., 2014):

$$\Lambda(t) = \frac{[CO_2] + [HCO_3^-] + [CO_3^{2-}]}{[CO_2]} = 1 + \frac{k_1}{[H^+]} + \frac{k_1 k_2}{[H^+]^2}. \tag{12}$$

Here, Λ is the ratio of the equilibrium of sum of dissolved inorganic carbon (DIC) relative to CO_2 (aq). To find Λ at a given time, we must know the concentration of hydrogen ions. By definition, we have the total dissolved inorganic carbon as

$$[DIC] = [\mathrm{CO}_2(aq)] + [HCO_3^-] + [CO_3^{2-}] \,. \tag{13}$$

After some simple algebraic manipulation of the equations for k_1 and k_2 on (11) and plugging into our $[DIC]$ on (13), we get

$$[DIC] = [\mathrm{CO}_2(aq)] \left(1 + \frac{k_1}{[H^+]} + \frac{k_1 k_2}{[H^+]^2}\right) \,. \tag{14}$$

Because the charges of the ions must be balanced, we can calculate the $[H^+]$ concentration using the alkalinity (Alk) as

$$Alk = [HCO_3^-] + 2[CO_3^-] = [\mathrm{CO}_2(aq)] \left(\frac{k_1}{[H^+]} + \frac{2k_1 k_2}{[H^+]^2}\right) \tag{15}$$

$$= \frac{C_U}{\Lambda} \left(\frac{k_1}{[H^+]} + \frac{k_1 k_2}{[H^+]^2}\right) \,. \tag{16}$$

Therefore, we find the concentration of hydrogen ions by solving the quadratic

$$[H^+]^2 + [H^+]k_1\left(1 - \frac{C_U}{Alk} + k_1 k_2 \left(1 - \frac{2C_U}{Alk}\right)\right) = 0 \tag{17}$$

where we take the positive root to be our hydrogen concentration.

The ability to store carbon decreases significantly as the pH increases. Our whole ocean carbon chemistry and flux can be represented with

$$\frac{dC_A}{dt} = -k_a C_A + k_a \frac{k_H}{\delta_a \Lambda} C_U + E(t) \,, \tag{18}$$

$$\frac{dC_U}{dt} = k_a C_A - k_a \frac{k_H}{\delta_a \Lambda} C_U - k_d C_U + \frac{k_d}{\delta_d} C_L \,, \tag{19}$$

$$\frac{dC_L}{dt} = k_d C_U - \frac{k_d}{\delta_d} C_L \,. \tag{20}$$

2.2. Model outline

Fig. 1 provides a simplified representation of our model's dynamics. Anthropogenic emissions, from fossil fuels and land use change, and the permafrost feedback, are the primary sources of CO_2 and CH_4 emissions, our primary warming agents. Biogenic methane emissions are included as a baseline, non-mitigable CH_4 source that contributes to warming, set at a constant 300 Mt CH_4 per year, between the 220-368 Mt estimated by Jackson et al. (2020). CO_2 circulates between the terrestrial and ocean compartments. Temperature perturbation is calculated from the change in radiative forcing from emissions which warm the upper and, in turn, the lower ocean. This temperature increase then

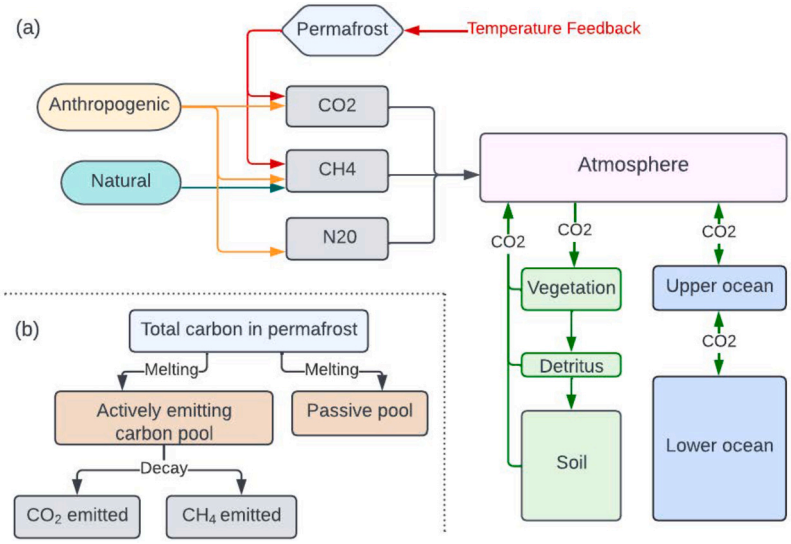

Fig. 1. Simplified Model Dynamics. Model outline: (a) The model includes CO_2, CH_4, and N_2O emissions into the atmosphere. Note, methane emissions are from anthropogenic and biogenic (natural) sources, and from permafrost emissions. CO_2 is from anthropogenic sources and the permafrost. N_2O is only from anthropogenic emissions. Carbon cycles between the atmosphere (as CO_2), terrestrial boxes (the vegetation, detritus, and soil), and the ocean boxes (upper and lower). Increases in temperature amplify permafrost emissions. (b) Permafrost sub-model schematic. Total carbon in the permafrost (C_{PF}, see Equation (31)) melts to expose soil. In the exposed soil, there is an actively emitting labile carbon pool (L_C and L_M, see Equations (34) and (35)), and a passive or non-labile carbon pool. From the actively emitting carbon pool, carbon is released as CO_2 or CH_4 in constant proportion.

feeds back into the permafrost module, causing permafrost melt and subsequent release of methane and CO_2.

2.3. Radiative forcing

Radiative forcing (RF) is calculated for each greenhouse gas using equations provided in the IPCC's Fifth Assessment Report (Myhre et al., 2014). RF from CO_2 has a log-linear temperature response to excess carbon past pre-industrial conditions (C_0). CH_4 and N_2O have interacting RF due to infrared band overlap (Myhre et al., 1998, 2014). Formulas for RF (W m^{-2}) are as follows:

$$\Delta N_{CO_2} = \alpha \times \ln\left(\frac{C}{C_0}\right)$$

where $\alpha = 5.35$ (21)

$$\Delta N_{CH_4} = \alpha \times (\sqrt{M} - \sqrt{M_0}) - (f(M, N_0) - f(M_0, N_0),$$

where $\alpha = 0.036$ (22)

$$\Delta N_{N_2O} = \alpha \times (\sqrt{N} - \sqrt{N_0}) - (f(M_0, N) - f(M_0, N_0), \text{ where } \alpha = 0.12 \quad (23)$$

$$f(M, N) = 0.47 \times \ln[1 + 2.01 \times 10^{-5}(MN)^{0.75} + 5.31 \times 10^{-15} M(MN)^{1.52}] \quad (24)$$

C, M, and N refer to current atmospheric concentrations of CO_2 in ppm, CH_4 in ppb, N_2O in ppb respectively. C_0, M_0 and N_0 refer to concentrations in 1750. The α term is the radiative forcing coefficient with units of $\frac{W}{m^2}$ and varies with each equation as indicated.

We also include differential equations for CH_4 and N_2O concentrations as a function of emissions and a fixed decay rate to reflect their atmospheric perturbation lifetimes as given by the IPCC (Myhre et al., 2014). We assume CO_2 does not decay from the atmosphere in the same way, but cycles into various ocean and terrestrial stores as described by the carbon cycle equations. The changes in CH_4 and N_2O are represented by

$$\frac{dCH_4}{dt} = E_{anthro} + E_{bio} + E_{pf} - \frac{CH_4}{\nu_1} \quad (25)$$

$$\frac{dN_2O}{dt} = E_{anthro} - \frac{N_2O}{\nu_2}, \quad (26)$$

where ν_1 is 12 years and ν_2 is 114 years. These perturbation lifetimes are approximations, as the lifetime for CH_4 is varied and depends on atmospheric conditions. We assume these rates to be constant.

2.4. Temperature response

Our model uses a two-box temperature response model described by Pierrehumbert (2014). This gives an accurate temperature response based on historical atmospheric concentrations of greenhouse gases and for projected emission streams (see 2).

We use T_{mix} to describe the temperature perturbation of the upper, or mixed, layer of the ocean. This model uses the mixed ocean layer temperature perturbation as a proxy for Earth surface temperature perturbation because ocean temperatures largely dictate surface temperature. T_{deep} represents the temperature perturbation of the deep ocean. The model describes the heat transfer between the two layers. We use μ to represent the heat capacity of each layer. The model uses γ for the heat transfer coefficient between the mixed and deep layers, and $\hat{\lambda}$ for the climate sensitivity parameter, both in units of $\frac{W}{m^2 K}$.

Temperature changes are driven by the change in radiative forcing, ΔN. The radiative forcing for each greenhouse gas is calculated and added together as a net ΔN, giving the following:

$$\mu_{mix}\frac{dT'_{mix}}{dt} = -\hat{\lambda}T'_{mix} - \gamma(T'_{mix} - T'_{deep}) + \Delta N(t) \quad (27)$$

$$\mu_{deep}\frac{dT'_{deep}}{dt} = \gamma(T'_{mix} - T'_{deep}) \quad (28)$$

2.5. Permafrost feedback

A permafrost feedback is included in our model, as it is one of the major short term climate feedbacks. Fig. 1 shows how a portion of carbon in the permafrost becomes vulnerable as the permafrost thaws. This now vulnerable pool is subject to decomposition by microbial activity and thus emitted into the atmosphere as CO_2 or CH_4. A portion of the permafrost carbon is considered fixed or "passive", as it is non-labile and will not be released during the timescales of our study. We make the assumption that the extent of the permafrost decreases linearly with

Table 1
Model parameters. Terrestrial and oceanic carbon cycle values are used to calculate carbon flux between the terrestrial stores, oceanic stores, and the atmosphere. Rows without units are unitless values. In our model, we convert all masses (GtC) to moles. Parameters k_1 and k_2 were converted to mole fraction by multiplying by 18/1000. (⋆) We raised the alkalinity parameter by a factor 1.02 to better match pre-industrial CO2 uptake rates. This is still within the reported experimental range for ocean alkalinity. Temperature response parameters come from Pierrehumbert (2014). We also convert γ and $\hat{\lambda}$ from watts to joules per year when running the model.

Model Parameters			
Parameter	Value	Unit	Description
Terrestrial Carbon Parameters (Hartin et al. (2016))			
f_{ds}	0.60		fraction of detritus carbon that transfers to the soil
f_{ld}	0.01		fraction land use carbon that enters detritus
f_{ls}	0.89		fraction land use carbon that enters soil
f_{lv}	0.10		fraction land use carbon that enters vegetation
f_{nd}	0.60		fraction of NPP carbon that enters the detritus
f_{ns}	0.05		fraction of NPP carbon that enters the soil
f_{nv}	0.35		fraction of NPP carbon that enters the vegetation
f_{rd}	0.25		fraction of respiration carbon that enters the detritus
f_{rs}	0.02		fraction of respiration carbon that enters the soil
f_{vd}	0.034		fraction of vegetation carbon that enters the detritus
f_{vs}	0.001		fraction of vegetation carbon that enters the soil
β	0.36		carbon fertilization parameter
Q_{10}	2.45		Q_{10} respiration factor
Oceanic Carbon Parameters (Glotter et al. (2014))			
k_1	8.00×10^{-7}	mol/kg	disassociation constant
k_2	4.63×10^{-10}	mol/kg	disassociation constant
k_a	0.2	yrs $^{-1}$	turnover time for upper ocean
k_d	0.05	yrs $^{-1}$	turnover time for deep ocean
k_H	1.23×10^{3}		Henry's constant
Alk	767.0⋆	GtC	alkalinity of the ocean
δ_d	50		ratio between upper and lower ocean
δ_a	calculated		ratio between upper ocean and atmosphere
AM	1.77×10^{20}	moles	moles of the atmosphere
OM	7.8×10^{22}	moles	moles of the ocean
Temperature Parameters (Pierrehumbert (2014))			
μ_{mix}	3.154×10^{8}	J m^{-2} K^{-1}	heat capacity of mixed layer
μ_{deep}	6.307×10^{9}	J m^{-2} K^{-1}	heat capacity of deep ocean
$\hat{\lambda}$	1.2	W m^{-2} K^{-1}	climate sensitivity parameter
γ	1.2	W m^{-2} K^{-1}	heat transfer coefficient
Permafrost Parameters (Kessler (2017))			
C_{PF}	1035	GtC	total GtC in the permafrost
τ	70	years	e-folding time for decomposition
β	0.172		coefficient for permafrost melt rate
η	0.40		fraction of non-labile carbon
ω	0.023		fraction of carbon released as methane

increase of global mean temperature and that carbon content of the permafrost is spatially homogeneous (Kessler, 2017).

We follow the logic of Kessler's model (Kessler, 2017) but adapted into differential equation form. The total carbon in the permafrost is C_{PF}. L_c and L_m combine to form the actively releasing labile carbon pool, where L_c is the proportion that is destined to be released as CO_2, and L_m is the proportion that is emitted as CH_4. Together, they represent the labile portion of the pool of carbon that is now vulnerable due to a decrease in permafrost extent. L_c and L_m each have their own emission stream $E(t)$. These pools are assumed to be 0 when initializing the model at year 2010. The proportion of carbon that is emitted as CO_2 or CH_4 is determined by the proportion parameter ω.

We describe the intact frozen carbon in the permafrost as the total carbon pool at initial time t_0 times the proportion of the permafrost left (PF_{extent}):

$$C_{frozen} = C_{PF}(t_0) PF_{extent}(t). \tag{29}$$

We describe the extent of permafrost at time t as

$$PF_{extent}(t) = 1 - \beta \times (T(t) - T(t_0)), \tag{30}$$

where the permafrost extent decreases linearly with rise in global mean temperature (T) above an equilibrium temperature ($T(t_0)$) (Kessler, 2017). In our model, we use the temperature at year 2010 as $T(t_0)$, while Kessler uses the temperature at the year 2000 as t_0, so our model gives slightly less melting. Additionally, the model does not allow C_{PF} to increase by permafrost refreezing.

As temperature increases, the extent of the permafrost decreases, and there is newly thawed soil that is now vulnerable to microbial decomposition. We represent this decomposition as exponential decay (Kessler, 2017).

The loss of carbon from the labile pools is represented by the exponential decay term $-\frac{1}{\tau}$. The carbon that has decayed from the permafrost is then added into our emissions stream. This is the same for

the active labile carbon pool being emitted as methane, because it is the remaining proportion (ω), and it shares the same decay rate $-\frac{1}{\tau}$.

The Kessler equations adapted into differential equation form are represented as

$$\frac{dC_{PF}}{dt} = C_{frozen}(t) - C_{PF} = \rho : \quad \rho \leq 0 \tag{31}$$

$$\frac{dL_C}{dt} = -\rho \times (1-\eta) \times (1-\omega) - \frac{1}{\tau} L_C \tag{32}$$

$$\frac{dL_M}{dt} = -\rho \times (1-\eta) \times \omega - \frac{1}{\tau} L_M \tag{33}$$

$$E_{PF\,C}(t) = \frac{1}{\tau} L_C \tag{34}$$

$$E_{PF\,M}(t) = \frac{1}{\tau} L_M \quad . \tag{35}$$

Summary of atmospheric carbon With the permafrost emissions added, we generalize our atmospheric carbon pool as follows:

$$\frac{dC_A}{dt} = E_{anthro} + E_{PF} + E_{LC} + F_T + F_O, \tag{36}$$

where E_{anthro} is fossil fuel emissions, E_{PF} is the emissions from the permafrost, E_{LC} is land use emissions, F_T is the flux of carbon between the terrestrial stores from net primary productivity and respiration ($-NPP + RH_{det,soil}$ see Equations (1), (2) and (3)), and F_O is the flux of carbon into the oceanic sinks ($-k_a C_A + k_a \frac{k_H}{\delta_a \Lambda} C_U$ see Equations (18)).

2.6. Validation and initial conditions

At the outset, we obtain pre-industrial initial conditions by imposing atmospheric CO_2 concentration at 1750 levels and running the model for a few thousand years to allow the levels of carbon in the ocean and terrestrial stores to stabilize. We then use these stabilized values as our initial conditions at 1750 for the vegetation, detritus, soil, upper ocean and lower ocean boxes.

We validated our model's temperature response and carbon cycle modules using historical data (Stocker et al., 2013). Our initial conditions for 1750 are given in Table 2. We drove the model from 1750 to 2010 using historical emissions data from the AR5 report (Stocker et al., 2013), allowing our model to calculate atmospheric CO_2 concentrations based on its carbon cycle modules (Fig. 2 (b)). The model also calculated temperature from the radiative forcing from atmospheric CO_2 concentrations (Fig. 2 (a)), which shows a reasonably similar temperature result for 2010 (Morice et al., 2021).

To obtain initial conditions for the year 2010, we drove the rest of model using imposed historical CO_2, CH_4, and N_2O atmospheric concentrations (Stocker et al., 2013) After so running the model to 2010, we took the carbon content of our upper ocean, lower ocean, vegetation, detritus, and soil boxes, along with the temperatures, as the initial conditions for projecting the model forwards.

2.7. Future emission scenarios

To determine the impact of methane mitigation strategies on permafrost climate feedbacks, we projected our model forward using the AR5's extended RCP 2.6, 4.5, and 6.0 CO_2 and N_2O emission streams (Meinshausen et al., 2011). We combine these RCP CO_2 and N_2O emission streams with our own calculated CH_4 emission stream based on different annual reduction plans. All our CH_4 emission streams start at 2010 with 330 Mt of CH_4 emitted that year and extend to 2300. To examine the impact of just the rate of phase-out, not magnitude, we take our initial value of 330 Mt and reduce it by a given percentage annually until it reaches the same "floor" level of the given RCP. For example, RCP 2.6's projected methane emission stream falls from 330 Mt/year to 142 Mt/year by 2100, where it then remains until 2300. Therefore, we take 330 Mt, and reduce it by a given percentage annually until it reaches 142 Mt and then hold that level constant. We can then compare varying accelerated rates of phase-out to the given "baseline" RCP scenario. For reference, the floor values for RCPs 4.5 and 6.0 are 266 Mt/year and 252 Mt/year, respectively.

To compare magnitude of phase-out, we take our projected methane emission streams to a lower final value than the RCP.

3. Results

We began by generating temperature time series for all scenarios. First, to see the effect of the permafrost module, we ran our "baseline" unaltered RCP emission scenarios from 2010 to 2300, and then ran the same scenarios again with the permafrost module in effect. We saw a significant change in temperatures with the permafrost module in effect, which can be seen in Fig. 3. Each RCP scenario has two main temperature projections, with the higher branch showing the permafrost feedback module in effect.

We also compared each RCP scenario with a rapid 10% annual methane emission reduction plan, shown by the dashed lines in Fig. 3. Once the 10% reduction plan reached the target methane emission rate of the given RCP, emissions were then held constant. For example, we compared the baseline RCP 2.6 with our RCP 2.6 with the 10% annual methane phase-out; both reached the same final target of 142 Mt CH_4 emitted annually (but at different times), and remained at this level through 2300. This comparison was made with and without the permafrost feedback. A 10% phase-out is considered very accelerated, and the target emission rate was reached within less than 5 years.

We compared our accelerated methane mitigation plans to the RCP's standard methane projections. For each RCP scenario, we used the IPCC's CO_2 emission projections, shown in gigatonnes of carbon in Fig. 4 (a), (c), and (e). We included each RCP's given N_2O emission projections to accurately calculate methane's radiative forcing by taking into account the band overlap explained in Section 2.3. We then compared the results of our methane mitigation plans with the baseline RCP scenarios. For RCP 2.6, we only considered 5% and 10% methane reduction rates, as a 1% annual reduction was actually slower than the baseline RCP 2.6. For RCP 4.5 and 6.0, we used a 1% and 10% annual reduction rate, seen in Fig. 4 (b), (d), and (f). Fig. 4 shows these different emissions pathways.

3.1. RCP 2.6

We ran the model under the RCP 2.6 scenario with and without the permafrost module to the year 2300 (see Fig. 5 (a)). Without permafrost, the final temperature perturbation in 2300 reaches 1.38 °C above pre-industrial levels. With the permafrost feedback, temperature reached 1.61 °C, a difference of 0.23 °C. Additionally, the model gives 97.7 GtC emitted from the permafrost by 2300.

Using the RCP 2.6 scenario, we examined two highly accelerated methane reduction scenarios, where we reduced anthropogenic methane from 330 Mt in 2010 by 5% or 10% annually until we reached a constant emission rate of 142 Mt of CH_4 per year. The baseline RCP 2.6 scenario reaches a minimum or "target" level of 142 MtCH_4 per year at 2100, and remains at this level through 2300. Therefore, these accelerated mitigation scenarios only differed from RCP 2.6 in how long it took to reach that target.

We found that the rate of methane mitigation had a negligible effect on temperature at 2300, but had a noticeable effect before 2100. The largest difference in temperature occurs at 2050, where there is a 0.06 °C difference between the standard RCP 2.6 scenario compared to the 10% phase-out (see SI 4).

At the year 2300, cumulative 97.7 GtC was emitted from the permafrost under the baseline RCP 2.6, while 95.3 GtC was emitted under a 5% accelerated methane reduction plan, and 94.4 GtC was emitted with a 10% methane reduction plan. This may be because under RCP 2.6's aggressive CO_2 mitigation scenario, CH_4 emission mitigation has a

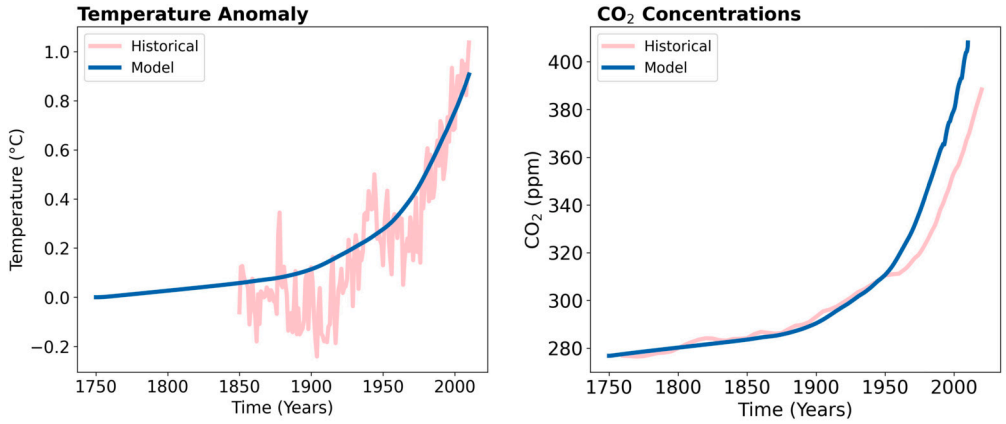

Fig. 2. Validation of the model against historical temperatures and atmospheric CO_2 concentrations. (a) Historical temperature anomaly data is given in pink. The blue line gives the temperature anomaly as predicted by our model, driven by emissions data while solving for atmospheric carbon. (b) shows atmospheric carbon concentrations from historical data in pink, versus our solved carbon concentrations in blue. The overshoot in modeled CO_2 concentration past 1950 may be due to an unaccounted for increase in biotic carbon uptake.

Table 2
Initial conditions for the year 2010, either found by driving the model with historical atmospheric concentration data or from other works (reference given in this case). These are the initial conditions used for our projections.

Initial Conditions					
Variable	Unit	Year		Description	Notes
		1750	2010		
T_{mix}	$C°$	0	0.81	surface temperature	
T_{deep}	$C°$	0	0.22	lower ocean temperature	
C_A	GtC	587.92	824.91	carbon in atmosphere	Glotter et al. (2014)
C_U	GtC	725.39	740.35	carbon in upper ocean	
C_L	GtC	36263.18	36310.28	carbon in lower ocean

Table 3
Temperature perturbation at year 2100 and 2300, with and without the permafrost feedback effect under different RCP scenarios. Note that these results do not include accelerated methane phase-outs.

Temperature Anomaly from Permafrost			
Year	RCP 2.6	RCP 4.5	RCP 6
2100, without PF (°C)	1.73	2.60	3.15
2100, with PF (°C)	1.86	2.77	3.31
Difference (°C)	0.13	0.17	0.16
% Difference	7.5%	6.5%	5.1%
2300, without PF (°C)	1.38	3.44	4.66
2300, with PF (°C)	1.61	3.9	5.13
Difference (°C)	0.23	0.46	0.47
% Difference	16.7%	13.4%	10.1%

relatively strong effect: We find that rapid methane mitigation has less effect on permafrost carbon release under other RCP scenarios.

Atmospheric concentrations of CO_2 are largely the same for all scenarios, and atmospheric concentrations for CH_4 reflect our differing reduction strategies, as well as slightly different permafrost emissions courses (see Fig. 5 (c) and (d).

3.2. RCP 4.5

We evaluated the impact of rate of mitigation under the RCP 4.5 emission scenario using the same basic procedures. First, we looked at temperature perturbation of the baseline RCP 4.5 scenario with and without a permafrost feedback effect. At 2300, the baseline RCP 4.5 resulted in a temperature anomaly 2300 of 3.44 °C, and with the permafrost module, 3.9 °C (see Table 3). 277.8 GtC was emitted from the permafrost by year 2300.

The target value of CH_4 emissions per year was set to 266 $MtCH_4$ per year, consistent with the value the RCP 4.5 reaches at 2100 and remains constant at through 2300. We performed a 1% or 10% methane mitigation plan to reduce emissions from 330 to 266 Mt CH_4 per year. In Fig. 6 (d), the atmospheric concentrations of CH_4 are shown for the different scenarios. The mitigation plans reduced atmospheric methane concentrations compared to the baseline RCP before year 2100. After the year 2100, atmospheric concentrations remained the same between all scenarios, as expected since our reduction plans meet the same target value as the RCP 4.5.

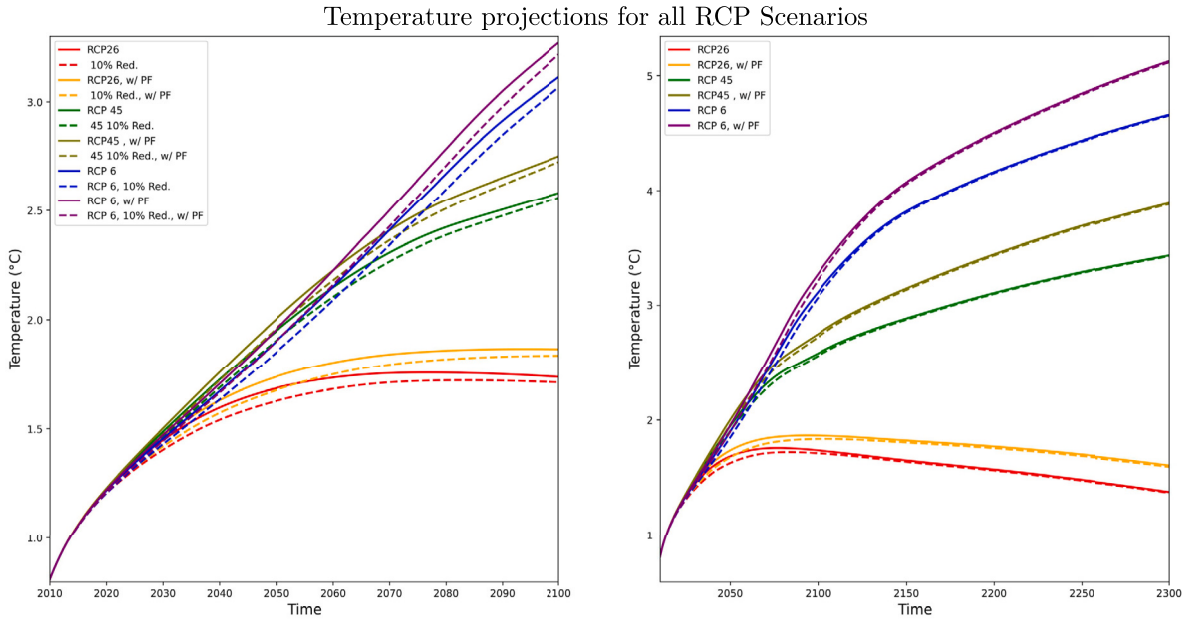

Fig. 3. Temperature responses for RCP 2.6, 4.5, and 6 emission scenarios, with and without a permafrost feedback effect, (a) from 2010-2100 and (b) from 2010-2300. Dashed lines show a 10% annual methane phase-out for the given scenario while solid lines show the baseline RCP scenario. Greatest differences in temperature between baseline RCP and 10% annual phase-out are seen before 2100. From 2100-2300, the projections with and without the rapid 10% methane reduction plans are largely the same, with or without the permafrost feedback in effect.

The 1% and 10% phase-out schemes yield effectively the same final temperature perturbation, although there was a transient temperature difference before year 2100 (see Fig. 3). The temperature projections converged and were virtually identical by the year 2300 (see Table 6).

3.3. RCP 6

We evaluated methane mitigation plans compared with baseline RCP 6 projections (Figure 9) and found results qualitatively similar with those of RCP 4.5. Temperature perturbation at the year 2300 without the permafrost module was 4.66 °C, and 5.13 °C with the permafrost module (see Table 3). 392.9 GtC was emitted from the permafrost by the year 2300. The target methane emission rate for RCP 6 was 252 $MtCH_4$ yearly. Our methane mitigation scenarios went from 330 $MtCH_4$ emitted in year 2010, reduced by 1% or 10% annually until reaching 252 $MtCH_4$ and were then held constant for future years.

Significantly lower atmospheric concentrations of methane from 2010-2100 under the mitigation strategies did not effect temperature projections or significantly impact permafrost emissions (see Supplemental Information for figure). Permafrost emissions were only marginally lower (by 1.7 GtC) in the year 2100 from the 10% mitigation scenario compared to the baseline RCP 6.

3.4. Final magnitude versus rate of mitigation

We compared the effect of the final magnitude and rate of methane mitigation on final temperature perturbation at the year 2300 while including the permafrost feedback module. We used the RCP 4.5 scenario for this comparison. We ran the model with methane reduction rates between 0.1% and 10% to targets between 125 Mt CH_4 and 275 Mt CH_4 per year to obtain a temperature perturbation at the year 2300.

Importantly, reduction rates below 0.5% never reached the low end target of 125 Mt CH_4 emissions per year at 2300. If emissions were reduced by less than 0.5% annually, there was not enough time from 2010 to 2300 to reduce emissions from 330 Mt CH_4 per year to 125 Mt CH_4 per year. For example, with a reduction rate of 0.1%, there was still 246 Mt CH_4 being emitted at the year 2300, and with 0.25% reduction rate, there was 160 Mt CH_4 emitted at 2300. This accounts for the difference in temperature perturbation at the year 2300 between the rates of 0.1 and 0.25% (see the slight bend on the left-hand side in Fig. 7) and the higher rates which converge to 3.7 °C. We found temperature perturbation responded highly linearly to the magnitude of mitigation, and not rate of reduction.

4. Discussion

4.1. Findings

4.1.1. Overall

We used a simplified climate model to assess the long-term impact of methane emission mitigation rates in the context of permafrost feedback. While the urgency of mitigating CO_2 emissions is well-established due to the long atmospheric residence time of CO_2, methane mitigation priorities remain less clear (Pierrehumbert, 2014; Global, 2022; Dreyfus et al., 2022; Nisbet et al., 2020). Although methane has a short atmospheric residence time, its potency suggests a potential need for accelerated phase-out (Myhre et al., 2014). Our model indicates that, despite a strong permafrost feedback, the rate of methane mitigation may be relatively unimportant for long-term temperature perturbation. However, further investigation is necessary to account for unmodeled methane-climate feedbacks and dynamics.

4.1.2. Permafrost feedback impact

We observed a notable difference in global mean temperature anomaly attributable to the permafrost feedback before considering methane mitigation. At year 2100, we observed a difference of 0.13-0.15 °C (4.7-7.5%) between all RCP scenarios, and at 2300, a difference of 0.23-0.47 °C (10.1-16.7%) (see Table 3). The permafrost feedback is significant and should be included in future climate modeling.

4.1.3. Accelerated methane mitigation scenarios vs. IPCC baseline

Contrasting our methane mitigation scenarios with the baseline RCP scenarios, we found that our accelerated mitigation scenarios did not substantially impact long-term permafrost thaw or temperature perturbation. Rather, we found that long term temperature perturbation was largely determined by the (final) magnitude of methane mitigation. Our

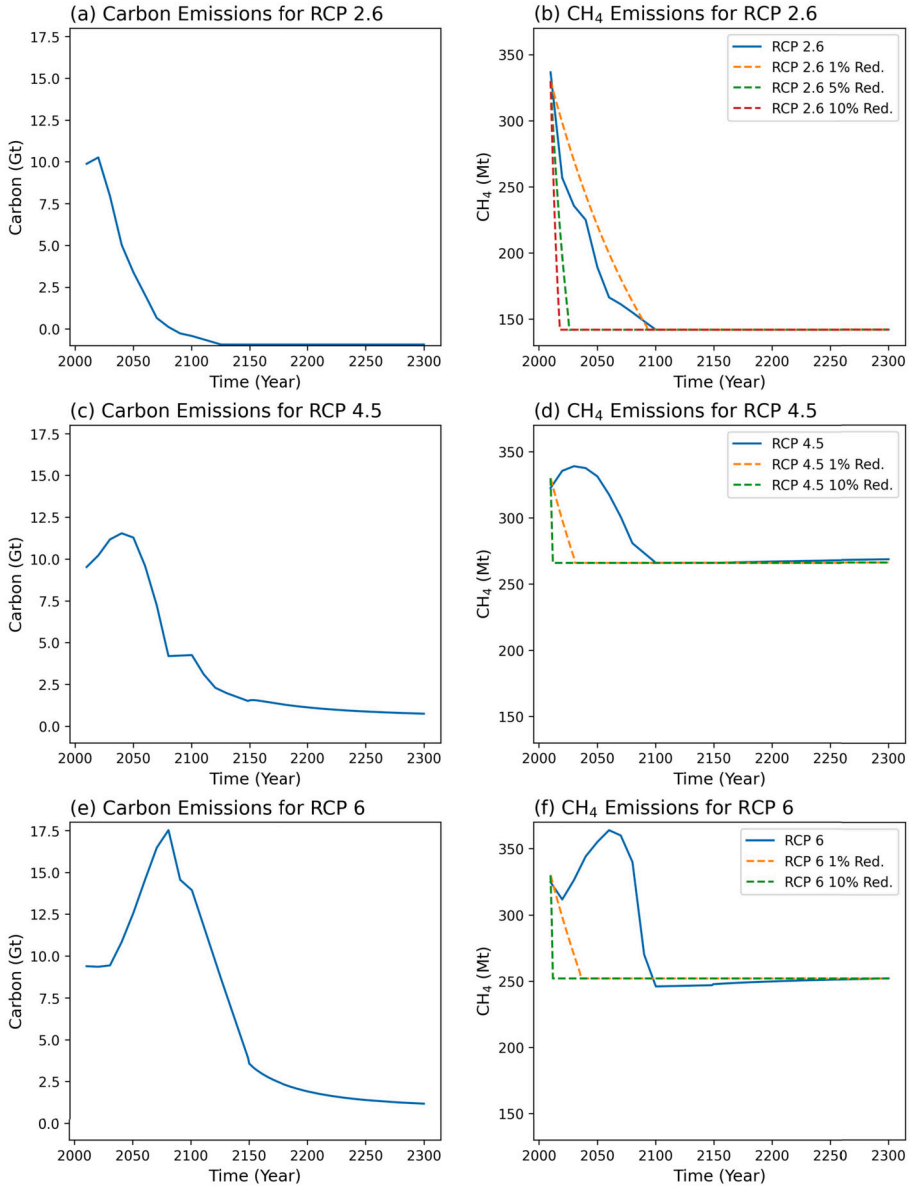

Fig. 4. Emissions streams for all RCP scenarios and RCP scenarios with accelerated methane phase-out. Solid lines represent baseline RCP scenarios, while dashed lines represent our imposed methane mitigation scenarios. Figures show total imposed emissions per year, not including permafrost feedback emissions. In Figures (a), (c), and (e), carbon emissions in gigatonnes are shown, as given by the RCP projection. In Figures (b), (d), and (f), CH_4 emissions in megatonnes are shown for the baseline RCP and our reduction scenarios.

findings showed that mitigation must be sufficiently swift to achieve lower target levels by year 2300, but beyond that, the impact of rate was negligible. Our most rapid methane mitigation scenario, reaching target levels within 10 years with a 10% annual reduction, showed a slight difference in temperature this century (see Fig. 3). This, however, was transient, and CO_2 ultimately determined the long-term temperature course.

4.2. Model limitations

4.2.1. Other emissions

We aimed to capture the essential dynamics between anthropogenic emissions and permafrost thaw and decomposition, not conclusively predict future temperature anomalies. Therefore, we included radiative forcing only from CO_2, CH_4, and N_2O, with which were able to adequately recreate surface temperature up to the year 2010, and from which we start our future projections. Black carbon, aerosols, halocarbons, ozone and other compounds could be included although they are not expected to make significant changes in the qualitative results, as historically, the cooling from aerosols has masked the warming from these other compounds (Dreyfus et al., 2022). Also, as CO_2 is mitigated, co-emitted aerosols will decline (Dreyfus et al., 2022). However, with less cooling to mask other greenhouse gases, methane could end up being relatively more important.

We also do not explicitly include fossil methane which oxidizes to new atmospheric CO_2, although upon testing inclusion at a constant 25% rate, we found negligible difference in our results (0.02 °C difference at 2300 under RCP 4.5, see Supplemental Information 6).

4.2.2. Permafrost uncertainty

There are major uncertainties still in permafrost modeling, primarily concerning microbial decomposition and spatial heterogeneity (Schneider Von Deimling et al., 2012). Our use of global mean temperature perturbation does not reflect regional temperature differences or spatial heterogeneity in carbon stores. Additionally, there is uncertainty to the rate of microbial decay of permafrost carbon, or “e-folding” time.

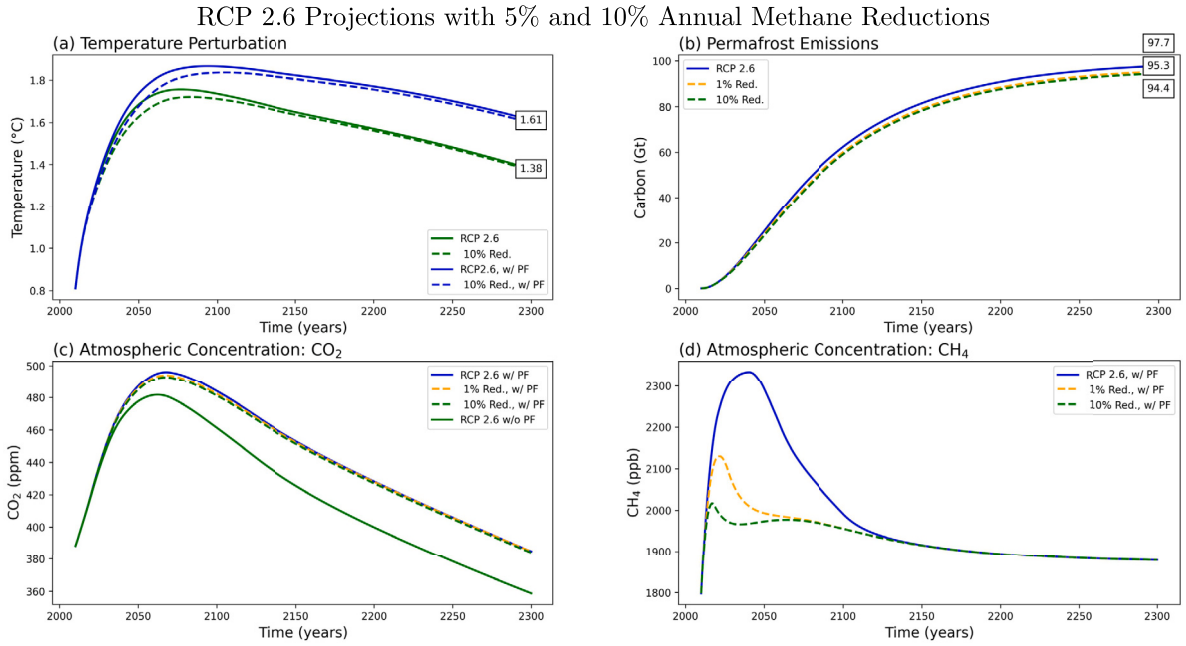

Fig. 5. Results for 5% and %10 methane phase-out strategies using the RCP 2.6 CO_2 scenario. Dotted lines represent our imposed methane mitigation scenarios, while solid lines represent the "baseline" RCP 2.6 scenario. We look at temperature perturbation at the year 2300 in (a), permafrost emissions at the year 2300 in (b), and atmospheric concentrations of CO_2 and CH_4 in (b) and (c).

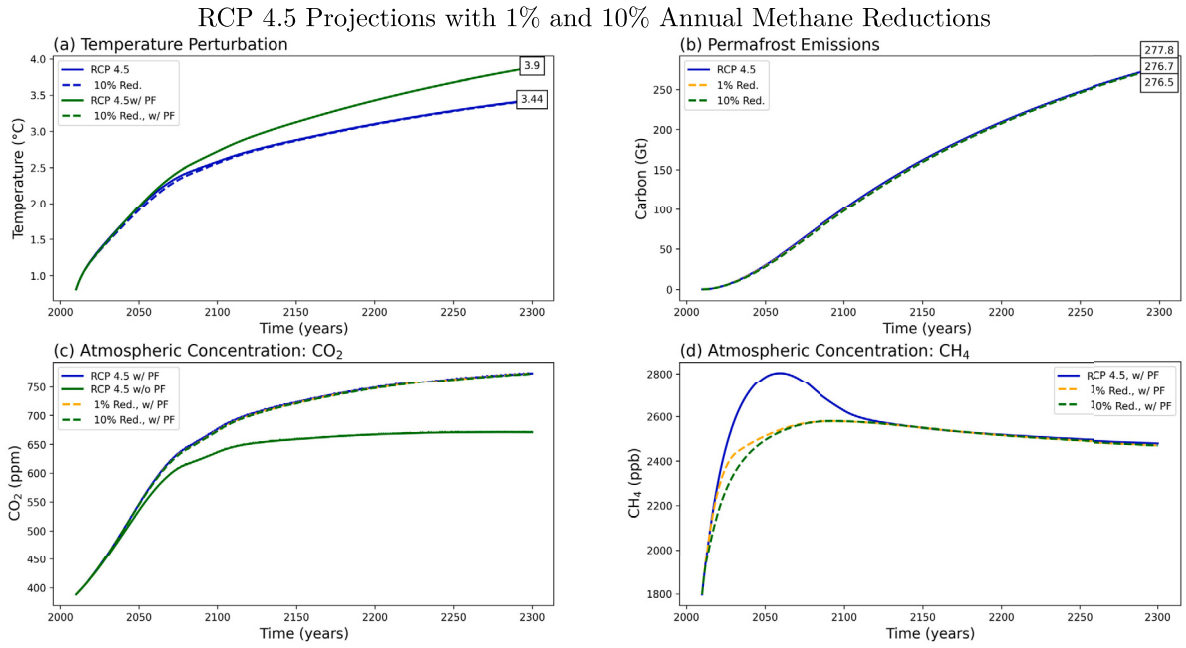

Fig. 6. RCP 4.5 results for 1% and %10 reduction rates to annual methane emissions. (a) shows the final temperature perturbations with and without the permafrost feedback module in effect, with the dashed line showing the 10% reduction scenario. (b) shows the permafrost emissions in gigatonnes of carbon for the baseline RCP scenario compared to the 1% and 10% reduction plans. (c) and (d) show atmospheric concentrations of CO_2 and CH_4 respectively over time.

We use 70 yr^{-1}, but it could be between 0-200 yr^{-1} and may be variable (Kessler, 2017). We found our results insensitive to the decay rate (see: Supplemental Information 5).

4.2.3. Impact of variable nitrogen oxide (NOx) emissions

The quantity of nitrogen oxides (NOx) in the atmosphere affects the rate of methane breakdown and therefore impacts atmospheric methane concentrations. Atmospheric NOx increases the oxidizing capacity of the atmosphere via increased hydroxyl radicals (OH), and hence decreases methane lifetime. Thus, decreases in anthropogenic NOx emission rates can lead to higher methane concentrations, as seemed to have happened during 2020 COVID-19 lockdowns (Stevenson et al., 2022). Both NOx and methane emissions decreased during COVID-19 lockdowns and yet, despite lower anthropogenic methane emissions, the atmospheric methane growth rate spiked sharply. Decreased OH as a result of lower NOx emissions and increased natural wetlands methane emissions were likely of roughly equal importance in explaining this spike (Peng et al., 2022). Indeed, methane growth rates saw the largest increase since NOAA began record keeping in 1984 (Stevenson et al., 2022).

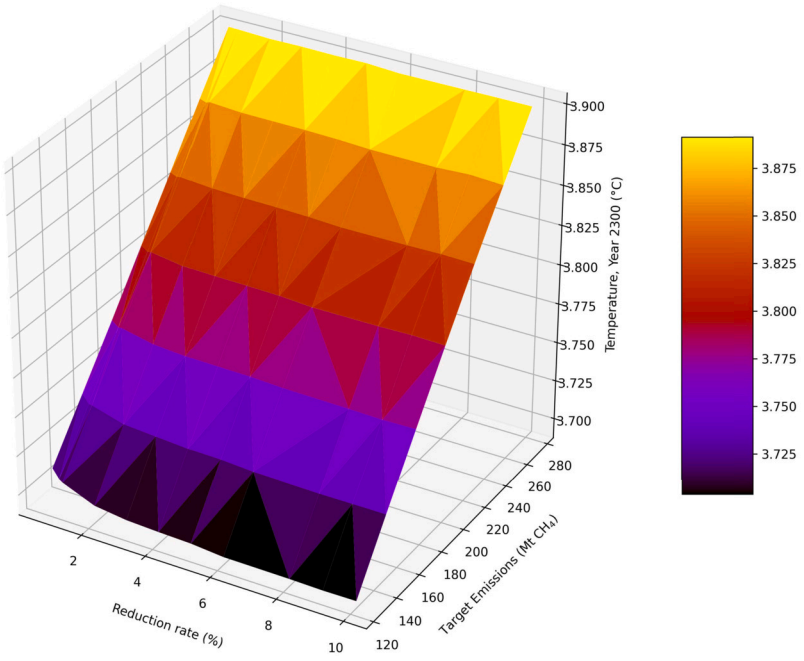

Fig. 7. The effect of reduction rate and target emission level on temperature perturbation at year 2300. Reduction rates vary between 0.5% and 10% and target emission levels vary between 125 and 275 Mt CH_4. Time span is from 2010 to 2300, and the RCP 4.5 CO_2 emission scenario is used.

Our model, focused on the response of methane concentrations to direct emissions alone, would not have captured this abrupt rise. Methane concentrations depend not only on the methane emissions pathway, but also on NOx and other greenhouse gas emissions pathways, the rate of other methane-climate feedbacks such as the wetlands, and temporal trends (Cheng and Redfern, 2022; Peng et al., 2022; Stevenson et al., 2022). Importantly, we assume methane concentrations to be stabilized when our rates of anthropogenic methane emissions have stabilized to a target value. However, further research must be done to understand how different anthropogenic CH4 and NOx emissions pathways can influence the rates of natural CH4 sources and sinks. Therefore, there is need for refinement in our underlying assumption about the relationship of anthropogenic methane emissions and overall methane concentrations to fully answer our guiding question.

4.2.4. Methane-climate variability

There are other methane-climate feedbacks which we have left unmodeled that are potentially of importance. These feedbacks operate on varying timescales and may depend on the rate of change of global mean temperature, rather than absolute changes in temperature (Cheng and Redfern, 2022). Variable rates in temperature increase and even precipitation may impact the intensity and rapidity of methane-climate feedbacks, particularly the wetland-climate feedback (Peng et al., 2022). This wetland feedback is particularly important, as demonstrated by the sharp spike in atmospheric methane growth in 2020 (Stevenson et al., 2022).

However, other methane-climate feedbacks may be sensitive to the rate of change of temperature. A faster rate of change in global mean temperature (and even rate of change in precipitation over time) may intensify the wetland-climate feedback. While our permafrost model is indirectly affected by the rate of temperature change (i.e., a faster increase causes more warming early in time), there is no direct interaction with the rate. Permafrost thaw is expected to respond to the overall change in the temperature gradient; however, there may be other factors involved in process that could have some dependence on the rate of temperature change, such as heterotrophic respiration (Brown and Markewitz, 2018; Nissan et al., 2023). It is important to emphasize that the addition of other methane-climate feedbacks that are more explicitly rate-dependent may qualitatively affect our results and conclusions.

4.2.5. Methane-concentration variability

As discussed above, atmospheric methane concentrations depend on more than the stabilized rates of methane emissions. We used simplified anthropogenic emission scenarios in our study to simulate the effect of different timelines on stabilized lower CH4 emission rates. As seen in 2020-2021, natural CH_4 and anthropogenic NOx emissions were unprecedentedly high and low respectively, resulting overall in a surge in the atmospheric methane growth rate (Feng et al., 2023). Variability in atmospheric methane concentration not explained by anthropogenic emissions could suggest a higher priority for anthropogenic methane mitigation, although it is unclear if this would affect our basic conclusions regarding the importance of the rate of methane mitigation.

These other important methane-climate dynamics should be included in future studies (Fig. 8) to fully answer our motivating question.

4.2.6. Hysteresis and path dependence

We also note that our study does not address the importance of early mitigation under all mechanisms for possible path dependence and hysteresis in the Earth System, beyond the hysteresis in the permafrost model considered. Numerical experiments on Earth system models of intermediate complexity suggest significant temperature change irreversibility when a large cumulative CO_2 course is followed by large-scale negative emissions (Jeltsch-Thömmes et al., 2020). In such scenarios, temperature overshoot could permanently destabilize permafrost with long lasting consequences (De Vrese and Brovkin, 2021). The AR5 emissions scenarios we have considered do not include large-scale negative carbon emissions (RCP 2.6 does posit smaller-scale negative emissions later in time); therefore, in this study, we are primarily concerned with the forward path and the effect of mitigation rates on the ultimate temperature perturbation under the forward path. Whether mitigation rates are of greater importance when a backward path of negative emissions is taken therefore remains an open question. In particular, the SSP1-1.9 scenario in the newer Sixth Assessment Report (Intergovernmental Panel on Climate Change, 2023) does include appreciable negative emissions after 2050, and both Earth system hysteresis and methane mitigation rates could be of more importance in this setting.

We may also draw an analogy between potential hysteresis in the Earth system with respect to *cumulative* CO_2 emissions, and potential hysteresis with respect to the *rate* of methane emissions. That is, it is

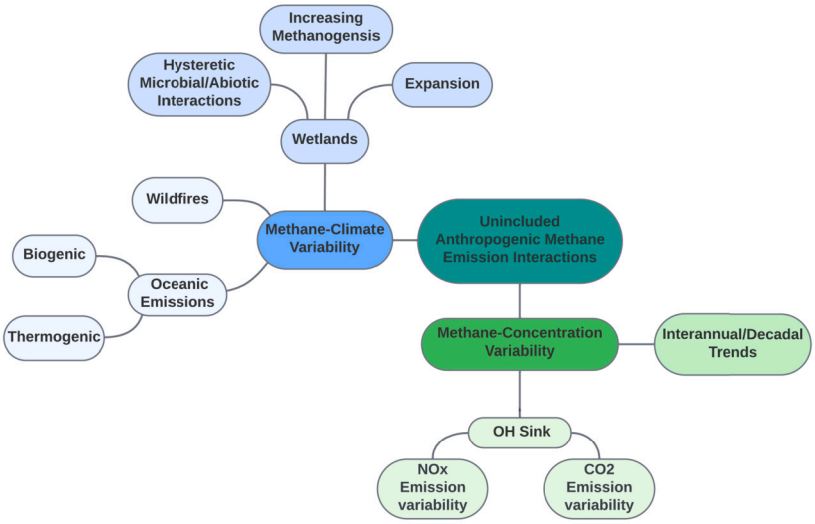

Fig. 8. Additional Important Methane-Climate Processes. Unmodeled factors, such as variable nitrogen oxide (NOx) emissions, contribute to atmospheric methane concentrations, influencing breakdown rates and oxidizing capacity of the atmosphere. Recent anomalies, like the surge in 2020 methane growth rates, demonstrate the need to consider NOx and other greenhouse gas emissions pathways, as well as additional methane-climate feedbacks like those associated with wetlands (Qu et al., 2022; Peng et al., 2022; Feng et al., 2023). Variability in methane-climate feedbacks, influenced by changing global mean temperatures and precipitation rates, can significantly impact outcomes (Zhang et al., 2023; Chang et al., 2021; Schaefer, 2019). The rising relevance of other methane sources, such as wildfires, in the 21st century, adds complexity (Qu et al., 2022). Understanding these dynamics is crucial for refining our assumptions about anthropogenic methane emissions and addressing the complexities of emission mitigation priorities.

generally agreed that the long-term cumulative emission of the former, and emissions rate of the latter, determine the climate impact, yet overshoot of either may affect be of importance. This work suggests that relatively modest increases in anthropogenic methane emissions followed by a decline (e.g., as in RCP 6) do not result in any hysteresis effect via the permafrost. This is but one of multiple relevant processes, and other methane-climate feedbacks have been shown to be pathway-dependent (Chang et al., 2021; Cheng and Redfern, 2022). Other climate feedbacks, such as Atlantic meridional overturning circulation (AMOC) shutdown may also be irreversible (Jackson et al., 2020), and some authors have expressed concern over cascading feedbacks (Lenton et al., 2019). Further study is required to understand whether the hysteresis in methane emissions *rates* (and not just cumulative CO_2 emissions) implies a greater need for more rapid methane phaseout.

4.3. Model comparisons

4.3.1. Permafrost feedback

Our model suggests warming over the next century attributable to permafrost within the range of other works. Macdougall et al. used a modified version of the Earth System Climate Model (ESCM) and found temperature difference attributable to permafrost thaw at 2100 to be 0.1-0.8 °C, estimated at 0.27 °C (consistent across different emission scenarios) (MacDougall et al., 2012). Crichton et al. added a permafrost-carbon module to the Earth System Model of Intermediate Complexity (EMIC), CLIMBER-2, and found increases of 10-40% of the maximum temperature change (Crichton et al., 2016). Burke et al. used the land surface model JULES (Joint UK Land Environment Simulator), along with ORCHIDEE-MICT (Organizing Carbon and Hydrology in Dynamic Ecosystems), modified to include permafrost carbon, coupled to the Integrated Model Of Global Effects of climatic aNomalies (IMOGEN), an intermediate-complexity climate and ocean carbon model. They found a difference of 0.2-12% of the maximum temperature change (Burke et al., 2017). Woodard et al. used a permafrost implementation in Hector v.2.3pf and predicted approximately 0.2 °C or 4–15% of additional warming by 2100 across all RCP scenarios (Woodard et al., 2021).

In comparison, we found between 0.13 and 0.17 °C (5.1-7.5%) temperature perturbation attributable to the permafrost at 2100. This is on the low end but within the previously found range. We found a difference at 2300 (assumed maximum temperature change) of 0.23-0.47 °C (10.1-16.7%) which is on the low range of Crichton et al. (2016) but on the high range of Burke et al. (2017).

4.3.2. Recent insights and methane priorities

Methane mitigation priorities are becoming clearer with recent research. By rapidly reducing anthropogenic methane to the greatest "economically feasible" extent, Ocko et al. saw a substantial near-term climate benefit at 2050 under RCP 8.5 (Ocko et al., 2021) and argue that because of this, rapid phaseout should be prioritized to minimize risk of overshooting climate boundaries and slow the rate of warming this century. However, by 2100 they found magnitude of mitigation was the most important factor. Although we focused on longer time scales and less extreme RCPs, we came to the same conclusions: fast mitigation does bend the temperature curve in the short term, with the largest benefit at 2050. However, by 2100, the fast mitigation and delayed mitigation pathways meet up to reach nearly the same temperature anomaly, and our inclusion of a large feedback does not change this result.

Research about methane mitigation priorities in relation to positive climate feedbacks are understudied. We find that the inclusion of the permafrost feedback alone does not indicate prioritizing rapid methane phaseout, however other feedbacks should be included in the future. Various studies indicate that CO_2 is the first priority, and that attention should not be given to CH_4 mitigation at the expense of CO_2 mitigation (McKeough, 2022; Pierrehumbert, 2014). Our research tentatively agrees with this body of literature, but we recognize the need for further study of this topic, especially in the context of other methane-climate feedbacks and methane-concentration pathway variability.

5. Conclusions

A benefit to an accelerated methane mitigation plan is that methane and CO_2 mitigation are coupled. As much of anthropogenic methane emissions are from fossil fuels (108-135 $MtCH_4$ per year), CO_2 mitigation will also mean mitigating methane (Jackson et al., 2020; Rogelj et al., 2014). As other studies have concluded, mitigating CO_2 immediately is of the utmost importance because of its long lasting climate

effects, and methane mitigation is not a substitute (Pierrehumbert, 2014; McKeough, 2022; Rogelj et al., 2014). Our simplified model using AR5 emissions scenarios found that the extent of permafrost thaw was largely dependent on CO_2 emissions and magnitude (not rate) of methane mitigation. Bringing methane emission levels down to the lowest levels possible will play an important role in avoiding the climate boundary when done *in addition* to mitigating CO_2.

Our simplified model indicates marginal long-term benefit from rapid methane phase-out in relation to permafrost thaw. However, there is still a considerable short-term benefit which may have effects on other sensitive feedbacks. Positive feedbacks, such as Amazon rainforest dieback, boreal forest loss, ice sheet melt, reduction in sea ice, increased wetland methanogenesis etc., may amplify each other and have considerable effect on outcomes (Lenton et al., 2019; Ritchie et al., 2021). Inclusion of these feedbacks would improve our understanding of methane mitigation priorities. Additionally, more work must be done to understand the relationship between the rate of methane emissions and methane concentrations, as well as emissions of other anthropogenic aerosols and gases. Future work should consider the rate of methane phaseout in light of other methane-climate dynamics, variability in the relationship between methane concentration and emissions, and possible hysteresis in the Earth System with respect to methane emissions rates.

HIGHLIGHTS

- Climate change is affecting ecosystems at multiple scales.
- Individual/species: changes in morphology and behavior, phenology, and range shifts observed
- Ecosystems: shifts in productivity, species interactions, and emergent properties observed
- Together, these changes are impacting ecosystem services and human well-being.
- Natural resource managers need proactive, flexible approaches to deal with changes.

Natural resource management

ABSTRACT

Climate change is a pervasive and growing global threat to biodiversity and ecosystems. Here, we present the most up-to-date assessment of climate change impacts on biodiversity, ecosystems, and ecosystem services in the U.S. and implications for natural resource management. We draw from the 4th National Climate Assessment to summarize observed and projected changes to ecosystems and biodiversity, explore linkages to important ecosystem services, and discuss associated challenges and opportunities for natural resource management. We find that species are responding to climate change through changes in morphology and behavior, phenology, and geographic range shifts, and these changes are mediated by plastic and evolutionary responses. Responses by species and populations, combined with direct effects of climate change on ecosystems (including more extreme events), are resulting in widespread changes in productivity, species interactions, vulnerability to biological invasions, and other emergent properties. Collectively, these impacts alter the benefits and services that natural ecosystems can provide to society. Although not all impacts are negative, even positive changes can require costly societal adjustments. Natural resource managers need proactive, flexible adaptation strategies that consider historical and future outlooks to minimize costs over the long term. Many organizations are beginning to explore these approaches, but implementation is not yet prevalent or systematic across the nation.

1. Introduction

Climate change is a pervasive and growing global threat to biodiversity and ecosystems (Díaz et al., 2019). Climate change affects individual species and the way they interact with other organisms and their habitats, which alters the structure and function of ecosystems and the goods and services that natural systems provide to society (Díaz et al., 2019). Understanding the direction and magnitude of ecological responses allows human communities to better anticipate these changes and adapt as necessary.

Periodic assessments of current and future climate change impacts on ecosystems are important for developing and updating natural resource management plans and evaluating adaptation actions (West et al., 2009). The National Climate Assessment (NCA) is a key assessment in the United States, required by the Global Change Research Act to summarize current and projected impacts of climate change on a variety of sectors and regions in the U.S. every four years (USGCRP, 2018). Here, we draw upon the recently published Fourth NCA (NCA4) Volume II to present the most up-to-date assessment of climate change impacts on biodiversity, ecosystems, and ecosystem services in the U.S. (USGCRP, 2018). We synthesize, extend, and integrate the NCA4 chapters focused on natural resources: "Ecosystems, Ecosystem Services, and Biodiversity" (Ch. 7); "Forests" (Ch.6); "Oceans and Marine Resources" (Ch. 9); "Coastal Effects" (Ch. 8); and "Tribes & Indigenous Peoples" (Ch.15) (USGCRP, 2018).

We provide a more in-depth, technical analysis of topics of interest to scientists and practitioners, and review climate change impacts at multiple scales, including: 1) the individual organisms, populations, and species of biodiversity which comprise ecosystems; 2) the properties and processes that characterize ecosystems; and 3) the goods and services that ecosystems provide which support human economies and well-being (Fig. 1). Further, we explore natural resource management challenges posed by climate change and present examples of on-the-ground adaptation actions. Many topics covered in this review are complex and deserve a review of their own. However, by covering multiple scales in one place, we provide a holistic overview of how climate change is affecting different ecosystems and how these changes may in turn affect human well-being, including impacts to vulnerable communities, tribes, and Indigenous peoples.

2. Individuals, populations, and species

Although climate change impacts are widespread, they are not uniform, and accumulating evidence indicates that climate change responses vary as a function of relative vulnerability due to differences in exposure, sensitivity, and adaptive capacity (Beever et al., 2016; Foden and Young, 2016; Glick et al., 2011; Kovach et al., 2019). Below, we discuss major impacts observed at the scale of individuals, populations, and species, and review the mechanisms driving changes.

2.1. Behavior and morphology

One way that organisms cope with changes in their environment is by altering their behavior or morphology. Behavioral responses to climate change can result from changes in temperature and manifest before changes at the population and species level, such as distribution changes or population declines (Beever et al., 2017). Behavioral responses include seeking shade or refuge, altering feeding times, changing site use, and shifting circadian or circannual rhythms (e.g., hibernation, migration; Beever et al., 2017; Bradshaw and Holzapfel, 2007; McCann et al., 2017).

Morphological changes commonly entail changes in body size (Cheung et al., 2013; Eastman et al., 2012; Ozgul et al., 2010). For example, increasing summer temperatures have been associated with reduced body size and increased wing length in North American migratory birds (Weeks et al., 2019). In ectotherms, where metabolic rate is sensitive to temperature (Gardner et al., 2011), warmer temperatures can lead to faster growth rates but can ultimately lead to smaller body size (Atkinson, 1994). This direct impact of temperature on growth has been observed, for example, in American lobster (*Homarus americanus*; Le Bris et al., 2017) and Atlantic cod (*Gadus morhua*; Pershing et al., 2016) during recent warming in the northwest Atlantic. Morphological responses, however, are complex and highly variable: changes in phenotype may not be observed if genetic change is counteracted by environmental effects (Conover et al., 2009). Moreover, short term benefits may not be adaptive in the long term (Section 2.4).

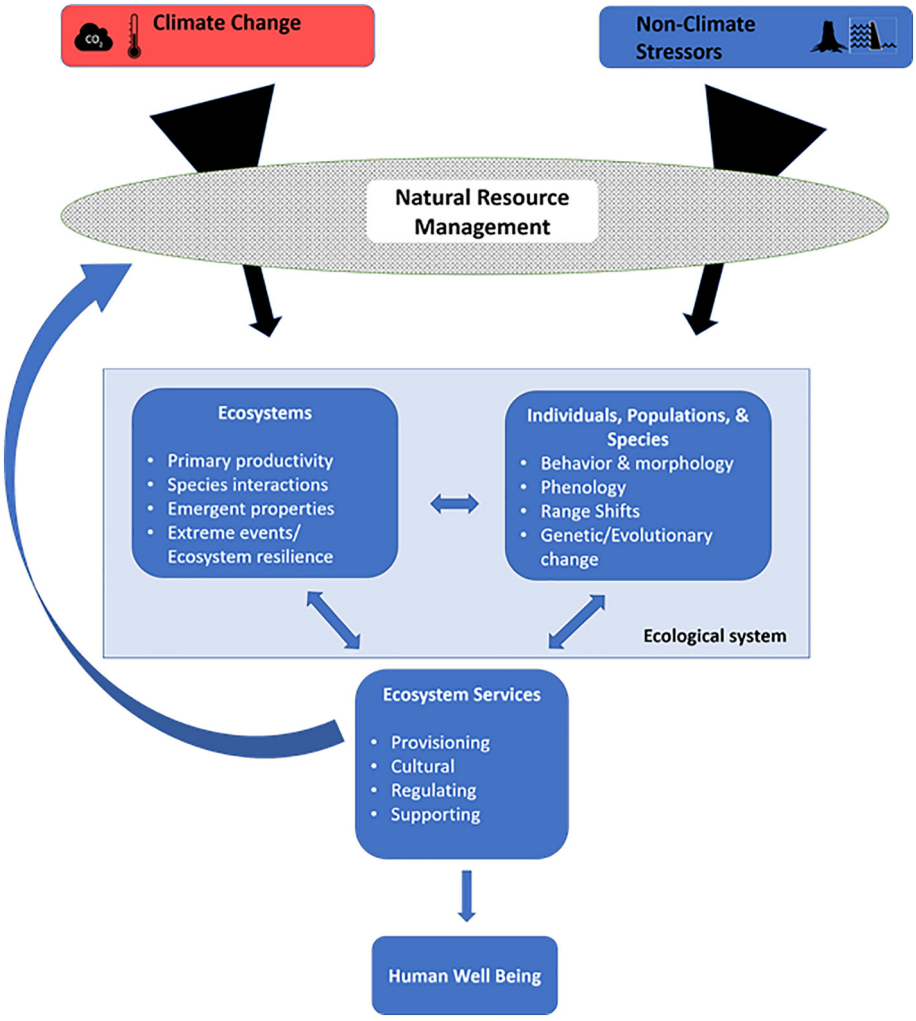

Fig. 1. Climate change and non-climate stressors interact and affect ecological systems at multiple scales. These combined stressors affect individuals, populations, and species, as well as ecosystem processes and properties. The relative impact of climate change versus other stressors varies depending on the species or ecosystem. Diverse biological communities and functioning ecosystems are critical to maintaining the ecosystem services (Millennium Ecosystem Assessment, 2005) that support human well-being (Díaz et al., 2019). Natural resource management affects biodiversity, ecosystems and their services and can moderate or exacerbate climate change and non-climate stressors.

2.2. Phenology

Phenology, or the seasonal timing of recurring biological events, is a critical part of ecological relationships (Rudolf, 2019), and a primary indicator of species responses to climate change (Staudinger et al., 2019). Across much of the terrestrial U.S., broad changes in seasonality are evidenced by an earlier start to spring compared to 20th-century averages (Ault et al., 2015; Monahan et al., 2016). Although changes in phenology are well documented, trends are far from homogenous (Cohen et al., 2018), a result of high variability in climate drivers and phenological responses across habitat types (Chmura et al., 2019; Fu et al., 2015; Pearson, 2019). Migratory birds provide clear examples of phenological shifts, with extensive documentation of earlier migration (Lehikoinen et al., 2019) and earlier breeding (Lany et al., 2016) in response to rising temperatures and altered precipitation patterns.

Phenological shifts in marine and aquatic habitats are less well documented in comparison to terrestrial systems, largely due to difficulty detecting and tracking aquatic organisms (Staudinger et al., 2019). Nonetheless, there have been clear, directional shifts in the timing of seasonal aquatic and marine abiotic drivers, including earlier transitions from winter to spring temperatures (Thomas et al., 2017) and earlier ice melting and runoff (Post, 2017; Staudinger et al., 2019). Marine phytoplankton can respond rapidly to such abiotic changes, resulting in altered timing of phytoplankton blooms (Wasmund et al., 2019), which in turn can create a mismatch with secondary consumers and change the food web structure (Post, 2017; Sundby et al., 2016). Phenological changes have also been observed in freshwater and riparian systems, including advances in the winter spawning phenology of coho (*Oncorhynchus kisutch*) and chum salmon (*O. keta*) in the Pacific Northwest, which has driven phenological changes in bald eagle (*Haliaeetus leucocephalus*) populations (Rubenstein et al., 2019).

Differential shifts in phenology among interacting organisms could drive population declines through reduced reproductive success and/or increased predation or competition (Visser and Gienapp, 2019; Wann et al., 2019; Zimova et al., 2016). Additionally, phenology changes in species with multiple life stages are complex and shifts that are beneficial for one life stage may be detrimental to another (Campbell et al., 2019; Schluter et al., 1991). However, few species have had documented population-level consequences of mistimed reproduction, perhaps due to mitigating effects of density-dependence and greater ability to alter prey or behavior (Dunn and Møller, 2014; Staudinger et al., 2019). Asynchronous phenological shifts have the potential to disrupt the functioning, persistence, and resilience of population dynamics, ecosystems, and ecosystem services (Asch et al., 2019; Mayor et al., 2017; Staudinger et al., 2019; Visser and Gienapp, 2019).

2.3. Geographic range shifts

Climate change is driving large-scale shifts in species distribution, abundance, and reorganization of terrestrial and aquatic ecosystems (Lenoir and Svenning, 2015; Pacifici et al., 2017; Staudinger et al., 2012). Geographic range shifts are widespread across taxa and ecosystems: a recent review of plant and animal species in temperate North America found 55% have either contracted the warm edge or expanded the cool edge of their range (Wiens, 2016). Documented shifts poleward, upslope, and deeper average tens of kilometers per decade (Burrows et al., 2011; Chen et al., 2011). Northern Hemisphere birds, for example, are decreasing in abundance along species' southern and lower elevational range edges (Ralston et al., 2017; Tayleur et al., 2015).

Marine organisms have also demonstrated range shifts, in some cases at faster rates than observed in terrestrial systems and at pace with climate velocities (García Molinos et al., 2015; Poloczanska et al., 2013). The majority of marine taxa surveyed in a 2013 review, for example, shifted in directions consistent with climate velocity (Pinsky et al., 2013). This response, however, is not uniform, with some fish demonstrating a lag effect, potentially due to species-specific sensitivities (Alabia et al., 2018). Arctic marine environments are experiencing changes to sea ice cover, increasing temperatures, and ocean acidification, resulting in range shifts for marine fish, arthropods, and marine mammals (Mecklenburg et al., 2016; Taylor et al., 2017; U.S. Environmental Protection Agency, 2016). Some temperate marine ecosystems are 'tropicalizing', with herbivorous tropical fish expanding poleward, causing decreases in macroalgal plant communities (Vergés et al., 2014).

Despite evidence for widespread range shifts, fewer shifts have been documented than expected from projections, and some shifts are counterintuitive to expectations from projections based solely on temperature changes (Crimmins et al., 2011; Foster and D'Amato, 2015; Morley et al., 2017; Rowe et al., 2015). Indirect effects of climate change and interactive ecological and evolutionary processes can complicate predictions (Estrada et al., 2016; MacLean and Beissinger, 2017; Pacifici et al., 2017). Microclimates, complex topography, and factors such as land use change also need to be considered to accurately predict shifts (Elsen and Tingley, 2015; Guo et al., 2018; Hannah et al., 2014; Kleisner et al., 2016, 2017; Sirami et al., 2017). Moreover, documenting range shifts is challenging, requiring baseline information on historical ranges that is missing for many species, ecosystems, and geographic areas. Additionally, life stages that are most responsive to climate may not be the focus of monitoring or might show lag effects (Alexander et al., 2018). Limited and occasionally conflicting evidence could actually indicate that some species are able to adapt in place, at least for now (Beever et al., 2015; Berg et al., 2010; Jurgens and Gaylord, 2018). Although range shifts are generally regarded as a primary mechanism by which species can effectively adapt to climate change, shifts should be considered in the context of entire ecosystems: an adaptive shift for one species may negatively impact recipient communities (Wallingford et al., in review) (Box 1).

2.4. Mechanisms and rate of change

An organism's response to climate change can be driven by genetic (evolutionary) or non-genetic (plastic) processes (e.g., Franks et al., 2014; Kingsolver and Buckley, 2017). This distinction is important because the mechanism determines the rate of response and whether individuals, populations, and species will be able to keep pace with rapidly changing conditions (Boutin and Lane, 2014). Plastic responses occur within an individual's lifetime and are almost immediate, whereas evolutionary change requires multiple generations (Harrisson et al., 2014; Hendry et al., 2011). Current research is starting to explore the role of epigenetic responses, wherein environmental drivers alter gene expression and can be passed to future generations, occur between generations, and are considered intermediate responses (Jeremias et al., 2018). The distinction between plastic/epigenetic responses and evolutionary change is not always clear, as an organism's ability to respond through these mechanisms can be heritable and subject to evolutionary pressure (Banta and Richards, 2018; Grenier et al., 2016).

Some rapid responses reflect a long history of genetic adaptation to natural variability in climate, and may facilitate persistence during directional climate change by allowing populations to persist long enough for genetic adaptation to occur (Fox et al., 2019; Snell-Rood et al., 2018). While often effective at increasing survival in the short term, some plastic responses are not beneficial over the long term (Ghalambor et al., 2007): they may entail tradeoffs with fecundity (e.g., smaller body sizes typically produce fewer eggs and more boom/bust population dynamics; Waples and Audzijonyte, 2016), or they may lead to interactions with other species or habitats that ultimately lower survival (Bonamour et al., 2019; Schlaepfer et al., 2002). Negative effects of plastic responses are often delayed and difficult to measure, so tracking long-term demographic responses to ensure populations of concern are truly coping with climate change is important.

The pace of climate change often exceeds average rates of evolutionary change (De Meester et al., 2018). However, evolution can happen in very few generations if populations survive strong selection and favorable genetic variation is already present (Hendry, 2017).Strong selection typically involves high mortality, so populations face extirpation before they can effectively adapt via evolution (Bay et al., 2018). Indeed, recent meta-analyses demonstrate that even species demonstrating adaptive phenotypic responses may be adapting too slowly to keep pace with climate change (Radchuk et al., 2019).

Substantial theoretical and empirical work has focused on predicting and measuring rates of response to climate change in recent years (Bell, 2013; Carlson et al., 2014; Gomulkiewicz et al., 2018; Kopp and Matuszewski, 2014; Pelletier and Coltman, 2018). Rapid trait changes are common and well documented, but most cases are consistent with plastic rather than evolutionary mechanisms (Eastman et al., 2012; Merilä and Hendry, 2014). Although examples do exist of evolutionary responses across multiple taxa (Boutin and Lane, 2014; Charmantier and Gienapp, 2014; Crozier and Hutchings, 2013; Franks et al., 2014), the comparative lack of evidence may be due to complex selection and genetic landscapes, methodological constraints that hinder measurement of genetic change (Merilä, 2012), and altered species interactions which may outpace evolutionary responses (Section 3.2). Evolutionary rates are complicated to predict because selection acts on many traits simultaneously, possibly with opposing costs and benefits in different life stages or habitats (Crozier et al., 2008). However, because responses vary in the extent to which they reduce extinction risk, tracking multiple responses and understanding their limitations is critical for successful resource management.

3. Ecosystems

Observed ecosystem-level changes in response to climate change are due to direct impacts from changing climate drivers and interacting effects of species- and population-level responses. Here, we focus on several key ecosystem-level characteristics and properties affected by climate change: primary production; species interactions and emergent properties, including biological invasions; and the impact of extreme events on ecosystem resilience.

3.1. Primary productivity

Almost all life on Earth relies on primary producers, photosynthetic organisms that are the foundation of most food webs and are responsible for producing Earth's oxygen and regulating important components of carbon cycling and sequestration. Climate change has had varying effects on primary production across spatial and temporal scales (Lipton et al., 2018). Changes in primary production are likely to be amplified at higher trophic levels (Chust et al., 2014; Lefort et al., 2015; Stock

Box 1
Examples of climate-driven changes to ecosystems.

Terrestrial

Photo: U.S. Geological Survey

Photo: U.S. Forest Service

The 2012–2017 drought across California resulted in direct physiological stress to trees and facilitated bark beetle outbreaks, causing an unprecedented mortality of 129 million trees in Sierra Nevada forests (Asner et al., 2016; Cal Fire, 2018; Stephens et al., 2018). High levels of mortality among ponderosa pine led to increases in the relative proportion of incense cedar (*Calocedrus decurrens*), which has increased the likelihood of high-intensity surface fires and large wildfires (Stephens et al., 2018). The combined effects of drought, insects, and altered community composition has drastically changed this ecosystem.

Marine

Non-native invasive species such as European green crab (*Carcinus maenas*) are now present off the California coast, alongside recent "invasions" (due to climate-driven range expansion) of the Humboldt squid (*Dosidicus gigas*) (Epstein and Smale, 2017; Grosholz et al., 2000; Zeidberg and Robison, 2007). Both Humboldt squid and green crab are voracious predators that feed on a variety of native prey (Field et al., 2013; Grosholz et al., 2000). Although ultimate synergistic impact on California marine communities is not yet known, impacts from these species that have already been observed separately include prey population reductions, alteration of the resource base available to migratory shorebirds, and potential fundamental modification of ecosystem structure.

et al., 2014), resulting in further changes to ecosystem function and potentially substantial changes to entire ecosystems.

Globally, terrestrial primary production increased during the late 20th and early 21st centuries due to the fertilizing effect of increasing atmospheric CO_2, nutrient additions from human activities, longer growing seasons, and forest regrowth (Campbell et al., 2017; Domke et al., 2018; Graven et al., 2013; Wenzel et al., 2016; Zhu et al., 2016). However, regional trends vary, and different components of climate change may have opposing impacts on production; while increased atmospheric CO_2 can increase vegetation growth (e.g., Norby et al., 2002), excess or lack of nutrients, water deficits, and air pollution can limit growth (Norby et al., 2010; Oren et al., 2001; Pan et al., 2009). Warming and increased atmospheric CO_2 may also affect belowground biogeochemical processes, such as carbon and nitrogen cycling (Melillo et al., 2017), which can affect terrestrial production (Campbell et al., 2009).

Climate-driven changes to forest primary productivity vary by forest type and elevation. Primary production will likely decrease in forests where soil water availability is limited during the growing season (Latta et al., 2010), but will likely increase in energy-limited forests where snow and cold temperatures restrict the growing season (Latta et al., 2010; Marcinkowski et al., 2015; Wang et al., 2017). However, even in energy-limited forests, drought and extreme temperatures could limit growth increases (Anderegg et al., 2015; Hember et al., 2017). It is also unclear if fertilization effects will continue as forests age (Norby et al., 2010).

In marine and aquatic systems, phytoplankton is responsible for nearly all primary production and generates almost half of the total global primary production. Phytoplankton growth rates affect CO_2 uptake from seawater and organic carbon export to the deep ocean, and also impact fisheries productivity (Tyrrell, 2019). Like terrestrial systems, climate change impacts to marine primary production vary regionally; warming in temperate and tropical oceans can increase stratification, limiting upwelling of deep nutrients that stimulate new production (IPCC, 2013). In contrast, reduced ice cover at higher latitudes increases sunlight availability to the ocean surface, increasing phytoplankton growing seasons and annual primary production (Wasmund et al., 2019). Understanding how these changes impact the food web is crucial for maintaining sustainable fisheries.

3.2. Species interactions, emergent properties, and biological invasions

Variability in species' exposure and responses to climate change are primary drivers of altered species interactions. Emergent properties of ecosystems, including community characteristics such as food-web

structure and function that are mediated by species interactions, are changing as species shift their distributions (Section 2.3) and phenologies (Section 2.2) in response to climate impacts (Breeggemann et al., 2016). Higher trophic levels, for example, are expected to be more sensitive to climate change because of changes in predatory demand and search and encounter rates (Abbott et al., 2014; Daly and Brodeur, 2015; Dell et al., 2014). However, functional responses vary and depend on species composition, abiotic conditions (Davis et al., 2017; McCluney and Sabo, 2016; Verdeny-Vilalta and Moya-Laraño, 2014), body size (Ewald et al., 2013), and predator-prey interactions (Peers et al., 2014; Van Zuiden et al., 2016). Collectively, these changes are resulting in novel (i.e., species composition or function is completely transformed) or hybrid (i.e., some historical characteristics persist but structure and composition lie outside the historical range of variability) ecosystems and altered interspecific relationships with no historical analog (Hobbs et al., 2009).

Emergent ecosystem properties are more difficult to predict than direct impacts to individual species because they develop from interactions radiating throughout the system. Modeling is commonly used to evaluate changes in species interactions, but high uncertainty remains for many species and ecosystems due to lack of baseline research on biotic interactions, community structure and function, adaptive capacity, and interactions of climate and non-climate stressors (Beever et al., 2016; Blois et al., 2013; Rosenblatt and Schmitz, 2014). A growing number of studies are assessing how direct and indirect climate impacts may alter ecosystem properties. For example, fossil records have shown that ecosystems respond similarly to past climate change events by becoming dominated with generalist species (Blois et al., 2013) which may be an indicator of what could be expected under contemporary climate change. Research is also providing more nuanced evaluations of behavioral changes, including phenological, reproductive, and foraging changes (Beever et al., 2016), such as how increasing temperatures are increasing ratsnake predation on birds in the southeastern U.S. (DeGregorio et al., 2015). Finally, studies are suggesting that possessing population-specific traits (Dell et al., 2014; Rasmann et al., 2014) or local adaptations (Davis et al., 2017; Herstoff and Urban, 2014) may allow species to transition and persist in novel environments (Cannizzo and Griffen, 2016). More sophisticated models that account for multi-species interactions, community structure, dispersal, and evolution are needed to make robust predictions, although complex models may not always increase predictive capability (Alexander et al., 2016; Herstoff and Urban, 2014; Novak et al., 2011; Young, 2014).

Of additional concern is that climate change is facilitating the introduction and spread of non-native invasive species. Global economic costs of invasive species are currently estimated to be over $1.4 trillion annually and climate change has the potential to intensify these impacts (Burgiel et al., 2014). Many non-native invasive species are opportunistic generalists that can take advantage of changing conditions, colonize disturbed areas, and out-compete species, thereby altering community composition, dominance, production, and increasing extinction risk in some cases (e.g., Schmitt et al., 2019; Yeruham et al., 2020). For example, disturbance along with warming temperatures, was found to be important for plant invasions at cold, high-altitude regions in South America and Scandinavia (Lembrechts et al., 2016). Moreover, many non-native invasive plants respond more positively than native plants to increasing CO_2, nitrogen deposition, and temperature, likely increasing their competitiveness under increasing climate change (Liu et al., 2017). Stronger competitive abilities will likely lead to higher non-native invasive plant abundance and declines of native species abundances and community diversity (Bradley et al., 2019). Infiltration of non-native species into natural communities has already negatively impacted biodiversity (Bradley et al., 2019). Although new interactions resulting from invasive and native range-shifting species often negatively impact ecosystems (Carey et al., 2012; Valéry et al., 2009; Vergés et al., 2016; Wallingford et al., in review) and related services (Blois et al., 2013), species responses can have counter-intuitive outcomes. For example, the introduction of a non-native invasive bryozoan in the Gulf of Maine is thought to have resulted in substantial expansion of a native nudibranch species due to increased availability of a novel food source (Dijkstra et al., 2013). In some cases, climate change could also indirectly benefit native species by reducing populations of invasive species (Wenger et al., 2011).

3.3. Extreme events and ecosystem resilience

Climate change has altered the duration, magnitude, and frequency of extreme events, including droughts, forest fires, and heatwaves (Jay et al., 2018). Many of these events have significant impacts on ecosystems and interact with other climate-driven changes, reducing ecological resilience.

More extreme droughts and wildfires, driven by rising temperatures and altered precipitation patterns, affect ecosystem structure and function, particularly in forested ecosystems. Over the last two decades, warming and more variable precipitation have increased forest drought severity in the West, Southeast, and the Lake States (Clark et al., 2016), reducing tree growth and increasing mortality (Peters et al., 2015). However, responses vary (Choat et al., 2012) and can be lagged in long-lived species (Walter et al. 2013). Drought weakens tree defenses, increasing susceptibility to other disturbances, including insects, pathogens, invasive species (Trottier et al., 2017), and wildfires (Littell et al., 2016; Logan and Powell, 2009; Weed et al., 2013; see Box 1). While drought impacts have direct long-term consequences, drought-facilitated disturbances can result in more immediate changes to forest ecosystem structure and function (Loehman et al., 2017).

Earlier spring warming (Westerling et al., 2006), increased vapor pressure deficit (Abatzoglou and Williams, 2016), and reduced summer precipitation (Dennison et al., 2014; Holden et al., 2018) have increased fire season length and area burned across the western U.S. (Abatzoglou and Kolden, 2013; Gergel et al., 2017; Luce et al., 2014; McKenzie and Littell, 2017; Westerling, 2016). Climate changes have interacted with forest management practices to create large, dense forest with high fuel loads, especially in lower-elevation ponderosa pine (*Pinus ponderosa*) and dry mixed-conifer forests in the West (Keane et al., 2002). Fire frequency and area burned will likely increase in fire-prone forests (Barbero et al., 2015; Liu et al., 2015); by the 2050s, annual area burned in the U.S. might increase by 2–6 times compared to present (Kitzberger et al., 2017; Litschert et al., 2012; Ojima et al., 2014), However, frequency and severity will depend on topography, fuel levels, and fire suppression efforts (Abt et al., 2015; Butry et al., 2010).

In the North Atlantic, storms are getting stronger due to rising ocean temperatures and sea level rise (Elsner et al., 2008; Malmstadt et al., 2010). There is also evidence that tropical cyclones are bringing more extreme rainfall, even if wind speeds have not increased (Patricola and Wehner, 2018). Increased storm intensity can impact ecosystems and human communities through extreme flooding, erosive waves, and higher storm surge, making recovery from extreme events more challenging. Rising ocean temperatures have also led to periods of extraordinarily warm conditions across the globe, known as marine heatwaves (Hobday et al., 2016, 2018). The U.S. experienced significant heatwaves in the northwest Atlantic in 2012 (Mills et al., 2013) and 2016 (Pershing et al., 2018) and the northeast Pacific in 2014–2015 (Bond et al., 2015). Rising ocean temperatures are driving widespread coral bleaching, contributing to coral cover loss, impacting fish communities, and increasing exposure of nearby shores to waves (Eakin et al., 2019).

4. Ecosystem services

Diverse biological communities and functioning ecosystems are critical to maintaining ecosystem services that support human well-being (Díaz et al., 2019). Therefore, climate change impacts to species, populations, and ecosystems affect the availability and delivery of ecosystem

services, including changes to provisioning, regulating, supporting, and cultural services.

4.1. Provisioning services

Climate-induced changes in provisioning services, the material goods that people obtain from ecosystems and biodiversity, can have profound impacts on human economies and well-being. For example, climate impacts to forested watersheds, including increased temperatures, changes to precipitation and snowfall, and disturbances such as wildfires, are altering freshwater supply for municipalities, agriculture, and power generation (Barnett et al., 2008; Stewart et al., 2005). Surface water shortages are likely in dry years in some locations (Li et al., 2017). Rising stream temperatures also affect water quality (Warziniack et al., 2018). Similarly, wildfires can increase sediment deposition and debris in streams, lakes, and reservoirs (Luce et al., 2012). These changes will stress water supplies, potentially increasing water treatment costs (Warziniack et al., 2018).

Changes in water supply, along with other climate change impacts, can alter agricultural production. Droughts and other extreme events can decrease crop yield and quality (Gowda et al., 2018), with production declines projected for several important crop species as temperatures rise (Zhao et al., 2017). In contrast, changes to growing season length can have both positive and negative effects on crop yield and prices (U.S. Environmental Protection Agency, 2016),

In marine systems, fish and invertebrate harvesting contributes $212 billion in sales annually to the US economy (National Marine Fisheries Service, 2018), and climate change is affecting the availability, distribution (section 2.3), and quality of commercially important species (Kleisner et al., 2016; Peer and Miller, 2014; Pershing et al., 2015; Walsh et al., 2015). Rising ocean temperatures also decrease oxygen levels, which may reduce average fish body size by 14–24% by 2050 (Cheung et al., 2013). In freshwater systems, rising stream temperatures will negatively affect some harvested species (Crozier et al., 2019; Isaak et al., 2012). Future warming is expected to reduce the catch potential of all U.S. regions except the Arctic (Lam et al., 2016).

4.2. Regulating services

Biodiversity and ecosystems provide important regulation services, such as sequestering carbon, moderating the impacts of extreme events (section 3.3), maintaining soil and air quality, and controlling disease spread.

Carbon storage is an important service that will become increasingly important as climate change accelerates. Although forest area has increased nationally since 2000 (EPA, 2017; Oswalt et al., 2014), it is unclear whether carbon storage from afforestation will continue to outweigh emissions from deforestation (Coulston et al., 2015). Moreover, carbon storage in many forests will likely decrease due to higher temperatures, increased water stress and disturbances (section 3.1), and lower rates of CO_2 uptake in aging forests when compared to regrowth forests after past disturbances (Oswalt et al., 2014; Pugh et al., 2019; USDA, 2016; Wear and Coulston, 2015). Coastal wetlands are highly productive ecosystems that store carbon (Davis et al., 2015; Howard et al., 2017), and also provide natural defenses against erosion, waves, flooding, and storm surge (Arkema et al., 2013). As human development or sea level rise degrade coastal wetlands, their capacity to provide these services diminishes.

Ecosystems also regulate the distribution, abundance, and life cycles of disease carrying organisms (Corvalan et al., 2005). Climate change is affecting the ability of ecosystems to provide this service as species ranges (section 2.3), abundances, and habitat conditions shift. For example, Aedes mosquitoes, which transmit diseases such as dengue, are expanding their geographic distribution in the southern U.S., increasing disease risk (Ebi and Nealon, 2016).

4.3. Supporting services

Supporting ecosystem services facilitate basic ecosystem function, such as primary productivity (see section 3.1), nutrient cycling, and maintenance of genetic diversity. As temperatures rise, decomposition of soil organic matter generally increases, potentially increasing soil carbon losses and altering C:N balances (Davidson and Janssens, 2006). These changes are impacted by biotic interactions, including indirect changes to soil microbial community composition (Crowther et al., 2011).

The same activities responsible for climate change (e.g., fossil fuel combustion) result in increased nitrogen deposition, which has significant impacts on terrestrial and aquatic ecosystems, including through eutrophication (Galloway et al., 2008). The combination of higher nutrient loading and rising temperatures is increasing the frequency, duration, and extent of cyanobacteria responsible for harmful algal blooms, which can negatively impact human and animal health (Hilborn and Beasley, 2015). Estimates suggest that by the end of this century, conditions may allow blooms of the toxic alga *Alexandrium catanella* to be up to two months earlier and persist for up to an additional month (Moore et al., 2008; Sandifer and Sutton-Grier, 2014), with resulting impacts on aquaculture, recreation, and other activities.

4.4. Cultural services

Cultural services are the non-material benefits that people gain from biodiversity and ecosystems, such as cultural identity, recreation, and mental and physical health. Despite their importance to human well-being, cultural services have been understudied compared to other ecosystem services (Runting et al., 2017). Indigenous peoples were among the earliest voices connecting culture and environmental change through science, scholarship, and other forms of expression (ACIA, 2004; Maynard, 1998).

There is growing evidence that human health benefits from exposure to natural ecosystems (Donatuto et al., 2014; Sandifer et al., 2015); conversely, climate-driven extremes such as increased temperatures and storms can decrease mental and physical health (Bell et al., 2016; Obradovich et al., 2018). Indirect economic costs (such as lost livelihoods) can also cause adverse socio-psychological impacts (Becker et al., 2015; Morris and Deterding, 2016; Shen and Aydin, 2014).

Although quantifying the value of ecosystems to cultural services is difficult, studies suggest that Americans place a high cultural value on natural systems: for example, a recent survey found that nearly 49 million adults nationwide participated in ocean and coastal recreation, spending more than 1.2 billion days along the coasts and over $141 billion in ocean recreation-related goods and services (National Marine Fisheries Service, 2018). As climate change alters the ability of ecosystems to provide jobs, recreational opportunities, and restorative experiences, communities will experience declines in mental and physical health and potential losses of nature-based tourism dollars (Sandifer and Sutton-Grier, 2014).

5. Vulnerability of human communities

The adaptive capacity of human communities to deal with changes in ecosystem services will partly determine the magnitude of impacts on well-being. While some human communities have been proactive in identifying and planning for changes, others are more vulnerable due to a reduced ability to adapt.

Tribes and Indigenous peoples in the U.S. (groups whose exercise of self-determination as governing entities pre-dates the establishment of the U.S.; Jantarasami et al., 2018) have over 800 climate change initiatives and have led or participated in numerous climate change studies; many have developed their own climate change plans (Jantarasami et al., 2018). Since 1998, tribes and Indigenous peoples

Table 1
Example management responses to changing biodiversity, ecosystems, and ecosystem services that can increase resilience, use updated technology or infrastructure, or be incorporated into governance approaches.

	Increasing ecosystem resilience	Utilizing technology and infrastructure	Improved governance
Individuals, populations, species	Maintaining population sizes, connectivity, and gene flow to allow for shifting ranges and increases in evolutionary resilience of populations and species	Matching individual genotypes with future environments under projected climate change increases adaptability of species	Considering climate change impacts on threatened and endangered species in listing decisions can improve overall understanding of vulnerability
Ecosystems	Reduction of non-climate stressors, such as pollution and invasive species to minimize climate change impacts	Adopting use of natural and nature-based infrastructure to improve resilience of natural communities, leveraging programs in place addressing other stressors	Implementing use of boundary organizations (e.g., North American Marine Protected Areas Network) can promote dialogue of diverse stakeholders in ecosystems that cross multiple jurisdictional boundaries and look for efficiencies in addressing multiple stressors
Ecosystem services	Maintain biodiversity and ecological redundancy to minimize losses in valuable services	Forecasting environmental conditions to prepare for economic changes in a particular industry (e.g., fishery)	Promoting consideration of ecosystem services and related climate impacts within federal planning and decision frameworks

have collaborated on the NCA, focusing on Indigenous concerns, knowledge of vulnerability, and goals for adaptation and mitigation.

Although tribes and Indigenous peoples continue to exercise self-governance, federal policies provide uneven levels of political engagement and support. Indigenous leadership is critical to addressing climate change; however, federal, state, and local governments pose barriers to tribal and Indigenous mitigation and adaptation efforts (Jantarasami et al., 2018). Historical and contemporary land-reduction, land-use restrictions, and poorly implemented treaty rights and consultation requirements exacerbate economic and health risks, which in many cases are associated with threats to Indigenous cultural maintenance. For example, climate-driven range shifts in culturally important species pose challenges to tribes and Indigenous peoples when tribal land areas are small and have limited connectivity (Rapp et al., 2019). Indigenous peoples face risks related to resettlement due to the impacts of climate change, such as coastal erosion and sea ice loss in Alaska. Despite a history of forced relocations, there are structural barriers for Indigenous peoples to participate in current policy processes trying to plan for climate-driven resettlement (Jantarasami et al., 2018).

Across the U.S., coastal communities are also particularly vulnerable to climate change impacts from rising sea levels and more intense storms, which are exacerbating high tide and storm surges, erosion, and saltwater intrusion. High tide flooding is already forcing some cities to install costly pump stations to clear floodwaters and mobilize emergency responders to routinely close flooded streets.

Society's most vulnerable populations, including children, the elderly, economically disadvantaged, homeless, and those with preexisting mental illness tend to be the most heavily impacted by climate changes and resulting impacts to ecosystem services (Dodgen et al., 2016).

6. Implications for natural resource management

Natural resource management traditionally focuses on maintaining or restoring to historical conditions (e.g., National Park System Advisory Board, 2012). While historical context may still motivate management decisions, restoring to historical baselines may not be realistic as the climate changes (Stein et al., 2014). In some cases, management practices to resist change may be effective; in others, managers may choose to accept ecosystem changes or to alter management practices to direct changes in order to minimize loss of valued species and services as ecosystems transform (Aplet and Mckinley, 2017; Millar and Stephenson, 2015; Stein et al., 2013).

Adaptive and proactive approaches that are continually updated to reflect emerging and anticipated climate change impacts will be needed (Bradford et al., 2018; Holsman et al., 2019; Stein et al., 2014; Table 1). For example, the U.S. has a rigorous, science-based system for detecting changes in fish abundance, productivity, and catch, which informs fishery management decisions such as seasonal and spatial closures, annual quotas, and stock rebuilding plans (Pinsky and Mantua, 2014). Collection of this type of information is important for future assessment and updating of management objectives (Stein et al., 2014). NOAA Fisheries has developed adaptation strategies that incorporate climate and ecosystem-related factors into fishery decision-making (Busch et al., 2016; Hare et al., 2016a; Link et al., 2015). Decision support tools, including scenario planning (Cobb and Thompson, 2012; Mahmoud et al., 2009; Peterson et al., 2003) and structured decision-making (Gregory et al., 2012) can help decision-makers explore broad scenarios of risk and develop and prioritize actions that account for uncertainty, optimize tradeoffs, and reflect institutional capacity. Below, we discuss strategies for increasing resilience of ecosystems and human communities.

6.1. Increasing ecosystem resilience

To create effective adaptation strategies, managers need to understand which species are most at risk and why. One way to determine relative risk is through climate change vulnerability assessments that examine species exposure, sensitivity, and adaptive capacity to climate change, and exposure to non-climate stressors (Glick et al., 2011; Hare et al., 2016b; Spencer et al., 2019; Staudinger et al., 2015). Managers can then take proactive steps to increase resilience (Table 1).

Systems that are already degraded from non-climate stressors have lower resilience; therefore, restoring and conserving areas that support valued resources are important. Many strategies for reducing other stressors are things that managers already know, such as restoring populations and habitats, increasing connectivity, and reducing stress from disease, pollution and invasive species (Box 2). For example, prescribed burning and reducing forest stand density can lower wildfire risk in some forest types and can increase resistance and resilience to drought and insect outbreaks (Bottero et al., 2017; Sohn et al., 2016; Vernon et al., 2018). Similarly, in aquatic systems, effective strategies include reconnecting floodplains and side channels, ensuring effective passage for aquatic organisms, and maintaining large trees in forested riparian areas for shade and recruitment to streams (Peterson and Halofsky, 2018; Pollock et al., 2014).

Limiting invasive species spread can help maintain biodiversity, ecosystem function, and resilience (Fischer et al., 2006; Katsanevakis et al., 2014; Oliver et al., 2015). Dialogue between managers, scientists, and policymakers can help ensure that climate change mitigation does not exacerbate invasive species spread (Beaury et al., 2019). Similarly, invasive species policies that explicitly address climate change will enable proactive management (Pyke et al., 2008). Managers may also benefit from considering potential negative effects from native species range expansions (Burgiel et al., 2014; Carey et al., 2012; Giakoumi et al., 2019; Wallingford et al., in review).

Restoring habitat and increasing connectivity to enable species to disperse across the landscape and follow physiological niches is another

Box 2
Examples of on-the-ground adaptation.

Restoring meadows in the Sierra Nevada

Photo: Toni Lyn Morelli

The Sierra Nevada region is critical to the California water supply. Snow in the mountains melts slowly during spring and summer, providing water for ecosystems and people. Climate change is projected to cause more winter precipitation to fall as rain and earlier snowmelt, leading to decreased summer water flows (Viers et al., 2013). Increased frequency and severity of floods is also anticipated. Well-functioning mountain meadows can attenuate floods and increase groundwater storage (National Wildlife Federation, 2010), and some have been identified as climate change refugia for wildlife (Morelli et al., 2017). However, historic land use changes have degraded approximately 40–60% of Sierra meadows. In 2015, Federal, state, and NGO partners restored four meadows with high ecological value located in areas projected to experience the most significant changes in hydrology (Fair and Hunt, 2015; National Wildlife Federation, 2010).

Nature-based infrastructure

Photo: Linda Walters

The use of nature-based designs for coastal resilience structures like living shorelines tends to be more effective at withstanding extreme events (Powell et al., 2019). For example, during Tropical Storm Irene in 2011, stream-designed road crossings survived a category 3 hurricane while nearly 1000 traditional culverts were damaged or destroyed (Sutton-Grier et al., 2018). In another example, living shorelines fared much better under a category 1 hurricane in North Carolina than traditional bulk heads (Gittman et al., 2014).

key climate adaptation action (Anderson et al., 2015; Mcguire et al., 2016; Timpane-Padgham et al., 2017). For example, the recent recovery plan for Atlantic salmon (*Salmo salar*) included identifying vacant habitats, creating redundant populations, and revisiting critical habitat designations to ensure sufficient climate resilient habitats under future conditions (USFWS and NMFS, 2019). Additionally, conserving climate change refugia (areas relatively buffered from contemporary climate change that enable persistence of valued resources), has become a focus of conservation efforts for highly valued vulnerable ecosystems and species (Keppel et al., 2015; Morelli et al., 2016).

Restoring populations can be an effective way to increase genetic diversity and potential for species to evolve and adapt to changing climatic conditions (Sgrò et al., 2011). More active approaches such as diverse seed sourcing, translocation of genes or individuals to accelerate evolution, and assisted migration may be warranted for species with limited dispersal ability or that face movement barriers (Anderson et al., 2014; Isaac-Renton et al., 2014; Whiteley et al., 2015). Unforeseen and unwanted consequences are possible for any assisted migration, but developing policies to analyze and manage potential consequences could minimize unintended outcomes (Invasive Species Advisory Committee, 2017; Schwartz et al., 2012).

6.2. Leveraging technology and infrastructure

Human communities may need to adapt by updating technology and infrastructure (Table 1). Extreme events often motivate adaptation. For example, the inability of the lobster supply chain to handle the sudden influx of soft-shell lobster during the 2012 heatwave (Mills et al., 2013) led to increased domestic processing capacity and expanded marketing. These adaptations allowed the fishery to achieve record value during a subsequent heatwave in 2016 (Pershing et al., 2018). To-date, most documented cases of adaptation to climate impacts on the ocean have been reactive. However, it is now possible to forecast temperature, pH, and oxygen conditions several months in advance (Jacox et al., 2017; Siedlecki et al., 2016; Tommasi et al., 2017). Ensuring that these data products are distributed and used effectively will require considerable engagement with the user community (Hobday et al., 2019; Siedlecki et al., 2016).

In coastal ecosystems, there is growing interest in natural and nature-based infrastructure (NNBI) to increase coastal community resilience (Powell et al., 2019; Spalding et al., 2014; Sutton-Grier et al., 2015). NNBI strategies include restoring or creating coastal ecosystems like salt marsh, mangroves, oyster or coral reefs, beaches, and dunes to mitigate waves and erosion (Ferrario et al., 2014; Möller et al., 2014; Powell et al., 2019; Rodriguez et al., 2014; Zhang et al., 2012), but also include hybrid combinations of natural and built infrastructure such as living shorelines or using combinations of habitat restoration and flood walls (Box 2) (Gittman et al., 2014; Sutton-Grier et al., 2015). NNBI approaches provide co-benefits in terms of habitat, water quality, and recreation, and can be cheaper and survive extreme events better than traditional infrastructure (Gittman et al., 2014; Powell et al., 2019; Sutton-Grier et al., 2018). Although long-term planning may require some coastal communities to relocate due to prohibitively high cost or infeasibility of sea level rise protection, NNBI approaches can at least mitigate some short-term impacts and allow communities more time to consider options. NNBI approaches are often not as well known or trusted in comparison to traditional grey (e.g., seawall) approaches; therefore it is important to increase information on the performance of these techniques, communicate their ecosystem service benefits, and increase coordination and planning around shared socio-ecological goals (Powell et al., 2019).

6.3. Strengthening governance

Federal agencies that manage natural resources are increasingly considering climate change impacts in their management plans (e.g.

Busch et al., 2016; Link, 2016; National Fish Wildlife and Plants Climate Adaptation Partnership, 2012; National Park Service, 2013; Swanston and Janowiak, 2012; Table 1). For example, the National Marine Fisheries Service has developed guidance on how climate change information should be considered in Endangered Species Act (ESA) decisions (National Marine Fisheries Service, 2016). The U.S. Fish and Wildlife Service has also considered climate change in listing decisions, biological opinions, and proposed alternative actions under the ESA (e.g., U.S. Fish and Wildlife Service, 2008, 2010), although climate change is still not included for many species. Even when climate change has been listed as a threat, specific management actions are often lacking (Delach et al., 2019). Federal agencies have also been directed to promote consideration of ecosystem services and related climate impacts within existing planning and decision frameworks (Executive Office of the President of the United States, 2015).

Despite progress, institutional barriers such as a focus on near-term planning, fixed policies and protocols, jurisdictional restrictions, and an established practice of managing based on historical conditions remain

Box 3

An integrated case study: climate change impacts on salmon across the U.S.

Individual, population, and species level responses

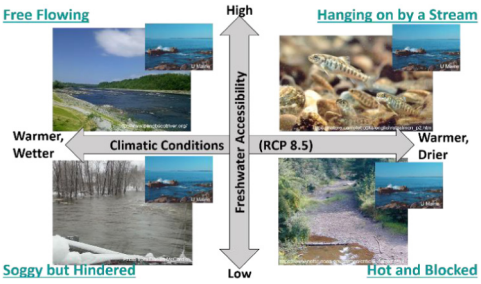
Bureau of Land Management

Photo: National Park Service

- In the Northwest, abnormally warm temperatures have led to losses of migrating and spawning salmon in the Columbia River (NOAA Fisheries, 2016).
- In Alaska, some salmon populations have benefited from warmer temperatures, earlier spring, and increased density of zooplankton prey (Schindler et al., 2005).
- Coho salmon on the west coast of the U.S. are expected to shift their range north by 2050 (Cheung et al., 2015). Under a high greenhouse gas emissions scenario, projected stream temperature increases could lead to a 22% reduction in salmon habitat in Washington by late century (Niemi et al., 2009).
- Sockeye salmon (*Oncorhynchus nerka*) in the Columbia River have been migrating earlier. Nearly two--thirds of this response was explained by evolutionary rather than plastic responses (Crozier et al., 2011).
- In the Penobscot River in the Gulf of Maine, adult Atlantic salmon (*Salmo salar*) have arrived as much as 2–3 weeks earlier to their freshwater spawning grounds between the late 1970s and early 2000s (Huntington et al., 2003; Juanes et al., 2004).

Ecosystem level responses

- Kodiak brown bears (*Ursus arctos middendorffi*) have responded to phenological shifts in sockeye salmon and red elderberry (*Sambucus racemosa*). During years with warmer springs, elderberry fruited earlier and overlapped with the salmon spawning run, causing bears to eat less salmon and more berries (Deacy et al., 2017).
- In the Pacific Northwest, warming stream temperatures are likely to reduce the amount of rearing habitat for Chinook salmon (*Oncorhynchus tshawytscha*), but will likely increase the range of invasive smallmouth bass (*Micropterus dolomieu*) (Lawrence et al., 2014).



Impacts to ecosystem services

Matt Nagle, Puyallup Tribal News

- As Kodiak brown bear diet shifted away from salmon (see panel 2), this reduced the distribution of marine derived nutrients being distributed into the surrounding terrestrial landscape, with implications for ecological function (Deacy et al., 2017).
- Shifts in availability and declines of salmon and other cold-water fishes impact cherished cultural resources, particularly in the Pacific Northwest where they are important to tribal nations such as the Nez Perce Tribe as cultural, subsistence, and economic resources. Tribes view salmon as an extension of life and an indicator of environmental health, and loss of salmon is equated with loss of tribal identity and culture (Colombi, 2012).

Implications for management

(Pictorial representation of scenarios used in Borggaard et al., 2019)

- Atlantic salmon and many distinct Pacific salmon population groups are federally protected species. Climate change is expected to exacerbate pre-existing anthropogenic stressors, which have reduced adaptive capacity (Crozier et al., 2019; Hare et al., 2016b). The Pacific Salmon Climate Vulnerability Assessment identified life stages that are most vulnerable to climate change and established a methodology for future status reviews to monitor and update recovery needs and prioritize recovery actions (Crozier et al., 2019).
- In the Yakima Basin, water resource managers, conservation groups, and state and federal agencies are enhancing reservoir storage capacity to ensure minimum flows for fish, allow passage above dams for access to cool, historical habitat, restore a more natural hydrograph, and improve riparian conditions for natural temperature and flow stabilization to bolster salmon runs and riparian habitat during droughts. Actions to redistribute water also impacted farmers, but agreements were made to sustain conditions needed to support salmon (NOAA Fisheries, 2015).
- NOAA used Atlantic salmon as a pilot case study for Scenario Planning - a structured process that embraces uncertainty and explores plausible alternative future conditions to help manage risk and prioritize actions - to explore actions to increase resilience to changing conditions in riverine and marine environments in response to declining population trends (Borggaard et al., 2019). Some outcomes from this effort have already been incorporated into the most recent revision of the Atlantic Salmon Recovery Plan (USFWS and NMFS, 2019).

a challenge (Kemp et al., 2015; Stein et al., 2014). Even with agency-level directives for climate adaptation, implementing actions on the ground can be difficult due to lack of funding and time, negative public perceptions, and difficulty transferring science between researchers and managers (Kemp et al., 2015). Boundary organizations that work at the interface of research and management, such as the U.S. Geological Survey Climate Adaptation Science Centers and the NOAA Regional Integrated Sciences and Assessment Programs, can help address some of these issues by bringing together multiple stakeholders and working with managers to develop adaptation plans.

Promoting local climate adaptation initiatives can also be an effective management strategy. Self-determination and self-governance of tribes and Indigenous peoples, as well as involvement of communities of color or natural resource users such as anglers in particular localities, supports the use of local knowledge and cultural practices that can track, adapt to and mitigate environmental change (Maldonado et al., 2013; Norton-Smith et al., 2016; Vinyeta et al., 2015). For many tribes and Indigenous peoples, their political rights are connected to cultural responsibilities to live sustainably (Borrows, 1997; De Chavez and Tauli-Corpuz, 2009). These cultural responsibilities often involve rich scientific traditions of observation and ecosystem stewardship (Shilling and Nelson, 2018; Trosper, 2009). Tribal and Indigenous governments have emphasized the importance of Indigenous scientists and knowledge keepers working collaboratively to observe changes and create adaptation strategies (Grossman and Parker, 2012; Houser et al., 2001). These governments are in unique positions to cooperate with local, state, and federal government to coordinate regional conservation and adaptation efforts that emphasize strategic foresight and sustainability (Krakoff, 2008; Morishima, 2014; Whyte et al., 2014).

7. Conclusion

Climate change is a pervasive and growing threat to biodiversity, ecosystems, and ecosystem services in the U.S. Climate impacts have been and will continue to be observed at the level of individuals, populations, and species through changes in behavior and morphology, phenology, and range shifts, and at the ecosystem level through changes in primary production, species interactions and emergent properties, and extreme events. Ecosystems and biodiversity underpin important services to people, thus these changes impact provisioning, regulating, supporting, and cultural services, with implications for human well-being. Effective management will require flexible, proactive approaches that account for potential climate change impacts (Box 3). Managers are beginning to implement these strategies, but face challenges due to lack of information and institutional barriers. Widespread incorporation of climate change into natural resource management is yet to be achieved, but examples are emerging that help increase awareness and provide case studies in different sectors. Moving forward, evaluations of effectiveness and demonstrative case studies of adaptation success stories are needed to promote and guide climate-smart management.

Supporting Information

ABSTRACT: Beef cattle production systems are the largest contributors of greenhouse gas (GHG) and ammonia (NH_3) emissions in the livestock industry. Here, we present the first meta-analysis and integrated assessment of gaseous emissions and mitigation potentials for a typical beef cattle feedlot system, including methane (CH_4), nitrous oxide (N_2O), and NH_3 losses from enteric fermentation and manure management based on data from 104 studies. A total of 14 integrated emission factors (EF) and the mitigation efficiencies (ME) of 17 available options were provided. The estimated GHG and NH_3 emissions from the baseline feedlot system were 2786 ± 108 kg carbon dioxide equivalents (CO_2-eq) per animal unit (AU) per year and 49.1 ± 1.5 kg NH_3 AU^{-1} $year^{-1}$, respectively. Enteric CH_4 fermentation and manure on the feedlot contributed 67.5% and 80.8% of the total system GHG and NH_3 emissions, respectively. The highest ME values were found for lipid additives for enteric CH_4 fermentation and urease inhibitor additives (UI) for NH_3 emissions from manure on the feedlot, being −14.9% ($p < 0.05$) and −59.5% ($p < 0.001$), respectively. The recommended mitigation combinations of a low-crude-protein (CP) diet and a UI additive for manure on the feedlot could reduce the GHG of the system by 4.9% and NH_3 by 50.9%. The results of this study have important implications for developing sustainable beef cattle feedlot systems from the viewpoint of GHG and NH_3 mitigation.

1. INTRODUCTION

Greenhouse gas (GHG) and ammonia (NH_3) emissions are two major atmospheric issues that influence human health and the global environment. From the United Nations Framework Convention on Climate Change to the Kyoto Protocol and the Paris Agreement, human beings are more aware of the influence of GHG emissions, and urgent action should be taken to avoid the risk of a temperature rise of more than 2 °C.[1] Methane (CH_4) and nitrous oxide (N_2O) are identified as two major non-CO_2 GHGs that have strong global warming potentials (GWP), being 28 and 265 times higher than that of CO_2, respectively.[1] Reducing non-CO_2 global warming agents has garnered increasing attention in recent years.[2−4] The "immediacy" of the climate benefit and the co-benefit of their reduction are expected to provide a strong incentive for nations to consider adopting policies and take rapid responses.[5,6] NH_3, also contributes to a series of problems, including odor emanation, water eutrophication,[7] soil acidification,[8] and GHG emissions because NH_3 is a precursor of N_2O.[9] Furthermore, NH_3 stimulates the formation of secondary particulate matter (PM),[10] which has negative effects on people and the environment.

Livestock production represents the largest anthropogenic source of CH_4 and N_2O emissions[11,12] and contributes 18% of all anthropogenic GHG emissions.[13] Here, CO_2 emissions from livestock are not estimated because annual net CO_2 emissions are assumed to be zero; the CO_2 photosynthesized by plants is returned to the atmosphere as respired CO_2.[9] Nondairy cattle, predominantly beef cattle account for 53.9% of the global enteric CH_4 emissions, while the dairy sector takes second place with 19.1%.[14] Beef cattle are the largest single contributor of manure NH_3 emissions, accounting for 41.0% of all animal sectors.[15]

Beef cattle feedlot production is one of the most typical beef cattle production methods in intensive production systems.[16,17] In beef cattle feedlot systems, cattle excrete fresh

manure (urine plus feces) onto the manure feedlot surface. After a period of time (120−365 days), machinery removes the dry manure from the feedlot into the manure stockpile area, where it is stored or composted prior to sale off-site or spreading as an organic fertilizer on agricultural land.[18,19] For beef feedlot manure management, only 1% of the excreted volatized solid (VS) and N is managed in sediment basins or retention ponds as liquid slurry; thus, the gas emissions from this liquid part are often not taken into account when considering the system-level gas emissions.[16,20]

Much work in the literature has evaluated gas emissions or mitigations targeted at one specific gas or one emission stage,[21−27] while little research has considered it in a comprehensive way. FAO conducted an LCA study on GHG emissions from beef meat production, though NH_3 emission was not considered in this study, and the study was not specified for beef cattle feedlot systems.[28] Watts et al.[19] reported emission factors of 75.0 kg NH_3 hd^{-1} $year^{-1}$, 3.16 kg N_2O hd^{-1} $year^{-1}$, and 0.84−1.69 kg CH_4 hd^{-1} $year^{-1}$ for the manure management chain of a beef cattle feedlot system in Australia, but enteric CH_4 emissions were not considered. In addition, neither of these two studies considered or evaluated gas mitigation for beef cattle production.[19,28] Considering the interactions between different gases and the mass flow causing linkage of gas emissions between the former and later stages,[29,30] evaluation of the impact of a combination of mitigation measures on simultaneous CH_4, N_2O, and NH_3 emissions is necessary, specifically for beef cattle feedlot systems.

The overall objective of this study was to make a quantitative assessment of GHG and NH_3 emissions from beef cattle feedlot production systems and the effects of (sets of) mitigation options on the CH_4, N_2O, and NH_3 emissions from the whole production chain using meta-analysis. A comprehensive data set was collated and developed for CH_4, N_2O, and NH_3 emission factors (EFs) for each stage of the feedlot production system, including enteric fermentation, manure on the feedlot, the manure composting or stockpiling stage, and the land application stage. This meta-analysis also quantified the efficiencies of 17 mitigation strategies, including 7 dietary manipulations, 5 management strategies for manure on the feedlot, 3 management strategies for manure composting and stockpiling, and 2 land application mitigation measures. System-level GHG and NH_3 emissions for the feedlot production system, with or without mitigation measures, were analyzed, and the most-effective designs for reduction of GHG and NH_3 emissions for the feedlot systems were recommended.

2.1. Data Sources and Selection Criteria. The ISI Web of Knowledge database (www.isiwebofknowledge.com) and the Chinese journal database (www.cnki.net) were used to search all published datasets as of December 2017. Specific search terms were combined and used, including animal categories (beef, cattle, bull, steer, bovine, heifer, and livestock), manure, manure management (feedlot, pad, yard, open-lot, pen, compost, and stockpile), land application (surface spread, and incorporation), gaseous emissions (NH_3, CH_4, N_2O, and GHG gas), and mitigation measures (diet, crude protein, additive, amendment, urease inhibitor, biofilter, biotrickling, cover, nitrification inhibitor, incorporation, reduction, mitigation, and abatement). Literature sources used in this study were selected on the basis of following criteria: (1) the research object was beef cattle; (2) the study included at least one of the CH_4, N_2O, and NH_3 gases; (3) gas emission flux or gas emission factor was available; and (4) for literature related to mitigation, only studies that reported at least one control group were selected, so that emission mitigation efficiency (ME) could be calculated.

Application of the selection criteria resulted in 104 peer-reviewed papers containing 528 effective observations from experimental studies, which were used in the meta-analysis. Data were collected from both published tables and text for all selected research articles as well as extracted from published figures using the GetData Graph Digitizer software (version 2.22).[31] In addition to the gaseous emission data, related information allowing the interpretation of the observations such as beef cattle number, cattle weight, emission flux, and other gas emission relevant information such as study location, seasons, and manure property parameters were recorded (see data set S1 and tabs for raw data). The locations and distributions of the data used in this study are summarized in Figure 1, which was created by using ArcGIS software (version 10.0).[32] It can be seen that most studies were distributed in North American, Oceania, Europe, and East Asia.

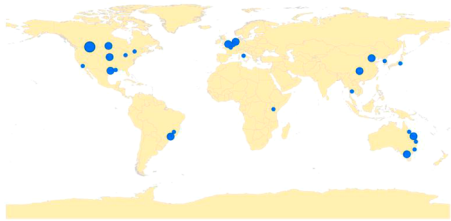

Figure 1. Location and distribution of the literature sources used in this study. Larger circles mean more literature was available in the specific region. (This figure was created using ArcGIS software.)

2.2. Data Analysis. *2.2.1. Calculation of Emission Factors in the Different Phases.* To perform statistical analysis, the various units of gas emissions from enteric fermentation and manure on the feedlot stage were converted into kg AU^{-1} $year^{-1}$ (1 AU [animal unit] being equal to one beef animal weighing 500 kg of live weight) using the calculation method presented in Table S1. The CH_4 EFs for manure management (compost and stockpile) were calculated as kg CH_4−C $(Mg\ DM)^{-1}$. The NH_3 and N_2O EFs for manure management (composting and stockpiling) and land application phases were calculated as the percentage of total nitrogen (TN), i.e., kg NH_3−N $(kg\ TN)^{-1}$ and kg N_2O−N $(kg\ TN)^{-1}$. When unit conversion was not possible due to lack of key information, the original emission data were excluded from the statistical analysis. The EFs for each phase of the feedlot production system, including the median, mean value, standard error and interquartile range (IQR), were calculated with SPSS software (version 20.0, SPSS, Inc., Chicago, IL). The results were not weighted according to sample size; therefore, all of the observations had equal impact on the results. Given the influence of a few measurements with very high values or very low values on the mean values, median values instead of means were used as the basis for subsequent calculations because median values are quite robust with regard to outliers.[33] The 95% confidence interval (95% CI) of the median was calculated using eq 1:

DOI: 10.1021/acs.est.8b02475
Environ. Sci. Technol. 2018, 52, 11232−11242

$$95\%\ \mathrm{CI} = 1.58 \times \frac{IQR}{\sqrt{N}} \quad (1)$$

where N represent the number of observations for each emission factor.

2.2.2. Calculation of the Mitigation Efficiency of Each Measure. The efficiencies of individual mitigation measures for the corresponding phases were assessed by comparing the results of control and treatment groups using the following formula:

$$E_m = \left(\frac{ER_{trt}}{ER_{ctrl}} - 1\right) \times 100\% \quad (2)$$

where E_m is ME, ER_{trt} is the gas emissions in the experimental group with mitigation measures, and ER_{ctrl} is the gas emissions in the control group without mitigation measures. Thus, a negative or positive E_m value indicates that the selected measure can reduce or increase gas emissions, respectively. The median E_m values for each measure were calculated using an analytical approach adapted from Benayas et al.[34] and Tuomisto et al.[35] The normality of the data was tested using the Kolmogorov–Smirnov test. Not all of the E_m values for each mitigation measure were normally distributed; therefore, the Wilcoxon Signed-Rank test was used to determine if the median E_m values were significantly different from 0 when there were sufficient results for specific measures. SPSS 20.0 software was used for the statistical analyses.

2.2.3. Design of an Integrated Feedlot Production System and Calculation of System-Level GHG and NH_3 Emissions. Design of an Integrated Feedlot Production System. Usually, for the beef cattle feedlot system, breeds such as Angus cross-bred steers and Simmentals with entry weights typically ranging from 250 to 450 kg and exit weights ranging from 400 to 700 kg depending on market type were fattened on the feedlot.[19,36] The baseline scenario was designed based on the typical management manner of beef cattle feedlot systems, including enteric fermentation, manure deposited on the feedlot, manure composting, and land application by surface spreading (Figure 2). The integrated mitigation scenarios were set with individual mitigation options included into the corresponding phases of the feedlot production system (Figure 2), and these scenarios are displayed in Table S2.

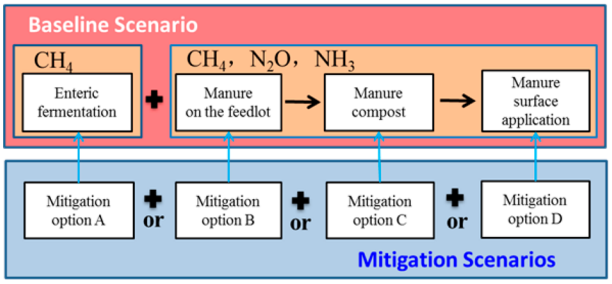

Figure 2. Block diagram of system gas emissions for the baseline scenario (red box) and the mitigation scenario (blue box) through the operation unit (black boxes).

Calculation of GHG and NH_3 Emissions for the Baseline and Mitigation Scenarios. The system GHG and NH_3 emissions for the baseline scenario of a beef-cattle feedlot system were calculated based on the summation method for CH_4 and mass flow for NH_3 and N_2O. The indirect N_2O emissions arising from N deposition and N leaching or runoff were also considered. The detailed calculation process is presented in section 1 of the Supporting Information.

The system gas emissions under mitigation scenarios for the feedlot production system were the sum of the emissions from each phase and were based on the numerous calculation schemes described in section 2 of the Supporting Information. The calculations are presented in data set S1 (see the "Feedlot system" tab).

2.2.4. Uncertainty Analysis. Monte Carlo simulations (10 000 runs) with R (version 3.3.1) were applied to estimate the uncertainty of the system-level emissions. The calculated median values of the gas emission factors and mitigation efficiency factors, as well as their 95% confidence intervals (CI), were included in the uncertainty analysis. The probability density functions (PDF) were assumed as normal distributions for each input data.[30]

3. RESULTS AND DISCUSSION

3.1. Gaseous Emission Factors for Each Phase of the Beef Cattle Feedlot System. *3.1.1. Enteric CH_4 Emissions.* A total of 100 observations of enteric CH_4 emissions were collected to analyze the beef cattle enteric CH_4 EFs, with 52 monitored using a sulfur hexafluoride (SF_6) tracer method and 48 monitored using a respiration chamber method. The world over median CH_4 EF for enteric fermentation is 67.2 kg AU^{-1} $year^{-1}$, with a 95% CI value of 62.0–72.4 kg AU^{-1} $year^{-1}$ (Table 1). The CH_4 EF varies with region, and North America and Western Europe showed higher enteric CH_4 EF values, while Latin America showed the lowest EF values (Figure 3), which may arise from differences of feed or the herd breed. For example, McGinn et al.[37] reported that the measured enteric CH_4 EF from Australia feedlot cattle is 22% lower than that from Canada feedlot cattle, and the difference was attributed to the lighter weight of the Australia cattle (and, consequently, their lower intake) and supplementation of their diet with lipids. It can be seen that the meta-analysis results for Asia are comparable with the Intergovernmental Panel on Climate Change (IPCC) recommended values, while for North America, Western Europe, Oceania, and Latin America, the discrepancy may arise from newly collected data from recent years (68 of 100 data were sourced from publication years after 2006), which may have been triggered by breed evolution or feed stuff improvement. For example, bulls having a lower residual feed intake (RFI) would be more feed efficient and would have a lower daily rate of CH_4 production, while RFI has been shown to be moderately heritable.[38] Australian cattle can now be commercially tested for RFI, and the estimated breeding values (EBVs) of bulls are used in sire selection,[39] thus causing the lower CH_4 EF in this region. This meta-analysis result could be used to support the refinement of the IPCC guidelines.

3.1.2. Gas Emissions from Manure on the Feedlot. CH_4 Emissions. The CH_4 emission rates from manure on the feedlot were measured using chamber methods, with an EF of 0.23 kg AU^{-1} $year^{-1}$ (95% CI, 0–0.83 kg AU^{-1} $year^{-1}$; Table 1), which is at the lowest level of IPCC recommended values of 0–31 kg CH_4 hd^{-1} $year^{-1}$.[9] The reason for the low manure CH_4 EF is that manure on the feedlot is dry based, with 99% of the organic matter being dry managed.[16,20]

NH_3 Emissions. The NH_3 EF from manure on the feedlot was 39.65 (95% CI, 34.18–45.12) kg AU^{-1} $year^{-1}$, which is higher than 8.52 (95% CI, 2.83–14.21) kg AU^{-1} $year^{-1}$ for

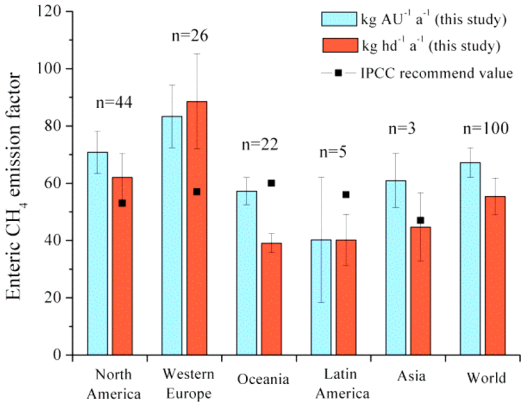

Figure 3. Regional enteric CH_4 emission factors of beef cattle expressed in terms of per AU or per herd (median ±95% CI); *n* = number of observations; squares indicate the IPCC recommended values.

beef cattle feeding and loafing yards in the United Kingdom[40,41] and 3.5 kg AU^{-1} $year^{-1}$ for a beef cattle bedding system.[42] The high NH_3 EF from manure on the feedlot occurred because it is managed under an open air environment. For beef cattle feeding and loafing yards, the floor would commonly be scraped once a week, thus not accumulating much manure[16,40] and leading to low NH_3 and N_2O emissions. For bedding systems, the bedding material can absorb part of the urine, and the occurrence of nitrification and denitrification microbes on the bedding material can also lead to the NH_3 being converted to N_2O, thus leading to the lowest NH_3 EF.[42]

N_2O Emissions. The median N_2O EF from beef cattle manure on the feedlot was 1.96 kg AU^{-1} $year^{-1}$, with the 95% CI being of 0−13.37 kg AU^{-1} $year^{-1}$ (Table 1). The EFs monitored with dynamic chamber or static chamber methods are usually lower than 1 kg AU^{-1} $year^{-1}$,[23−26,43] but the N_2O EFs appeared to be high at 12−42 kg AU^{-1} $year^{-1}$ when obtained with the wind tunnel method.[44,45] The air flow rate used in the two wind tunnels by Rahman et al.[44] and Borhan et al.[45] was high compared to the normally used wind tunnel flow rate for measuring N_2O emissions from the soil surface (1.75 versus 0.29 m^3 s^{-1}).[46,47] Moreover, the surface condition of the feedlot also influenced N_2O emissions. Surface conditions that are moist and muddy are localized microsites with physical and chemical conditions favoring intense microbial activity, thus presenting a median N_2O emission flux that was over 20 times greater and significantly higher than those for the other surface conditions, such as dry and loose conditions and flooded conditions.[48]

3.1.3. Manure Composting or Stockpiling Phase. CH_4 EFs. The CH_4 EFs from composting and stockpiling were 6.16 (95% CI, 4.40−7.92) and 6.31 (95% CI, 3.56−9.06) kg CH_4−C (Mg DM)$^{-1}$, respectively (Table 1). Stockpiling showed a relatively higher median value of CH_4 EF than composting, also with a higher variation than that of composting. The maximum CH_4 EF observed for stockpiling even reached 41.99 kg CH_4−C (Mg DM)$^{-1}$, which is much higher than that of 15.36 kg CH_4−C (Mg DM)$^{-1}$ for composting. Because the composting process usually resulted in an aerobic process, neither aeration nor pile turning happened during the manure stockpiling process; thus, the anaerobic environment caused high CH_4 emission during stockpiling.

N_2O EFs. The N_2O EFs of composting and stockpiling were 0.0062 (95% CI, 0−0.2744) and 0.0056 (95% CI, 0.0016−

DOI: 10.1021/acs.est.8b02475

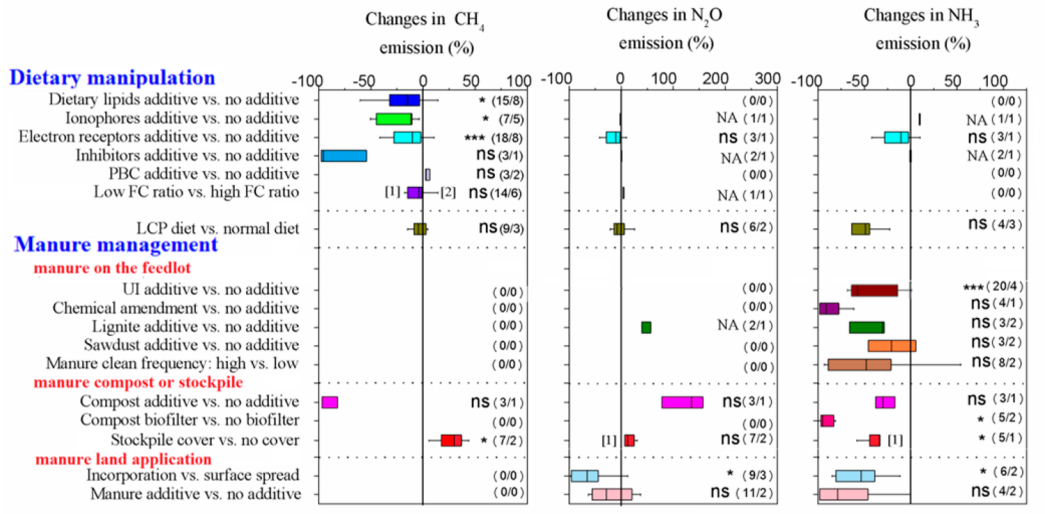

Figure 4. Box-and-whisker plots of the efficiencies of mitigation strategies for CH_4, N_2O, and NH_3 emissions (see Tables S6–S8 for numeric data). Vertical lines of the boxplot represent the median, upper, and lower quartiles. The whiskers show values that extend to 1.5 orders of the box length. The numbers in the square brackets represent the number of outliers (>1.5 orders of the box length). Values in parentheses indicate the number of observations for the statistical analysis and the number of studies from which the observations originated. Wilcoxon Signed Rank test: triple asterisks indicate $P < 0.001$, double asterisks indicate $P < 0.01$, and a single asterisk indicate $P < 0.05$; ns, not significantly different from zero; NA, not applicable. PBC, plant bioactive compounds; FC ratio, forage-to-concentrate ratio; LCP, low crude protein; and UI, urease inhibitor.

0.0096) kg N_2O–N (kg TN)$^{-1}$, respectively (Table 1). The 95% CI of composting was obviously higher than that of stockpiling, and the collected EF of composting was in the range of 0.0002–0.0202 kg N_2O–N (kg TN)$^{-1}$, indicating that the N_2O EFs for composting vary significantly under different conditions. Our collected N_2O EF data for beef cattle manure compost was lower than the IPCC recommended value of 0.006–0.1 kg N_2O–N (kg TN)$^{-1}$.[9] IPCC value was generally recommended for all kinds of animal manure, thus leading the exhibited higher range, and our results can be supplemented for the specific use of beef cattle manure compost. For solid stockpiling, the IPCC recommended an EF of 0.005 kg N_2O–N (kg TN)$^{-1}$,[9] which is comparable with the meta-analyzed results of this study.

NH_3 EFs. The NH_3 EF from beef cattle manure composting was obviously higher than that of stockpiling at 0.2340 (95% CI, 0.0716–0.3964) and 0.0054 (95% CI, 0.0004–0.0104) kg NH_3–N (kg TN)$^{-1}$, respectively (Table 1). The NH_3 EF of the composting process ranged from 0.060–0.416 kg NH_3–N (kg TN)$^{-1}$, and that of the stockpiling process ranged from 0.001–0.045 kg NH_3–N (kg TN)$^{-1}$. The ventilation process with aerobic composting leads to high NH_3 emissions during the composting process, which also leads to the high nutrient loss of composting.

3.1.4. Manure Land Application. For upland cropping systems, CH_4 emissions are low, and the cropping system is usually seen as a sink for CH_4.[49] As such, CH_4 emissions and mitigation during manure upland application are not considered in the following system-level emission calculations.

N_2O EFs. The N_2O EFs for the surface spreading and incorporation of beef cattle manure were 0.0023 (95% CI, 0.0015–0.0031) and 0.0006 (95% CI, 0.0004–0.0008) kg N_2O–N (kg TN)$^{-1}$, respectively (Table 1). For N_2O, EF varies greatly within one specific land application method. For instance, the N_2O EF values for incorporation ranged from 0.0001–0.0009 kg N_2O–N (kg TN)$^{-1}$ in the study by Chiyoka et al.,[50] while they are 0.0185–0.0331 kg N_2O–N (kg TN)$^{-1}$ in the study by Chang et al.[51] The complex N_2O production processes and the variable manure and soil properties in each study lead to the variability among N_2O emission results.[52] Moreover, the comparison revealed that the N_2O EF of surface spreading was significantly higher than that of incorporation ($p < 0.05$) because their 95% CIs did not overlap. Webb et al.[53] suggested that some stored farmyard manure (FYM) emitted N_2O at the time of spreading on the soil surface; however, if FYM is buried through ploughing, the increased length of the diffusion pathway through the soil matrix may lead to the reduction of N_2O emissions.

NH_3 EFs. Surface spreading showed the largest NH_3 EF of 0.1042 (95% CI, 0.0561–0.1523) kg NH_3–N kg (TN)$^{-1}$, while the EF was 0.0543 (95% CI, 0.0113–0.0973) kg NH_3–N kg (TN)$^{-1}$ for manure incorporation (Table 1). The NH_3 EF of beef cattle manure surface application seems low compared with that of other manure, with higher EF values in the range of 0.195–0.363 kg NH_3–N kg (TN)$^{-1}$ and 0.129–0.345 kg NH_3–N kg (TN)$^{-1}$ having been observed for poultry manure and pig manure surface application, respectively.[54−56] Beef cattle manure had been stored on the feedlot for a long time, leading to much of the easily decomposed N being lost during this phase and causing the low NH_3 emission during the final land application process. In addition, the low original N content of the freshly excreted beef cattle manure would also be a reason for the low NH_3 emission. Li[57] reported that the TN content of fresh swine manure was 154% higher than that of fresh beef cattle manure, being 8.94 g kg wet basis^{-1} (WB) and 3.52 g kg WB^{-1}, respectively.

3.2. Mitigation Measures. Various mitigation practices have been developed for reducing GHG and NH_3 emissions for the beef cattle production. The changes in CH_4, N_2O, and NH_3 emissions under different mitigation practices at each phase are presented in Figure 4.

3.2.1. Dietary Manipulation. Feed Additive. For ruminant production, feed additives are used to reduce enteric fermentation for reducing CH_4 emissions. Common feed additives include dietary lipids, ionophores, electron receptors, inhibitors, plant bioactive compounds (PBC), etc.[58] There

DOI: 10.1021/acs.est.8b02475
Environ. Sci. Technol. 2018, 52, 11232–11242

were 21 publications found related to feed additives, among which 9 were related to dietary lipid additives, including coconut oil, crude glycerin supplements, sunflower oil, etc., and the ME for dietary lipid additives was −14.9% ($p < 0.05$; Figure 4). The most commonly used ionophore is monensin, and it showed a strong anti-methanogenic effect, leading to the ME being −11.5% ($p < 0.05$). However, ionophores are banned in the European Union and are therefore not applicable everywhere.[58] In the electron receptor category, nitrate, fumaric, and malic acids have been studied most, with the median mitigation effect being −15.2% ($p < 0.001$). Inhibitors such as bromochloromethane additives were quite effective in reducing enteric CH_4 emissions, with CH_4 reductions of −97.8%∼−54.3% in the study by Tomkins et al.[59] However, in the case of electron receptors and the inhibitors, the environmental and animal health implications are questionable.[59,60] The CH_4 mitigating effect of PBC in vivo remains controversial, and it was calculated that the PBC additives such as saponin and essential oil caused an increase of 2.8% on beef cattle CH_4 emission ($p = 0.109$). The CH_4 mitigation effect could be related to differences in feed retention times within the rumen as influenced by the level of saponin intake and composition of basal diet or in the quality of the PBC among experiments.[61] Thus, considering the mitigation effect along with the safety of each feed additive, dietary lipids were still the most recommended additive for enteric CH_4 mitigation. In addition, considering the potential negative effect of dietary lipids on feed intake, fiber digestibility, and overall animal productivity, the maximum recommended inclusion rate of dietary lipids in ruminant diets is 6% to 7% (total fat) of the dietary DM.[58]

Feed additives are mainly used for CH_4 mitigation from enteric fermentation, while little research has been performed related to N_2O and NH_3 mitigation with feed additives. Lee et al.[62] found no obvious effect on N_2O and NH_3 emissions from manure when the diet was amended with 1%, 2%, and 3% encapsulated calcium ammonium nitrate. Also, some additives such as ionophores may alter microbes in the rumen, which may lead to changes in volatile organic compound (VOC), such as ethanol (EtOH) and methanol (MeOH).[63] Because VOC can interact with nitrogen oxides (NOx) to form ozone (smog), which may impair human health and well being as well as the regional and global environment, it should also be considered in the future study.

Reducing the Forage-to-Concentrate Ratio. Reducing the FC ratio can lower CH_4 emission by −3.8% ($p = 0.221$). The reduced CH_4 output arising from the reduced FC ratio is due to a shift in ruminal fermentation patterns from acetate to propionate[64] and a decline in the ruminal pH.[65] When cattle were fed diets containing 90% or more concentrates, cattle CH_4 conversion factors (Ym) can be reduced by 50% compared with that from forage based diets.[9] However, compared to forage offered to cattle, concentrate was preferentially consumed due to its palatability, which would consequently contribute to more feed intake[66] and may, however, increase the enteric fermentation CH_4 emission, thus causing CH_4 mitigation efficiency from a low FC ratio to be low. The effect of low FC ratio on N_2O and NH_3 emissions was not appreciable.

Low Crude Protein Diet. The effect of a low crude protein (LCP) diet on CH_4 was not appreciable. However, a LCP diet is highly beneficial because it limits N at the source, resulting in a lower N content in the excreta (−12.8%, $p < 0.01$, Table S9) and, thus, may reduce N-related gaseous emissions during subsequent manure management phases. The effect of LCP on N_2O emission was not obvious, being of −3.5% ($p = 0.753$, Figure 4). However, it delivers an obvious mitigation potential for NH_3 emissions during the manure on the feedlot phase, being of −46.5% ($p = 0.068$). The only four observations collected for NH_3 mitigation caused the result to be not significant. LCP also provides other environmental co-benefits, such as reduced N losses in runoff and eutrophication.

3.2.2. Mitigation Measures for Manure on the Feedlot. No research was available on CH_4 mitigation from manure on the feedlot, and only one publication was available that considered both N_2O and NH_3 mitigation from manure on the feedlot.[26] Most studies about gas mitigation from beef cattle manure on the feedlot focus on the only subject of NH_3, mainly through the use of additives or increasing the manure clean frequency.

Manure Additives on the Feedlot. The commonly used additives for manure on the feedlot include urease inhibitors (UI), chemical amendments, lignite, and sawdust. The NH_3 mitigation mechanism for each additive varies. Urease inhibitors can block the hydrolysis of urea to ammonium[67] and, thereby, decrease NH_3 production. A total of 20 observations among the 34 observations collected in this study were about UI additives, and the median NH_3 ME of UI was −59.5% ($p < 0.001$). Considering that the inhibitor effect of the UI would be lower in soil conditions of high moisture, a high amount of UI should be applied when in high moisture conditions.[68,69] Chemical amendments such as alum ($Al_2(SO_4)_3$) and calcium chloride ($CaCl_2$) reduce NH_3 emissions by decreasing the pH and increasing the function of H^+ through cation exchange,[70] and the median NH_3 ME of chemical amendment was −85.0% ($p = 0.068$). For chemical amendment, only four observations were available for its specific use on beef cattle manure, resulting in an insignificant outcome ($p = 0.068$). The NH_3 mitigation mechanism of lignite is similar to that of chemical amendments. Lignite is acidic in nature (pH 3.69) and has a high cation exchange capacity.[71] In addition, lignite contains up to 20% labile carbon, which can absorb NH_4^+, and the high humic acid content can suppress urea hydrolysis.[71] The median NH_3 ME of lignite was −30.0%; because only three observations were available for its specific use on beef cattle manure, it resulted in an insignificant outcome ($p = 0.18$). Sun et al.[26] reported that N_2O emission increased from 0.10−0.14 to 0.14−0.22 g N_2O−N $head^{-1}$ day^{-1} with lignite additives for manure on the feedlot. However, considering the overall GHG emissions, the increase in direct N_2O emissions can be counteracted by the lower indirect N_2O emission due to decreased NH_3 volatilization (NH_3 emission decreased from 38.6−61.3 to 27.6−42.7 g NH_3−N $head^{-1}$ day^{-1}); thus, the lignite additive was effective in reducing the total GHG emission. Sawdust additive can widen the C-to-N ratio of the manure, showing a tendency to retain more nitrogen.[72] With the collected three observations, it was calculated that the sawdust additive can reduce NH_3 emission by 21% ($p = 0.285$). Among all of the additives, chemical amendment showed the highest NH_3 mitigation effect; however, the benefit-to-cost ratio was about a factor of 10 lower than that of UI.[70]

Increasing the Clean Frequency. No research monitored the effect of clean frequency on CH_4 and N_2O emissions. Only one study by Wilson et al.[73] reported that increasing the manure removal frequency (such as once a month, compared to the common frequency of once at the end of the feeding

DOI: 10.1021/acs.est.8b02475
Environ. Sci. Technol. 2018, 52, 11232−11242

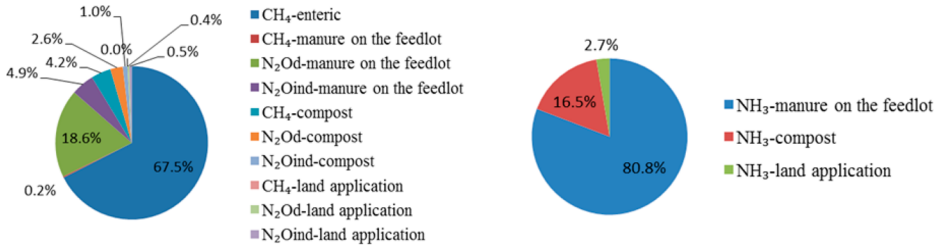

Figure 5. GHG and NH_3 emissions from the beef-cattle feedlot system by category of emissions.

period) can reduce NH_3 emissions by 19.1−20.8%. In addition, manure removal is also suggested to be used along with manure additives. For example, the effects of lignite will decline when the acidity is neutralized and the cation exchange capacity reduced through the accumulation of manure on the feedlot. Thus, after routine manure removal from pens, lignite needs to be reapplied to optimize the reduction of NH_3 emissions.[71]

3.2.3. Mitigation Measures for Manure Composting and Stockpiling. Compost Additives. There are only two papers that studied the impact of compost additives on gas emissions from beef cattle manure, with one study specified for CH_4 and N_2O[27] and the other for NH_3.[74] The results showed that additives can be effective in both CH_4 and NH_3 mitigation, with ME values of −97.0% (p = 0.102) and −30.0% (p = 0.109),[27,74] but it may increase N_2O emission by 135.0% (p = 0.109).[27] This is further explained by the phosphogypsum additive reducing N loss via NH_3 mitigation, while more N was retained in the form of NH_4^+-N in compost, which could thus serve as substrate for the nitrification and denitrification process, causing the increase of N_2O.[27]

Compost Biofilter. No research is available for the effect of biofilter on compost CH_4 and N_2O emissions specifically for beef cattle manure. The NH_3 emissions from compost can be reduced by 80.5−99.9% with compost biofilter,[75,76] with a median ME of 95% (p < 0.05). Because biofilters can only be used when the discharged air is being collected, and the manure from feedlot systems is usually being composted in an open air, this method is not considered in our system-level mitigation design.

Stockpile Covering. For beef manure stockpiling, CH_4 and N_2O emissions can be increased by 29.8% (p < 0.05) and 13.0% (p = 0.128) with straw or sawdust coverings, respectively; however, NH_3 emission could be reduced by 33.0% (p < 0.05). Covering caused an anaerobic environment in the pile, thus leading to higher CH_4 emission. Meanwhile, simultaneous aerobic and anaerobic conditions formed at the surface of pile under the cover, and the carbon input sourcing from the straw and sawdust stimulating the nitrification and denitrification process in the pile both triggered the increased N_2O emissions. However, one of the total seven observations collected by Zhu et al.[77] indicated that the N_2O emission may be reduced, with the reason being unclear, causing the result to be insignificant (p = 0.128).

3.2.4. Mitigation Measures for Land Application. Among the different manure application methods, manure incorporation can decrease N_2O and NH_3 emission simultaneously in comparison to surface application in some conditions. Incorporation can decrease N_2O emission by 65.0% (p < 0.05) in comparison to manure surface application, and it showed a significant NH_3 mitigation effect of 64.8% (p < 0.05). As indicated earlier in section 3.1.4, heavily textured soil inhibition of the N_2O diffusion pathway was caused by incorporation, thus decreasing N_2O emission. Combined with the advantage of nutrient conservation and odor reduction, beef cattle manure incorporation can be a highly recommended alternative application method.

Manure additives such as biochar and nitrification inhibitors resulted an integrated N_2O mitigation efficiency of −28.0% (p = 0.100). The biochar additions cannot always keep the N_2O emissions being reduced, causing the integrated N_2O mitigation effect to be not significant.[78] Manure additives such as lava meal can reduce NH_3 emission by 62.5% (p = 0.068). The adsorption of NH_4^+ by the lava meal, and also the precipitation of NH_4^+-N into struvite due to the presence of some P and especially Mg salts in the lava meal, cause the NH_3 emission being reduced.[79] However, only four observations was collected for the additives effect on NH_3, causing the result to be not significant.

3.2.5. Other Mitigation Options. When the collected manure was used for anaerobic fermentation, biogas recovery and utilization can exhibit a high GHG mitigation potential. However, CH_4 leakage from biogas digester, and the CH_4, N_2O, and NH_3 emissions from the digested slurry storage and land application stages should all be considered when calculating the mitigation effect. Unfortunately, no literature with a direct comparison of biogas digesters versus the baseline scenario for beef cattle manure was identified. Therefore, we could not give quantitative data on the mitigation efficiency of biogas digester.

3.3. Gas Emissions from the Baseline Scenario of a Beef Cattle Feedlot Production System. *3.3.1. GHG Emission.* The GHG emission from a baseline scenario of beef cattle feedlot production system is 2786 ± 108 kg CO_2-eq AU^{-1} $year^{-1}$. Among the gases, CH_4 contributed most of the GHG emissions, accounting for 72.0% of the total GHG emissions. The enteric CH_4 emission was 1882 ± 3 kg CO_2-eq kg AU^{-1} $year^{-1}$, accounting for 67.5% of the total GHG emissions (Figure 5). The GHG emission arising from manure management is 904 ± 127 kg CO_2-eq kg AU^{-1} $year^{-1}$. Among the manure on the feedlot stage, the manure composting stage, and the land application stage account for 23.8%, 7.8%, and 0.9% of the overall GHG emissions, respectively. The GHG mitigation priority should be focused on the enteric CH_4 emissions and manure N_2O emissions on the feedlot.

The N_2O emissions for manure on the feedlot stage, compost stage, and land application stage are 1.96, 0.28, and 0.04 kg N_2O AU^{-1} $year^{-1}$, respectively, which totaled 2.28 kg N_2O AU^{-1} $year^{-1}$. The calculated N_2O emission from Watts et al.[19] was 2.20, 0.69, and 0.28 kg N_2O AU^{-1} $year^{-1}$, respectively, for each stage of manure management and totaled to 3.17 kg N_2O AU^{-1} $year^{-1}$. The higher N_2O emissions from Watts' study may have arisen from the higher N excreta data used (75.2 kg $herd^{-1}$ $year^{-1}$), which was higher than the ASAE

DOI: 10.1021/acs.est.8b02475
Environ. Sci. Technol. 2018, 52, 11232−11242

(2005) recommended value of 62.05 kg N AU^{-1} $year^{-1}$ used in this study.[80]

3.3.2. NH_3 Emission. The total NH_3 emissions from a beef cattle feedlot system is 49.1 ± 1.5 kg NH_3 AU^{-1} $year^{-1}$. The manure on the feedlot stage was the leading sector, accounting for 80.8% of the total NH_3 emissions, while the manure composting and land application stages accounted for 16.5% and 2.7%, respectively (Figure 5). Nearly 60% of the total N excreta was lost from manure on the feedlot, and only 9−19% of the excreted N was transferred to the next stage.[81] Watts et al.[19] estimated that 85%, 9%, and 6% of the total NH_3 emissions were from the manure on the feedlot stage, stockpiling stage and land application stage, respectively, which is similar to the results of this study. The lower percentage of 9% for the manure stockpiling stage in Watts's study was lower than the 16.5% found in our study, which may have been caused by the lower NH_3 emissions from stockpiling compared to composting.

3.4. Gas Emissions of Beef Cattle Feedlot Production Systems under Mitigation Scenarios. Considering the major emission sources, efficiency and operability of mitigation options, 11 mitigation scenarios were designed for beef-cattle feedlot production systems. The GHG and NH_3 emissions from the scenarios are presented in Figure 6.

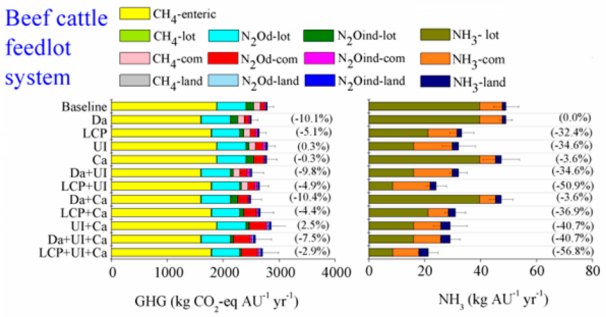

Figure 6. GHG and NH_3 emissions of baseline scenarios and mitigation scenarios for beef cattle feedlot production systems, with the baseline scenarios defined in Figure 2. The numbers in parentheses indicate the mitigation efficiency. N_2Od, direct N_2O emission; N_2Oind, indirect N_2O emission; lot, manure on the feedlot; com, compost; land, land application; LCP, low crude protein, Da, diet lipid addition; UI, UI additive for manure on the lot; Ca, compost additive; and AU, animal unit (1 AU = 500 kg).

The system-level GHG mitigation efficiencies of all mitigation scenarios were less than 11% (Figure 6). Of all of the mitigation strategies, dietary additives (Da) showed a high GHG mitigation potential for the whole system, with GHG emissions of 2505 ± 113 kg CO_2-eq AU^{-1} $year^{-1}$ for the solo use of Da, a 10.1% reduction from the baseline.

For system-level NH_3 mitigation, the most effective mitigation design was the combination of a LCP diet, a UI additive for manure on the feedlot, and compost additive (LCP plus UI plus Ca). The NH_3 emission was 21.2 ± 3.5 kg NH_3 AU^{-1} $year^{-1}$, with an efficiency of −56.8% compared with the baseline emissions. The single use of UI additive for manure on the feedlot or a LCP diet could reduce the overall system NH_3 emissions by 34.6% and 32.4%, respectively (Figure 6). The combination of LCP and UI lead to the system NH_3 emission being 24.1 ± 3.7 kg NH_3 AU^{-1} $year^{-1}$ (−50.9%), which was similar to the most effective NH_3 mitigation design of LCP plus UI plus Ca. This result also reveals that controlling the NH_3 emissions from the manure on the feedlot stage is fundamental for system-level NH_3 mitigation.

Considering the mitigation effect of each mitigation scenario, as well as the economy and simplicity of each option, the most recommended mitigation scenario is the combination of LCP and UI (LCP plus UI). The GHG and NH_3 emissions under the LCP plus UI scenario were 2648 ± 162 kg CO_2-eq AU^{-1} $year^{-1}$ (−4.9%) and 24.1 ± 3.7 kg NH_3 AU^{-1} $year^{-1}$ (−50.9%), respectively.

3.5. Implications of Results. This study provides the first insights into the simultaneous evaluation of GHG and NH_3 emissions and mitigations for beef cattle feedlot management systems, based on the database of the EFs and MEs for CH_4, N_2O, and NH_3 during each stage of the beef cattle feedlot production system. Both EFs and MEs were valuable for evaluating the gas emissions and identifying abundant mitigation options. These EFs could be applied to support the revision or refinement of the IPCC default EFs. However, the application of EFs or recommended mitigation strategies should take into account local circumstances, including climate, weather, and soil properties in different locations. In addition, the economic feasibility for the mitigation measures should also be further considered.

Scenario analysis for the beef cattle feedlot system implies that NH_3 emissions could be reduced by 30%−50% and that the highest system-level GHG emissions mitigation potential was only 10.1%. With the increasing demand for beef production and to decrease GHG emissions after the Paris Agreement, low emission beef cattle production systems are urgently needed. The results of our analysis have important implications for developing sustainable beef cattle feedlot systems from the viewpoint of GHG and NH_3 mitigation.

REINING IN ANIMAL AGRICULTURE'S EMISSIONS BY SHRINKING THE HERD: EARLY SIGNS OF A NECESSARY GLOBAL POLICY SHIFT

BY
DAINA BRAY*

We will be unable to achieve the temperature goals of the Paris Agreement without radically reforming our food systems. Despite animal agriculture's significant responsibility for climate change—emitting the majority of agricultural greenhouse gases (GHGs), likely 15% or more of all human-caused GHGs, around a third of anthropogenic methane and more than half of nitrous oxide (two climate super-pollutants)—policymakers have so far largely failed to rein in its emissions. In recent years, international bodies including the Intergovernmental Panel on Climate Change, U.N. Environment Programme, World Health Organization, and World Bank have begun to explicitly make the connection between animal agriculture's outsized emissions and the need to reduce consumption of animal products, especially in high-income, high-consuming countries. While national-level policy in the United States has not yet embraced these recommendations, policymakers in other countries—led by Europe—are experimenting with policies that would change diets and ultimately "shrink the herd," i.e., reduce the number of animals raised for food. Recent farmer protests and

*Clinical Lecturer and Senior Research Scholar in Law, Yale Law School. The author is grateful to Professor Douglas Kysar, Viveca Morris, and Caroline Zhang of the Law, Environment & Animals Program at Yale Law School for their guidance and contributions, to Cleo Verkuijl of the Stockholm Environment Institute and Thomas Poston, Yale Law School graduate, for their review and input, and to Nargis Aslami, Yale Law School graduate, for her research assistance. These contributions are greatly appreciated.

weakening of policy proposals in Europe illustrate the political realities of seeking reform in this area. But sooner government action would enable better outcomes, before the climate crisis forces changes to food systems. Developing effective and lasting policy on climate and animal agriculture will require consensus building, incremental approaches, attention to international equity, and a commitment to a just transition.

I. INTRODUCTION

> Say the order of your time feels unjust and unsustainable and yet massively entrenched, but also falling apart before your eyes.
>
> ~Kim Stanley Robinson,
> *The Ministry for the Future*[1]

> [A]s the world keeps warming, it will become clear that political leaders' climate pledges require that we phase down all sorts of polluting machines: not just the metal ones that burn fossil fuels but also the ones that have brains, and hearts, and use up three-quarters of the world's agricultural land, and overheat the planet.

[1] KIM STANLEY ROBINSON, THE MINISTRY FOR THE FUTURE 124 (2020) (including a cover inscription by writer Jonathan Lethem describing it as "[t]he best science fiction nonfiction novel I've ever read").

~Noah Gordon,
Carnegie Endowment for
International Peace[2]

Despite the immense scale of greenhouse gas (GHG) emissions from the U.S. animal agriculture sector,[3] the federal government remains largely unwilling to espouse reductions to meat and dairy consumption as part of its climate mitigation strategy. Indeed, after a British tabloid article falsely implied that President Biden was planning to limit meat consumption in order to meet emissions targets and Republican politicians began spreading the story (some even calling him "The Hamburglar"), a Biden spokesperson was quick to post a reassuring photo of Biden smiling while grilling steaks.[4]

U.S. Agriculture Secretary Tom Vilsack, a former dairy lobbyist,[5] has downplayed the growing momentum—led by some other national governments and in the international arena[6]—around elevating plant-based foods to help the climate. Despite the unprecedented focus on food systems and dietary change at the Conference of the Parties to the U.N. Framework Convention on Climate Change in Dubai (COP28),[7] when asked about reducing meat consumption as part of climate mitigation, Secretary Vilsack replied: "I don't hear much about that."[8]

[8] Marcia Brown & Meredith Lee Hill, *Tom Vilsack at COP28*, POLITICO (Dec. 11, 2023, 10:00 AM), https://www.politico.com/newsletters/weekly-agriculture/2023/12/11/tom-vilsack-at-cop28-00131018. More than 250 advocacy groups and experts sent Secretary Vilsack a letter in response, noting the prominent discussions of meat and dairy reduction at COP28 and arguing that the United States must incorporate meat and dairy reduction into its climate strategies. Letter from Ctr. for Biological Diversity et al. to Thomas J. Vilsack, U.S. Sec'y of Agric. 2 (Jan. 11, 2024), https://www.biologicaldiversity.org/programs/population_and_sustainability/pdfs/usda_sec_vilsack_letter.pdf.

Other U.S. lawmakers did not share his insouciance. Commenting on ongoing food system discussions at COP28, U.S. Senator Chuck Grassley of Iowa asserted that the talks were "targeting farmers" and that "[t]hey're really after the livestock business."[9] Representative Mike Flood of Nebraska went so far as to propose that the U.S. House of Representatives adopt a resolution to express disapproval of the recommendations shared by the U.N. Food & Agriculture Organization (FAO) at COP28[10] and "oppose[] the use of any Federal resources to support attempts to reduce meat consumption."[11]

The reactionary posture of many U.S. lawmakers when it comes to the animal agriculture industry has been a frustration for decades for those who seek to address its numerous and significant externalized harms to people, animals, and the environment.[12] But changemakers may take inspiration from a nascent wave of policies around the world that would have the concomitant impact of reducing both GHG emissions and animal numbers. Such policies may address supply (e.g., by buying out farmers) or demand (e.g., by shifting dietary guidelines and procurement policies), and they may combine various approaches. This Article focuses on policies that would ultimately result in a reduction of the total number of animals (rather than technological approaches[13]) because policies that "shrink the herd" are the only ones that guarantee a reduction in emissions while at the same time reducing the other harmful externalities of industrial animal agriculture.

These are not new ideas.[14] What is new is the acceleration of policy proposals and activity over the last half decade. This Article aims to collect progress and challenges for policymakers and advocates who would look to learn from leading examples—and who may also be inspired by the degree of activity in a policy area that can sometimes seem intractable. Part II provides background on animal agriculture's role in the climate crisis, followed by an overview of global momentum and international signaling in Part III. Part IV describes examples of climate animal agriculture policies around the world. Recent farmer

protests in the Netherlands are described in Part V as an example of political headwinds, followed by a gathering of lessons in Part VI.

II. BACKGROUND: ANIMAL AGRICULTURE AND CLIMATE

Last year was the hottest year on record,[15] shattering prior temperatures and causing scientists to use words like "mind-boggling," "staggering," and "absolutely gobsmackingly bananas."[16] The summer of 2024 was the warmest on record,[17] and this year is "virtually certain" to be the warmest year on record, exceeding even the unprecedented temperatures of 2023.[18] While some of the recent warming was likely associated with the El Niño weather pattern, many scientists are concerned at what may be the beginning of an accelerating trend.[19]

Higher temperatures not only have major impacts around the world—including extreme heat and drought and associated wildfires, tropical cyclones, and major floods[20]—but are also concerning because of their ability to induce irreversible changes. Tipping points are changes to climatic systems that become self-perpetuating at certain levels of warming.[21] A 2023 report found that at least five major systems were at risk of reaching tipping points, namely: the Greenland and West Antarctic ice sheets, warm-water coral reefs, North Atlantic Subpolar Gyre circulation, and permafrost regions.[22] The report described the risk of triggering tipping points as amongst "the gravest threats faced by humanity," which would "severely damage our planet's life-support systems and threaten the stability of our societies."[23]

To confront this challenge collectively, nearly all countries in the world have signed onto the Paris Agreement, a climate change treaty.[24] The primary goals of the Agreement are to maintain global average

temperatures well below 2ºC above pre-industrial levels, and to use best efforts to limit the increase to 1.5ºC.[25] According to the Intergovernmental Panel on Climate Change (IPCC), the UN body responsible for assessing the science related to climate change,[26] limiting the temperature increase to as close as possible to 1.5ºC is necessary to avoid the worst effects of climate change.[27] But, on our current path, we will reach 3.2ºC by 2100.[28] 2024 is on track to be the first year averaging more than 1.5ºC above preindustrial temperatures.[29] While one year spent above an average of 1.5ºC does not breach the Paris Agreement targets—which require a sustained increase over a longer period[30]—there is a growing understanding amongst scientists that breaching 1.5ºC is, at this point, likely inevitable.[31] To increase the chances of a safer future, time is of the essence. In 2023, the United Nations advised that GHG emissions would need to be halved by the end of this decade, describing a looming "climate cataclysm."[32]

But policy makers the world over have so far largely failed to address a key contributor to climate change: animal agriculture.[33] It will not be possible to adhere to climate targets without addressing food systems.[34] Animal agriculture is the biggest factor,[35] accounting for

Meeting the 1.5°C target requires rapid and ambitious changes to food systems as well as to all nonfood sectors."); *see also* U.N. ENV'T PROGRAMME, EMISSIONS GAP REPORT 2022: THE CLOSING WINDOW—CLIMATE CRISIS CALLS FOR RAPID

nearly sixty percent of global food system emissions[36] and almost eighty percent of U.S. agricultural emissions.[37] Overall, animal agriculture is likely responsible for somewhere between 14.5% and 20% of global GHG emissions.[38]

Animal agriculture also bears outsized responsibility for emissions of the climate super-pollutants methane and nitrous oxide. Nitrous oxide is an exceptionally powerful GHG, around 280 times more potent than carbon dioxide over its first twenty years in the atmosphere.[39] According to a U.N. estimate, more than half of all nitrous oxide comes from animal agriculture.[40]

Animal agriculture is also responsible for almost one third of all anthropogenic methane emissions globally and 36% in the United States.[41] During its first twenty years after release, methane is about 80

Here's How to Reduce Them*, U.N. ENV'T PROGRAMME, (Aug. 20, 2021)

times more powerful than carbon dioxide.[42] But an average methane molecule only lasts in the atmosphere for about a decade, while carbon dioxide can persist for hundreds of years.[43] The potency of methane, combined with its shorter life in the atmosphere, creates a mitigation opportunity. As explained by the U.N. Environment Programme (UNEP): "[R]educing methane emissions now would have an impact in the near term and is critical for helping keep the world on a path to 1.5°C."[44] In light of both its emissions of climate super-pollutants and association with land use change, a "global phaseout" of animal agriculture over the next fifteen years "would have the same effect, through the end of the century, as a 68% reduction of CO_2 emissions."[45]

Nonetheless, animal agriculture has frequently benefitted from light or no environmental regulation around the world.[46] The United States is a particularly cogent example. In the climate realm, the United States has consistently and almost entirely exempted the animal agriculture industry from air pollution GHG regulation regimes.[47] Even in Europe—while ahead of the United States in addressing animal agriculture's climate impacts[48]—significant continent-wide policy has so far failed to address the climate harms of animal agriculture. Efforts to use the EU Industrial Emissions Directive (IED), which regulates pollutants from industrial facilities, to regulate GHG emissions from large-scale animal agriculture floundered in 2023 when industry lobbying resulted in the European Parliament removing all cattle farms and some targeted pig and poultry farms from the reach of the

regulation.[49] The decision to postpone the implementation of stronger animal agriculture emissions controls in the IED was recently identified as an "ambition gap" by the European Scientific Advisory Board on Climate Change,[50] an independent body established in 2021 by the European Climate Law to advise the EU on climate change.[51] Moreover, the removal of a reference from the EU 2040 Climate Roadmap to efforts to reduce non-carbon dioxide GHGs (primarily methane and nitrous oxide) in agriculture by at least 30% by 2040 was viewed by many as a capitulation to the industry.[52]

In addition to benefitting from regulatory exclusion and gaps, animal agriculture enjoys high levels of government support.[53] For example, a recent report from the European Scientific Advisory Board on Climate Change described how the EU Common Agricultural Policy's subsidization of "the livestock sector . . . is a direct subsidy for GHG-intensive food products and undermines the goal of having food products reflect their true costs."[54] Across the EU and United States, animal

agriculture receives about one thousand times more government funding—including for research and development—than alternative products, even though it is dramatically more established.[55]

Meanwhile, global consumption of animal products continues to increase. Per the FAO, by 2030, global meat consumption will increase fourteen percent as compared to 2018–2020 levels.[56] Increasing consumption of animal products will increase their related GHG emissions (including the potential to undo any efficiency gains in production[57]) and exacerbate the many harms of the industry, including other environmental damage and harms to health, communities, and animals.[58]

III. GLOBAL MOMENTUM AND INTERNATIONAL SIGNALING

This Part describes emergent recognition from international and multinational bodies and in international agreements about the need to reduce GHG emissions from animal agriculture through dietary change. The first section provides a chronology of international and EU developments—with the EU highlighted because it is a leader in this area—and the second describes COP28 as an example both of progress and obstacles to change.

A. International and EU Activity

Widespread awareness of the significant contributions of animal agriculture to climate change goes back at least as far as the publication of the FAO report, *Livestock's Long Shadow*, in 2006.[59] The report did not shy away from animal agriculture's environmental impacts, noting in its opening lines that "[l]ivestock activities have significant impact on virtually all aspects of the environment, including air and climate change, land and soil, water and biodiversity" and that "[l]ivestock's impact on the environment is already huge, and it is growing and rapidly changing."[60] In the report, the FAO determined that animal agriculture "has such deep and wide-ranging environmental impacts that it should rank as one of the leading focuses for environmental policy" and estimated that the sector was responsible for 18% of all

global GHG emissions.[61] This was the first global emissions reckoning for the industry, which had not been evaluated as its own sector in any of the IPCC synthesis reports issued beginning in 1990.[62] These findings reportedly resulted in significant industry pushback on the FAO.[63] Several years later, the UNEP also commented on the environmental and climate profile of animal agriculture in a report aimed at identifying the highest impact goods: "Animal products, both meat and dairy, in general require more resources and cause higher emissions than plant-based alternatives."[64] In their reports, neither the FAO nor the UNEP explicitly called for a reduction in consumption of animal products as a part of the response to climate change.

Recent years have seen international bodies more willing to make that connection. In a 2018 report, the IPCC considered the differing impacts of global warming of 1.5ºC and 2.0ºC above preindustrial levels—concluding that the former was near certain to occur and the latter would be dramatically worse—along with GHG emission pathways to both scenarios.[65] The IPCC explicitly recognized the importance of reducing consumption of animal products—"particularly where consumption is higher than suggested human health guidelines"—as well as the uncertainty of the best policy pathways to achieve that end in the face of increasing consumption.[66] The report highlighted that "plant-based proteins" and "cultured meat" could "radically reduce agricultural and land-use emissions," "less resource-intensive diets" would reduce demand for land, and "[l]ower consumption of livestock products by 2050 could also substantially reduce deforestation and cumulative carbon losses."[67]

Also in 2018, announcing the awarding of the Champions of the Earth Award in the Science and Innovation Category to the founders of two prominent plant-based meat companies, the UNEP issued a statement strikingly entitled "*Tackling the World's Most Urgent Problem: Meat*," and shared the awardees' views in these terms: "[O]ur use of animals as a food-production technology has brought us to the verge of catastrophe. . . . There is no pathway to achieve the Paris climate objectives without a massive decrease in the scale of animal agriculture . . . ."[68]

In 2019, the "EAT-*Lancet* Commission," a group of experts in human health, agriculture, political sciences, and sustainability, released an influential report.[69] The Commission described the effort as "the first attempt to set universal scientific targets for the food system that apply to all people and the planet."[70] The report concluded:

> Transformation to healthy diets by 2050 will require substantial dietary shifts. Global consumption of fruits, vegetables, nuts and legumes will have to double, and consumption of foods such as red meat and sugar will have to be reduced by more than 50%. A diet rich in plant-based foods and with fewer animal source foods confers both improved health and environmental benefits.[71]

Also in 2019, a joint report from the FAO and the World Health Organization (WHO) described "the combined health and environmental benefits of shifting towards a more plant-based diet."[72]

In Europe, in September 2020, the European Commission recognized in a communication about its 2030 climate ambition that a "strong decrease of consumption of animal products for nutrition could potentially reduce emissions by more than 30 million tonnes by 2030."[73] The next month, in its strategy to reduce methane emissions, the Commission recognized that, "[g]iven the high share of methane emissions in agriculture that result from livestock, lifestyle and diet changes can also contribute significantly to reducing EU methane emissions."[74]

Then, in 2021, the European Parliament adopted its "Farm to Fork Strategy," which the European Commission described as "at the heart of the European Green Deal."[75] The Strategy aims to make food systems "fair, healthy and environmentally-friendly,"[76] recognizes both the health and environmental benefits of reducing meat consumption,[77] and commits to dedicating EU funds to research alternative proteins.[78] But advocates said that it was "deeply disappointing" that a call to end government spending on promoting meat production and consumption that had appeared in an earlier draft did not make it into the final strategy.[79] Moreover, as one European agriculture expert put it: "Remarkably, the EU Farm-to-Fork Strategy, while emphasizing the need to reduce methane and nutrient emissions from livestock, does not mention a reduction in total livestock numbers as either a goal or a policy option."[80]

According to the UNEP's 2021 Global Methane Assessment, "the adoption of healthy diets (vegetarian or with a lower meat and dairy content)" is one of three key measures to reduce emissions from animal agriculture.[81] Also in 2021, at COP26 in Glasgow more than a hundred countries signed the "Global Methane Pledge," undertaking to reduce methane emissions by 30 percent by 2030.[82] But the Pledge took quite different approaches to the other two main sectoral sources of methane than it did to agriculture, calling for "all feasible reductions in the energy and waste sectors" but only "abatement of agricultural emissions through technology innovation as well as incentives and partnerships with farmers."[83] The signatories apparently were not willing to commit to "all feasible reductions" in emissions from agriculture.

A 2022 IPCC report on "Climate Change and Land" identified "a shift toward plant-based diets" as one of the top three options (along with reducing deforestation and food waste) to reduce emissions from agriculture, forestry, and other land use.[84] Less clearly, the IPCC's Sixth Assessment Report released in March 2023 stated that "unbalanced diets" contribute to "agricultural expansion," "increase[] ecosystem and human vulnerability and lead[] to competition for land and/or water resources."[85] The report also recognized that, along with other measures, shifting to "sustainable healthy diets" could "reduce ecosystem conversion, and methane and nitrous oxide emissions, and free up land for reforestation and ecosystem restoration."[86]

[85] IPCC SIXTH ASSESSMENT REPORT SYNTHESIS, *supra* note 44, at 50. A prior 2022 IPCC report had defined "balanced diets" as "featur[ing] plant-based foods, such as those based on coarse grains, legumes, fruits and vegetables, nuts and seeds, and animal-source foods produced in resilient, sustainable, and low-greenhouse gas emissions systems." INTERGOV'TAL PANEL ON CLIMATE CHANGE, CLIMATE CHANGE 2022: IMPACTS, ADAPTATION AND VULNERABILITY 12 n.32 (Hans-Otto Pörtner et al. eds., 2022).

[86] IPCC SIXTH ASSESSMENT REPORT SYNTHESIS, *supra* note 44, at 29; *see also id.* at 106. The IPCC defines "[s]ustainable healthy diets" as "promot[ing] all dimensions of individuals' health and well-being; hav[ing] low environmental pressure and impact; [being] accessible, affordable, safe and equitable; [and] culturally acceptable . . . ." *Id.* at 29 n.53.

According to reporting after the release of the 2023 report, more direct references to the climate impacts of animal agriculture were removed from drafts after pressure from delegates from Brazil and Argentina (both major meat-producing and exporting countries).[87] In particular, a leaked draft had reportedly included much more precise and definitive language:

> A shift to diets with a higher share of plant-based protein in regions with excess consumption of calories and animal-source food can lead to substantial reductions in GHG emissions . . . . Plant-based diets can reduce GHG emissions by up to 50% compared to the average emission intensive Western diet.[88]

The European Commission's Agricultural Outlook for 2022–2032 evaluated the impacts of reducing farm animal density in Europe to comply with nitrogen pollution and habitat protection laws. The Commission concluded that reductions would reduce GHG emissions in the EU, and that such measures should be paired with complementary policies (including dietary changes, improved emissions efficiency, and trade measures) to prevent "leakage," i.e., European consumers importing more animal products to meet demand.[89] Interestingly, the analysis showed that farmer incomes would grow even as production declined, as a result of higher prices for animal products and reduced feed costs.[90]

In late 2023, the European Union announced that, through the European Innovation Council, it would spend €50 million in 2024 to help scale up alternative proteins including precision fermentation.[91] And lest it seem that the United States is lagging entirely behind international bodies and the European Union in acknowledging the role of dietary shifts in climate mitigation, in late 2023, the Fifth National Climate Assessment addressed food systems for the first time, notably

acknowledging that shifts to plant-based and cultivated meats "offer the potential to reduce GHG emissions."[92]

In a January 2024 report on EU progress toward climate neutrality, the European Scientific Advisory Board on Climate Change included the following in its key recommendations:

> The [EU common agricultural policy] CAP should be better aligned with EU climate goals . . . [including by] shifting CAP support away from emission-intensive agricultural practices, including livestock production, and towards lower-emitting products . . . .
>
> [T]he EU should strengthen measures to encourage healthier, more plant-based diets, and develop a strategy for a just transition to a food system consistent with climate neutrality.[93]

The Board also noted that the EU's 2018 Long-Term Strategy was not ambitious enough in the timelines it considered for dietary change, and that "further (and faster) reductions in animal product consumption would be recommended," both for climate and health reasons.[94]

Most recently, a groundbreaking 2024 report from the World Bank on emissions from the agrifood system encouraged high-income countries to "decrease consumer demand for emissions-intensive, animal-source foods by fully pricing environmental and health externalities, repurposing subsidies, and promoting sustainable food options."[95] A lead author of the report commented that the recommendation is decidedly *not* to shift support away from agriculture, but rather to "use it in more effective ways that actually contribute to healthier diets and a healthier planet."[96]

In addition to the climate context, calls for dietary change away from animal products have emerged in relation to other critical and related global issues, most prominently public health and biodiversity. Such guidance is based not only on the specific risks that dietary change could help address (for example, zoonotic disease for public health and

deforestation for biodiversity[97]), but also because climate change will itself exacerbate public health and biodiversity risks.[98] In one prominent example, the Kunming-Montreal Global Biodiversity Framework (GBF), adopted by the parties to the Convention on Biological Diversity in 2022, requires establishment of national targets to encourage sustainable consumption choices and, "by 2030, [to] reduce the global footprint of consumption in an equitable manner."[99] Focusing on the food system in its plan for implementation of the GBF, the International Union for Conservation of Nature, a membership group of government and civil society organizations that advises and works at the intersection of development, economics, and conservation, called for "[m]inimizing impacts of food production on species by reducing consumption of animal protein . . . especially in developed countries [to limit] negative impacts on wild species."[100]

B. COP28

The meeting of the Conference of the Parties to the U.N. Framework Convention on Climate Change in Dubai in November 2023 (COP28), which included a flurry of activity around food systems, is a prominent, recent example of the growing energy around this issue on the global stage.[101] While this new focus was laudable, the fact that food systems had never before received this level of attention—despite their

101 One might wonder whether the prominence of food at COP28 was driven, at least in part, by the interest of its host country and president, Sultan Al Jaber, who is the CEO of the United Arab Emirates national fuel company, in diverting attention away from fossil fuels. Fiona Harvey, *Cop28 President Denies on Eve of Summit He Abused His Position to Sign Oil Deals*, GUARDIAN (Nov. 29, 2023, 12:17 PM), https://www.theguardian.com/environment/2023/nov/29/cop28-president-denies-on-eve-of-summit-he-abused-his-position-to-sign-oil-deals. Nonetheless, as described herein, COP28 was the most significant COP to date for food.

significant emissions—is illustrative of the lack of attention to the climate impacts of agriculture.[102]

1. COP28: Progress
